Figure 38-2 illustrates how Unicast RPF drops packets that fail validation. In this example, a customer has sent a packet having a source address of 209.165.200.225, which is received at interface Gigabit Ethernet 1/1. Unicast RPF checks the FIB to see if 209.165.200.225 has a return path to Gigabit Ethernet 1/1. If there is a matching path, the packet is forwarded. There is no reverse entry in the routing table that routes the customer packet back to source address 209.165.200.225 on interface Gigabit Ethernet 1/1, and so the packet is dropped.

Figure 38-2 Unicast RPF Dropping Packets That Fail Verification

Unicast Reverse Path Forwarding with ACL Support

The Unicast Reverse Path Forwarding ACL Support feature adds the access control list (ACL) support to the Unicast Reverse Path Forwarding feature. With the ACL support, Unicast Reverse Path Forwarding (RPF) can determine whether to drop or to forward data packets that have malformed or forged IP source addresses. The ACL support for Unicast Reverse Path Forwarding feature was introduced for IPv4 family on Catalyst 4500-E series switches and Catalyst 4500-X series switches starting with the Cisco IOS Release 15.2(6)E2.

Implementing Unicast RPF

Unicast RPF has several key implementation principles:

- The packet must be received at an interface that has the best return path (route) to the packet source (a process called *symmetric routing*). There must be a route in the FIB matching the route to the receiving interface. Adding a route in the FIB is done with a static route, network statement, or dynamic routing. (ACLs permit the use of Unicast RPF when packets will arrive by specific, less optimal asymmetric input paths.)
- IP source addresses at the receiving interface must match the routing entry for the interface.
- Unicast RPF is an input function and is applied only on the input interface of a switch at the upstream end of a connection.

Given these implementation principles, Unicast RPF becomes a tool that network administrators can use not only for their customers but also for their downstream network or ISP, even if the downstream network or ISP has other connections to the Internet.

**Caution**

Using optional BGP attributes such as weight and local preference, you can modify the best path back to the source address. Modification affects the operation of Unicast RPF.

This section provides information about the implementation of Unicast RPF:

- [Security Policy and Unicast RPF, page 38-5](#)
- [Where to Use Unicast RPF, page 38-5](#)
- [Routing Table Requirements, page 38-7](#)
- [Where Not to Use Unicast RPF, page 38-7](#)
- [Unicast RPF with BOOTP and DHCP, page 38-8](#)

Security Policy and Unicast RPF

Consider the following points in determining your policy for deploying Unicast RPF:

- Unicast RPF must be applied at the interface downstream from the larger portion of the network, preferably at the edges of your network.
- The farther downstream you apply Unicast RPF, the finer the granularity you have in mitigating address spoofing and in identifying the sources of spoofed addresses. For example, applying Unicast RPF on an aggregation switch helps mitigate attacks from many downstream networks or clients and is simple to administer, but it does not help identify the source of the attack. Applying Unicast RPF at the network access server helps limit the scope of the attack and trace the source of the attack; however, deploying Unicast RPF across many sites does add to the administration cost of operating the network.
- The more entities that deploy Unicast RPF across Internet, intranet, and extranet resources, the better the chances of mitigating large-scale network disruptions throughout the Internet community, and the better the chances of tracing the source of an attack.
- Unicast RPF will not inspect IP packets encapsulated in tunnels, such as GRE, LT2P, or PPTP. Unicast RPF must be configured at a home gateway so that Unicast RPF processes network traffic only after the tunneling and encryption layers have been stripped off the packets.

Where to Use Unicast RPF

Unicast RPF can be used in any single-homed environment where there is essentially only one access point out of the network; that is, one upstream connection. Networks having one access point offer the best example of symmetric routing, which means that the interface where a packet enters the network is also the best return path to the source of the IP packet. Unicast RPF is best used at the network perimeter for Internet, intranet, or extranet environments, or in ISP environments for customer network terminations.

Enterprise Networks with a Single Connection to an ISP

In enterprise networks, one objective of using Unicast RPF for filtering traffic at the input interface (a process called *ingress filtering*) is for protection from malformed packets arriving from the Internet. Traditionally, local networks with one connection to the Internet use ACLs at the receiving interface to prevent spoofed packets from the Internet from entering their local network.

ACLs work well for many single-homed customers; however, there are trade-offs when ACLs are used as ingress filters, including two commonly referenced limitations:

- Packet per second (PPS) performance at very high packet rates

Note This restriction applies only to software packet forwarding. Hardware packet forwarding is the same on both ACL and uRPF.

- Maintenance of the ACL (whenever new addresses are added to the network)

Unicast RPF is one tool that addresses both of these limitations. With Unicast RPF, ingress filtering is done at CEF PPS rates. This processing speed makes a difference when the link is more than 1 Mbps. Additionally, since Unicast RPF uses the FIB, no ACL maintenance is necessary, and thus the administration overhead of traditional ACLs is reduced. The following figure and example demonstrate how Unicast RPF is configured for ingress filtering.

Figure 38-3 illustrates an enterprise network that has a single link to an upstream ISP. In this example, Unicast RPF is applied at interface Gigabit Ethernet 1/1 on the Enterprise switch for protection from malformed packets arriving from the Internet. Unicast RPF is also applied at interface Gigabit Ethernet 2/1 on the ISP switch for protection from malformed packets arriving from the enterprise network.

Figure 38-3 Enterprise Network Using Unicast RPF for Ingress Filtering

Using the topography in Figure 38-3, a typical configuration (assuming that CEF is turned on) on the ISP switch appears as follows:

```
interface Gigabit Ethernet 2/1
  description Link to Enterprise Network
  ip address 192.168.3.1 255.255.255.255
  no switchport
  ip address 10.1.1.2 255.255.255.0
  ip verify unicast source reachable-via rx allow-default
```

The gateway switch configuration of the enterprise network (assuming that CEF is turned on) appears as follows:

```
interface Gigabit Ethernet 1/2
  description ExampleCorp LAN
  ip address 192.168.10.1 255.255.252.0
  no ip redirects
  no ip directed-broadcast
  no ip proxy-arp

interface Gigabit Ethernet 1/1
```

```
description Link to Internet
no switchport
ip address 10.1.1.1 255.255.255.0
ip verify unicast source reachable-via rx allow-default
no ip proxy-arp
no ip redirects
no ip directed-broadcast
```

Unicast RPF works with a single default route. No additional routes or routing protocols exist. Network 192.168.10.0/22 is a connected network. Packets arriving from the Internet with a source address in the range 192.168.10.0/22 are dropped by Unicast RPF.

Routing Table Requirements

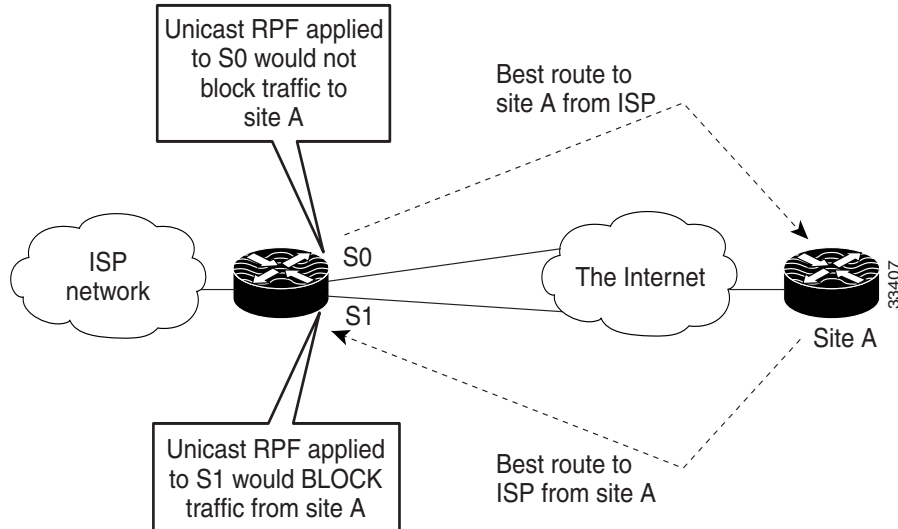

To work correctly, Unicast RPF needs proper information in the CEF tables. This requirement does not mean that the switch must have the entire Internet routing table. The amount of routing information needed in the CEF tables depends on where Unicast RPF is configured and what functions the switch performs in the network. For example, in an ISP environment, a switch that is a leased-line aggregation switch for customers needs only the information based on the static routes redistributed into the IGP or IBGP (depending on which technique is used in the network). Unicast RPF is configured on the customer interfaces, creating the requirement for minimal routing information. In another scenario, a single-homed ISP could place Unicast RPF on the gateway link to the Internet. The full Internet routing table is required. Requiring the full routing table helps protect the ISP from external DoS attacks that use addresses that are not in the Internet routing table.

Where Not to Use Unicast RPF

Do not use Unicast RPF on interfaces that are internal to the network. Internal interfaces are likely to have routing asymmetry (see [Figure 38-4](#)), meaning multiple routes to the source of a packet. Apply Unicast RPF only where there is natural or configured symmetry. Provided administrators carefully plan which interfaces they activate Unicast RPF on, routing asymmetry is not a serious problem.

For example, switches at the edge of the network of an ISP are more likely to have symmetrical reverse paths than switches that are in the core of the ISP network. Switches that are in the core of the ISP network have no guarantee that the best forwarding path out of the switch is the path selected for packets returning to the switch. We do not recommend that you apply Unicast RPF where there is a chance of asymmetric routing, unless you use ACLs to allow the switch to accept incoming packets. ACLs permit the use of Unicast RPF when packets will arrive by specific, less optimal asymmetric input paths. However, it is simplest to place Unicast RPF only at the edge of a network or, for an ISP, at the customer edge of the network.

[Figure 38-4](#) illustrates how Unicast RPF can block legitimate traffic in an asymmetrical routing environment.

Figure 38-4 Unicast RPF Blocking Traffic in an Asymmetrical Routing Environment

Unicast RPF with BOOTP and DHCP

Unicast RPF will allow packets with 0.0.0.0 source and 255.255.255.255 destination to pass so that Bootstrap Protocol (BOOTP) and Dynamic Host Configuration Protocol (DHCP) functions work properly.

Restrictions

Restrictions for applying Unicast RPF to multihomed clients include the following:

- Clients should not be multihomed to the same switch because action defeats the purpose of building a redundant service for the client.
- Customers must ensure that the packets flowing up the link (out to the Internet) match the route advertised out the link. Otherwise, Unicast RPF filters those packets as malformed packets.

Limitation

Unicast loose mode is not supported.

Related Features and Technologies

For more information about Unicast RPF-related features and technologies, review the following:

- Unicast RPF requires Cisco express forwarding (CEF) to function properly on the switch. For more information about CEF, refer to the *Cisco IOS Switching Services Configuration Guide*.
- Unicast RPF can be more effective at mitigating spoofing attacks when combined with a policy of *ingress* and *egress* filtering using Cisco IOS access control lists (ACLs).

- Ingress filtering applies filters to traffic received at a network interface from either internal or external networks. With ingress filtering, packets that arrive from other networks or the Internet and that have a source address that matches a local network, private, or broadcast address are dropped. In ISP environments, for example, ingress filtering can apply to traffic received at the switch from either the client (customer) or the Internet.
- Egress filtering applies filters to traffic exiting a network interface (the sending interface). By filtering packets on switches that connect your network to the Internet or to other networks, you can permit only packets with valid source IP addresses to leave your network.

For more information on network filtering, refer to RFC 2267 and to the *Cisco IOS IP Configuration Guide*.

Prerequisites to Configuring Unicast RPF

Prior to configuring Unicast RPF, configure ACLs:

- Configure standard or extended ACLs to mitigate transmission of invalid IP addresses (perform egress filtering). Permit only valid source addresses to leave your network and get onto the Internet. Prevent all other source addresses from leaving your network for the Internet.
- Configure standard or extended ACLs entries to drop (deny) packets that have invalid source IP addresses (perform ingress filtering). Invalid source IP addresses include the following types:
 - Reserved addresses
 - Loopback addresses
 - Private addresses (RFC 1918, *Address Allocation for Private Internets*)
 - Broadcast addresses (including multicast addresses)
 - Source addresses that fall outside the range of valid addresses associated with the protected network

Unicast RPF Configuration Tasks

The following sections describe the configuration tasks for Unicast RPF. Each task in the list is identified as either optional or required.

- [Configuring Unicast RPF, page 38-9](#) (Required)
- [Configuring Unicast RPF with ACL Support, page 38-10](#)
- [Verifying Unicast RPF, page 38-11](#) (Optional)

See the section “[Unicast RPF Configuration Example: Inbound and Outbound Filters](#)” at the end of this chapter.

Configuring Unicast RPF

Unicast RPF is an input-side function that is enabled on an interface operates on IP packets received by the switch.

To configure Unicast RPF, perform the following task:

	Command	Purpose
Step 1	Switch(config-if)# interface <i>type</i>	<p>Selects the input interface on which you want to apply Unicast RPF. It is the receiving interface, allowing Unicast RPF to verify the best return path before forwarding the packet on to the next destination.</p> <p>The interface type is specific to your switch and the types of interface cards installed on the switch. To display a list of available interface types, enter the interface ? command.</p>
Step 2	Switch(config-if)# ip verify unicast source reachable-via rx allow-default	Enables Unicast RPF on the interface.
Step 3	Switch(config-if)# exit	Exits interface configuration mode. Repeat Steps 2 and 3 for each interface on which you want to apply Unicast RPF.

Configuring Unicast RPF with ACL Support

To configure Unicast RPF with ACL Support, perform the following task:

	Command	Purpose
Step 1	Switch(config-if)# interface <i>type</i>	<p>Selects the input interface on which you want to apply Unicast RPF. It is the receiving interface, allowing Unicast RPF to verify the best return path before forwarding the packet on to the next destination.</p> <p>The interface type is specific to your switch and the types of interface cards installed on the switch. To display a list of available interface types, enter the interface ? command.</p>
Step 2	Switch(config-if)# ip address ipv4-address/prefix-length	Configures an IPv4 address and enables IPv4 processing on an interface.
Step 3	Switch(config-if)# ip verify unicast source reachable-via rx allow-default access-list	Enables Unicast RPF on the interface.
Step 4	Switch(config-if)# exit	Exits interface configuration mode. Repeat Steps 2 and 3 for each interface on which you want to apply Unicast RPF.

Verifying Unicast RPF

To verify that Unicast RPF is operational, use the **show cef interface** command. The following example shows that Unicast RPF is enabled at interface Gigabit Ethernet 3/1:

```
Switch# show cef interface gigabitEthernet 3/1
GigabitEthernet3/1 is up (if_number 79)
  Corresponding hwidb fast_if_number 79
  Corresponding hwidb firstsw->if_number 79
  Internet address is 10.1.1.1/24
  ICMP redirects are always sent
  IP unicast RPF check is enabled <=====
  Input features: uRPF <=====
  Inbound access list is not set
  Outbound access list is not set
  IP policy routing is disabled
  BGP based policy accounting on input is disabled
  BGP based policy accounting on output is disabled
  Hardware idb is GigabitEthernet3/1
  Fast switching type 1, interface type 155
  IP CEF switching enabled
  IP CEF switching turbo vector
  IP Null turbo vector
  IP prefix lookup IPv4 mtrie 8-8-8-8 optimized
  Input fast flags 0x4000, Output fast flags 0x0
  ifindex 78(78)
  Slot 3 Slot unit 1 VC -1
  Transmit limit accumulator 0x0 (0x0)
  IP MTU 1500
```

Monitoring and Maintaining Unicast RPF

To monitor and maintain Unicast RPF, perform this task:

Command	Purpose
Switch# show ip traffic	Displays global switch statistics about Unicast RPF drops and suppressed drops.
Switch(config-if)# no ip verify unicast	Disables Unicast RPF at the interface.

Unicast RPF counts the number of packets dropped or suppressed because of malformed or forged source addresses. Unicast RPF counts dropped or forwarded packets that include the following global and per-interface information:

- Global Unicast RPF drops
- Per-interface Unicast RPF drops
- Per-interface Unicast RPF suppressed drops

The **show ip traffic** command shows the total number (global count) of dropped or suppressed packets as dropped by software; it does not include those dropped by hardware. The Unicast RPF drop count is included in the IP statistics section.

```
Switch# show ip traffic
```

```
IP statistics:
```

```
Rcvd: 1471590 total, 887368 local destination
      0 format errors, 0 checksum errors, 301274 bad hop count
      0 unknown protocol, 0 not a gateway
      0 security failures, 0 bad options, 0 with options
Opts: 0 end, 0 nop, 0 basic security, 0 loose source route
      0 timestamp, 0 extended security, 0 record route
      0 stream ID, 0 strict source route, 0 alert, 0 other
Frgs: 0 reassembled, 0 timeouts, 0 couldn't reassemble
      0 fragmented, 0 couldn't fragment
Bcast: 205233 received, 0 sent
Mcast: 463292 received, 462118 sent
Sent: 990158 generated, 282938 forwarded
! The second line below ("0 unicast RPF") displays Unicast RPF packet dropping
information.
Drop: 3 encapsulation failed, 0 unresolved, 0 no adjacency
      0 no route, 0 unicast RPF, 0 forced drop
```

A nonzero value for the count of dropped or suppressed packets can mean one of two things:

- Unicast RPF is dropping or suppressing packets that have a bad source address (normal operation).
- Unicast RPF is dropping or suppressing legitimate packets because the route is misconfigured to use Unicast RPF in environments where asymmetric routing exists; that is, where multiple paths can exist as the best return path for a source address.

The **show ip interface** command shows the total of dropped or suppressed packets at a specific interface. If Unicast RPF is configured to use a specific ACL, that ACL information is displayed along with the drop statistics.

```
Switch> show ip interface fast 2/1
```

```
Unicast RPF ACL 197
1 unicast RPF drop
1 unicast RPF suppressed drop
```

The **show access-lists** command displays the number of matches found for a specific entry in a specific access list.

```
Switch> show access-lists
```

```
Extended IP access list 197
deny ip 192.168.201.0 0.0.0.63 any log-input (1 match)
permit ip 192.168.201.64 0.0.0.63 any log-input (1 match)
deny ip 192.168.201.128 0.0.0.63 any log-input
permit ip 192.168.201.192 0.0.0.63 any log-input
```

Unicast RPF Configuration Example: Inbound and Outbound Filters

The following example uses a very simple single-homed ISP to demonstrate the concepts of ingress and egress filters used in conjunction with Unicast RPF. The example illustrates an ISP-allocated classless interdomain routing (CIDR) block 209.165.202.128/28 that has both inbound and outbound filters on the upstream interface. Be aware that ISPs are usually not single-homed. Provisions for asymmetrical flows (when outbound traffic goes out one link and returns by using a different link) must be designed into the filters on the border switches of the ISP.

```

ip cef distributed
!
interface Serial 5/0/0
  description Connection to Upstream ISP
  ip address 209.165.200.225 255.255.255.252
  no ip redirects
  no ip directed-broadcast
  no ip proxy-arp
  ip verify unicast reverse-path rx allow-default
  ip access-group 111 in
  ip access-group 110 out
!
access-list 110 permit ip 209.165.202.128 0.0.0.31 any
access-list 110 deny ip any any log
access-list 111 deny ip host 0.0.0.0 any log
access-list 111 deny ip 127.0.0.0 0.255.255.255 any log
access-list 111 deny ip 10.0.0.0 0.255.255.255 any log
access-list 111 deny ip 172.16.0.0 0.15.255.255 any log
access-list 111 deny ip 192.168.0.0 0.0.255.255 any log
access-list 111 deny ip 209.165.202.128 0.0.0.31 any log
access-list 111 permit ip any any

```

Unicast RPF with ACL Support Configuration Example:

The following example shows URPF with ACL support configured on an interface of the switch.

```

Switch# configure terminal
Switch(config)# interface gigabitethernet 0/0/1
Switch(config-if)# ip address 192.168.200.2 255.255.255.0
Switch(config-if)# ip verify unicast source reachable-via rx allow-default 100
Switch(config-if)# end

```

Feature Information for Unicast Reverse Path Forwarding

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

Table 38-1 lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 38-1 Feature Information for Power over Ethernet

Feature Name	Releases	Feature Information
Unicast Reverse Path Forwarding	Cisco IOS Release 12.2(40)SG	This feature was introduced.
	Cisco IOS Release 15.2(6)E2	The ACL support for the Unicast Reverse Path Forwarding feature was introduced for IPv4 family.

Configuring IP Multicast

This chapter describes IP multicast routing on the Catalyst 4500 series switch. It also provides procedures and examples to configure IP multicast routing.

This chapter includes the following major sections:

- [About IP Multicast, page 39-1](#)
- [Configuring IP Multicast Routing, page 39-13](#)
- [Monitoring and Maintaining IP Multicast Routing, page 39-23](#)
- [Configuration Examples, page 39-29](#)

Note

For more detailed information on IP Multicast, refer to this URL:

http://www.cisco.com/en/US/products/ps6552/products_ios_technology_home.html

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About IP Multicast

Note

Controlling the transmission rate to a multicast group is not supported.

At one end of the IP communication spectrum is IP unicast, where a source IP host sends packets to a specific destination IP host. In IP unicast, the destination address in the IP packet is the address of a single, unique host in the IP network. These IP packets are forwarded across the network from the source to the destination host by routers. At each point on the path between source and destination, a router uses a unicast routing table to make unicast forwarding decisions, based on the IP destination address in the packet.

At the other end of the IP communication spectrum is an IP broadcast, where a source host sends packets to all hosts on a network segment. The destination address of an IP broadcast packet has the host portion of the destination IP address set to all ones and the network portion set to the address of the subnet. IP hosts, including routers, understand that packets, which contain an IP broadcast address as the

destination address, are addressed to all IP hosts on the subnet. Unless specifically configured otherwise, routers do not forward IP broadcast packets, so IP broadcast communication is normally limited to a local subnet.

IP multicasting falls between IP unicast and IP broadcast communication. IP multicast communication enables a host to send IP packets to a *group* of hosts anywhere within the IP network. To send information to a specific group, IP multicast communication uses a special form of IP destination address called an *IP multicast group address*. The IP multicast group address is specified in the IP destination address field of the packet.

To multicast IP information, Layer 3 switches and routers must forward an incoming IP packet to all output interfaces that lead to *members* of the IP multicast group. In the multicasting process on the Catalyst 4500 series switch, a packet is replicated in the Integrated Switching Engine, forwarded to the appropriate output interfaces, and sent to each member of the multicast group.

We tend to think of IP multicasting and video conferencing as the same thing. Although the first application in a network to use IP multicast is often video conferencing, video is only one of many IP multicast applications that can add value to a company's business model. Other IP multicast applications that have potential for improving productivity include multimedia conferencing, data replication, real-time data multicasts, and simulation applications.

This section contains the following subsections:

- [IP Multicast Protocols, page 39-2](#)
- [IP Multicast Implementation on the Catalyst 4500 Series Switch, page 39-4](#)
- [Configuring IP Multicast Routing, page 39-13](#)

IP Multicast Protocols

The Catalyst 4500 series switch primarily uses these protocols to implement IP multicast routing:

- Internet Group Management Protocol (IGMP)
- Protocol Independent Multicast (PIM)
- IGMP snooping and Cisco Group Management Protocol

[Figure 39-1](#) shows where these protocols operate within the IP multicast environment.

Figure 39-1 IP Multicast Routing Protocols

Internet Group Management Protocol

IGMP messages are used by IP multicast hosts to send their local Layer 3 switch or router a request to join a specific multicast group and begin receiving multicast traffic. With some extensions in IGMPv2, IP hosts can also send a request to a Layer 3 switch or router to leave an IP multicast group and not receive the multicast group traffic.

Using the information obtained by using IGMP, a Layer 3 switch or router maintains a list of multicast group memberships on a per-interface basis. A multicast group membership is active on an interface if at least one host on the interface sends an IGMP request to receive multicast group traffic.

Protocol-Independent Multicast

PIM is *protocol independent* because it can leverage whichever unicast routing protocol is used to populate the unicast routing table, including EIGRP, OSPF, BGP, or static route, to support IP multicast. PIM also uses a unicast routing table to perform the reverse path forwarding (RPF) check function instead of building a completely independent multicast routing table. PIM does not send and receive multicast routing updates between routers like other routing protocols do.

PIM Dense Mode

PIM Dense Mode (PIM-DM) uses a *push* model to flood multicast traffic to every corner of the network. PIM-DM is intended for networks in which most LANs need to receive the multicast, such as LAN TV and corporate or financial information broadcasts. It can be an efficient delivery mechanism if active receivers exist on every subnet in the network.

For more detailed information on PIM Dense Mode, refer to this URL:

http://www.cisco.com/en/US/docs/ios-xml/ios/ipmulti_optim/configuration/12-2sx/imc_pim_dense_rfrsh.html

PIM Sparse Mode

PIM Sparse Mode (PIM-SM) uses a *pull* model to deliver multicast traffic. Only networks with active receivers that have explicitly requested the data are forwarded the traffic. PIM-SM is intended for networks with several different multicasts, such as desktop video conferencing and collaborative computing, that go to a small number of receivers and are typically in progress simultaneously.

Bidirectional PIM Mode

In bidirectional PIM (Bidir-PIM) mode, traffic is routed only along a bidirectional shared tree that is rooted at the rendezvous point (RP) for the group. The IP address of the RP functions as a key enabling all routers to establish a loop-free spanning tree topology rooted in that IP address.

Bidir-PIM is intended for many-to-many applications within individual PIM domains. Multicast groups in bidirectional mode can scale to an arbitrary number of sources without incurring overhead due to the number of sources.

For more detailed information on Bidirectional Mode, refer to this URL:

http://www.cisco.com/en/US/prod/collateral/iosswrel/ps6537/ps6552/ps6592/prod_white_paper0900aecd80310db2.pdf.

Rendezvous Point (RP)

If you configure PIM to operate in sparse mode, you must also choose one or more routers to be rendezvous points (RPs). Senders to a multicast group use RPs to announce their presence. Receivers of multicast packets use RPs to learn about new senders. You can configure Cisco IOS software so that packets for a single multicast group can use one or more RPs.

The RP address is used by first hop routers to send PIM register messages on behalf of a host sending a packet to the group. The RP address is also used by last hop routers to send PIM join and prune messages to the RP to inform it about group membership. You must configure the RP address on all routers (including the RP router).

A PIM router can be an RP for more than one group. Only one RP address can be used at a time within a PIM domain for the same group. The conditions specified by the access list determine for which groups the router is an RP (as different groups can have different RPs).

IGMP Snooping

IGMP snooping is used for multicasting in a Layer 2 switching environment. With IGMP snooping, a Layer 3 switch or router examines Layer 3 information in the IGMP packets in transit between hosts and a router. When the switch receives the IGMP Host Report from a host for a particular multicast group, the switch adds the host's port number to the associated multicast table entry. When the switch receives the IGMP Leave Group message from a host, it removes the host's port from the table entry.

Because IGMP control messages are transmitted as multicast packets, they are indistinguishable from multicast data if only the Layer 2 header is examined. A switch running IGMP snooping examines every multicast data packet to determine whether it contains any pertinent IGMP control information. If IGMP snooping is implemented on a low end switch with a slow CPU, performance could be severely impacted when data is transmitted at high rates. On the Catalyst 4500 series switches, IGMP snooping is implemented in the forwarding ASIC, so it does not impact the forwarding rate.

IP Multicast Implementation on the Catalyst 4500 Series Switch

The Catalyst 4500 series switch supports an ASIC-based Integrated Switching Engine that provides Ethernet bridging at Layer 2 and IP routing at Layer 3. Because the ASIC is specifically designed to forward packets, the Integrated Switching Engine hardware provides very high performance with ACLs and QoS enabled. At wire-speed, forwarding in hardware is significantly faster than the CPU subsystem software, which is designed to handle exception packets.

The Integrated Switching Engine hardware supports interfaces for inter-VLAN routing and switch ports for Layer 2 bridging. It also provides a physical Layer 3 interface that can be configured to connect with a host, a switch, or a router.

[Figure 39-2](#) shows a logical view of Layer 2 and Layer 3 forwarding in the Integrated Switching Engine hardware.

Figure 39-2 Logical View of Layer 2 and Layer 3 Forwarding in Hardware

This section contains the following subsections:

Restrictions on IP Multicast

Restrictions on IP Multicast include the following:

- Packets that have a multicast destination IP address and unicast MAC address are dropped.
- Starting with Release IOS XE 3.3.0SG and IOS 15.1(1)SG, the seven RP restriction was removed.
- IPv4 Bidirectional (Bidir) PIM is supported on the Catalyst 4500 series switch. IPv6 Bidir PIM is not.
- For some multicast groups, when more than 8K mroutes are installed in a system, the network may experience higher traffic losses upon switchover of the HA system. This is due to flushing the old multicast forwarding entries before the new entries are updated. As the number of routes increase, more time is required for the entries to be updated in the MFIB. To reduce the traffic loss in this scenario, you should increase the multicast route-flush timer (using the **ip multicast redundancy routeflush maxtime** command) to a value exceeding the default (30 seconds).

CEF, MFIB, and Layer 2 Forwarding

The implementation of IP multicast on the Catalyst 4500 series switch is an extension of centralized Cisco Express Forwarding (CEF). CEF extracts information from the unicast routing table, which is created by unicast routing protocols, such as BGP, OSPF, and EIGRP and loads it into the hardware Forwarding Information Base (FIB). With the unicast routes in the FIB, when a route is changed in the upper-layer routing table, only one route needs to be changed in the hardware routing state. To forward unicast packets in hardware, the Integrated Switching Engine looks up source and destination routes in ternary content addressable memory (TCAM), takes the adjacency index from the hardware FIB, and gets the Layer 2 rewrite information and next-hop address from the hardware adjacency table.

The new Multicast Forwarding Information Base (MFIB) subsystem is the multicast analog of the unicast CEF. The MFIB subsystem extracts the multicast routes that PIM and IGMP create and refines them into a protocol-independent format for forwarding in hardware. The MFIB subsystem removes the protocol-specific information and leaves only the essential forwarding information. Each entry in the MFIB table consists of an (S,G) or (*,G) route, an input RPF VLAN, and a list of Layer 3 output interfaces. The MFIB subsystem, together with platform-dependent management software, loads this multicast routing information into the hardware FIB and Replica Expansion Table (RET).

The Catalyst 4500 series switch performs Layer 3 routing and Layer 2 bridging at the same time. There can be multiple Layer 2 switch ports on any VLAN interface.

Figure 39-3 shows a functional overview of how the Catalyst 4500 series switch combines unicast routing, multicast routing, and Layer 2 bridging information to forward in hardware.

Figure 39-3 Combining CEF, MFIB, and Layer 2 Forwarding Information in Hardware

Like the CEF unicast routes, the MFIB routes are Layer 3 and must be merged with the appropriate Layer 2 information. The following example shows an MFIB route:

```

(*,224.1.1.3)
RPF interface is Vlan3
Output Interfaces are:
Vlan 1
Vlan 2
  
```

The route (*,224.1.2.3) is loaded in the hardware FIB table and the list of output interfaces is loaded into the MET. A pointer to the list of output interfaces, the MET index, and the RPF interface are also loaded in the hardware FIB with the (*,224.1.2.3) route. With this information loaded in hardware, merging of the Layer 2 information can begin. For the output interfaces on VLAN1, the Integrated Switching Engine must send the packet to all switch ports in VLAN1 that are in the spanning tree forwarding state. The same process applies to VLAN 2. To determine the set of switch ports in VLAN 2, the Layer 2 Forwarding Table is used.

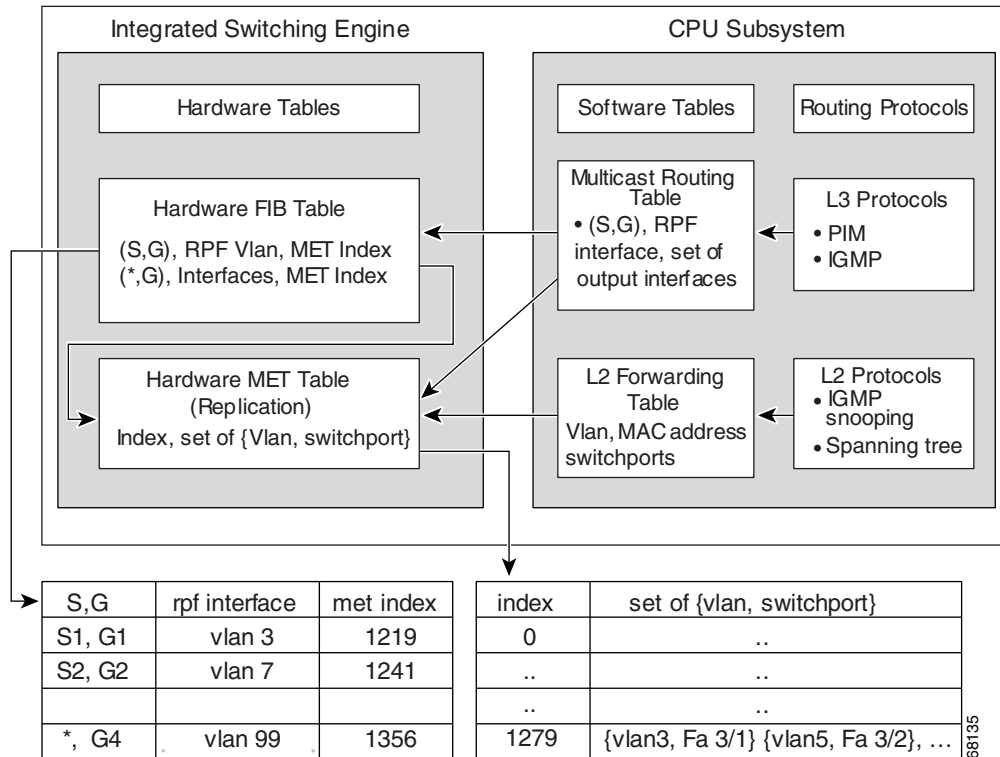

When the hardware routes a packet, in addition to sending it to all of the switch ports on all output interfaces, the hardware also sends the packet to all switch ports (other than the one it arrived on) in the input VLAN. For example, assume that VLAN 3 has two switch ports in it, Gig 3/1 and Gig 3/2. If a host on Gig 3/1 sends a multicast packet, the host on Gig 3/2 might also need to receive the packet. To send a multicast packet to the host on Gig 3/2, all of the switch ports in the ingress VLAN must be added to the port set that is loaded in the MET.

If VLAN 1 contains 1/1 and 1/2, VLAN 2 contains 2/1 and 2/2, and VLAN 3 contains 3/1 and 3/2, the MET chain for this route would contain these switch ports: (1/1,1/2,2/1,2/2,3/1, and 3/2).

If IGMP snooping is on, the packet should not be forwarded to all output switch ports on VLAN 2. The packet should be forwarded only to switch ports where IGMP snooping has determined that there is either a group member or router. For example, if VLAN 1 had IGMP snooping enabled, and IGMP snooping determined that only port 1/2 had a group member on it, then the MET chain would contain these switch ports: (1/1,1/2, 2/1, 2/2, 3/1, and 3/2).

IP Multicast Tables

Figure 39-4 shows some key data structures that the Catalyst 4500 series switch uses to forward IP multicast packets in hardware.

Figure 39-4 IP Multicast Tables and Protocols

The Integrated Switching Engine maintains the hardware FIB table to identify individual IP multicast routes. Each entry consists of a destination group IP address and an optional source IP address. Multicast traffic flows on primarily two types of routes: (S,G) and (*,G). The (S,G) routes flow from a source to a group based on the IP address of the multicast source and the IP address of the multicast group destination. Traffic on a (*,G) route flows from the PIM RP to all receivers of group G. Only sparse-mode groups use (*,G) routes. The Integrated Switching Engine hardware contains space for a total of 128,000 routes, which are shared by unicast routes, multicast routes, and multicast fast-drop entries.

Output interface lists are stored in the multicast expansion table (MET). The MET has room for up to 32,000 output interface lists. (For RET, we can have up to 102 K entries (32 K used for floodsets, 70,000 used for multicast entries)). The MET resources are shared by both Layer 3 multicast routes and by Layer 2 multicast entries. The actual number of output interface lists available in hardware depends on the specific configuration. If the total number of multicast routes exceed 32,000, multicast packets might not be switched by the Integrated Switching Engine. They would be forwarded by the CPU subsystem at much slower speeds.

**Note**

For RET, a maximum of 102 K entries is supported (32 K used for floodsets, 70 K used for multicast entries).

**Note**

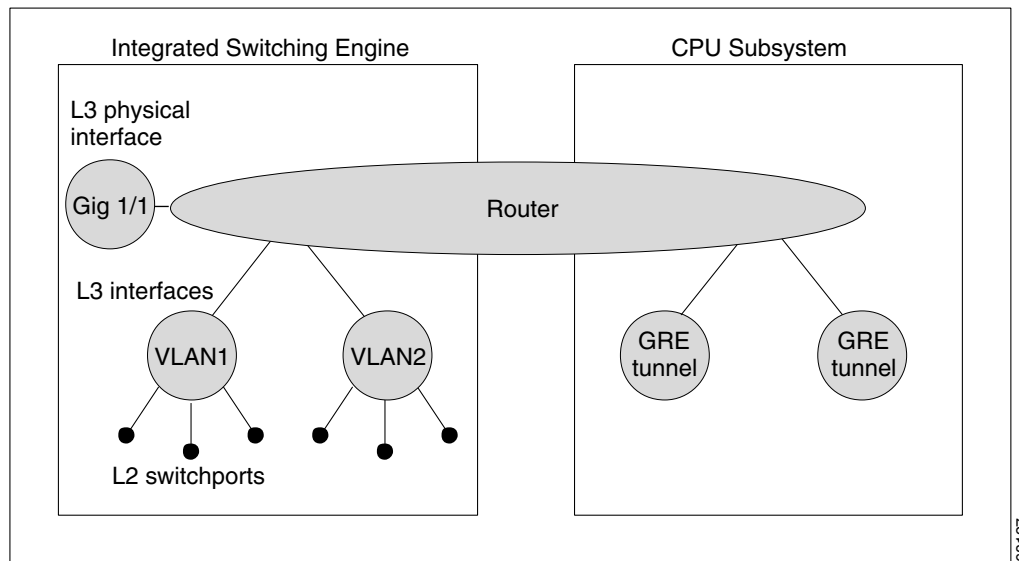

Prior to Release IOS XE 3.3.0SG and IOS 15.1(1)SG, partial routing is not supported on Supervisor Engine 6-E, Supervisor Engine 6L-E, Supervisor Engine 7-E, and Supervisor Engine 7L-E; only hardware and software routing are supported. Starting with Release IOS XE 3.3.0SG and IOS 15.1(1)SG, partial routing is supported on all supervisor engines.

Hardware and Software Forwarding

The Integrated Switching Engine forwards the majority of packets in hardware at very high rates of speed. The CPU subsystem forwards exception packets in software. Statistical reports should show that the Integrated Switching Engine is forwarding the vast majority of packets in hardware.

Figure 39-5 shows a logical view of the hardware and software forwarding components.

Figure 39-5 Hardware and Software Forwarding Components

In the normal mode of operation, the Integrated Switching Engine performs inter-VLAN routing in hardware. The CPU subsystem supports generic routing encapsulation (GRE) tunnels for forwarding in software.

Replication is a particular type of forwarding where, instead of sending out one copy of the packet, the packet is replicated and multiple copies of the packet are sent out. At Layer 3, replication occurs only for multicast packets; unicast packets are never replicated to multiple Layer 3 interfaces. In IP multicasting, for each incoming IP multicast packet that is received, many replicas of the packet are sent out.

IP multicast packets can be transmitted on the following types of routes:

- Hardware routes
- Software routes
- Partial routes

Hardware routes occur when the Integrated Switching Engine hardware forwards all replicas of a packet. Software routes occur when the CPU subsystem software forwards all replicas of a packet. Partial routes occur when the Integrated Switching Engine forwards some of the replicas in hardware and the CPU subsystem forwards some of the replicas in software.

Partial Routes

Note

The conditions listed below cause the replicas to be forwarded by the CPU subsystem software, but the performance of the replicas that are forwarded in hardware is not affected.

The following conditions cause some replicas of a packet for a route to be forwarded by the CPU subsystem:

- The switch is configured with the **ip igmp join-group** command as a member of the IP multicast group on the RPF interface of the multicast source.
- The switch is the first-hop to the source in PIM sparse mode. The switch must send PIM-register messages to the RP.

Software Routes

Note

If any one of the following conditions is configured on the RPF interface or the output interface, all replication of the output is performed in software.

The following conditions cause all replicas of a packet for a route to be forwarded by the CPU subsystem software:

- The interface is configured with multicast helper.
- The interface is a generic routing encapsulation (GRE) or Distance Vector Multicast Routing Protocol (DVMRP) tunnel.
- The interface uses non-Advanced Research Products Agency (ARPA) encapsulation.

The following packets are always forwarded in software:

- Packets sent to multicast groups that fall into the range 224.0.0.* (where * is in the range from 0 to 255). This range is used by routing protocols. Layer 3 switching supports all other multicast group addresses.
- Packets with IP options.

Non-Reverse Path Forwarding Traffic

Traffic that fails an Reverse Path Forwarding (RPF) check is called non-RPF traffic. Non-RPF traffic is forwarded by the Integrated Switching Engine by filtering (persistently dropping) or rate limiting the non-RPF traffic.

In a redundant configuration where multiple Layer 3 switches or routers connect to the same LAN segment, only one device forwards the multicast traffic from the source to the receivers on the outgoing interfaces. [Figure 39-6](#) shows how non-RPF traffic can occur in a common network configuration.

Figure 39-6 Redundant Multicast Router Configuration in a Stub Network

In this kind of topology, only Router A, the PIM designated router (PIM DR), forwards data to the common VLAN. Router B receives the forwarded multicast traffic, but must drop this traffic because it has arrived on the wrong interface and fails the RPF check. Traffic that fails the RPF check is called non-RPF traffic.

Multicast Fast Drop

In IP multicast protocols, such as PIM-SM and PIM-DM, every (S,G) or (*,G) route has an incoming interface associated with it. This interface is referred to as the reverse path forwarding interface. In some cases, when a packet arrives on an interface other than the expected RPF interface, the packet must be forwarded to the CPU subsystem software to allow PIM to perform special protocol processing on the packet. One example of this special protocol processing that PIM performs is the PIM Assert protocol.

By default, the Integrated Switching Engine hardware sends all packets that arrive on a non-RPF interface to the CPU subsystem software. However, processing in software is not necessary in many cases, because these non-RPF packets are often not needed by the multicast routing protocols. The problem is that if no action is taken, the non-RPF packets that are sent to the software can overwhelm the CPU.

Prior to Release IOS XE 3.3.0SG and IOS 15.1(1)SG, to prevent this situation from happening, the CPU subsystem software would load fast-drop entries in the hardware when it receives an RPF failed packet that is not needed by the PIM protocols running on the switch. Any packet matching a fast-drop entry would be bridged in the ingress VLAN, but is not sent to the software so the CPU subsystem is not overloaded by processing these RPF failures unnecessarily. However, this process involved maintaining fast-drop entries in hardware. Because the FLCAM space is limited, the number of fast-drop entries installed in hardware was also limited.

Beginning with Release IOS XE 3.3.0SG and IOS 15.1(1)SG, rather than installing fast-drop entries, your switch uses Dynamic Buffer Limiting (DBL). This flow-based congestion avoidance mechanism provides active queue management by tracking the queue length for each traffic flow. When the queue length of a flow exceeds its set limit, DBL drops packets. Rate DBL limits the non-rpf traffic to the cpu subsystem so that the CPU is not overwhelmed. The packets are rate limited per flow to the CPU. Because installing fast-drop entries in the CAM is inaccessibly, the number of fast-drop flows that can be handled by the switch need not be limited.

Protocol events, such as a link going down or a change in the unicast routing table, can impact the set of packets that can safely be fast dropped. A packet that was correctly fast dropped before might, after a topology change, need to be forwarded to the CPU subsystem software so that PIM can process it. The CPU subsystem software handles flushing fast-drop entries in response to protocol events so that the PIM code in IOS can process all the necessary RPF failures.

The use of fast-drop entries in the hardware is critical in some common topologies because you may have persistent RPF failures. Without the fast-drop entries, the CPU is exhausted by RPF failed packets that it did not need to process.

Multicast Forwarding Information Base

The Multicast Forwarding Information Base (MFIB) subsystem supports IP multicast routing in the Integrated Switching Engine hardware on the Catalyst 4500 series switch. The MFIB logically resides between the IP multicast routing protocols in the CPU subsystem software (PIM, IGMP, MSDP, MBGP, and DVMRP) and the platform-specific code that manages IP multicast routing in hardware. The MFIB translates the routing table information created by the multicast routing protocols into a simplified format that can be efficiently processed and used for forwarding by the Integrated Switching Engine hardware.

To display the information in the multicast routing table, use the **show ip mroute** command. To display the MFIB table information, use the **show ip mfib** command.

The MFIB table contains a set of IP multicast routes. IP multicast routes include (S,G) and (*,G). Each route in the MFIB table can have one or more optional flags associated with it. The route flags indicate how a packet that matches a route should be forwarded. For example, the Internal Copy (IC) flag on an MFIB route indicates that a process on the switch needs to receive a copy of the packet. The following flags can be associated with MFIB routes:

- Internal Copy (IC) flag—Sets on a route when a process on the router needs to receive a copy of all packets matching the specified route.
- Signalling (S) flag—Sets on a route when a process needs to be notified when a packet matching the route is received; the expected behavior is that the protocol code updates the MFIB state in response to receiving a packet on a signalling interface.
- Connected (C) flag—When set on an MFIB route, has the same meaning as the Signaling (S) flag, except that the C flag indicates that only packets sent by directly connected hosts to the route should be signaled to a protocol process.

A route can also have a set of optional flags associated with one or more interfaces. For example, an (S,G) route with the flags on VLAN 1 indicates how packets arriving on VLAN 1 should be handled, and whether packets matching the route should be forwarded onto VLAN 1. The per-interface flags supported in the MFIB include the following:

- Accepting (A)—Sets on the interface that is known in multicast routing as the RPF interface. A packet that arrives on an interface that is marked as Accepting (A) is forwarded to all Forwarding (F) interfaces.
- Forwarding (F)—Used in conjunction with the Accepting (A) flag as described above. The set of Forwarding interfaces that form what is often referred to as the multicast “olist” or output interface list.
- Signaling (S)—Sets on an interface when some multicast routing protocol process in Cisco IOS needs to be notified of packets arriving on that interface.

**Note**

When PIM-SM routing is in use, the MFIB route might include an interface as in this example:

```
PimTunnel [1.2.3.4].
```

it is a virtual interface that the MFIB subsystem creates to indicate that packets are being tunnelled to the specified destination address. A PimTunnel interface cannot be displayed with the normal **show interface** command.

S/M, 224/4

An (S/M, 224/4) entry is created in the MFIB for every multicast-enabled interface. This entry ensures that all packets sent by directly connected neighbors can be register-encapsulated to the PIM-SM RP. Typically, only a small number of packets are forwarded using the (S/M,224/4) route, until the (S,G) route is established by PIM-SM.

For example, on an interface with IP address 10.0.0.1 and netmask 255.0.0.0, a route is created matching all IP multicast packets in which the source address is anything in the class A network 10. This route can be written in conventional subnet/masklength notation as (10/8,224/4). If an interface has multiple assigned IP addresses, then one route is created for each such IP address.

Multicast HA

Starting with Release IOS XE 3.4.0SG and IOS 15.1(2)SG, the Catalyst 4500 series switches support multicast HA, which ensures uninterrupted multicast traffic flow in the event of a supervisor engine failure. MFIB states are synced to the standby supervisor engine prior to a switchover, ensuring NSF availability with a fast convergence upon switchover during a supervisor engine failure. Multicast HA (SSO / NSF / ISSU) is supported for the PIM Sparse, Dense, Bidir, and SSM Modes; and at Layer 2 for IGMP and MLD Snooping.

For details on Multicast HA, please refer to the following URLs:

http://www.cisco.com/en/US/docs/ios-xml/ios/ipmulti_resil/configuration/xe-3s/imc_high_availability.html

Configuring IP Multicast Routing

The following sections describe IP multicast routing configuration tasks:

- [Default Configuration in IP Multicast Routing, page 39-14](#)
- [Enabling IP Multicast Routing, page 39-14](#)
- [Enabling PIM on an Interface, page 39-15](#)
- [Enabling Bidirectional Mode, page 39-16](#)
- [Enabling PIM-SSM Mapping, page 39-17](#)
- [Configuring a Rendezvous Point, page 39-17](#)
- [Configuring a Single Static RP, page 39-21](#)
- [Load Splitting of IP Multicast Traffic, page 39-22](#)

For more detailed information on IP multicast routing, such as Auto-RP, PIM Version 2, and IP multicast static routes, refer to the *Cisco IOS IP and IP Routing Configuration Guide, Cisco IOS Release 12.3*.

Default Configuration in IP Multicast Routing

Table 39-1 shows the IP multicast default configuration.

Table 39-1 Default IP Multicast Configuration

Feature	Default Value
Rate limiting of RPF	Enabled globally
IP multicast routing	Disabled globally Note When IP multicast routing is disabled, IP multicast traffic data packets are not forwarded by the Catalyst 4500 series switch. However, IP multicast control traffic continues to be processed and forwarded. IP multicast routes can remain in the routing table even if IP multicast routing is disabled.
PIM	Disabled on all interfaces
IGMP snooping	Enabled on all VLAN interfaces Note If you disable IGMP snooping on an interface, all output ports are forwarded by the Integrated Switching Engine. When IGMP snooping is disabled on an input VLAN interface, multicast packets related to that interface are sent to all forwarding switch ports in the VLAN.

Note

Source-specific multicast and IGMP v3 are supported.

For more information about source-specific multicast with IGMPv3 and IGMP, see the following URL:

http://www.cisco.com/en/US/docs/ios/ipmulti/configuration/guide/imc_cfg_ssm.html

Enabling IP Multicast Routing

Enabling IP multicast routing allows the Catalyst 4500 series switch to forward multicast packets. To enable IP multicast routing on the router, enter this command:

Command	Purpose
Switch(config)# ip multicast-routing	Enables IP multicast routing.

Enabling PIM on an Interface

Enabling PIM on an interface also enables IGMP operation on that interface. An interface can be configured to be in dense mode, sparse mode, or sparse-dense mode. The mode determines how the Layer 3 switch or router populates its multicast routing table and how the Layer 3 switch or router forwards multicast packets it receives from its directly connected LANs. You must enable PIM in one of these modes for an interface to perform IP multicast routing.

When the switch populates the multicast routing table, dense-mode interfaces are always added to the table. Sparse-mode interfaces are added to the table only when periodic join messages are received from downstream routers, or when there is a directly connected member on the interface. When forwarding from a LAN, sparse-mode operation occurs if there is an RP known for the group. If so, the packets are encapsulated and sent toward the RP. When no RP is known, the packet is flooded in a dense-mode fashion. If the multicast traffic from a specific source is sufficient, the receiver's first-hop router can send join messages toward the source to build a source-based distribution tree.

There is no default mode setting. By default, multicast routing is disabled on an interface.

Enabling Dense Mode

To configure PIM on an interface to be in dense mode, enter this command:

Command	Purpose
Switch(config-if)# ip pim dense-mode	Enables dense-mode PIM on the interface.

For an example of how to configure a PIM interface in dense mode, see the “[PIM Dense Mode Example](#)” section.

Enabling Sparse Mode

To configure PIM on an interface to be in sparse mode, enter this command:

Command	Purpose
Switch(config-if)# ip pim sparse-mode	Enables sparse-mode PIM on the interface.

For an example of how to configure a PIM interface in sparse mode, see the “[PIM Sparse Mode Example](#)” section.

Enabling Sparse-Dense Mode

When you enter either the **ip pim sparse-mode** or **ip pim dense-mode** command, sparseness or denseness is applied to the interface as a whole. However, some environments might require PIM to run in a single region in sparse mode for some groups and in dense mode for other groups.

An alternative to enabling only dense mode or only sparse mode is to enable sparse-dense mode. The interface is treated as dense mode if the group is in dense mode; the interface is treated in sparse mode if the group is in sparse mode. If you want to treat the group as a sparse group, and the interface is in sparse-dense mode, you must have an RP.

If you configure sparse-dense mode, the idea of sparseness or denseness is applied to the group on the switch, and the network manager should apply the same concept throughout the network.

Another benefit of sparse-dense mode is that Auto-RP information can be distributed in a dense-mode manner; yet, multicast groups for user groups can be used in a sparse-mode manner. You do not need to configure a default RP at the leaf routers.

When an interface is treated in dense mode, it is populated in a multicast routing table's outgoing interface list when either of the following is true:

- When members or DVMRP neighbors exist on the interface
- When PIM neighbors exist and the group has not been pruned

When an interface is treated in sparse mode, it is populated in a multicast routing table's outgoing interface list when either of the following is true:

- When members or DVMRP neighbors exist on the interface
- When an explicit join has been received by a PIM neighbor on the interface

To enable PIM to operate in the same mode as the group, enter this command:

Command	Purpose
Switch(config-if) # ip pim sparse-dense-mode	Enables PIM to operate in sparse or dense mode, depending on the group.

Enabling Bidirectional Mode

Most of the configuration requirements for Bidir-PIM are the same as those for configuring PIM-SM. You need not enable or disable an interface for carrying traffic for multicast groups in bidirectional mode. Instead, you configure which multicast groups you want to operate in bidirectional mode. Similar to PIM-SM, you can perform this configuration with Auto-RP, static RP configurations, or the PIM Version 2 bootstrap router (PIMv2 BSR) mechanism.

To enable Bidir-PIM, perform this task in global configuration mode:

Command	Purpose
Switch(config) # ip pim bidir-enable	Enables bidir-PIM on a switch.

To configure Bidir-PIM, enter one of these commands, depending on which method you use to distribute group-to-RP mappings:

Command	Purpose
Switch(config)# ip pim rp-address <i>rp-address</i> [<i>access-list</i>] [<i>override</i>] bidir	Configures the address of a PIM RP for a particular group, and specifies bidirectional mode. Use this command when you are not distributing group-to-RP mappings using either Auto-RP or the PIMv2 BSR mechanism
Switch(config)# ip pim rp-candidate <i>type number</i> [<i>group-list</i> <i>access-list</i>] bidir	Configures the router to advertise itself as a PIM Version 2 candidate RP to the BSR, and specifies bidirectional mode. Use this command when you are using the PIMv2 BSR mechanism to distribute group-to-RP mappings.
Switch(config)# ip pim send-rp-address <i>type number scope ttl-value</i> [<i>group-list</i> <i>access-list</i>] [<i>interval</i> <i>seconds</i>] bidir	Configures the router to use Auto-RP to configure the groups the router is willing to act as RP, and specifies bidirectional mode. Use this command when you are using Auto-RP to distribute group-to-RP mappings.

For an example of how to configure bidir-PIM, see the “[Bidirectional PIM Mode Example](#)” section on page 39-29.

Enabling PIM-SSM Mapping

The Catalyst 4500 series switch supports SSM mapping, enabling an SSM transition in cases either where neither URD nor IGMP v3-lite is available, or when supporting SSM on the end system is impossible or unwanted due to administrative or technical reasons. With SSM mapping, you can leverage SSM for video delivery to legacy set-top boxes (STBs) that do not support IGMPv3 or for applications that do not take advantage of the IGMPv3 host stack.

For more details, refer to this URL:

http://www.cisco.com/en/US/docs/ios-xml/ios/ipmulti_igmp/configuration/15-s/imc_ssm_map.html

Configuring a Rendezvous Point

A rendezvous point (RP) is required in networks running Protocol Independent Multicast sparse mode (PIM-SM). In PIM-SM, traffic is forwarded only to network segments with active receivers that have explicitly requested multicast data.

The most commonly used methods to configure a rendezvous point (described here) are the use of Static RP and the use of the Auto-RP protocol. Another method (not described here) is the use of the Bootstrap Router (BSR) protocol.

Configuring Auto-RP

Auto-rendezvous point (Auto-RP) automates the distribution of group-to-rendezvous point (RP) mappings in a PIM network. To make Auto-RP work, a router must be designated as an RP mapping agent, which receives the RP announcement messages from the RPs and arbitrates conflicts. The RP mapping agent then sends the consistent group-to-RP mappings to all other routers by way of dense mode flooding.

All routers automatically discover which RP to use for the groups they support. The Internet Assigned Numbers Authority (IANA) has assigned two group addresses, 224.0.1.39 and 224.0.1.40, for Auto-RP.

The mapping agent receives announcements of intention to become the RP from Candidate-RPs. The mapping agent then announces the winner of the RP election. This announcement is made independently of the decisions by the other mapping agents.

To configure a rendezvous point, perform this task:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# ip multicast-routing	Enables IP multicast routing.
Step 4	Switch(config)# interface [FastEthernet GigabitEthernet Loopback Null Port-channel TenGigabitEthernet Tunnel Vlan] <i>number</i>	Selects an interface that is connected to hosts on which PIM can be enabled.
Step 5	Switch(config-if)# ip pim [sparse-mode sparse-dense-mode]	Enables PIM sparse or sparse-dense mode on an interface. When configuring Auto-RP in sparse mode, you must also configure the Auto-RP listener in the next step.
Step 6	Switch(config-if)# exit	Returns to global configuration mode.
Step 7	Repeat Steps 4 and 5 on all PIM interfaces.	—
Step 8	Switch(config)# ip pim autorp listener	Causes IP multicast traffic for the two Auto-RP groups 224.0.1.39 and 224.0.1.40 to be PIM dense mode flooded across interfaces operating in PIM sparse mode. <ul style="list-style-type: none"> • Skip this step if you are configuring sparse-dense mode in Step 8.

	Command or Action	Purpose
Step 9	<pre>Switch(config)# ip pim send-rp-announce {interface-type interface-number ip-address} scope ttl-value [group-list access-list] [interval seconds] [bidir]</pre>	<p>Sends RP announcements out all PIM-enabled interfaces.</p> <ul style="list-style-type: none"> • Perform this step on the RP router only. • Use the <i>interface-type</i> and <i>interface-number</i> arguments to define which IP address is to be used as the RP address. • Use the <i>ip-address</i> argument to specify a directly connected IP address as the RP address. <p>Note If the <i>ip-address</i> argument is configured for this command, the RP-announce message is sourced by the interface to which this IP address is connected (that is, the source address in the IP header of the RP-announce message is the IP address of that interface).</p> <ul style="list-style-type: none"> • This example shows that the interface is enabled with a maximum of 31 hops. The IP address by which the router wants to be identified as RP is the IP address associated with loopback interface 0. Access list 5 describes the groups for which this router serves as RP.
Step 10	<pre>Switch(config)# ip pim send-rp-discovery [interface-type interface-number] scope ttl-value [interval seconds]</pre>	<p>Configures the router to be an RP mapping agent.</p> <ul style="list-style-type: none"> • Perform this step on the RP router only. • Use the optional <i>interface-type</i> and <i>interface-number</i> arguments to define which IP address is to be used as the source address of the RP mapping agent. • Use the scope keyword and <i>ttl-value</i> argument to specify the Time-to-Live (TTL) value in the IP header of Auto-RP discovery messages. • Use the optional interval keyword and <i>seconds</i> argument to specify the interval at which Auto-RP discovery messages are sent. <p>Note Lowering the interval at which Auto-RP discovery messages are sent from the default value of 60 seconds results in more frequent floodings of the group-to-RP mappings. In some network environments, the disadvantages of lowering the interval (more control packet overhead) may outweigh the advantages (more frequent Requirementsgroup-to-RP mapping updates).</p> <ul style="list-style-type: none"> • The example shows limiting the Auto-RP discovery messages to 31 hops on loopback interface 1.

	Command or Action	Purpose
Step 11	Switch(config)# ip pim rp-announce-filter rp-list access-list group-list access-list	Filters incoming Auto-RP announcement messages coming from the RP. <ul style="list-style-type: none"> Perform this step on the RP router only. Two example access lists that apply to this step could be: <pre>access-list 1 permit 10.0.0.1 access-list 1 permit 10.0.0.2 access-list 2 permit 224.0.0.0 15.255.255.255</pre>
Step 12	Switch(config)# interface type number	Selects an interface that is connected to hosts on which PIM can be enabled.
Step 13	Switch(config-if)# interface ethernet 1 ip multicast boundary access-list [filter-autorp]	Configures an administratively scoped boundary. <ul style="list-style-type: none"> Perform this step on the interfaces that are boundaries to other routers. The access list is not shown in this task. An access list entry that uses the deny keyword creates a multicast boundary for packets that match that entry.
Step 14	Switch(config-if)# end	Returns to EXEC mode.
Step 15	Switch# show ip pim autorp	(Optional) Displays the Auto-RP information.
Step 16	Switch# show ip pim rp [mapping] [rp-address]	(Optional) Displays RPs known in the network and shows how the router learned about each RP.
Step 17	Switch# show ip igmp groups [group-name group-address interface-type interface-number] [detail]	(Optional) Displays the multicast groups having receivers that are directly connected to the router and that were learned through Internet Group Management Protocol (IGMP). <ul style="list-style-type: none"> A receiver must be active on the network at the time that this command is issued to ensure the presence of receiver information on the resulting display.
Step 18	Switch# show ip mroute [group-address group-name] [source-address source-name] [interface-type interface-number] [summary] [count] [active kbps]	(Optional) Displays the contents of the IP multicast routing (mroute) table.

This example illustrates how to configure Auto-RP:

```
Switch> enable
Switch# configure terminal
Switch(config)# ip multicast-routing
Switch(config)# interface ethernet 1
Switch(config-if)# ip pim sparse-mode
Switch(config-if)# end
Switch(config)# ip pim autorp listener
Switch(config)# ip pim send-rp-announce loopback0 scope 31 group-list 5
Switch(config)# ip pim send-rp-discovery loopback 1 scope 31
Switch(config)# ip pim rp-announce-filter rp-list 1 group-list 2
Switch(config)# interface ethernet 1
Switch(config-if)# ip multicast boundary 10 filter-autorp
Switch(config-if)# end
Switch# show ip pim autorp
```

```
Switch# show ip pim rp mapping
Switch# show ip igmp groups
Switch# show ip mroute cbone-audio
```

Configuring a Single Static RP

If you are configuring PIM sparse mode, you must configure a PIM RP for a multicast group. An RP can either be configured statically in each device, or learned through a dynamic mechanism. This task explains how to statically configure an RP, as opposed to the router learning the RP through a dynamic mechanism such as Auto-RP.

PIM designated routers (DRs) forward data from directly connected multicast sources to the RP for distribution down the shared tree. Data is forwarded to the RP in one of two ways. It is encapsulated in register packets and unicast directly to the RP, or, if the RP has itself joined the source tree, it is multicast forwarded per the RPF forwarding algorithm. Last hop routers directly connected to receivers may, at their discretion, join themselves to the source tree and prune themselves from the shared tree.

A single RP can be configured for multiple groups that are defined by an access list. If no RP is configured for a group, the router treats the group as dense using the PIM dense mode techniques. (You can prevent this occurrence by configuring the **no ip pim dm-fallback** command.)

If a conflict exists between the RP configured with the **ip pim rp-address** command and one learned by Auto-RP, the Auto-RP information is used, unless the override keyword is configured.

To configure a single static RP, perform this task:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# ip multicast-routing	Enables IP multicast routing.
Step 4	Switch(config)# interface <i>type number</i>	Selects an interface that is connected to hosts on which PIM can be enabled.
Step 5	Switch(config-if)# ip pim [sparse-mode sparse-dense-mode]	Enables PIM on an interface. You must use sparse mode.
Step 6	Repeat Steps 4 and 5 on every interface that uses IP multicast.	—
Step 7	Switch(config-if)# exit	Returns to global configuration mode.
Step 8	Switch(config)# ip pim rp-address <i>rp-address</i> [<i>access-list</i>] [override]	Configures the address of a PIM RP for a particular group. <ul style="list-style-type: none"> • Perform this step on any router. • The <i>access-list</i> argument specifies the number or name of an access list that defines for which multicast groups the RP should be used. • The override keyword specifies that if there is a conflict between the RP configured with this command and one learned by Auto-RP, the RP configured with this command prevails.
Step 9	Switch(config)# end	Ends the current configuration session and returns to EXEC mode.

	Command or Action	Purpose
Step 10	Switch# show ip pim rp [mapping] [rp-address]	(Optional) Displays RPs known in the network and shows how the router learned about each RP.
Step 11	Switch# show ip igmp groups [group-name group-address interface-type interface-number] [detail]	(Optional) Displays the multicast groups having receivers that are directly connected to the router and that were learned through IGMP. <ul style="list-style-type: none"> A receiver must be active on the network at the time that this command is issued to ensure that receiver information is present on the resulting display.
Step 12	Switch# show ip mroute [group-address group-name] [source-address source-name] [interface-type interface-number] [summary] [count] [active kbps]	(Optional) Displays the contents of the IP multicast routing (mroute) table.

This example shows how to configure a single-static RP:

```
Switch> enable
Switch# configure terminal
Switch(config)# ip multicast-routing
Switch(config)# interface ethernet 1
Switch(config-if)# ip pim sparse-mode
Switch(config-if)# exit
Switch(config)# ip pim rp-address 192.168.0.0
Switch(config)# end
Switch# show ip pim rp mapping
Switch# show ip igmp groups
Switch# show ip mroute cbone-audio
```

Load Splitting of IP Multicast Traffic

Note

This feature is only supported on Enterprise Services. It is not supported on IP Base and LAN Base.

If two or more equal-cost paths from a source are available, unicast traffic is load split across those paths. However, by default, multicast traffic is not load split across multiple equal-cost paths. In general, multicast traffic flows down from the reverse path forwarding (RPF) neighbor. According to the Protocol Independent Multicast (PIM) specifications, this neighbor must have the highest IP address if more than one neighbor has the same metric.

Use the **ip multicast multipath** command to enable load splitting of IP multicast traffic across multiple equal-cost paths.

Note

The **ip multicast multipath** command does not work with bidirectional Protocol Independent Multicast (PIM).

To enable IP multicast multipath, perform this task:

	Command	Purpose
Step 1	Switch# config t	Enters configuration mode.
Step 2	Switch(config)# ip multicast multipath	Enables IP multicast multipath.
Step 3	Switch(config)# end	Exits configuration mode.

Note

The **ip multicast multipath** command load splits the traffic but does not load balance the traffic. Traffic from a source uses only one path, even if the traffic far outweighs traffic from other sources.

Configuring load splitting with the **ip multicast multipath** command causes the system to load split multicast traffic across multiple equal-cost paths based on source address using the S-hash algorithm. When the **ip multicast multipath** command is configured and multiple equal-cost paths exist, the path in which multicast traffic travel is selected based on the source IP address. Multicast traffic from different sources is load split across the different equal-cost paths. Load splitting does not occur across equal-cost paths for multicast traffic from the same source sent to different multicast groups.

The following example shows how to enable ECMP multicast load splitting on a router based on a source address using the S-hash algorithm:

```
Switch(config)# ip multicast multipath
```

The following example shows how to enable ECMP multicast load splitting on a router based on a source and group address using the basic S-G-hash algorithm:

```
Switch(config)# ip multicast multipath s-g-hash basic
```

The following example shows how to enable ECMP multicast load splitting on a router based on a source, group, and next-hop address using the next-hop-based S-G-hash algorithm:

```
Switch(config)# ip multicast multipath s-g-hash next-hop-based
```

Monitoring and Maintaining IP Multicast Routing

You can remove all contents of a particular cache, table, or database. You also can display specific statistics. The following sections describe how to monitor and maintain IP multicast:

- [Displaying System and Network Statistics, page 39-24](#)
- [Displaying the Multicast Routing Table, page 39-24](#)
- [Displaying IP MFIB, page 39-26](#)
- [Displaying Bidirectional PIM Information, page 39-27](#)
- [Displaying PIM Statistics, page 39-28](#)
- [Clearing Tables and Databases, page 39-28](#)

Displaying System and Network Statistics

You can display specific statistics, such as the contents of IP routing tables and databases. Information provided can be used to determine resource utilization and solve network problems. You can also display information about node reachability and discover the routing path your device's packets are taking using the network.

To display various routing statistics, enter any of these commands:

Command	Purpose
Switch# ping [<i>group-name</i> <i>group-address</i>]	Sends an ICMP Echo Request to a multicast group address.
Switch# show ip mroute [<i>hostname</i> <i>group_number</i>]	Displays the contents of the IP multicast routing table.
Switch# show ip pim interface [<i>type number</i>] [<i>count</i>]	Displays information about interfaces configured for PIM.
Switch# show ip interface	Displays PIM information for all interfaces.

Displaying the Multicast Routing Table

The following is sample output from the **show ip mroute** command for a router operating in dense mode. This command displays the contents of the IP multicast FIB table for the multicast group named cbone-audio.

```
Switch# show ip mroute cbone-audio
```

```
IP Multicast Routing Table
Flags: D - Dense, S - Sparse, C - Connected, L - Local, P - Pruned
R - RP-bit set, F - Register flag, T - SPT-bit set
Timers: Uptime/Expires
Interface state: Interface, Next-Hop, State/Mode

(*, 224.0.255.1), uptime 0:57:31, expires 0:02:59, RP is 0.0.0.0, flags: DC
  Incoming interface: Null, RPF neighbor 0.0.0.0, Dvmrp
  Outgoing interface list:
    Ethernet0, Forward/Dense, 0:57:31/0:02:52
    Tunnel0, Forward/Dense, 0:56:55/0:01:28

(198.92.37.100/32, 224.0.255.1), uptime 20:20:00, expires 0:02:55, flags: C
  Incoming interface: Tunnel0, RPF neighbor 10.20.37.33, Dvmrp
  Outgoing interface list:
    Ethernet0, Forward/Dense, 20:20:00/0:02:52
```

The following is sample output from the **show ip mroute** command for a router operating in sparse mode:

```
Switch# show ip mroute
```

```
IP Multicast Routing Table
Flags: D - Dense, S - Sparse, C - Connected, L - Local, P - Pruned
R - RP-bit set, F - Register flag, T - SPT-bit set
Timers: Uptime/Expires
Interface state: Interface, Next-Hop, State/Mode

(*, 224.0.255.3), uptime 5:29:15, RP is 198.92.37.2, flags: SC
```

```

Incoming interface: Tunnel0, RPF neighbor 10.3.35.1, Dvmrp
Outgoing interface list:
    Ethernet0, Forward/Sparse, 5:29:15/0:02:57

(198.92.46.0/24, 224.0.255.3), uptime 5:29:15, expires 0:02:59, flags: C
Incoming interface: Tunnel0, RPF neighbor 10.3.35.1
Outgoing interface list:
    Ethernet0, Forward/Sparse, 5:29:15/0:02:57

```

**Note**

Interface timers are not updated for hardware-forwarded packets. Entry timers are updated approximately every five seconds.

The following is sample output from the **show ip mroute** command with the **summary** keyword:

```

Switch# show ip mroute summary

IP Multicast Routing Table
Flags: D - Dense, S - Sparse, C - Connected, L - Local, P - Pruned
      R - RP-bit set, F - Register flag, T - SPT-bit set, J - Join SPT
Timers: Uptime/Expires
Interface state: Interface, Next-Hop, State/Mode

(*, 224.255.255.255), 2d16h/00:02:30, RP 171.69.10.13, flags: SJPC

```

**Note**

Multicast route byte and packet statistics are supported only for the first 1024 multicast routes. Output interface statistics are not maintained.

Displaying IP MFIB

You can display all routes in the MFIB, including routes that might not exist directly in the upper-layer routing protocol database but that are used to accelerate fast switching. These routes appear in the MFIB, even if dense-mode forwarding is in use.

To display various MFIB routing routes, enter one of these commands:

Command	Purpose
Switch# show ip mfib	Displays the (S,G) and (*,G) routes that are used for packet forwarding. Displays counts for fast, slow, and partially switched packets for every multicast route.
Switch# show ip mfib all	Displays all routes in the MFIB, including routes that may not exist directly in the upper-layer routing protocol database, but that are used to accelerate fast switching. These routes include the (S/M,224/4) routes.
Switch# show ip mfib log [n]	Displays a log of the most recent <i>n</i> MFIB-related events, the most recent first. <i>n</i> represents the number of events.

The following is sample output from the **show ip mfib** command:

```
IP Multicast Forwarding Information Base
Entry Flags: C - Directly Connected, S - Signal,
              IC - Internal Copy
Interface Flags: A - Accept, F - Forward, S - Signal,
                 NP - Not platform switched
Packets: Fast/Partial/Slow Bytes: Fast/Partial/Slow:
(171.69.10.13, 224.0.1.40), flags (IC)
  Packets: 2292/2292/0, Bytes: 518803/0/518803
  Vlan7 (A)
  Vlan100 (F NS)
  Vlan105 (F NS)
(*, 224.0.1.60), flags ()
  Packets: 2292/0/0, Bytes: 518803/0/0
  Vlan7 (A NS)
(*, 224.0.1.75), flags ()
  Vlan7 (A NS)
(10.34.2.92, 239.192.128.80), flags ()
  Packets: 24579/100/0, 2113788/15000/0 bytes
  Vlan7 (F NS)
  Vlan100 (A)
(*, 239.193.100.70), flags ()
  Packets: 1/0/0, 1500/0/0 bytes
  Vlan7 (A)
..
```

The fast-switched packet count represents the number of packets that were switched in hardware on the corresponding route.

The partially switched packet counter represents the number of times that a fast-switched packet was also copied to the CPU for software processing or for forwarding to one or more non-platform switched interfaces (such as a PimTunnel interface).

The slow-switched packet count represents the number of packets that were switched completely in software on the corresponding route.

Displaying Bidirectional PIM Information

To display bidir-PIM information, enter one of these commands:

Command	Purpose
Switch(config)# show ip pim interface [<i>type number</i>] [<i>df</i> <i>count</i>] [<i>rp-address</i>]	Displays information about the elected designated forward (DF) for each RP of an interface, along with the unicast routing metric associated with the DF.
Switch(config)# show ip pim rp [<i>mapping</i> <i>metric</i>] [<i>rp-address</i>]	Displays information about configured RPs, learned by using Auto-RP or BSR, along with their unicast routing metric.

Displaying PIM Statistics

The following is sample output from the **show ip pim interface** command:

```
Switch# show ip pim interface
```

Address	Interface	Mode	Neighbor Count	Query Interval	DR
198.92.37.6	Ethernet0	Dense	2	30	198.92.37.33
198.92.36.129	Ethernet1	Dense	2	30	198.92.36.131
10.1.37.2	Tunnel0	Dense	1	30	0.0.0.0

The following is sample output from the **show ip pim interface** command with a **count**:

```
Switch# show ip pim interface count
```

Address	Interface	FS	Mpackets In/Out
171.69.121.35	Ethernet0	*	548305239/13744856
171.69.121.35	Serial0.33	*	8256/67052912
198.92.12.73	Serial0.1719	*	219444/862191

The following is sample output from the **show ip pim interface** command with a **count** when IP multicast is enabled. The example lists the PIM interfaces that are fast-switched and process-switched, and the packet counts for these. The H is added to interfaces where IP multicast is enabled.

```
Switch# show ip pim interface count
```

```
States: FS - Fast Switched, H - Hardware Switched
Address      Interface      FS  Mpackets In/Out
192.1.10.2   Vlan10         * H 40886/0
192.1.11.2   Vlan11         * H 0/40554
192.1.12.2   Vlan12         * H 0/40554
192.1.23.2   Vlan23         *   0/0
192.1.24.2   Vlan24         *   0/0
```

Clearing Tables and Databases

You can remove all contents of a particular cache, table, or database. Clearing a cache, table, or database might be necessary when the contents of the particular structure have become, or are suspected to be, invalid.

To clear IP multicast caches, tables, and databases, enter one of these commands:

Command	Purpose
Switch# clear ip mroute	Deletes entries from the IP routing table.
Switch# clear ip mfib counters	Deletes all per-route and global MFIB counters.

**Note**

IP multicast routes can be regenerated in response to protocol events and as data packets arrive.

Configuration Examples

The following sections provide IP multicast routing configuration examples:

- [PIM Dense Mode Example, page 39-29](#)
- [PIM Sparse Mode Example, page 39-29](#)
- [Bidirectional PIM Mode Example, page 39-29](#)
- [Sparse Mode with a Single Static RP Example, page 39-30](#)
- [Sparse Mode with Auto-RP: Example, page 39-30](#)

PIM Dense Mode Example

This example is a configuration of dense-mode PIM on an Ethernet interface:

```
ip multicast-routing
interface ethernet 0
 ip pim dense-mode
```

PIM Sparse Mode Example

This example is a configuration of sparse-mode PIM. The RP router is the router with the address 10.8.0.20.

```
ip multicast-routing
 ip pim rp-address 10.8.0.20 1
interface ethernet 1
 ip pim sparse-mode
```

Bidirectional PIM Mode Example

By default, a bidirectional RP advertises all groups as bidirectional. Use an access list on the RP to specify a list of groups to be advertised as bidirectional. Groups with the **deny** keyword operate in dense mode. A different, nonbidirectional RP address is required for groups that operate in sparse mode, because a single access list only allows either a **permit** or **deny** keyword.

The following example shows how to configure an RP for both sparse and bidirectional mode groups. 224/8 and 227/8 are bidirectional groups, 226/8 is sparse mode, and 225/8 is dense mode. The RP must be configured to use different IP addresses for sparse and bidirectional mode operations. Two loopback

interfaces are used to allow this configuration and the addresses of these interfaces must be routed throughout the PIM domain so that the other routers in the PIM domain can receive Auto-RP announcements and communicate with the RP:

```
ip multicast-routing !Enable IP multicast routing
ip pim bidir-enable !Enable bidir-PIM
!
interface loopback 0
description One Loopback address for this routers Bidir Mode RP function
ip address 10.0.1.1 255.255.255.0
ip pim sparse-dense-mode
!
interface loopback 1
description One Loopback address for this routers Sparse Mode RP function
ip address 10.0.2.1 255.255.255.0
ip pim sparse-dense-mode
ip pim send-rp-announce Loopback0 scope 10 group-list 45 bidir
ip pim send-rp-announce Loopback1 scope 10 group-list 46
ip pim send-rp-discovery scope 10
access-list 45 permit 224.0.0.0 0.255.255.255
access-list 45 permit 227.0.0.0 0.255.255.255
access-list 45 deny 225.0.0.0 0.255.255.255
access-list 46 permit 226.0.0.0 0.255.255.255
```

Sparse Mode with a Single Static RP Example

The following example sets the PIM RP address to 192.168.1.1 for all multicast groups and defines all groups to operate in sparse mode:

```
ip multicast-routing
interface ethernet 1
 ip pim sparse-mode
ip pim rp-address 192.168.1.1
no ip pim dm-fallback
```

Note

The same RP cannot be used for both bidirectional and sparse mode groups.

The following example sets the PIM RP address to 172.16.1.1 for the multicast group 225.2.2.2 only:

```
access list 1 225.2.2.2 0.0.0.0
 ip pim rp-address 172.17.1.1
```

Sparse Mode with Auto-RP: Example

The following example configures sparse mode with Auto-RP:

```
ip multicast-routing
ip pim autorp listener
ip pim send-rp-announce Loopback0 scope 16 group-list 1
ip pim send-rp-discovery Loopback1 scope 16
no ip pim dm-fallback
access-list 1 permit 239.254.2.0 0.0.0.255
access-list 1 permit 239.254.3.0 0.0.0.255
.
.
access-list 10 permit 224.0.1.39
access-list 10 permit 224.0.1.40
access-list 10 permit 239.254.2.0 0.0.0.255
access-list 10 permit 239.254.3.0 0.0.0.255
```

Configuring ANCP Client

This chapter describes Access-Network Control Protocol (ANCP) Client on a Catalyst 4500 series switch. It includes the following sections:

- [About ANCP Client, page 40-1](#)
- [Enabling and Configuring ANCP Client, page 40-2](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About ANCP Client

ANCP Multicast enables you to control multicast traffic on a Catalyst 4500 series switch using either ANCP (instead of IGMP) or direct static configuration on the CLI. You can configure the switch as an ANCP client that connects to a remote ANCP server with multicast enabled. You can then initiate joins and leaves from that server. Use the switch in a system in which a subscriber requests that a digital right management (DRM) server receive a given channel (multicast) *potentially* through any private protocol mechanism.

Note

The ANCP client does not allow more than four multicast streams per-port per-VLAN. If a fifth join arrives, it is rejected.

If the digital right management (DRM) server determines that a subscriber is allowed to receive a multicast, it requests that the ANCP server sends an ANCP join command to the ANCP client (Catalyst 4500 series switch) for the port on which the subscriber is connected.

Note

IGMP snooping must be enabled on an ANCP client (Catalyst 4500 series switch) for processing multicast commands (join, leave, leave all requests, and request for active flows report) from the ANCP server. For information on enabling IGMP snooping, Refer to [Chapter 28, “Configuring IGMP Snooping and Filtering, and MVR.”](#)

The ANCP protocol must be able to identify the port on which multicast must be added. (This port can be identified either using the identifier configured on the CLI or with the DHCP option 82 that was inserted by the Catalyst 4500 switch while the subscriber received an IP address with DHCP. Either way, you should be consistent in identifying a given port.

Enabling and Configuring ANCP Client

Note

If you intend to use DHCP option 82 rather than CLI mapping (with the **ancp client port identif...** command) you must enter the **ip dhcp snooping** command before configuring the ANCP client.

You can identify a port with the **ancp mode client** command or with DHCP option 82.

This section includes these topics:

- [Identifying a Port with the ANCP Protocol, page 40-2](#)
- [Identifying a Port with DHCP Option 82, page 40-4](#)

Identifying a Port with the ANCP Protocol

To make the Catalyst 4500 series switch operate as an ANCP client and to build and initialize its relevant data, enter the **ancp mode client** command. The **no** version of this command disables ANCP. This command disconnects the ANCP client from the ANCP server and terminates any existing multicast streams that have been enabled with ANCP.

To configure a switch to communicate with a single ANCP server, use the **[no] ancp client server interface** command. This command directs the ANCP client to initiate a TCP connection to the remote ANCP server identified with the IP address. If the TCP connection fails, the connection times out and retries for the connection every 120 seconds until it succeeds. The **interface** command specifies the interface from which the local ANCP client obtains its IP address. The **no** command terminates the TCP connection to the ANCP server but retains any existing ANCP activated multicast stream.

Separate commands enable the ANCP client and configure the IP address of the ANCP server. You can reconfigure the IP address of the remote ANCP server without losing existing ANCP activated multicast streams.

To identify a port with the ANCP protocol, follow these steps:

Step 1 Enable ANCP as follows:

```
Switch(config)> ancp mode client
```

Step 2 Configure the IP address of the remote server as the interface to acquire the source IP address:

```
Switch(config)> ancp client server ipaddress of server interface interface
```

The interface might be a loopback; this allows the client to reach the server using the interface.

Step 3 (Optional) Enable the ANCP multicast client to identify this VLAN interface using the port-identifier as opposed to the Option 82 circuit-id:

```
Switch(config)> ancp client port identifier [port-identifier] vlan [number] interface [interface]
```

The **no** version of this command prompts a warning message if any multicast stream is activated by ANCP using the port-identifier on a port:

```
Switch(config)# no ancp client port identifier bbb vlan 10 interface GigabitEthernet3/5
Warning: Multicast flows seems to exist for this port, remove mapping and delete flows
anyway?[confirm]y
Switch(config)#
```

The ANCP client tries to connect to the server. If it fails, it tries again 10 seconds later. If it fails again, it tries at 20 seconds intervals, until it reaches the timeout setting (120 seconds). It remains timed out until it reconnects.

Note

If the connection fails again and the client attempts to reconnect and it fails, the wait time returns to 10 seconds (and so on).

To determine whether the ANCP client is successfully connected to the server, enter the **show ancp status** command, which displays the status of the ANCP TCP connection with the remote ANCP server.

```
Switch# show ancp status
ANCP enabled on following interfaces

Et0/0
  ANCP end point(s) on this interface:
  =====

  ANCP state ESTAB
  Neighbor 10.1.1.1 Neighbor port 6068
  Hello interval 100 Sender instance 1 Sender name 372F61C
  Sender port 0 Partition ID 0 TCB 36E27E8
  Capabilities negotiated: Transactional Multicast

Switch#
```

In the preceding example, only one capability (transactional multicast) is negotiated (or supported). This capability is the only one that the ANCP client supports. Because the server also supports this capability, the two entities can now communicate.

The server can send ANCP multicast commands (join, leave, leave all requests, and request for active flows report) as defined in the multicast portion of the ANCP protocol. At any time, an administrator can use the **show ancp multicast [interface vlan] [group | source]** command to see the information the ANCP client has obtained about the current multicast flows.

Example 1

```
ANCP_Client# show ancp multicast group 239.6.6.6
ANCP Multicast Streams
ClientID          VLAN  Interface          Joined on
  Group 239.6.6.6
0x0106000700130103  19   Gi1/3              15:06:23 UTC Tue Aug 26 2008
ANCP_Client#
```

Example 2

```
ANCP_Client# show ancp multicast interface Fa2/3 vlan 19
ANCP Multicast Streams
Interface FastEthernet2/3          VLAN 19: client ID 0x0106000700130203
  Group          Source          Joined on
  239.5.6.7      -              15:03:14 UTC Tue Aug 26 2008
ANCP_Client#
```

Note

Specifying the **show ancp multicast** command without parameters or keywords lists everything.

Identifying a Port with DHCP Option 82

Note

To use DHCP option 82, you need to enable DHCP and DHCP snooping (see [Chapter 60, “Configuring DHCP Snooping, IP Source Guard, and IPSG for Static Hosts”](#)).

If you identify the port with DHCP option 82, you need to configure the Catalyst 4500 series switch as a DHCP relay to insert the DHCP option 82. This action adds a tag in the DHCP packet from the DHCP client so that the DHCP server knows the port connected to this specific DHCP client. The DHCP server can then map the IP address it is providing to the client with the DHCP option 82 it received from the switch. The DHCP server only needs to lookup the DHCP option 82 associated with a given IP address and provide it to the ANCP server. This allows the ANCP client on the switch to identify the proper port using an identifier the switch understands. To configure DHCP snooping on the Catalyst 4500 series switch, use the following commands:

```
Switch(config)# ip dhcp snooping
Switch(config)# ip dhcp snooping vlan vlan-range
```

By default, DHCP option 82 is inserted when DHCP snooping is activated. Turning this default off could cause ANCP to function improperly with the DHCP circuit-id; it must remain active. To activate it, enter this command:

```
Switch(config)# ip dhcp snooping information option
```

Note

The DHCP option 82 circuit-ID is inserted in the Active-Flow report (when queried for all multicast flows) even if a configured circuit-ID exists.

ANCP allows a remote server to request the list of active flows from the ANCP client (Catalyst 4500 series switch is the ANCP client). This list is very similar to the output from the **show ancp multicast** command except that it follows the ANCP protocol packet format (see IETF.org). Observe that the **show ancp multicast** command provides the flows that have been activated with the **anyp port client identifier** command while the ANCP active flow request only reports the client ID in DHCP option 82 circuit-ID format, regardless of the activation mechanism.

Refer to [Chapter 60, “Configuring DHCP Snooping, IP Source Guard, and IPSG for Static Hosts”](#) for details on the CLI.

ANCP Guidelines and Restrictions

When using (or configuring) ANCP, consider these guidelines and restrictions:

- Entering a **shut** command on a port removes ANCP activated multicast streams from the port. They must be reactivated by the ANCP server.
- Entering a **suspend** or **shut** command on a VLAN removes ANCP-activated multicast streams from the VLAN.
- Deleting a VLAN removes ANCP-activated multicast streams from the VLAN.
- If a port enters the errdisable or blocked state, ANCP-activated multicast streams are removed from the port.
- Disabling IGMP snooping globally or per-VLAN might disrupt ANCP client functionality.
- An ANCP client does not account for the Layer 3 interface state changes (if PIM interface at Layer 3 shuts down, ANCP does not remove the streams). When a PIM interface is running again, multicast streams are received by subscribers.

Configuring Bidirectional Forwarding Detection

Note

Bidirectional Forwarding Detection (BFD) support was introduced Starting with Cisco IOS Release IOS 15.1(1)SG, on Supervisor Engine 6-E, Supervisor Engine 6L-E. Starting with Cisco IOS XE 3.5.0E and IOS 15.2(1)E, on Supervisor Engine 7-E, and 7L-E. Starting with Cisco IOS XE 3.6.0E and IOS 15.2(2)E, on Supervisor Engine 8-E. Starting with Cisco IOS XE 3.10.0E, on Supervisor Engine 9-E

This document describes how to enable the BFD protocol, which is a detection protocol designed to provide fast forwarding path failure detection times for all media types, encapsulations, topologies, and routing protocols.

BFD provides a consistent failure detection method for network administrators in addition to fast forwarding path failure detection. Because the network administrator can use BFD to detect forwarding path failures at a uniform rate, rather than the variable rates for different routing protocol hello mechanisms, network profiling and planning are simplified, and reconvergence time is more consistent and predictable.

Note

For details on all the BFD commands introduced in this chapter, see the URL:

http://www.cisco.com/en/US/docs/ios/iproute_pi/command/reference/iri_book.html

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the [“Technical Assistance” section on page 41-29](#).

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Contents

- [Prerequisites for Bidirectional Forwarding Detection, page 41-2](#)
- [Restrictions for Bidirectional Forwarding Detection, page 41-2](#)
- [Information About Bidirectional Forwarding Detection, page 41-3](#)
- [How to Configure Bidirectional Forwarding Detection, page 41-8](#)
- [Configuration Examples for Bidirectional Forwarding Detection, page 41-17](#)
- [Additional References, page 41-28](#)

Prerequisites for Bidirectional Forwarding Detection

Prerequisites include:

- IP routing must be enabled on all participating switches.
- One of the IP routing protocols supported by BFD must be configured on the switches before BFD is deployed. You should implement fast convergence for the routing protocol that you plan to use. See the IP routing documentation for your version of Cisco IOS software for information on configuring fast convergence. See the [“Restrictions for Bidirectional Forwarding Detection” section on page 41-2](#) for more information on BFD routing protocol support in Cisco IOS software.

Restrictions for Bidirectional Forwarding Detection

Restrictions include:

- BFD Hardware offloading of sessions is not supported with the use of authentication on the 4500 Sup7E and Sup8E. Enable BFD Echo mode to work with authentication.
- BFD works only for directly connected neighbors. BFD neighbors must be no more than one IP hop away. Multihop configurations are not supported.

Cisco IOS Release 15.1(1)SG

- Catalyst 4500 series switches support up to 128 BFD sessions with a minimum hello interval of 100 ms and a multiplier of 3. The multiplier specifies the minimum number of consecutive packets that can be missed before a session is declared down.
- If SSO is enabled on a dual RP system, the following limitations apply:
 - The minimum hello interval is 100 ms with a multiplier of 5 or higher.
 - Smaller values may be configured but may flap during an SSO switchover.
- To enable echo mode the peer system must be configured with the **no ip redirects** command.

Cisco IOS Release XE 3.5.0E and IOS 15.2(1)E

- Catalyst 4500 series switches support up to 100 BFD sessions with a minimum hello interval of 100 ms and a multiplier of 3. The multiplier specifies the minimum number of consecutive packets that can be missed before a session is declared down.
- If SSO is enabled on a dual RP system, the following limitations apply:
 - The minimum hello interval is 100 ms with a multiplier of 5 or higher.

- Smaller values may be configured but may flap during an SSO switchover.
- To enable echo mode the peer system must be configured with the **no ip redirects** command.

**Note**

For the most accurate platform and hardware restrictions, see the Cisco IOS software release notes for your software version.

Information About Bidirectional Forwarding Detection

- [BFD Operation, page 41-3](#)
- [Benefits of Using BFD for Failure Detection, page 41-7](#)

BFD Operation

BFD provides a low-overhead, short-duration method of detecting failures in the forwarding path between two adjacent switches, including the interfaces, data links, and forwarding planes.

BFD is a detection protocol that you enable at the interface and routing protocol levels. Cisco supports the BFD asynchronous mode, which depends on the sending of BFD control packets between two systems to activate and maintain BFD neighbor sessions between switches. Therefore, to create a BFD session, you must configure BFD on both systems (or BFD peers). Once BFD has been enabled on the interfaces and at the router level for the appropriate routing protocols, a BFD session is created, BFD timers are negotiated, and the BFD peers will begin to send BFD control packets to each other at the negotiated interval.

Cisco supports BFD echo mode. Echo packets are sent by the forwarding engine and are forwarded back along the same path to perform detection. The BFD session at the other end does not participate in the actual forwarding of the echo packets. See [Configuring BFD Echo Mode, page 41-15](#) for more information.

This section includes the following subsections:

- [Neighbor Relationships, page 41-3](#)
- [BFD Detection of Failures, page 41-4](#)
- [BFD Version Interoperability, page 41-5](#)
- [BFD Session Limits, page 41-5](#)
- [BFD Support for Nonbroadcast Media Interfaces, page 41-5](#)
- [BFD Support for Nonstop Forwarding with Stateful Switchover, page 41-5](#)
- [BFD Support for Stateful Switchover, page 41-6](#)
- [BFD Support for Static Routing, page 41-6](#)

Neighbor Relationships

BFD provides fast BFD peer failure detection times independently of all media types, encapsulations, topologies, and routing protocols BGP, EIGRP, OSPF, and static routes. By sending rapid failure detection notices to the routing protocols in the local switch to initiate the routing table recalculation process, BFD contributes to greatly reduced overall network convergence time. [Figure 41-1](#) shows a

simple network with two switches running OSPF and BFD. When OSPF discovers a neighbor (1) it sends a request to the local BFD process to initiate a BFD neighbor session with the OSPF neighbor routers (2). The BFD neighbor session with the OSPF neighbor router is established (3).

Figure 41-1 Establishing a BFD Neighbor Relationship

Figure 41-2 shows what happens when a failure occurs in the network (1). The BFD neighbor session with the OSPF neighbor router is torn down (2). BFD notifies the local OSPF process that the BFD neighbor is no longer reachable (3). The local OSPF process tears down the OSPF neighbor relationship (4). If an alternative path is available, the routers will immediately start converging on it.

Figure 41-2 Tearing Down an OSPF Neighbor Relationship

A routing protocol needs to register with BFD for every neighbor it acquires. Once a neighbor is registered, BFD initiates a session with the neighbor if a session does not already exist.

OSPF registers with BFD when:

- A neighbor finite state machine (FSM) transitions to full state.
- Both OSPF BFD and BFD are enabled.

On broadcast interfaces, OSPF establishes a BFD session only with the designated router (DR) and backup designated router (BDR), but not between any two switches (routers) in DROTHER state.

BFD Detection of Failures

Once a BFD session has been established and timer negotiations are complete, BFD peers send BFD control packets that act in the same manner as an IGP hello protocol to detect liveness, except at a more accelerated rate. The following information should be noted:

- BFD is a forwarding path failure detection protocol. BFD detects a failure, but the routing protocol must take action to bypass a failed peer.
- Typically, BFD can be used at any protocol layer. However, the Cisco implementation of BFD supports only Layer 3 clients, in particular, the BGP, EIGRP, and OSPF routing protocols, and static routing.
- Cisco devices will use one BFD session for multiple client protocols in the Cisco implementation of BFD. For example, if a network is running OSPF and EIGRP across the same link to the same peer, only one BFD session will be established, and BFD will share session information with both routing protocols. However, IPv4 and IPv6 clients cannot share a BFD session.

BFD Version Interoperability

Starting with Cisco IOS Release 15.1(1)SG, the Catalyst 4500 series switch supports BFD Version 1 as well as BFD Version 0. All BFD sessions come up as Version 1 by default and will be interoperable with Version 0. The system automatically performs BFD version detection, and BFD sessions between neighbors will run in the highest common BFD version between neighbors. For example, if one BFD neighbor is running BFD Version 0 and the other BFD neighbor is running Version 1, the session will run BFD Version 0. The output from the **show bfd neighbors [details]** command will verify which BFD version a BFD neighbor is running.

See the [“Example: Configuring BFD in an EIGRP Network with Echo Mode Enabled by Default” section on page 41-17](#) for an example of BFD version detection.

BFD Session Limits

The minimum number of BFD sessions that can be created varies with the “hello” interval. With “hello” intervals of 50ms, 128 sessions are permitted. More sessions are permitted at larger hello intervals.

BFD Support for Nonbroadcast Media Interfaces

Starting with Cisco IOS Release 15.1(1)SG, the BFD feature is supported on VLAN interfaces on the Catalyst 4500 series switch.

The **bfd interval** command must be configured on an interface to initiate BFD monitoring.

BFD Support for Nonstop Forwarding with Stateful Switchover

Typically, when a networking device restarts, all routing peers of that device detect that the device went down and then came back up. This transition results in a routing flap, which could spread across multiple routing domains. Routing flaps caused by routing restarts create routing instabilities, which are detrimental to the overall network performance. Nonstop forwarding (NSF) helps to suppress routing flaps in devices that are enabled with stateful switchover (SSO), thereby reducing network instability.

NSF allows for the forwarding of data packets to continue along known routes while the routing protocol information is being restored after a switchover. With NSF, peer networking devices do not experience routing flaps. Data traffic is forwarded while the standby RP assumes control from the failed active RP during a switchover. The ability of line cards and forwarding processors to remain up through a switchover and to remain current with the Forwarding Information Base (FIB) on the active RP is key to NSF operation.

In devices that support dual RPs, SSO establishes one of the RPs as the active processor; the other RP is designated as the standby processor, and then synchronizes information between them. A switchover from the active to the standby processor occurs when the active RP fails, when it is removed from the networking device, or when it is manually taken down for maintenance.

BFD Support for Stateful Switchover

The BFD protocol provides short-duration detection of failures in the path between adjacent forwarding engines. In network deployments that use dual RP switches (to provide redundancy), the switches have a graceful restart mechanism that protects the forwarding state during a switchover between the active RP and the standby RP.

Stateful BFD on the Standby RP

To ensure a successful switchover to the standby RP, the BFD protocol uses checkpoint messages to send session information from the active RP Cisco IOS instance to the standby RP Cisco IOS instance. The session information includes local and remote discriminators, adjacent router timer information, BFD setup information, and session-specific information such as the type of session and the session version. In addition, the BFD protocol sends session creation and deletion checkpoint messages to create or delete a session on the standby RP.

The BFD sessions on the standby RP do not receive or send packets and do not process expired timers. These sessions wait for a switchover to occur and then send packets for any active sessions so that sessions do not time out on adjacent switches.

When the BFD protocol on the standby RP is notified of a switchover it changes its state to active, registers itself with Cisco Express Forwarding so that it can receive packets, and then sends packets for any elements that have expired.

BFD also uses checkpoint messages to ensure that sessions created by clients on the active RP are maintained during a switchover. When a switchover occurs, BFD starts an SSO reclaim timer. Clients must reclaim their sessions within the duration specified by the reclaim timer or else the session is deleted.

Timer values are different based on the number of BFD sessions and the platform.

Table 41-1 describes the timer value on Cisco 4500 series switches.

Table 41-1 BFD Timer Values on a Cisco 4500 Series Switches

Maximum Number of BFD Sessions	BFD Session Type	Minimum Timer Value (ms)	Clients	Comments
100	Async/echo	100 multiplier 3	All	A multiple of 5 is recommended for SSO switches.

BFD Support for Static Routing

Unlike dynamic routing protocols, such as OSPF and BGP, static routing has no method of peer discovery. Therefore, when BFD is configured, the reachability of the gateway is completely dependent on the state of the BFD session to the specified neighbor. Unless the BFD session is up, the gateway for the static route is considered unreachable, and therefore the affected routes will not be installed in the appropriate Routing Information Base (RIB).

For a BFD session to establish successfully, BFD must be configured on the interface on the peer and there must be a BFD client registered on the peer for the address of the BFD neighbor. When an interface is used by dynamic routing protocols, the latter requirement is usually met by configuring the routing protocol instances on each neighbor for BFD. When an interface is used exclusively for static routing, this requirement must be met by configuring static routes on the peers.

BFD is supported on IPv4 and IPv6 static routes.

**Note**

If a BFD configuration is removed from the remote peer while the BFD session is in the up state, the updated state of the BFD session is not signaled to the static route. This will cause the static route to remain in the RIB. The only workaround is to remove the static route BFD neighbor configuration so that the static route no longer tracks BFD session state.

Benefits of Using BFD for Failure Detection

When you deploy any feature, it is important to consider all the alternatives and be aware of any trade-offs.

The closest alternative to BFD in conventional EIGRP, BGP, and OSPF deployments is the use of modified failure detection mechanisms for EIGRP, BGP, and OSPF routing protocols.

If you set EIGRP hello and hold timers to their absolute minimums, the failure detection rate for EIGRP falls to within a one- to two-second range.

If you use fast hellos for either BGP or OSPF, this Interior Gateway Protocol (IGP) protocol reduces its failure detection mechanism to a minimum of one second.

Advantages to implementing BFD over reduced timer mechanisms for routing protocols include the following:

- Although reducing the EIGRP, BGP, and OSPF timers can result in minimum detection timer of one to two seconds, BFD can provide failure detection in less than one second.
- Because BFD is not tied to any particular routing protocol, it can be used as a generic and consistent failure detection mechanism for EIGRP, BGP, and OSPF.
- Because some parts of BFD can be distributed to the data plane, it can be less CPU-intensive than the reduced EIGRP, BGP, and OSPF timers, which exist wholly at the control plane.

Hardware Support for BFD

The Catalyst 4500 supports a limited number of BFD sessions in hardware. Placing a session in BFD hardware is termed *hardware offload*. The advantage of hardware offload is that session keep-alive is handled entirely in hardware, placing no load on the CPU.

Not all BFD sessions can be offloaded to hardware. The requirements for offloaded sessions are:

- BFD version 1
- IPv4
- No echo mode

**Note**

BFD Echo is only supported in software and not hardware, because of a limitation on the Catalyst 4500 series switches.

**Note**

Hardware offload does not work on existing IPv4 static BFD sessions (with BFD Echo enabled). Remove the existing static BFD configuration and reconfigure the static BFD configuration with hardware offload enabled (no BFD Echo) to allow the session to be hosted in hardware.

The number of offloaded sessions varies by supervisor engine:

WS-X45-SUP6-E, WS-X45-SUP6L-E, support 64 sessions in hardware. Further sessions must be supported in software.

WS-X45-SUP7-E, WS-X45-SUP7L-E, WS-X45-SUP8-E, WS-X45-SUP8L-E, and WS-X45-SUP9-E support all 100 sessions in hardware.

The **show bfd neighbor detail** command displays print statistics for software and hardware (offloaded) sessions. Hardware sessions provide a limited set of statistics. In particular, statistics for packet transmit and receive intervals are not available for hardware sessions.

The **holddown** and **hello counts** are zero for all offloaded sessions.

**Note**

Hardware offload is not supported for IPv6 BFD sessions.

How to Configure Bidirectional Forwarding Detection

You start a BFD process by configuring BFD on the interface. When the BFD process is started, no entries are created in the adjacency database; in other words, no BFD control packets are sent or received. BFD echo mode, which is supported in BFD Version 1, starting with Cisco IOS Release 15.1(1)SG, is enabled by default.

BFD echo packets are sent and received, in addition to BFD control packets. The adjacency creation takes place once you have configured BFD support for the applicable routing protocols. This section contains the following procedures:

- [Configuring BFD Session Parameters on the Interface, page 41-8](#) (required)
- [Configuring BFD Support for Dynamic Routing Protocols, page 41-9](#) (required)
- [Configuring BFD Support for Static Routing, page 41-14](#) (optional)
- [Configuring BFD Echo Mode, page 41-15](#) (optional)
- [Monitoring and Troubleshooting BFD, page 41-17](#) (optional)

Configuring BFD Session Parameters on the Interface

The steps in this procedure show how to configure BFD on the interface by setting the baseline BFD session parameters on an interface. Repeat the steps in this procedure for each interface over which you want to run BFD sessions to BFD neighbors.

To configure BFD session parameters, perform this task:

	Command or Action	Purpose
Step 1	enable Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Switch# configure terminal	Enters global configuration mode.
Step 3	interface <i>type number</i> Switch(config)# interface gigabitethernet 6/1	Enters interface configuration mode.
Step 4	bfd interval <i>milliseconds</i> min_rx <i>milliseconds</i> multiplier <i>interval-multiplier</i> Switch(config-if)# bfd interval 100 min_rx 100 multiplier 3 Switch(config-if)# no bfd echo	Enables BFD on the interface. Disables BFD echo mode to enable Hardware Off-load.
Step 5	end Switch(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.

Configuring BFD Support for Dynamic Routing Protocols

You can enable BFD support for dynamic routing protocols at the router level to enable BFD support globally for all interfaces or you can configure BFD on a per-interface basis at the interface level.

This section describes the following procedures:

- [Configuring BFD Support for BGP, page 41-9](#) (optional)
- [Configuring BFD Support for EIGRP, page 41-10](#) (optional)
- [Configuring BFD Support for OSPF, page 41-11](#) (optional)

Configuring BFD Support for BGP

This section describes the procedure for configuring BFD support for BGP so that BGP is a registered protocol with BFD and will receive forwarding path detection failure messages from BFD.

Prerequisites

BGP must be running on all participating switches.

The baseline parameters for BFD sessions on the interfaces over which you want to run BFD sessions to BFD neighbors must be configured. See the [“Configuring BFD Session Parameters on the Interface” section on page 41-8](#) for more information.

To configure BFD support for BGP, perform this task:

	Command or Action	Purpose
Step 1	enable Switch> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Switch# configure terminal	Enters global configuration mode.
Step 3	router bgp as-tag Switch(config)# router bgp tag1	Specifies a BGP process and enters router configuration mode.
Step 4	neighbor ip-address fall-over bfd Switch(config-router)# neighbor 172.16.10.2 fall-over bfd	Enables BFD support for fallover.
Step 5	end Switch(config-router)# end	Exits router configuration mode and returns the switch to privileged EXEC mode.
Step 6	show bfd neighbors [details] Switch# show bfd neighbors detail	(Optional) Verifies that the BFD neighbor is active and displays the routing protocols that BFD has registered.
Step 7	show ip bgp neighbor Switch# show ip bgp neighbor	(Optional) Displays information about BGP and TCP connections to neighbors.

What to Do Next

See the “[Monitoring and Troubleshooting BFD](#)” section on page 41-17 for more information on monitoring and troubleshooting BFD. If you want to configure BFD support for another routing protocol, see the following sections:

- [Configuring BFD Support for EIGRP, page 41-10](#)
- [Configuring BFD Support for OSPF, page 41-11](#)

Configuring BFD Support for EIGRP

This section describes the procedure for configuring BFD support for EIGRP so that EIGRP is a registered protocol with BFD and will receive forwarding path detection failure messages from BFD. There are two methods for enabling BFD support for EIGRP:

- You can enable BFD for all of the interfaces for which EIGRP is routing by using the **bfd all-interfaces** command in router configuration mode.
- You can enable BFD for a subset of the interfaces for which EIGRP is routing by using the **bfd interface type number** command in router configuration mode.

Prerequisites

EIGRP must be running on all participating switches.

The baseline parameters for BFD sessions on the interfaces over which you want to run BFD sessions to BFD neighbors must be configured. See the “[Configuring BFD Session Parameters on the Interface](#)” section on page 41-8 for more information.

To configure BFD support for EIGRP, perform this task:

	Command or Action	Purpose
Step 1	enable Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Switch# configure terminal	Enters global configuration mode.
Step 3	Switch eigrp as-number Switch(config)# router eigrp 123	Configures the EIGRP routing process and enters router configuration mode.
Step 4	bfd all-interfaces or bfd interface type number Switch(config-router)# bfd all-interfaces or Switch(config-router)# bfd interface gigabitethernet 6/1	Enables BFD globally on all interfaces associated with the EIGRP routing process. or Enables BFD on a per-interface basis for one or more interfaces associated with the EIGRP routing process.
Step 5	end Switch(config-router) end	Exits router configuration mode and returns the switch to privileged EXEC mode.
Step 6	show bfd neighbors [details] Switch# show bfd neighbors details	(Optional) Verifies that the BFD neighbor is active and displays the routing protocols that BFD has registered.
Step 7	show ip eigrp interfaces [type number] [as-number] [detail] Switch# show ip eigrp interfaces detail	(Optional) Displays the interfaces for which BFD support for EIGRP has been enabled.

What to Do Next

See the “[Monitoring and Troubleshooting BFD](#)” section on page 41-17 for more information on monitoring and troubleshooting BFD. If you want to configure BFD support for another routing protocol, see the following sections:

- [Configuring BFD Support for OSPF](#), page 41-11

Configuring BFD Support for OSPF

This section describes the procedures for configuring BFD support for OSPF so that OSPF is a registered protocol with BFD and will receive forwarding path detection failure messages from BFD. You can either configure BFD support for OSPF globally on all interfaces or configure it selectively on one or more interfaces.

There are two methods for enabling BFD support for OSPF:

- You can enable BFD on all the interfaces for which OSPF is routing by using the **bfd all-interfaces** command in router configuration mode. You can disable BFD support on individual interfaces using the **ip ospf bfd [disable]** command in interface configuration mode.
- You can enable BFD on a subset of the interfaces for which OSPF is routing by using the **ip ospf bfd** command in interface configuration mode.

See the following sections for tasks for configuring BFD support for OSPF:

- [Configuring BFD Support for OSPF for All Interfaces, page 41-12](#) (optional)
- [Configuring BFD Support for OSPF for One or More Interfaces, page 41-13](#) (optional)

Configuring BFD Support for OSPF for All Interfaces

To configure BFD for all OSPF interfaces, perform the steps in this section.

If you do not want to configure BFD on all OSPF interfaces and would rather configure BFD support specifically for one or more interfaces, see the [“Configuring BFD Support for OSPF for One or More Interfaces”](#) section on page 41-13.

Prerequisites

OSPF must be running on all participating switches.

The baseline parameters for BFD sessions on the interfaces over which you want to run BFD sessions to BFD neighbors must be configured. See the [“Configuring BFD Session Parameters on the Interface”](#) section on page 41-8 for more information.

To configure BFD support for OSPF for all interfaces:

	Command or Action	Purpose
Step 1	enable Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Switch# configure terminal	Enters global configuration mode.
Step 3	Switch ospf process-id Switch(config)# router ospf 4	Specifies an OSPF process and enters router configuration mode.
Step 4	bfd all-interfaces Switch(config-router)# bfd all-interfaces	Enables BFD globally on all interfaces associated with the OSPF routing process.
Step 5	end Switch(config-if)# end	Exits interface configuration mode and returns the switch to privileged EXEC mode.
Step 6	show bfd neighbors [details] Switch# show bfd neighbors detail	(Optional) Displays information that can help verify if the BFD neighbor is active and displays the routing protocols that BFD has registered.
Step 7	show ip ospf Switch# show ip ospf	(Optional) Displays information that can help verify if BFD for OSPF has been enabled.

What to Do Next

See the [“Monitoring and Troubleshooting BFD”](#) section on page 41-17 for more information on monitoring and troubleshooting BFD. If you want to configure BFD support for another routing protocol, see the following sections:

- [Configuring BFD Support for BGP, page 41-9](#)
- [Configuring BFD Support for EIGRP, page 41-10](#)

Configuring BFD Support for OSPF for One or More Interfaces

To configure BFD on one or more OSPF interfaces, perform the steps in this section.

Prerequisites

OSPF must be running on all participating switches.

The baseline parameters for BFD sessions on the interfaces over which you want to run BFD sessions to BFD neighbors must be configured. See the [“Configuring BFD Session Parameters on the Interface” section on page 41-8](#) for more information.

To configure BFD supporter for OSPF for one or more interfaces, perform this task:

	Command or Action	Purpose
Step 1	enable Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">Enter your password if prompted.
Step 2	configure terminal Switch# configure terminal	Enters global configuration mode.
Step 3	interface <i>type number</i> Switch(config)# interface gigabitethernet 6/1	Enters interface configuration mode.
Step 4	ip ospf bfd [disable] Switch(config-if)# ip ospf bfd	Enables or disables BFD on a per-interface basis for one or more interfaces associated with the OSPF routing process. Note You should use the disable keyword only if you enabled BFD on all of the interfaces that OSPF is associated with using the bfd all-interfaces command in switch configuration mode.
Step 5	end Switch(config-if)# end	Exits interface configuration mode and returns the switch to privileged EXEC mode.
Step 6	show bfd neighbors [details] Switch# show bfd neighbors details	(Optional) Displays information that can help verify if the BFD neighbor is active and displays the routing protocols that BFD has registered. Note If hardware-offloaded BFD sessions are configured with Tx and Rx intervals that are not multiples of 50 ms, the hardware intervals are changed. However, output from the show bfd neighbors details command displays the configured intervals, not the changed ones.
Step 7	show ip ospf Switch# show ip ospf	(Optional) Displays information that can help verify if BFD support for OSPF has been enabled.

What to Do Next

See the [“Monitoring and Troubleshooting BFD” section on page 41-17](#) for more information on monitoring and troubleshooting BFD. If you want to configure BFD support for another routing protocol, see the following sections:

- [Configuring BFD Support for BGP, page 41-9](#)

- [Configuring BFD Support for EIGRP, page 41-10](#)

Configuring BFD Support for Static Routing

Perform this task to configure BFD support for static routing. Repeat the steps in this procedure on each BFD neighbor. For more information, see the [“Example: Configuring BFD Support for Static Routing” section on page 41-27](#).

To configure BFD support for static routing, perform this task:

	Command or Action	Purpose
Step 1	enable Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Switch# configure terminal	Enters global configuration mode.
Step 3	interface type number Switch(config)# interface gigabitethernet6/1	Configures an interface and enters interface configuration mode.
Step 4	no switchport Switch(config-if)# no switchport	Changes the interface to Layer 3.
Step 5	ip address ip-address mask Switch(config-if)# ip address 10.201.201.1 255.255.255.0	Configures an IP address for the interface.
Step 6	bfd interval milliseconds min_rx milliseconds multiplier interval-multiplier Switch(config-if)# bfd interval 500 min_rx 500 multiplier 5	Enables BFD on the interface.
Step 7	exit Switch(config-if)# exit	Exits interface configuration mode and returns to global configuration mode.
Step 8	ip route static bfd interface-type interface-number ip-address [group group-name [passive]] Switch(config)# ip route static bfd Gi6/1 10.1.1.1 group group1 passive	Specifies a static route BFD neighbor. <ul style="list-style-type: none"> • The <i>interface-type</i>, <i>interface-number</i>, and <i>ip-address</i> arguments are required because BFD support exists only for directly connected neighbors.
Step 9	ip route [vrf vrf-name] prefix mask {ip-address interface-type interface-number [ip-address]} [dhcp] [distance] [name next-hop-name] [permanent track number] [tag tag] Example: Switch(config)# ip route 10.0.0.0 255.0.0.0 Gi6/1 10.201.201.2	Specifies a static route BFD neighbor.
Step 10	exit Example: Switch(config)# exit	Exits global configuration mode and returns to privileged EXEC mode.

	Command or Action	Purpose
Step 11	<code>show ip static route</code> Example: Switch# <code>show ip static route</code>	(Optional) Displays static route database information.
Step 12	<code>show ip static route bfd</code> Example: Switch# <code>show ip static route bfd</code>	(Optional) Displays information about the static BFD configuration from the configured BFD groups and nongroup entries.
Step 13	<code>exit</code> Example: Switch# <code>exit</code>	Exits privileged EXEC mode and returns to user EXEC mode.

Configuring BFD Echo Mode

BFD echo mode is enabled by default, but you can disable it such that it can run independently in each direction.

BFD echo mode works with asynchronous BFD. Echo packets are sent by the forwarding engine and forwarded back along the same path in order to perform detection—the BFD session at the other end does not participate in the actual forwarding of the echo packets. The echo function and the forwarding engine are responsible for the detection process; therefore, the number of BFD control packets that are sent out between two BFD neighbors is reduced. In addition, because the forwarding engine is testing the forwarding path on the remote (neighbor) system without involving the remote system, there is an opportunity to improve the interpacket delay variance, thereby achieving quicker failure detection times than when using BFD Version 0 with BFD control packets for the BFD session.

Echo mode is described as without asymmetry when it is running on both sides (both BFD neighbors are running echo mode).

Prerequisites

BFD must be running on all participating switches.

Before using BFD echo mode, you must disable the sending of Internet Control Message Protocol (ICMP) redirect messages by entering the **no ip redirects** command, to avoid high CPU utilization.

The baseline parameters for BFD sessions on the interfaces over which you want to run BFD sessions to BFD neighbors must be configured. See the [“Configuring BFD Session Parameters on the Interface” section on page 41-8](#) for more information.

Restrictions

BFD echo mode which is supported in BFD Version 1.

This section contains the following configuration tasks for BFD echo mode:

- [Configuring the BFD Slow Timer, page 41-16](#)
- [Disabling BFD Echo Mode Without Asymmetry, page 41-16](#)

**Note**

BFD echo mode does not work in conjunction with Unicast Reverse Path Forwarding (uRPF) configuration. If BFD echo mode and uRPF configurations are enabled, then the sessions will flap.

Configuring the BFD Slow Timer

The steps in this procedure show how to change the value of the BFD slow timer. Repeat the steps in this procedure for each BFD switch.

To configure the BFD slow timer, perform this task:

	Command or Action	Purpose
Step 1	enable Switch> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Switch# configure terminal	Enters global configuration mode.
Step 3	bfd slow-timer <i>milliseconds</i> Switch(config)# bfd slow-timer 12000	Configures the BFD slow timer.
Step 4	end Switch(config)# end	Exits global configuration mode and returns the switch to privileged EXEC mode.

Disabling BFD Echo Mode Without Asymmetry

The steps in this procedure show how to disable BFD echo mode without asymmetry —no echo packets are sent by the switch, and the switch does not forward BFD echo packets that are received from neighboring switches.

Repeat the steps in this procedure for each BFD switch.

To disable BFD echo mode without asymmetry, perform this task:

	Command or Action	Purpose
Step 1	enable Example: Switch> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Switch# configure terminal	Enters global configuration mode.
Step 3	interface <i>type number</i> Example: Switch(config)# interface GigabitEthernet 6/1	Enters interface configuration mode.

	Command or Action	Purpose
Step 4	<code>no bfd echo</code> Example: <code>Switch(config-if)# no bfd echo</code>	Disables BFD echo mode.
Step 5	<code>end</code> Example: <code>Switch(config-if)# end</code>	Exits global configuration mode and returns the switch to global configuration mode.

Monitoring and Troubleshooting BFD

This section describes how to retrieve BFD information for maintenance and troubleshooting. The commands in these tasks can be entered as needed, in any order.

For more information about BFD session initiation and failure, refer to the [“BFD Operation” section on page 41-3](#).

To monitor and troubleshoot BFD, perform the following steps:

	Command or Action	Purpose
Step 1	<code>enable</code> <code>Switch> enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	<code>show bfd neighbors [details]</code> <code>Switch# show bfd neighbors details</code>	(Optional) Displays the BFD adjacency database. <ul style="list-style-type: none"> The details keyword shows all BFD protocol parameters and timers per neighbor.
Step 3	<code>debug bfd [packet event]</code> <code>Switch# debug bfd packet</code>	(Optional) Displays debugging information about BFD packets.

Configuration Examples for Bidirectional Forwarding Detection

This section provides the following configuration examples:

- [Example: Configuring BFD in an EIGRP Network with Echo Mode Enabled by Default, page 41-17](#)
- [Example: Configuring BFD in an OSPF Network, page 41-22](#)
- [Example: Configuring BFD Hardware-Offload support in a BGP Network Network, page 41-25](#)
- [Example: Configuring BFD Support for Static Routing, page 41-27](#)

Example: Configuring BFD in an EIGRP Network with Echo Mode Enabled by Default

The following example shows how to configure BFD in an EIGRP network with echo mode enabled by default.

In this example, the EIGRP network contains SwitchA, SwitchB, and SwitchC. Gigabit Ethernet interface 6/1 on SwitchA is connected to the same network as Gigabit Ethernet interface 6/1 on SwitchB. Gigabit Ethernet interface 6/1 on SwitchB is connected to the same network as Gigabit Ethernet interface 6/1 on SwitchC.

SwitchA and SwitchB are running BFD Version 1, which supports echo mode, and SwitchC is running BFD Version 0, which does not support echo mode. We would say that the BFD sessions between SwitchC and its BFD neighbors are running echo mode with asymmetry. This is because echo mode will run on the forwarding path for RouterA and SwitchB, and their echo packets will return along the same path for BFD sessions and failure detections, while their BFD neighbor SwitchC runs BFD Version 0 and uses BFD control packets for BFD sessions and failure detections.

Figure 41-3 shows a large EIGRP network with several switches, three of which are BFD neighbors that are running EIGRP as their routing protocol.

Figure 41-3 EIGRP Network with Three BFD Neighbors Running V1 or V0

The example, starting in global configuration mode, shows the configuration of BFD.

Configuration for SwitchA

```
interface GigabitEthernet6/2
  no switch
  ip address 10.4.9.14 255.255.255.0
!
interface GigabitEthernet6/1
  no switchport
  ip address 172.16.1.1 255.255.255.0
  bfd interval 100 min_rx 50 multiplier 3
  no shutdown
!
router eigrp 11
  network 172.16.0.0
  bfd all-interfaces
  auto-summary
!
ip default-gateway 10.4.9.1
ip default-network 0.0.0.0
ip route 0.0.0.0 0.0.0.0 10.4.9.1
ip route 172.16.1.129 255.255.255.255 10.4.9.1
!
```

Configuration for SwitchB

```
!
```

```

interface GigabitEthernet6/2
  no switchport
  ip address 10.4.9.34 255.255.255.0
!
interface GigabitEthernet6/1
  no switchport
  ip address 172.16.1.2 255.255.255.0
  bfd interval 100 min_rx 50 multiplier 3
!
router eigrp 11
  network 172.16.0.0
  bfd all-interfaces
  auto-summary
!
ip default-gateway 10.4.9.1

ip route 172.16.1.129 255.255.255.255 10.4.9.1
!
!
end

```

The output from the **show bfd neighbors details** command from SwitchA verifies that BFD sessions have been created among all three switches and that EIGRP is registered for BFD support. The first group of output shows that SwitchC with the IP address 172.16.1.3 runs BFD Version 0 and therefore does not use the echo mode. The second group of output shows that SwitchB with the IP address 172.16.1.2 does run BFD Version 1, and the 50 millisecond BFD interval parameter had been adopted.

The relevant command output is shown in bold.

SwitchA

```

Figure 41-4 shows that Gigabit Ethernet interface 6/1 on SwitchB has failed. When Gigabit Ethernet interface 6/1 on SwitchB is shut down, the BFD values of the corresponding BFD sessions on SwitchA and SwitchB are reduced.

Figure 41-4 Gigabit Ethernet Interface 6/1 Failure

When Gigabit Ethernet interface 6/1 on SwitchB fails, BFD will no longer detect SwitchB as a BFD neighbor for SwitchA or for SwitchC. In this example, Gigabit Ethernet interface 6/1 has been administratively shut down on SwitchB.

The following output from the **show bfd neighbors** command on SwitchA now shows only one BFD neighbor for SwitchA in the EIGRP network. The relevant command output is shown in bold.

SwitchA# **show bfd neighbors**

OurAddr	NeighAddr	LD/RD	RH/RS	Holdown(mult)	State	Int
172.16.1.1	172.16.1.3	5/3	1(RH)	134 (3)	Up	Gi6/1

The following output from the **show bfd neighbors** command on SwitchC also now shows only one BFD neighbor for SwitchC in the EIGRP network. The relevant command output is shown in bold.

SwitchC# **show bfd neighbors**

OurAddr	NeighAddr	LD/RD	RH	Holdown(mult)	State	Int
172.16.1.3	172.16.1.1	3/5	1	114 (3)	Up	Gi6/1

Example: Configuring BFD in an OSPF Network

The following example shows how to configure BFD in an OSPF network.

In this example, the “simple” OSPF network consists of SwitchA and SwitchB. Gigabit Ethernet interface 6/1 on SwitchA is connected to the same network as Gigabit Ethernet interface 6/1 in SwitchB. The example, starting in global configuration mode, shows the configuration of BFD. For both SwitchA and SwitchB, BFD is configured globally for all interfaces associated with the OSPF process.

Configuration for SwitchA

```
!
interface GigabitEthernet 6/1
 no switchport
 ip address 172.16.10.1 255.255.255.0
 bfd interval 100 min_rx 100 multiplier 3
!
interface GigabitEthernet 6/2
 no switchport
 ip address 172.17.0.1 255.255.255.0
!
router ospf 123
 log-adjacency-changes detail
 network 172.16.0.0 0.0.0.255 area 0
 network 172.17.0.0 0.0.0.255 area 0
 bfd all-interfaces
```

Configuration for SwitchB

```
!
interface GigabitEthernet 6/1
 no switchport
 ip address 172.16.10.2 255.255.255.0
 bfd interval 100 min_rx 100 multiplier 3
!
interface GigabitEthernet 6/2
 no switchport
 ip address 172.18.0.1 255.255.255.0
!
router ospf 123
 log-adjacency-changes detail
 network 172.16.0.0 0.0.255.255 area 0
 network 172.18.0.0 0.0.255.255 area 0
 bfd all-interfaces
```

The output from the **show bfd neighbors details** command verifies that a BFD session has been created and that OSPF is registered for BFD support. The relevant command output is shown in bold.

SwitchA

SwitchA# **show bfd neighbors details**

```
OurAddr      NeighAddr    LD/RD RH  Holdown(mult)  State    Int
172.16.10.1  172.16.10.2  1/2  1    532 (3 )      Up       Gi6/1
Local Diag: 0, Demand mode: 0, Poll bit: 0

Example: Configuring BFD Hardware-Offload support in a BGP Network

The following example shows how to configure BFD Hardware-Offload support in a BGP network.

In this example, the “simple” BGP network consists of SwitchA and SwitchB. Gigabit Ethernet interface 6/1 on SwitchA is connected to the same network as Gigabit Ethernet interface 6/1 in SwitchB.

Configuration for SwitchA

```

!
interface GigabitEthernet 6/1
  no switchport
  ip address 10.1.1.1 255.255.255.0
  bfd interval 100 min_rx 100 multiplier 3
  no bfd echo

router bgp 10
  neighbor 10.1.1.2 remote-as 10
  neighbor 10.1.1.2 fall-over bfd

```

```
!
```

Configuration for SwitchB

```
!
interface GigabitEthernet 6/1
 no switchport
 ip address 10.1.1.2 255.255.255.0
 bfd interval 100 min_rx 100 multiplier 3
 no bfd echo

router bgp 10
 neighbor 10.1.1.1 remote-as 10
 neighbor 10.1.1.1 fall-over bfd
!
```

The output from the **show bfd neighbors details** command from SwitchA verifies that a BFD session has been created and that BGP is registered for BFD support. The relevant command output is shown in bold.

SwitchA

```
SwitchA# show bfd neighbors details
```

```
IPv4 Sessions
NeighAddr                      LD/RD          RH/RS          State          Int
10.1.1.1                        1/1           Up             Up             Gi3/2
Session state is UP and not using echo function.
Session Host: Hardware
OurAddr: 10.1.1.2
Local Diag: 0, Demand mode: 0, Poll bit: 0
MinTxInt: 50000, MinRxInt: 50000, Multiplier: 3
Received MinRxInt: 50000, Received Multiplier: 3
Holddown (hits): 0(0), Hello (hits): 50(0)
Rx Count: 8678
Tx Count: 8680
Elapsed time watermarks: 0 0 (last: 0)
Registered protocols:  BGP
Uptime: 00:06:18
Last packet: Version: 1          - Diagnostic: 0
                  State bit: Up    - Demand bit: 0
                  Poll bit: 0      - Final bit: 0
                  Multiplier: 3    - Length: 24
                  My Discr.: 1      - Your Discr.: 1
                  Min tx interval: 50000 - Min rx interval: 50000
                  Min Echo interval: 0
```

The output from the **show bfd neighbors details** command on SwitchB verifies that a BFD session has been created:

SwitchB

```
SwitchB# attach 6
```

```
Switch> show bfd neighbors details
```

```
IPv4 Sessions
NeighAddr                      LD/RD          RH/RS          State          Int
10.1.1.2                        1/1           Up             Up             Gi1/2
Session state is UP and not using echo function.
Session Host: Hardware
OurAddr: 10.1.1.1
```

```

Local Diag: 0, Demand mode: 0, Poll bit: 0
MinTxInt: 50000, MinRxInt: 50000, Multiplier: 3
Received MinRxInt: 50000, Received Multiplier: 3
Holddown (hits): 0(0), Hello (hits): 50(0)
Rx Count: 10138
Tx Count: 10139
Elapsed time watermarks: 0 0 (last: 0)
Registered protocols: BGP
Uptime: 00:07:22
Last packet: Version: 1
                State bit: Up
                Poll bit: 0
                Multiplier: 3
                My Discr.: 1
                Min tx interval: 50000
                Min Echo interval: 0
- Diagnostic: 0
- Demand bit: 0
- Final bit: 0
- Length: 24
- Your Discr.: 1
- Min rx interval: 50000

```

The output of the **show ip bgp neighbors** command verifies that BFD has been enabled for the BGP neighbors:

SwitchA

```
SwitchA# show ip bgp neighbors
```

```

BGP neighbor is 10.1.1.2, remote AS 45000, external link
  Using BFD to detect fast fallover
..

```

SwitchB

```
SwitchB# show ip bgp neighbors
```

```

BGP neighbor is 10.1.1.1, remote AS 40000, external link
  Using BFD to detect fast fallover
..

```

Example: Configuring BFD Support for Static Routing

In the following example, the network consists of SwitchA and SwitchB. Gigabit Ethernet interface 6/1 on SwitchA is connected to the same network as gigabit ethernet interface 6/1 on SwitchB. For the BFD session to come up, SwitchB must be configured.

SwitchA

```

configure terminal
no switchport
interface Gigabit Ethernet 6/1
ip address 10.201.201.1 255.255.255.0
bfd interval 500 min_rx 500 multiplier 5
ip route static bfd Gigabit Ethernet 6/1 10.201.201.2
ip route 10.0.0.0 255.0.0.0 Gigabit Ethernet 6/1 10.201.201.2

```

SwitchB

```

configure terminal
no switchport
interface Gigabit Ethernet 6/1
ip address 10.201.201.2 255.255.255.0
bfd interval 500 min_rx 500 multiplier 5
ip route static bfd Gigabit Ethernet 6/1 10.201.201.1
ip route 10.1.1.1 255.255.255.255 Gigabit Ethernet 6/1 10.201.201.1

```

**Note**

The static route on SwitchB exists solely to enable the BFD session between 10.201.201.1 and 10.201.201.2. If there is no useful static route to configure, select a prefix that will not affect packet forwarding, for example, the address of a locally configured loopback interface.

Configuring Policy-Based Routing

This chapter describes the tasks for configuring policy-based routing (PBR) on Catalyst 4500 series switches and includes these major sections:

- [Policy-Based Routing, page 42-1](#)
- [Policy-Based Routing Configuration Tasks, page 42-7](#)
- [Policy-Based Routing Configuration Examples, page 42-16](#)

A switch running the LAN Base license level supports PBR for IPv4 and IPv6.

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Note

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com, or refer to the software release notes for a specific release.

Policy-Based Routing

PBR gives you a flexible method of routing packets by allowing you to define policies for traffic flows, lessening reliance on routes derived from routing protocols. PBR gives you more control over routing by extending and complementing the existing mechanisms provided by routing protocols. PBR allows you to specify paths for certain traffic, such as priority traffic over a high-cost link.

You can set up PBR as a way to route packets based on configured policies. For example, you can implement routing policies to allow or deny paths based on the identity of a particular end system, or an application protocol. Enable PBR to provide the following advantages:

- Equal access
- Protocol-sensitive routing
- Source-sensitive routing
- Routing based on interactive versus batch traffic
- Routing based on dedicated links

Some applications or traffic can benefit from source-specific routing; for example, you can transfer stock records to a corporate office on a higher-bandwidth, higher-cost link for a short time while sending routine application data, such as e-mail, over a lower-bandwidth, lower-cost link

Policies can be based on IP address, port numbers, or protocols. For a simple policy, use any one of these descriptors; for a complicated policy, all of them.

Route Maps

The following topics are discussed in the section:

- [Understanding Route Maps, page 42-2](#)
- [PBR Route-Map Processing Logic, page 42-3](#)
- [Load Balancing with Recursive Next Hop, page 42-4](#)
- [Packet Matching Criteria, page 42-4](#)
- [PBR Route-Map Processing Logic Example, page 42-4](#)

Understanding Route Maps

All packets received on an interface with PBR enabled (except those sent directly to the switch IP) are handled by enhanced packet filters known as route maps. The route maps dictate the policy that determines where the packets are forwarded.

Route maps contain statements that can be marked as permit or deny. They are interpreted in the following ways:

- If a statement is marked as deny, the packets meeting the match criteria are sent back using the normal forwarding channels and destination-based routing is performed.
- If the statement is marked as permit and a packet matches the access-lists, then the first valid set clause is applied to that packet.

You can implement PBR by applying a route map on an incoming interface. A given interface can have only one route-map configured. A route map is configured at the global configuration parser mode. You can then apply this route map on one or more interfaces (in the interface configuration parser sub-mode).

Each route map statement contains **match** and **set** commands. The **match** command denotes the match criteria to be applied on the packet data. The **set** command denotes the PBR action to be taken on the packet.

The following example shows a single route map called rm-test and six route map statements:

```
route-map rm-test permit 21
  match ip address 101
  set ip next-hop 21.1.1.1
!
route-map rm-test permit 22
  match ip address 102
  set ip next-hop 22.2.2.1
!
route-map rm-test permit 23
  match ip address 101 2102
  set interface vlan23
!
route-map rm-test deny 24
  match ip address 104
  set ip next-hop 24.4.4.1
```

```
!  
route-map rm-test deny 25  
  match ip address 105  
  set ip next-hop 25.5.5.1  
!  
route-map rm-test permit 26  
  match ip address 2104  
  set ip next-hop 26.6.6.1
```

The numbers 21, 22, ... 26 are the sequence numbers of the route-map statements.

PBR Route-Map Processing Logic

When a packet is received on an interface configured with a route map, the forwarding logic processes each route map statement according to the sequence number.

If the route map statement encountered is a **route-map... permit** statement:

- The packet is matched against the criteria in the **match** command. This command may refer to an ACL that may itself have one or more permit and/or deny expressions. The packet is matched against the expressions in the ACL, and a permit/deny decision is reached.
- If the decision reached is permit, then the PBR logic executes the action specified by the **set** command on the packet.
- If the decision reached is deny, then the PBR action (specified in the **set** command) is not applied. Instead the processing logic moves forward to look at the next route-map statement in the sequence (the statement with the next higher sequence number). If no next statement exists, PBR processing terminates, and the packet is routed using the default IP routing table.

If the route map statement encountered is a **route-map... deny** statement:

- The packet is matched against the criteria given in the **match** command. This command may refer to an ACL that may itself have one or more permit and/or deny expressions. The packet is matched against the expressions in the ACL, and a permit/deny decision is reached.
- If the criteria decision is permit, then the PBR processing terminates, and the packet is routed using the default IP routing table.
- If the criteria decision is deny, then the PBR processing logic moves forward to look at the next route-map statement in the sequence (the statement with the next higher sequence number). If no next statement exists, PBR processing terminates, and the packet is routed using the default IP routing table.

Note

The **set** command has no effect inside a **route-map... deny** statement.

A route map statement can have multiple **set** commands that are applied in the following priority:

set ip next-hop verify-availability

set ip next-hop

set ip next-hop recursive

set interface

set default ip next-hop

set default interface

If both the **set ip next-hop** and **set ip next-hop recursive** commands are present in the same route-map statement, the **next-hop set** command is applied.

If the **set ip next-hop** command is not available then the **set ip next-hop recursive** command is applied.

If the **set ip recursive-next-hop** and the **set interface** command are not present, then the packet is routed using the default routing table; it is not dropped. If the packet is required to be dropped, use the **set next-hop recursive** command followed by a **set interface null0 configuration** command.

Load Balancing with Recursive Next Hop

If multiple equal-cost routes to the subnet have been configured by the **set ip next-hop recursive** command, load balancing will occur only if all the adjacencies to the routes are resolved. If any of the adjacencies have not been resolved, then load balancing will not happen and only one of the routes whose adjacency is resolved will be used. If none of the adjacencies are resolved, then packets will be processed in software, resulting in at least one of the adjacencies to be resolved and programmed in hardware. PBR relies on routing protocols or other means to resolve all adjacencies and make load balancing happen.

Packet Matching Criteria

Access Control Lists (ACLs) define the allowed match criteria for packets. Each ACL is applied to incoming packets in a certain order, stopping only when the packet characteristics match the ACL being applied. Unlike policy maps, route maps do not support the "match any" match semantics.

IPv6 packets are matched via a **match ipv6 address** statement in the associated PBR route-map. IPv6 PBR requires IPv6 ACL, although the statement may specify either an IPv6 ACL or an IPv6 Prefixlist.

Packets are matched using the following criteria:

- Input interface
- Source IPv4/IPv6 Address (Prefixlist/Standard/Extended ACL)
- Destination IPv4/IPv6 Address (Standard/Extended ACL)
- Protocol (Extended ACL)
- Source Port and Destination Port (Extended ACL)
- DSCP (Extended ACL)
- Flow-label (Extended ACL)
- Fragment (Extended ACL)

PBR Route-Map Processing Logic Example

Consider a route map called `rm-test` defined as follows:

```
access-list 101 permit tcp host 61.1.1.1 host 133.3.3.1 eq 101
access-list 102 deny tcp host 61.1.1.1 host 133.3.3.1 eq 102
access-list 2102 permit tcp host 61.1.1.1 host 133.3.3.1 eq 102
access-list 104 deny tcp host 61.1.1.1 host 133.3.3.1 eq 104
access-list 2104 permit tcp host 61.1.1.1 host 133.3.3.1 eq 104
access-list 105 permit tcp host 61.1.1.1 host 133.3.3.1 eq 105
```

```
route-map rm-test permit 21
  match ip address 101
  set ip next-hop 21.1.1.1
!
route-map rm-test permit 22
  match ip address 102
  set ip next-hop 22.2.2.1
```

```

!
route-map rm-test permit 23
  match ip address 101 2102
  set interface vlan23
!
route-map rm-test deny 24
  match ip address 104
  set ip next-hop 24.4.4.1
!

route-map rm-test deny 25
  match ip address 105
  set ip next-hop 25.5.5.1
!
route-map rm-test permit 26
  match ip address 2104
  set ip next-hop 26.6.6.1

```

- TCP packet from 61.1.1.1 to 133.3.3.1 with destination port 101
 - Matches ACL 101 in sequence #21.
 - PBR is switched through next-hop 21.1.1.1.

Note ACL 101 is also matched in sequence #23, but the processing doesn't reach that point

- TCP packet from 61.1.1.1 to 133.3.3.1 with destination port 102
 - In sequence #21, the ACL 101 action denies this packet (because all ACLs have an implicit deny). Processing advances to sequence #22.
 - In sequence #22, ACL 102 matches TCP port 102, but the ACL action is deny. Processing advances to sequence #23.
 - In sequence #23, ACL 2102 matches TCP port 102, and the ACL action is permit.
 - Packet is switched to output interface VLAN 23.
- TCP packet from 61.1.1.1 to 133.3.3.1 with destination port 105
 - Processing moves from sequence #21 to #24, because all ACLs in these sequence numbers have a deny action for port 105.
 - In sequence #25, ACL 105 has a permit action for TCP port 105.
 - The route-map deny command takes effect, and the packet is routed using the default IP routing table.

The Catalyst 4500 series switch supports matching route map actions with a packet by installing entries in the TCAM that match the set of packets described by the ACLs in the match criteria of the route map. These TCAM entries point at adjacencies that either perform the necessary output actions or forward the packet to software if either hardware does not support the action or its resources are exhausted.

If the route map specifies a **set interface ...** action, packets that match the **match** statement are routed in the software. Some packets may be dropped. Similarly, if the route-map specifies a **set default interface...** action and there is no matching IP route for the packet, the packet is routed in the software.

Note

The scale of hardware-based PBR is determined by the TCAM size and the time required for the CPU to flatten the ACL before programming into the hardware. The time take to flatten the ACL increases when a PBR policy requires a considerable number of route-maps. For example, a PBR policy of 1,200

route-maps (each containing ACLs with permit ACEs only) may require 6-7 minutes of flatten time before programming into hardware. This process may repeat if an adjacency change requires PBR reprogramming.

Policy-Based Routing with Object Tracking

Beginning in Cisco IOS XE Release 3.8.0E and Cisco IOS Release 15.2(4)E, you can configure Policy-Based Routing (PBR) to use object tracking, to verify the most viable next-hop IP address to which to forward packets, using an Internet Control Message Protocol (ICMP) ping as the verification method. PBR used with object tracking is most suitable for devices that have multiple Ethernet connections as the next hop. Normally, Ethernet interfaces connect to digital subscriber line (DSL) modems or cable modems, and do not detect a failure upstream in the ISP broadband network. The Ethernet interface remains up, and any form of static routing points to that interface. Using PBR with object tracking allows you to back-up two Ethernet interfaces, determine the interface that is available by sending ICMP pings to verify if the IP address can be reached, and then route traffic to that interface.

To verify the next-hop IP address for the device, PBR informs the object tracking process that it is interested in tracking a certain object. The tracking process, in turn, informs PBR when the state of the object changes.

Restrictions for Policy-Based Routing with Object Tracking

The **set next-hop verify-availability** command is not supported with the following:

- VRF instances
- Virtual switching system (VSS)
- IPv6 traffic

IPv4 and IPv6 Policy-Based Routing for VRF Instances

Virtual routing and forwarding (VRF) allows multiple routing instances in Cisco software. Beginning in Cisco IOS Release XE 3.7 0E and IOS 15.2(3)E, the Policy-Based Routing (PBR) feature is VRF-aware and works on multiple routing instances, beyond the default or global routing table.

Incoming packets are filtered through the match criteria that are defined in the route map. After a successful match occurs, the **set** command configuration determines the VRF through which outbound packets are policy routed.

Inherit-VRF, Inter-VRF, Global-to-VRF, and VRF-to-Global Routing

The Policy-Based Routing feature supports inherit-VRF, inter-VRF, and VRF-to-global routing.

With inherit-VRF, packets arriving at a virtual routing and forwarding (VRF) interface are routed, by looking-up the same VRF's routing table.

With inter-VRF routing, packets arriving at a VRF interface are routed, by looking-up a different VRF's routing table, as specified by the **set** command.

With VRF-to-global routing, packets arriving at a VRF interface are routed via the global routing table.

With global-to-VRF routing, packets arriving at the global interface (an interface that is not part of a VRF) are routed via a VRF routing table.

Restrictions for VRF-Aware Policy-Based Routing

- VRF is not supported at the LAN Base license level.
- The same route-map cannot be used to configure PBR:
 - on interfaces that belong to different VRFs
 - on one VRF interface and another global interface (an interface that is not part of a VRF).
- The **set vrf** and **set ip global next-hop** commands can be configured with the **set default interface**, **set interface**, **set ip default next-hop**, and **set ip next-hop** commands. But the **set vrf** and **set ip global next-hop** commands take precedence over the **set default interface**, **set interface**, **set ip default next-hop**, and **set ip next-hop** commands. No error message is displayed if you attempt to configure the **set vrf** command with any of these three set commands.
- The **set global** and **set vrf** commands cannot be simultaneously applied to a route map.
- When you use the **set vrf** command you specify the VRF table to be looked-up; this overrides the default or global routing table. If a route is not specified in the VRF routing table, then packets are dropped (even if a route exists in the global routing table).
- The **set next-hop verify-availability** and the **set ip next hop recursive** commands are not supported within VRF instances.

Policy-Based Routing Configuration Tasks

To configure PBR, perform the tasks described in the following sections. The task in the first section is required; the tasks in the remaining sections are optional. For configuration examples, see the [“Policy-Based Routing Configuration Examples” section on page 42-16](#).

- [Enabling IPv4 PBR, page 42-7](#) (Required)
- [Enabling IPv6 PBR, page 42-10](#) (Required)
- [Enabling Local IPv4 and Local IPv6 PBR, page 42-12](#) (Optional)
- [Verifying Next-Hop IP using Object Tracking , page 42-14](#) (Optional)
- [Unsupported Commands, page 42-15](#) (Optional)
- [Configuring IPv4 and IPv6 PBR for VRF Instances, page 42-12](#) (Optional)
- [Unsupported Commands, page 42-15](#)

Enabling IPv4 PBR

To enable PBR, you must create a route map that specifies the match criteria and the resulting action if all of the match clauses are met. Then you must apply that route-map on a particular interface. All packets arriving on the specified interface matching the match clauses are subject to PBR.

To enable IPv4 PBR on an interface, perform this task:

	Command	Purpose
Step 1	Switch(config)# route-map <i>map-tag</i> [permit deny] [<i>sequence-number</i>]	Defines a route map to control where packets are sent. This command puts the switch into route-map configuration mode.
Step 2	Switch(config-route-map)# match ip address { <i>access-list-number</i> <i>name</i> } [... <i>access-list-number</i> <i>name</i>]	Specifies the match criteria. The match criteria take the form of one or more Standard or Extended IP access-lists. The access-lists can specify the source and destination IP addresses, protocol types, and port numbers.
Step 3	Switch(config-route-map)# set ip next-hop <i>ip-address</i> [... <i>ip-address</i>]	Specifies the next-hop IP address to which matching packets are sent. The next-hop IP address specified here must belong to a subnet that is directly connected to this switch. If more than one next-hop IP address is specified, the first usable next-hop is chosen for routing matching packets. If the next-hop is (or becomes) unavailable for some reason, the next one in the list is chosen.
Step 4	Switch(config-route-map)# set ip next-hop verify-availability [<i>next-hop-address-sequence</i> track <i>object</i>]	(Optional) Configures the route map to verify the reachability of the tracked object. Note This option is not supported for IPv6 traffic. For information about defining new tracked object, see Verifying Next-Hop IP using Object Tracking , page 42-14
Step 5	Switch(config-route-map)# set ip next-hop recursive <i>ip-address</i>	Specifies a recursive next-hop IP address. Note The recursive next-hop can be a subnet that is not directly connected. The set ip next-hop recursive command does not ensure that packets are routed through the recursive-next-hop if there is an intermediate node with a shorter route to the destination such that the route does not pass through the recursive-next-hop.
Step 6	Switch(config-route-map)# set interface <i>interface-type interface-number</i> [... <i>type number</i>]	Specifies the output interface from which the packet will be sent. This action specifies that the packet is forwarded out of the local interface. The interface must be a Layer 3 interface (not a switchport). Packets are forwarded on the specified interface only if one of the following conditions is met: <ul style="list-style-type: none"> • The destination IP address in the packet lies within the IP subnet to which the specified interface belongs. • The destination IP address in the packet is reachable through the specified interface (as per the IP routing table). If the destination IP address on the packet does not meet either of these conditions, the packet is dropped. This action forces matching packets to be switched in software.k

	Command	Purpose
Step 7	Switch(config-route-map)# set ip default next-hop <i>ip-address</i> [... <i>ip-address</i>]	Sets next hop to which to route the packet if there is no explicit route for the destination IP address in the packet. Before forwarding the packet to the next hop, the switch looks up the packet's destination address in the unicast routing table. If a match is found, the packet is forwarded by way of the routing table. If no match is found, the packet is forwarded to the specified next hop.
Step 8	Switch(config-route-map)# set default interface <i>interface-type interface-number</i> [... <i>type</i> ... <i>number</i>]	<p>Specifies the output interface from which the packet will be sent if there is no explicit route for this destination. Before forwarding the packet to the next hop, the switch looks up the packet's destination address in the unicast routing table. If a match is found, the packet is forwarded by using the routing table. If no match is found, the packet is forwarded to the specified output interface.</p> <p>Packets are forwarded on the specified interface only if one of the following conditions is met:</p> <ul style="list-style-type: none"> • The destination IP address in the packet lies within the IP subnet to which the specified interface belongs. • The destination IP address in the packet is reachable through the specified interface (as per the IP routing table). <p>If the destination IP address on the packet does not meet either of these conditions, the packet is dropped. This action forces matching packets to be switched in software.</p>
Step 9	Switch(config-route-map)# interface <i>interface-type interface-number</i>	Specifies the interface. This command puts the switch into interface configuration mode.
Step 10	Switch(config-if)# ip policy route-map <i>map-tag</i>	Identifies the route map to use for PBR. One interface can only have one route map tag, but you can have multiple route map entries with different sequence numbers. These entries are evaluated in sequence number order until the first match. If no match exists, packets are routed as usual.

Use the **set** commands with each other. These commands are evaluated in the order shown in Step 3 in the previous task table. A usable next hop implies an interface. Once the local switch finds a next hop and a usable interface, it routes the packet.

Refer to the section [Policy-Based Routing Configuration Examples, page 42-16](#) for examples of IPv4 PBR.

Use the **show route-map map-tag** command to display the existing route map.

Note

Packet and byte counters in the output of the **show route-map map-tag** command are not updated.

Enabling IPv6 PBR

Note

With IOS XE 3.6.0E and IOS 15.2(2)E, IPv6 PBR is not supported on Supervisor Engine 8-E.

To enable PBR, you must create a route map that specifies the match criteria and the resulting action if all of the match clauses are met. Then you must apply that route-map on a particular interface. All packets arriving on the specified interface matching the match clauses are subject to PBR.

To enable IPv6 PBR on an interface, perform this task:

	Command	Purpose
Step 1	Switch(config)# route-map map-tag [permit deny] [sequence-number]	Defines a route map to control where packets are sent. This command puts the switch into route-map configuration mode.
Step 2	Switch(config-route-map)# match ipv6 address {access-list-number name} [...access-list-number name]	Specifies the match criteria. The match criteria take the form of one or more Standard or Extended ipv6 access-lists. The access-lists can specify the source and destination IP addresses, protocol types, and port numbers.
Step 3	Switch(config-route-map)# set ipv6 next-hop ip-address [... ip-address]	Specifies the next-hop IP address to which matching packets are sent. The next-hop IP address specified here must belong to a subnet that is directly connected to this switch. If more than one next-hop IP address is specified, the first usable next-hop is chosen for routing matching packets. If the next-hop is (or becomes) unavailable for some reason, the next one in the list is chosen.
Step 4	Switch(config-route-map)# set interface interface-type interface-number [... type number]	Specifies the output interface from which the packet will be sent. This action specifies that the packet is forwarded out of the local interface. The interface must be a Layer 3 interface (not a switchport). Packets are forwarded on the specified interface only if one of the following conditions is met: <ul style="list-style-type: none"> The destination IP address in the packet lies within the IP subnet to which the specified interface belongs. The destination IP address in the packet is reachable through the specified interface (as per the IP routing table). If the destination IP address on the packet does not meet either of these conditions, the packet is dropped. This action forces matching packets to be switched in software.k
Step 5	Switch(config-route-map)# set ipv6 default next-hop ip-address [... ip-address]	Sets next hop to which to route the packet if there is no explicit route for the destination IP address in the packet. Before forwarding the packet to the next hop, the switch looks up the packet's destination address in the unicast routing table. If a match is found, the packet is forwarded by way of the routing table. If no match is found, the packet is forwarded to the specified next hop.

	Command	Purpose
Step 6	Switch(config-route-map)# set default interface <i>interface-type interface-number</i> [...type ...number]	<p>Specifies the output interface from which the packet will be sent if there is no explicit route for this destination. Before forwarding the packet to the next hop, the switch looks up the packet's destination address in the unicast routing table. If a match is found, the packet is forwarded by using the routing table. If no match is found, the packet is forwarded to the specified output interface.</p> <p>Packets are forwarded on the specified interface only if one of the following conditions is met:</p> <ul style="list-style-type: none"> • The destination IP address in the packet lies within the IP subnet to which the specified interface belongs. • The destination IP address in the packet is reachable through the specified interface (as per the IP routing table). <p>If the destination IP address on the packet does not meet either of these conditions, the packet is dropped. This action forces matching packets to be switched in software.</p>
Step 7	Switch(config-route-map)# interface <i>interface-type interface-number</i>	Specifies the interface. This command puts the switch into interface configuration mode.
Step 8	Switch(config-if)# ipv6 policy route-map <i>map-tag</i>	Identifies the route map to use for PBR. One interface can only have one route map tag, but you can have multiple route map entries with different sequence numbers. These entries are evaluated in sequence number order until the first match. If no match exists, packets are routed as usual.

**Note**

The **recursive** option is supported for IPv4, but not for IPv6. An interface can have either an ipv4 route map or an ipv6 route map. An interface can be bound to only one route map.

Use the **set** commands with each other. These commands are evaluated in the order shown in Step 3 in the previous task table. A usable next hop implies an interface. Once the local switch finds a next hop and a usable interface, it routes the packet.

Refer to the following document for IPv6 PBR configuration examples.

<http://www.cisco.com/c/en/us/support/docs/ip/ip-version-6-ipv6/112218-policy-based-routing-ipv6-configex.html>

**Note**

Packet and byte counters in the output of the **show route-map map-tag** command are updated only for software switched packets. Counters for hardware switched packets are not updated.

Enabling Local IPv4 and Local IPv6 PBR

Packets that are generated by the switch are not normally policy-routed. To enable local PBR for such packets, indicate which route map the switch should use by entering this command:

IPv4

Command	Purpose
Switch(config)# ip local policy route-map <i>map-tag</i>	Identifies the IPv4 route map to use for local PBR.

IPv6

Command	Purpose
Switch(config)# ipv6 local policy route-map <i>map-tag</i>	Identifies the IPv6 route map to use for local PBR.

All packets originating on the switch are then subject to local PBR.
Use the **show ip local policy** command to display the route map used for local PBR, if one exists.

Configuring IPv4 and IPv6 PBR for VRF Instances

To enable PBR for multiple routing instances, configure your device in the following way:

	Command	Purpose
Step 1	Switch(config)# route-map <i>map-tag</i> [permit deny] [<i>sequence-number</i>]	Defines a route map to control where packets are sent. This command puts the switch into route-map configuration mode.
Step 2	For IPv4: Switch(config-route-map)# match ip address { <i>access-list-number</i> <i>name</i> } [... <i>access-list-number</i> <i>name</i>] For IPv6: Switch(config-route-map)# match ipv6 address { <i>access-list-number</i> <i>name</i> } [... <i>access-list-number</i> <i>name</i>]	Specifies the match criteria. The match criteria take the form of one or more Standard or Extended access-lists. The access-lists can specify the source and destination IP addresses, protocol types, and port numbers.

	Command	Purpose
Step 3	Set one of the following	Specifies the next-hop IP address under the VRF, to which the matched packets must be forwarded. The next-hop IP address must exist in the routing table, under the VRF.
	<p>For IPv4:</p> <pre>Switch(config-route-map)# set ip vrf [vrf name] next-hop ip address> [...ip-address]</pre> <p>For IPv6:</p> <pre>Switch(config-route-map)# set ipv6 vrf [vrf name] next-hop ip address> [...ip-address]</pre>	
Step 4	<p>For IPv4:</p> <pre>Switch(config-route-map)# set ip global next-hop ip address> [...ip-address]</pre> <p>For IPv6:</p> <pre>Switch(config-route-map)# set ipv6 global next-hop ip address> [...ip-address]</pre>	Specifies the next-hop IP address, from the global routing table, to which to forward matched packets. The next-hop IP address must exist in the global routing table.
	Set one of the following:	Specifies the next-hop IP address to which the matched packets must be forwarded when there is no explicit packet destination address in the routing table, under the VRF.
	<p>For IPv4:</p> <pre>Switch(config-route-map)# set ip default vrf [vrf name] next-hop ip address> [...ip-address]</pre> <p>For IPv6:</p> <pre>Switch(config-route-map)# set ipv6 default vrf [vrf name] next-hop ip address> [...ip-address]</pre>	
	<p>For IPv4:</p> <pre>Switch(config-route-map)# set ip default global next-hop ip address> [...ip-address]</pre> <p>For IPv6:</p> <pre>Switch(config-route-map)# set ipv6 default global next-hop ip address> [...ip-address]</pre>	Specifies the next-hop IP address to which the matched packets must be forwarded when there is no explicit packet destination address corresponding to the VRF to which the interface belongs, in the routing table. The next-hop address specified must exist in the global routing table.

	Command	Purpose
Step 5	<p>Set one of the following:</p> <p>For global routing:</p> <pre>Switch(config-route-map)# set global</pre> <p>For inter-VRF routing:</p> <pre>Switch(config-route-map)# set vrf [vrf name]</pre>	<p>Specifies that the global routing table should be looked-up to route packets,</p> <p>Use the set global command to configure VRF-to-Global routing.</p> <p>Use the set vrf command to specify the VRF table to be looked-up, to route packets.</p> <p>Use this command to configure Inter-VRF routing and route packets arriving at a particular VRF interface through a different VRF interface, by looking-up a different VRF's routing table. This command overrides the default or global routing table. If a route is not specified in the VRF routing table, then packets are dropped (even if a route exists in the global routing table)</p>
Step 6	<pre>Switch(config-route-map)# interface interface-type interface-number</pre>	Specifies the interface. This command puts the switch into interface configuration mode.
Step 7	<pre>Switch(config-if)# ipv6 policy route-map map-tag</pre>	Identifies the route map to use for PBR. One interface can only have one route map tag, but you can have multiple route map entries with different sequence numbers. These entries are evaluated in sequence number order until the first match. If no match exists, packets are routed as usual.

Verifying the PBR Configuration for VRF Instances

To verify the PBR configuration for VRF instances, enter the following steps in any order:

	Command	Purpose
Step 1	<pre>Switch# show ip access list [access-list-number access-list-name]</pre>	Displays the subnet ranges defined as match criteria in the standard access lists.
Step 2	<pre>Switch# show route-map [map-name]</pre>	Displays the match and set commands in the route map.

The following example shows you how to configure PBR for VRF instances:

```
Switch# enable
Switch# configure terminal
Switch(config)# route-map map1 permit 10
Switch(config-route-map)# set ipv6 vrf myvrf next-hop 2001.DB8:4:1::1/64
Switch(config-route-map)# end
Switch# show route-map map1
```

Verifying Next-Hop IP using Object Tracking

To verify the next-hop IP address using PBR with Object Tracking, perform the following steps:

Note

The **set ip next-hop verify-availability** command is not supported on VRF instances, on a virtual switching system (VSS), and with IPv6 traffic.

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch (config)# track [<i>object-number</i>] ip sla [<i>entry-number</i>]	Tracks the state of the specified IP SLA object.
Step 3	Switch (config)# ip sla [<i>operation-number</i>]	Starts a Cisco IOS IP Service Level Agreement (SLA) operation configuration and enters IP SLA configuration mode.
Step 4	Switch (config-ip-sla)# icmp echo [<i>ip-address</i>] source ip [<i>ip-address</i>]	Configures an IP SLA Internet Control Message Protocol (ICMP) echo probe operation and enters Echo configuration mode.
Step 5	Switch (config-ip-sla-echo)# frequency seconds	(Optional) Sets the rate at which a specified IP SLA operation repeats.
Step 6	Switch (config-ip-sla-echo)# threshold milliseconds	(Optional) Sets the length of time required for a rising threshold event to be declared.
Step 7	Switch (config-ip-sla-echo)# timeout milliseconds	(Optional) Sets the maximum time required for the IP SLA operation to be completed.
Step 8	Switch (config)# ip sla schedule [<i>operation-number</i>] [life { <i>forever</i> <i>seconds</i> }] [start-time { <i>hh</i> : <i>mm</i> } [<i>:ss</i>] [<i>monthday</i> <i>daymonth</i>] <i>pending</i> <i>now</i> <i>after hh</i> : <i>mm</i> : <i>ss</i> }] [<i>ageout seconds</i>]	Configures the scheduling parameters for a single Cisco IOS IP SLA operation.
Step 9	Switch(config)# route-map <i>map-tag</i> [<i>permit</i> <i>deny</i>] [<i>sequence-number</i>]	Specifies a route map and enters route-map configuration mode.
Step 10	Switch(config-route-map)# match ip address [<i>access-list-name</i>]	Distributes routes that have a destination IPv4 network number address that is permitted by a standard access list.
Step 11	Switch(config-route-map)# set ip next-hop verify-availability [<i>next-hop-address</i> <i>sequence</i> track <i>object</i>]	Configures the route map to verify the reachability of the tracked object.

The following example shows you how to verify the next-hop IP address in a route map:

```
Switch# enable
Switch# configure terminal
Switch(config)# track 100 ip sla 100
Switch(config)# ip sla 100
switch(config-ip-sla)# icmp-echo 172.19.255.253 source-ip 172.19.255.47
switch(config-ip-sla-echo)# timeout 1500
switch(config-ip-sla-echo)# threshold 1000
switch(config-ip-sla-echo)# frequency 2
switch(config)# ip sla schedule 100 life forever start-time now
switch(config)# route-map alpha permit 10
switch(config-route-map)# match ip address exlist
switch(config-route-map)# set ip next-hop verify-availability 95.1.1.2 1 track 100
switch# show route-map alpha
switch# show track 100
```

Unsupported Commands

The following PBR commands in config-route-map mode are in the CLI but not supported in Cisco IOS for the Catalyst 4500 series switches. If you attempt to use these commands, an error message displays:

- **match-length**
- **set ip qos** and **set ipv6 qos**
- **set ip tos** and **set ipv6 tos**
- **set ip precedence** and **set ipv6 precedence**
- **set ip df** and **set ipv6 df**
- **set ipv6 next-hop recursive**
- **set ipv6 next-hop verify-availability**

Policy-Based Routing Configuration Examples

The following sections provide PBR configuration examples:

- [Equal Access, page 42-16](#)
- [Differing Next Hops, page 42-17](#)
- [Deny ACE, page 42-17](#)

For information on how to configure policy-based routing, see the section “[Policy-Based Routing Configuration Tasks](#)” in this chapter.

Equal Access

The following example provides two sources with equal access to two different service providers. Packets arriving on interface fastethernet 3/1 from the source 10.1.1.1 are sent to the switch at 6.6.6.6 if the switch has no explicit route for the destination of the packet. Packets arriving from the source 2.2.2.2 are sent to the switch at 7.7.7.7 if the switch has no explicit route for the destination of the packet. All other packets for which the switch has no explicit route to the destination are discarded.

```
Switch (config)# access-list 1 permit ip 10.1.1.1
access-list 2 permit ip 2.2.2.2
!
interface fastethernet 3/1
 ip policy route-map equal-access
!

route-map equal-access permit 10
 match ip address 1
 set ip default next-hop 6.6.6.6
route-map equal-access permit 20
 match ip address 2
 set ip default next-hop 7.7.7.7
route-map equal-access permit 30
 set default interface null0
```

Note

If the packets you want to drop do not match either of the first two route-map clauses, then change **set default interface null0** to **set interface null0**.

Differing Next Hops

The following example illustrates how to route traffic from different sources to different places (next hops). Packets arriving from source 10.1.1.1 are sent to the next hop at 3.3.3.3; packets arriving from source 2.2.2.2 are sent to the next hop at 3.3.3.5.

```
access-list 1 permit ip 10.1.1.1
access-list 2 permit ip 2.2.2.2
!
interface fastethernet 3/1
 ip policy route-map Texas
!
route-map Texas permit 10
 match ip address 1
 set ip next-hop 3.3.3.3
!
route-map Texas permit 20
 match ip address 2
 set ip next-hop 3.3.3.5
```

Deny ACE

The following example illustrates how to stop processing a given route map sequence, and to jump to the next sequence. Packets arriving from source 10.1.1.1 skip sequence 10 and jump to sequence 20. All other packets from subnet 10.1.1.0 follow the set statement in sequence 10.

```
access-list 1 deny ip 10.1.1.1
access-list 1 permit ip 10.1.1.0 0.0.0.255
access-list 2 permit ip 10.1.1.1
access-list 2 permit ip 2.2.2.2
!
interface fastethernet 3/1
 ip policy route-map Texas
!
route-map Texas permit 10
 match ip address 1
 set ip next-hop 3.3.3.3
!
route-map Texas permit 20
 match ip address 2
 set ip next-hop 3.3.3.5
```

Examples of the show Command

The following **show** command illustrates that route map pbrv6-test has only one permit sequence.

In the example policy, IPv6 packets with an address matching the criteria defined by the access control list v6_acl are forwarded to the next hop 2006::2. If next-hop 2006::2 is unreachable, the matching packets are forwarded to 2005::2. If both next-hops are unreachable, the packets are forwarded using the routing table lookup. For packets that do not match the filter criteria, a standard routing table lookup is performed for packet forwarding.

```
Switch# show route-map pbrv6-test
route-map pbrv6-test, permit, sequence 10
  Match clauses:
    ipv6 address v6_acl
  Set clauses:
    ipv6 next-hop 2006::2 2005::2
```

```
Policy routing matches: 0 packets, 0 bytes
```

Configuring VRF-lite

Virtual Private Networks (VPNs) provide a secure way for customers to share bandwidth over an ISP backbone network. A VPN is a collection of sites sharing a common routing table. A customer site is connected to the service provider network by one or more interfaces, and the service provider associates each interface with a VPN routing table. A VPN routing table is called a VPN routing/forwarding (VRF) table.

With the VRF-lite feature, the Catalyst 4500 series switch supports multiple VPN routing/forwarding instances in customer edge devices. (VRF-lite is also termed multi-VRF CE, or multi-VRF Customer Edge Device). VRF-lite allows a service provider to support two or more VPNs with overlapping IP addresses using one interface.

This document addresses both IPv4 and IPv6 VRF-lite.

Note

Starting with Cisco IOS Release 12.2(52)SG, the Catalyst 4500 switch supports VRF-lite NSF support with routing protocols OSPF/EIGRP/BGP.

This chapter includes these topics:

- [About VRF-lite, page 43-2](#)
- [VRF-lite Configuration Guidelines, page 43-3](#)
- [Configuring VRF-lite for IPv4, page 43-5](#)
- [Configuring VRF-lite for IPv6, page 43-15](#)
- [VPN Co-existence Between IPv4 and IPv6, page 43-28](#)
- [Migrating from the Old to New CLI Scheme, page 43-28](#)

Note

The switch does not use Multiprotocol Label Switching (MPLS) to support VPNs. For information about MPLS VRF, refer to the *Cisco IOS Switching Services Configuration Guide* at: http://www.cisco.com/en/US/docs/ios/mps/configuration/guide/mp_vpn_ipv4_ipv6_ps6922_TSD_Products_Configuration_Guide_Chapter.html

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About VRF-lite

VRF-lite is a feature that enables a service provider to support two or more VPNs, where IP addresses can be overlapped among the VPNs. VRF-lite uses input interfaces to distinguish routes for different VPNs and forms virtual packet-forwarding tables by associating one or more Layer 3 interfaces with each VRF. Interfaces in a VRF can be either physical, such as Ethernet ports, or logical, such as VLAN SVIs, but a Layer 3 interface cannot belong to more than one VRF at any time.

Note

VRF-lite interfaces must be Layer 3 interfaces.

VRF-lite includes these devices:

- Customer edge (CE) devices provide customer access to the service provider network over a data link to one or more provider edge routers. The CE device advertises the site's local routes to the provider edge router and learns the remote VPN routes from it. A Catalyst 4500 series switch can be a CE.
- Provider edge (PE) routers exchange routing information with CE devices by using static routing or a routing protocol such as BGP, RIPv1, or RIPv2.

The PE is only required to maintain VPN routes for those VPNs to which it is directly attached, eliminating the need for the PE to maintain all of the service provider VPN routes. Each PE router maintains a VRF for each of its directly connected sites. Multiple interfaces on a PE router can be associated with a single VRF if all of these sites participate in the same VPN. Each VPN is mapped to a specified VRF. After learning local VPN routes from CEs, a PE router exchanges VPN routing information with other PE routers by using internal BGP (iBGP).

- Provider routers (or core routers) are any routers in the service provider network that do not attach to CE devices.

With VRF-lite, multiple customers can share one CE, and only one physical link is used between the CE and the PE. The shared CE maintains separate VRF tables for each customer and switches or routes packets for each customer based on its own routing table. VRF-lite extends limited PE functionality to a CE device, giving it the ability to maintain separate VRF tables to extend the privacy and security of a VPN to the branch office.

Figure 43-1 shows a configuration where each Catalyst 4500 series switches acts as multiple virtual CEs. Because VRF-lite is a Layer 3 feature, each interface in a VRF must be a Layer 3 interface.

Figure 43-1 Catalyst 4500 Series Switches Acting as Multiple Virtual CEs

Figure 43-1 illustrates the packet-forwarding process in a VRF-lite CE-enabled network.

- When the CE receives a packet from a VPN, it looks up the routing table based on the input interface. When a route is found, the CE forwards the packet to the PE.
- When the ingress PE receives a packet from the CE, it performs a VRF lookup. When a route is found, the router adds a corresponding MPLS label to the packet and sends it to the MPLS network.
- When an egress PE receives a packet from the network, it strips the label and uses the label to identify the correct VPN routing table. The egress PE then performs the normal route lookup. When a route is found, it forwards the packet to the correct adjacency.
- When a CE receives a packet from an egress PE, it uses the input interface to look up the correct VPN routing table. If a route is found, the CE forwards the packet within the VPN.

To configure VRF, create a VRF table and specify the Layer 3 interface associated with the VRF. You then configure the routing protocols in the VPN and between the CE and the PE. BGP is the preferred routing protocol used to distribute VPN routing information across the providers' backbone. The VRF-lite network has three major components:

- VPN route target communities—Lists all other members of a VPN community. You need to configure VPN route targets for each VPN community member.
- Multiprotocol BGP peering of VPN community PE routers—Propagates VRF reachability information to all members of a VPN community. You need to configure BGP peering in all PE routers within a VPN community.
- VPN forwarding—Transports all traffic between all VPN community members across a VPN service-provider network.

VRF-lite Configuration Guidelines

IPv4 and IPv6

- For the RIP, OSPF, PIM and PBR protocols, VRF is not supported at the LAN Base license level.
- A switch with VRF-lite is shared by multiple customers, and all customers have their own routing tables.
- Because customers use different VRF tables, you can reuse the same IP addresses. Overlapped IP addresses are allowed in different VPNs.
- VRF-lite lets multiple customers share the same physical link between the PE and the CE. Trunk ports with multiple VLANs separate packets among customers. All customers have their own VLANs.
- VRF-lite does not support all MPLS-VRF functionality: label exchange, LDP adjacency, or labeled packets.
- For the PE router, there is no difference between using VRF-lite or using multiple CEs. In Figure 43-1, multiple virtual Layer 3 interfaces are connected to the VRF-lite device.
- The Catalyst 4500 series switch supports configuring VRF by using physical ports, VLAN SVIs, or a combination of both. You can connect SVIs through an access port or a trunk port.
- A customer can use multiple VLANs as long because they do not overlap with those of other customers. A customer's VLANs are mapped to a specific routing table ID that is used to identify the appropriate routing tables stored on the switch.

- The Layer 3 TCAM resource is shared between all VRFs. To ensure that any one VRF has sufficient CAM space, use the **maximum routes** command.
- A Catalyst 4500 series switch using VRF can support one global network and up to 64 VRFs. The total number of routes supported is limited by the size of the TCAM.
- A single VRF can be configured for both IPv4 and IPv6.
- PBR and VRF cannot be configured on the same interface. Similarly, WCCP, Etherchannel and MEC cannot be configured on the same interface with VRF.
- If an incoming packet's destination address is not found in the vrf table, the packet is dropped. Also, if insufficient TCAM space exists for a VRF route, hardware switching for that VRF is disabled and the corresponding data packets are sent to software for processing.

IPv4 Specific

- You can use most routing protocols (BGP, OSPF, EIGRP, RIP and static routing) between the CE and the PE. However, we recommend using external BGP (EBGP) for these reasons:
 - BGP does not require multiple algorithms to communicate with multiple CEs.
 - BGP is designed for passing routing information between systems run by different administrations.
 - BGP makes simplifies passing attributes of the routes to the CE.
- VRF-lite does not support IGRP and ISIS.
- Beginning with Cisco IOS Release 12.2(50)SG, Multicast and VRF can be configured together on a Layer 3 interface.
- The Catalyst 4500 series switch supports all the PIM protocols (PIM-SM, PIM-DM, PIM-SSM, PIM BiDIR).
- The **capability vrf-lite** subcommand under **router ospf** should be used when configuring OSPF as the routing protocol between the PE and the CE.

IPv6 specific

- VRF-aware OSPFv3, BGPv6, EIGRPv6, and IPv6 static routing are supported.
- VRF aware ISISv6, RIPng, IPv6 Multicast Routing(MVRF), and PIMv6 are not supported.
- VRF-aware IPv6 route applications include: ping, telnet, ssh, tftp, ftp and traceroute. (This list does not include the Mgt interface, which is handled differently even though you can configure both IPv4 or IPv6 VRF under it.)

Configuring VRF-lite for IPv4

Configuring VRFs

To configure one or more VRFs, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ip routing	Enables IP routing.
Step 3	Switch(config)# ip vrf <i>vrf-name</i>	Names the VRF and enters VRF configuration mode.
Step 4	Switch(config-vrf)# rd <i>route-distinguisher</i>	Creates a VRF table by specifying a route distinguisher. Enter either an AS number and an arbitrary number (xxx:y) or an IP address and arbitrary number (A.B.C.D:y).
Step 5	Switch(config-vrf)# route-target { export import both } <i>route-target-ext-community</i>	Creates a list of import, export, or import and export route target communities for the specified VRF. Enter either an AS system number and an arbitrary number (xxx:y) or an IP address and an arbitrary number (A.B.C.D:y). Note This command is effective only if BGP is running.
Step 6	Switch(config-vrf)# import map <i>route-map</i>	(Optional) Associates a route map with the VRF.
Step 7	Switch(config-vrf)# interface <i>interface-id</i>	Enters interface configuration mode and specify the Layer 3 interface to be associated with the VRF. The interface can be a routed port or SVI.
Step 8	Switch(config-if)# ip vrf forwarding <i>vrf-name</i>	Associates the VRF with the Layer 3 interface.
Step 9	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 10	Switch# show ip vrf [brief detail interfaces] [<i>vrf-name</i>]	Verifies the configuration. Displays information about the configured VRFs.
Step 11	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Note

For complete syntax and usage information for the following commands, see the switch command reference for this release and see the *Cisco IOS Switching Services Command Reference* at: http://www.cisco.com/en/US/docs/ios/ipswitch/command/reference/isw_book.html

Use the **no ip vrf** *vrf-name* global configuration command to delete a VRF and to remove all interfaces from it. Use the **no ip vrf forwarding** interface configuration command to remove an interface from the VRF.

Configuring VRF-Aware Services

IP services can be configured on global interfaces and within the global routing instance. IP services are enhanced to run on multiple routing instances; they are VRF-aware. Any configured VRF in the system can be specified for a VRF-aware service.

VRF-aware services are implemented in platform-independent modules. VRF provides multiple routing instances in Cisco IOS. Each platform has its own limit on the number of VRFs it supports.

VRF-aware services have the following characteristics:

- The user can ping a host in a user-specified VRF.
- ARP entries are learned in separate VRFs. The user can display Address Resolution Protocol (ARP) entries for specific VRFs.

Configuring the User Interface for ARP

To configure VRF-aware services for ARP, perform this task:

Command	Purpose
Switch# show ip arp vrf <i>vrf-name</i>	Displays the ARP table (static and dynamic entries) in the specified VRF.
Switch(config)# arp vrf <i>vrf-name</i> <i>ip-address mac-address ARPA</i>	Creates a static ARP entry in the specified VRF.

Configuring Per-VRF for TACACS+ Servers

The per-VRF for TACACS+ servers feature enables you to configure per-virtual route forwarding (per-VRF) authentication, authorization, and accounting (AAA) on TACACS+ servers.

Before configuring per-VRF on a TACACS+ server, you must have configured AAA and a server group.

You can create the VRF routing table (shown in Steps 3 and 4) and configure the interface (Steps 6, 7, and 8). The actual configuration of per-VRF on a TACACS+ server is done in Steps 10 through 13.

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# ip vrf <i>vrf-name</i>	Configures a VRF table and enters VRF configuration mode.
Step 4	Switch (config-vrf)# rd <i>route-distinguisher</i>	Creates routing and forwarding tables for a VRF instance.
Step 5	Switch (config-vrf)# exit	Exits VRF configuration mode.
Step 6	Switch (config)# interface <i>interface-name</i>	Configures an interface and enters interface configuration mode.
Step 7	Switch (config-if)# ip vrf forwarding <i>vrf-name</i>	Configures a VRF for the interface.
Step 8	Switch (config-if)# ip address <i>ip-address mask</i> [secondary]	Sets a primary or secondary IP address for an interface.
Step 9	Switch (config-if)# exit	Exits interface configuration mode.

	Command or Action	Purpose
Step 10	aaa group server tacacs+ <i>group-name</i> Example: Switch (config)# aaa group server tacacs+ tacacs1	Groups different TACACS+ server hosts into distinct lists and distinct methods and enters server-group configuration mode.
Step 11	server-private {<i>ip-address</i> <i>name</i>} [<i>nat</i>] [<i>single-connection</i>] [<i>port port-number</i>] [<i>timeout seconds</i>] [<i>key</i> [0 7] <i>string</i>] Example: Switch (config-sg-tacacs+)# server-private 10.1.1.1 port 19 key cisco	Configures the IP address of the private TACACS+ server for the group server.
Step 12	Switch (config-sg-tacacs+)# ip vrf forwarding <i>vrf-name</i>	Configures the VRF reference of a AAA TACACS+ server group.
Step 13	Switch (config-sg-tacacs+)# ip tacacs source-interface <i>subinterface-name</i>	Uses the IP address of a specified interface for all outgoing TACACS+ packets.
Step 14	Switch (config-sg-tacacs)# exit	Exits server-group configuration mode.

The following example lists all the steps to configure per-VRF TACACS+:

```
Switch> enable
Switch# configure terminal
Switch (config)# ip vrf cisco
Switch (config-vrf)# rd 100:1
Switch (config-vrf)# exit
Switch (config)# interface Loopback0
Switch (config-if)# ip vrf forwarding cisco
Switch (config-if)# ip address 10.0.0.2 255.0.0.0
Switch (config-if)# exit
Switch (config-sg-tacacs+)# ip vrf forwarding cisco
Switch (config-sg-tacacs+)# ip tacacs source-interface Loopback0
Switch (config-sg-tacacs)# exit
```

For more information about configuring per-VRF for TACACS+ server,

http://www.cisco.com/en/US/docs/ios/sec_user_services/configuration/guide/sec_vrf_tacas_svrs.pdf

Configuring Multicast VRFs

To configure multicast within a VRF table, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ip routing	Enables IP routing.
Step 3	Switch(config)# ip vrf <i>vrf-name</i>	Names the VRF and enters VRF configuration mode.
Step 4	Switch(config-vrf)# ip multicast-routing vrf <i>vrf-name</i>	(Optional) Enables global multicast routing for VRF table.

	Command	Purpose
Step 5	Switch(config-vrf) # rd <i>route-distinguisher</i>	Creates a VRF table by specifying a route distinguisher. Enter either an AS number and an arbitrary number (xxx:y) or an IP address and arbitrary number (A.B.C.D:y).
Step 6	Switch(config-vrf) # route-target { export import both } <i>route-target-ext-community</i>	Creates a list of import, export, or import and export route target communities for the specified VRF. Enter either an AS system number and an arbitrary number (xxx:y) or an IP address and an arbitrary number (A.B.C.D:y). The <i>route-target-ext-community</i> value should be the same as the <i>route-distinguisher</i> value entered in Step 4.
Step 7	Switch(config-vrf) # import map <i>route-map</i>	(Optional) Associates a route map with the VRF.
Step 8	Switch(config-vrf) # interface <i>interface-id</i>	Enters interface configuration mode and specifies the Layer 3 interface to be associated with the VRF. The interface can be a routed port or a SVI.
Step 9	Switch(config-if) # ip vrf forwarding <i>vrf-name</i>	Associates the VRF with the Layer 3 interface.
Step 10	Switch(config-if) # ip address <i>ip-address mask</i>	Configures IP address for the Layer 3 interface.
Step 11	Switch(config-if) # ip pim [sparse-dense mode dense-mode sparse-mode]	Enables PIM on the VRF-associated Layer 3 interface.
Step 12	Switch(config-if) # end	Returns to privileged EXEC mode.
Step 13	Switch# show ip vrf [brief detail interfaces] [<i>vrf-name</i>]	Verifies the configuration. Display information about the configured VRFs.
Step 14	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

The following example shows how to configure multicast within a VRF table:

```
Switch(config)# ip routing
Switch(config)# ip vrf multiVrfA
Switch(config-vrf)# ip multicast-routing vrf multiVrfA
Switch(config-vrf)# interface GigabitEthernet3/1/0
Switch(config-if)# ip vrf forwarding multiVrfA
Switch(config-if)# ip address 172.21.200.203 255.255.255.0
Switch(config-if)# ip pim sparse-mode
```

For more information about configuring a multicast within a Multi-VRF CE, see the *Cisco IOS IP Multicast Configuration Guide, Release 12.4*.

Use the **no ip vrf vrf-name** global configuration command to delete a VRF and to remove all interfaces from it. Use the **no ip vrf forwarding** interface configuration command to remove an interface from the VRF.

Configuring a VPN Routing Session

Routing within the VPN can be configured with any supported routing protocol (RIP, OSPF, or BGP) or with static routing. The configuration shown here is for OSPF, but the process is the same for other protocols.

To configure OSPF in the VPN, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# router ospf <i>process-id vrf vrf-name</i>	Enables OSPF routing, specifies a VPN forwarding table, and enters router configuration mode.
Step 3	Switch(config-router)# log-adjacency-changes	(Optional) Logs changes in the adjacency state (the default state).
Step 4	Switch(config-router)# redistribute bgp autonomous-system-number subnets	Sets the switch to redistribute information from the BGP network to the OSPF network.
Step 5	Switch(config-router)# network <i>network-number area area-id</i>	Defines a network address and mask on which OSPF runs and the area ID for that network address.
Step 6	Switch(config-router)# end	Returns to privileged EXEC mode.
Step 7	Switch# show ip ospf process-id	Verifies the configuration of the OSPF network.
Step 8	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no router ospf process-id vrf vrf-name** global configuration command to disassociate the VPN forwarding table from the OSPF routing process.

The following example shows how to configure a single VRF named VRF-RED:

```
Switch(config)# ip vrf VRF-RED
Switch(config-vrf)# rd 1:1
Switch(config-vrf)# exit
Switch(config)# router eigrp virtual-name
Switch(config-router)# address-family ipv4 vrf VRF-RED autonomous-system 1
Switch(config-router-af)# network 10.0.0.0 0.0.0.255
Switch(config-router-af)# topology base
Switch(config-router-topology)# default-metric 10000 100 255 1 1500
Switch(config-router-topology)# exit-af-topology
Switch(config-router-af)# exit-address-family
```

Configuring BGP PE to CE Routing Sessions

To configure a BGP PE to CE routing session, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# router bgp <i>autonomous-system-number</i>	Configures the BGP routing process with the AS number passed to other BGP routers and enters router configuration mode.
Step 3	Switch(config-router)# network <i>network-number mask network-mask</i>	Specifies a network and mask to announce using BGP.
Step 4	Switch(config-router)# redistribute ospf process-id match internal	Sets the switch to redistribute OSPF internal routes.
Step 5	Switch(config-router)# network <i>network-number area area-id</i>	Defines a network address and mask on which OSPF runs and the area ID for that network address.

	Command	Purpose
Step 6	Switch(config-router-af)# address-family ipv4 vrf vrf-name	Defines BGP parameters for PE to CE routing sessions and enters VRF address-family mode.
Step 7	Switch(config-router-af)# neighbor <i>address remote-as as-number</i>	Defines a BGP session between PE and CE routers.
Step 8	Switch(config-router-af)# neighbor <i>address activate</i>	Activates the advertisement of the IPv4 address family.
Step 9	Switch(config-router-af)# end	Returns to privileged EXEC mode.
Step 10	Switch# show ip bgp [ipv4] [neighbors]	Verifies BGP configuration.
Step 11	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no router bgp autonomous-system-number** global configuration command to delete the BGP routing process. Use the command with keywords to delete routing characteristics.

VRF-lite Configuration Example

Figure 43-2 is a simplified example of the physical connections in a network similar to that in Figure 43-1. OSPF is the protocol used in VPN1, VPN2, and the global network. BGP is used in the CE to PE connections. The example commands show how to configure the CE switch S8 and include the VRF configuration for switches S20 and S11 and the PE router commands related to traffic with switch S8. Commands for configuring the other switches are not included but would be similar.

Figure 43-2 VRF-lite Configuration Example

99722

Configuring Switch S8

On switch S8, enable routing and configure VRF.

```
Switch# configure terminal  
Enter configuration commands, one per line. End with CNTL/Z.  
Switch(config)# ip routing  
Switch(config)# ip vrf v11  
Switch(config-vrf)# rd 800:1  
Switch(config-vrf)# route-target export 800:1  
Switch(config-vrf)# route-target import 800:1  
Switch(config-vrf)# exit  
Switch(config)# ip vrf v12  
Switch(config-vrf)# rd 800:2  
Switch(config-vrf)# route-target export 800:2  
Switch(config-vrf)# route-target import 800:2  
Switch(config-vrf)# exit
```

Configure the loopback and physical interfaces on switch S8. Fast Ethernet interface 3/5 is a trunk connection to the PE. Interfaces 3/7 and 3/11 connect to VPNs:

```
Switch(config)# interface loopback1  
Switch(config-if)# ip vrf forwarding v11  
Switch(config-if)# ip address 8.8.1.8 255.255.255.0  
Switch(config-if)# exit  
  
Switch(config)# interface loopback2  
Switch(config-if)# ip vrf forwarding v12  
Switch(config-if)# ip address 8.8.2.8 255.255.255.0  
Switch(config-if)# exit  
  
Switch(config)# interface FastEthernet3/5  
Switch(config-if)# switchport trunk encapsulation dot1q  
Switch(config-if)# switchport mode trunk  
Switch(config-if)# no ip address  
Switch(config-if)# exit  
  
Switch(config)# interface FastEthernet3/8  
Switch(config-if)# switchport access vlan 208  
Switch(config-if)# no ip address  
Switch(config-if)# exit  
  
Switch(config)# interface FastEthernet3/11  
Switch(config-if)# switchport trunk encapsulation dot1q  
Switch(config-if)# switchport mode trunk  
Switch(config-if)# no ip address  
Switch(config-if)# exit
```

Configure the VLANs used on switch S8. VLAN 10 is used by VRF 11 between the CE and the PE. VLAN 20 is used by VRF 12 between the CE and the PE. VLANs 118 and 208 are used for VRF for the VPNs that include switch S11 and switch S20, respectively:

```
Switch(config)# interface Vlan10  
Switch(config-if)# ip vrf forwarding v11  
Switch(config-if)# ip address 38.0.0.8 255.255.255.0  
Switch(config-if)# exit
```

```

Switch(config)# interface Vlan20
Switch(config-if)# ip vrf forwarding v12
Switch(config-if)# ip address 83.0.0.8 255.255.255.0
Switch(config-if)# exit

Switch(config)# interface Vlan118
Switch(config-if)# ip vrf forwarding v12
Switch(config-if)# ip address 118.0.0.8 255.255.255.0
Switch(config-if)# exit

Switch(config)# interface Vlan208
Switch(config-if)# ip vrf forwarding v11
Switch(config-if)# ip address 208.0.0.8 255.255.255.0
Switch(config-if)# exit

```

Configure OSPF routing in VPN1 and VPN2:

```

Switch(config)# router ospf 1 vrf v11
Switch(config-router)# redistribute bgp 800 subnets
Switch(config-router)# network 208.0.0.0 0.0.0.255 area 0
Switch(config-router)# exit
Switch(config)# router ospf 2 vrf v12
Switch(config-router)# redistribute bgp 800 subnets
Switch(config-router)# network 118.0.0.0 0.0.0.255 area 0
Switch(config-router)# exit

```

Configure BGP for CE to PE routing:

```

Switch(config)# router bgp 800
Switch(config-router)# address-family ipv4 vrf v12
Switch(config-router-af)# redistribute ospf 2 match internal
Switch(config-router-af)# neighbor 83.0.0.3 remote-as 100
Switch(config-router-af)# neighbor 83.0.0.3 activate
Switch(config-router-af)# network 8.8.2.0 mask 255.255.255.0
Switch(config-router-af)# exit

Switch(config-router)# address-family ipv4 vrf v11
Switch(config-router-af)# redistribute ospf 1 match internal
Switch(config-router-af)# neighbor 38.0.0.3 remote-as 100
Switch(config-router-af)# neighbor 38.0.0.3 activate
Switch(config-router-af)# network 8.8.1.0 mask 255.255.255.0
Switch(config-router-af)# end

```

Configuring Switch S20

Configure S20 to connect to CE:

```

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip routing
Switch(config)# interface Fast Ethernet 0/7
Switch(config-if)# no switchport
Switch(config-if)# ip address 208.0.0.20 255.255.255.0
Switch(config-if)# exit

Switch(config)# router ospf 101
Switch(config-router)# network 208.0.0.0 0.0.0.255 area 0
Switch(config-router)# end

```

Configuring Switch S11

Configure S11 to connect to CE:

```
Switch# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch(config)# ip routing
Switch(config)# interface Gigabit Ethernet 0/3
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# no ip address
Switch(config-if)# exit

Switch(config)# interface Vlan118
Switch(config-if)# ip address 118.0.0.11 255.255.255.0
Switch(config-if)# exit

Switch(config)# router ospf 101
Switch(config-router)# network 118.0.0.0 0.0.0.255 area 0
Switch(config-router)# end
```

Configuring the PE Switch S3

On switch S3 (the router), these commands configure only the connections to switch S8:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# ip vrf v1
Router(config-vrf)# rd 100:1
Router(config-vrf)# route-target export 100:1
Router(config-vrf)# route-target import 100:1
Router(config-vrf)# exit

Router(config)# ip vrf v2
Router(config-vrf)# rd 100:2
Router(config-vrf)# route-target export 100:2
Router(config-vrf)# route-target import 100:2
Router(config-vrf)# exit

Router(config)# ip cef
Router(config)# interface Loopback1
Router(config-if)# ip vrf forwarding v1
Router(config-if)# ip address 3.3.1.3 255.255.255.0
Router(config-if)# exit

Router(config)# interface Loopback2
Router(config-if)# ip vrf forwarding v2
Router(config-if)# ip address 3.3.2.3 255.255.255.0
Router(config-if)# exit

Router(config)# interface Fast Ethernet3/0.10
Router(config-if)# encapsulation dot1q 10
Router(config-if)# ip vrf forwarding v1
Router(config-if)# ip address 38.0.0.3 255.255.255.0
Router(config-if)# exit

Router(config)# interface Fast Ethernet3/0.20
Router(config-if)# encapsulation dot1q 20
Router(config-if)# ip vrf forwarding v2
Router(config-if)# ip address 83.0.0.3 255.255.255.0
Router(config-if)# exit

Router(config)# router bgp 100
Router(config-router)# address-family ipv4 vrf v2
Router(config-router-af)# neighbor 83.0.0.8 remote-as 800
Router(config-router-af)# neighbor 83.0.0.8 activate
Router(config-router-af)# network 3.3.2.0 mask 255.255.255.0
```

```

Router(config-router-af)# exit
Router(config-router)# address-family ipv4 vrf vl
Router(config-router-af)# neighbor 83.0.0.8 remote-as 800
Router(config-router-af)# neighbor 83.0.0.8 activate
Router(config-router-af)# network 3.3.1.0 mask 255.255.255.0
Router(config-router-af)# end

```

Displaying VRF-lite Status

To display information about VRF-lite configuration and status, perform one of the following tasks:

Command	Purpose
Switch# show ip protocols vrf <i>vrf-name</i>	Displays routing protocol information associated with a VRF.
Switch# show ip route vrf <i>vrf-name</i> [connected] [<i>protocol</i> [<i>as-number</i>]] [list] [mobile] [odr] [profile] [static] [summary] [supernets-only]	Displays IP routing table information associated with a VRF.
Switch# show ip vrf [brief detail interfaces] [<i>vrf-name</i>]	Displays information about the defined VRF instances.
Switch# show ip mroute vrf <i>instance-name</i> <i>a.b.c.d</i> active bidirectional count dense interface proxy pruned sparse ssm static summary	Displays information about the defined VRF instances.

This example shows how to display multicast route table information within a VRF instance:

```

Switch# show ip mroute vrf mcast2 234.34.10.18
IP Multicast Routing Table
Flags: D - Dense, S - Sparse, B - Bidir Group, s - SSM Group, C - Connected,
       L - Local, P - Pruned, R - RP-bit set, F - Register flag,
       T - SPT-bit set, J - Join SPT, M - MSDP created entry,
       X - Proxy Join Timer Running, A - Candidate for MSDP Advertisement,
       U - URD, I - Received Source Specific Host Report,
       Z - Multicast Tunnel, z - MDT-data group sender,
       Y - Joined MDT-data group, y - Sending to MDT-data group
       V - RD & Vector, v - Vector
Outgoing interface flags: H - Hardware switched, A - Assert winner
Timers: Uptime/Expires
Interface state: Interface, Next-Hop or VCD, State/Mode

(*, 234.34.10.18), 13:39:21/00:02:58, RP 10.1.1.1, flags: BC
Bidir-Upstream: Vlan134, RPF nbr 172.16.34.1
Outgoing interface list:
  Vlan45, Forward/Sparse-Dense, 00:00:02/00:02:57, H
  Vlan134, Bidir-Upstream/Sparse-Dense, 13:35:54/00:00:00, H

```

Note

For more information about the information in the displays, refer to the *Cisco IOS Switching Services Command Reference* at:

http://www.cisco.com/en/US/docs/ios/ipswitch/command/reference/isw_book.html

Configuring VRF-lite for IPv6

Configuring VRF-Aware Services

IP services can be configured on global interfaces and within the global routing instance. IP services are enhanced to run on multiple routing instances; they are VRF-aware. Any configured VRF in the system can be specified for a VRF-aware service.

VRF-aware services are implemented in platform-independent modules. VRF provides multiple routing instances in Cisco IOS. Each platform has its own limit on the number of VRFs it supports.

VRF-aware services have the following characteristics:

- The user can ping a host in a user-specified VRF.
- ARP entries are learned in separate VRFs. The user can display Address Resolution Protocol (ARP) entries for specific VRFs.

These services are VRF-aware:

- Ping
- Unicast Reverse Path Forwarding (uRPF)
- Traceroute
- FTP and TFTP
- Telnet and SSH
- NTP

Configuring the User Interface for ARP

To configure VRF-aware services for ARP, perform this task:

Command	Purpose
Switch# show ip arp vrf <i>vrf-name</i>	Displays the ARP table (static and dynamic entries) in the specified VRF.
Switch(config)# arp vrf <i>vrf-name</i> <i>ip-address mac-address ARPA</i>	Creates a static ARP entry in the specified VRF.

Configuring the User Interface for PING

To perform a VRF-aware ping, perform this task:

Command	Purpose
Switch# ping vrf <i>vrf-name ip-host</i>	Pings an IP host or address in the specified VRF.

Configuring the User Interface for uRPF

You can configure uRPF on an interface assigned to a VRF. Source lookup is performed in the VRF table.

To configure VRF-aware services for uRPF, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode and specifies the Layer 3 interface to configure.
Step 3	Switch(config-if)# no switchport	Removes the interface from Layer 2 configuration mode if it is a physical interface.
Step 4	Switch(config-if)# ip vrf forwarding <i>vrf-name</i>	Configures VRF on the interface.
Step 5	Switch(config-if-vrf)# ip address <i>ip-address subnet-mask</i>	Enters the IP address for the interface.
Step 6	Switch(config-if-vrf)# ip verify unicast source reachable-via rx allow-default	Enables uRPF on the interface.
Step 7	Switch(config-if-vrf)# end	Returns to privileged EXEC mode.

Configuring the User Interface for Traceroute

To configure VRF-aware services for traceroute, perform this task:

Command	Purpose
traceroute vrf <i>vrf-name ipaddress</i>	Specifies the name of a VPN VRF in which to find the destination address.

Configuring the User Interface for FTP and TFTP

You must configure some FTP and TFTP CLIs in order for FTP and TFTP to be VRF-aware. For example, if you want to use a VRF table that is attached to an interface (for example, E1/0), you need to configure the **ip [t]ftp source-interface E1/0** command to inform [t]ftp to use a specific routing table. In this example, the VRF table is used to look up the destination IP address. These changes are backward-compatible and do not affect existing behavior. You can use the source-interface CLI to send packets out a particular interface even if no VRF is configured on that interface.

To specify the source IP address for FTP connections, use the **ip ftp source-interface** show mode command. To use the address of the interface where the connection is made, use the **no** form of this command.

To configure the user interface for FTP and TFTP, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.

	Command	Purpose
Step 2	Switch(config)# ip ftp source-interface <i>interface-type interface-number</i>	Specifies the source IP address for FTP connections.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.

To specify the IP address of an interface as the source address for TFTP connections, use the **ip tftp source-interface** show mode command. To return to the default, use the **no** form of this command.

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ip tftp source-interface <i>interface-type interface-number</i>	Specifies the source IP address for TFTP connections.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.

Configuring the User Interface for Telnet and SSH

To configure VRF-aware for using Telnet and SSH, perform this task:

Command	Purpose
Switch# telnet <i>ip-address/vrf vrf-name</i>	Connects through Telnet to an IP host or address in the specified VRF.
Switch# ssh -l username -vrf vrf-name ip-host	Connects through SSH to an IP host or address in the specified VRF.

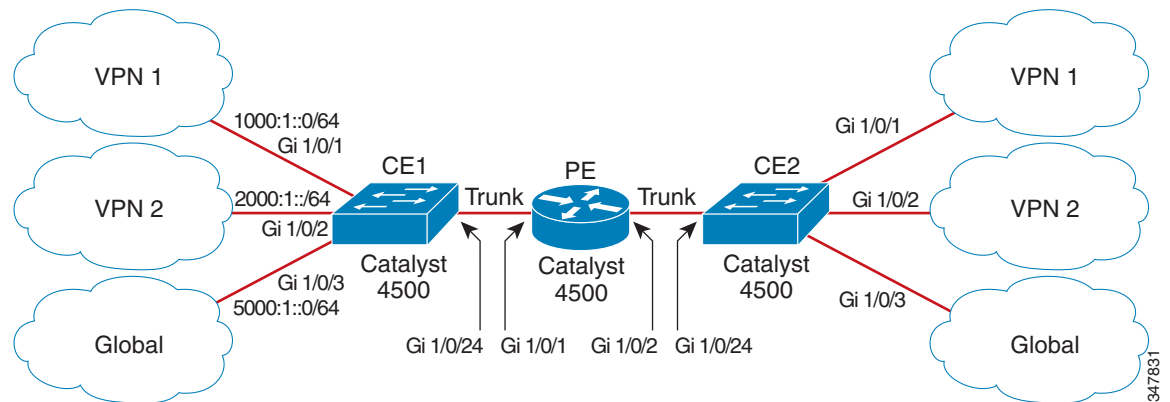

Configuring the User Interface for NTP

To configure VRF-aware for NTP, perform this task:

Command	Purpose
Switch# ntp server vrf vrf-name ip-host	Configure the NTP server in the specified VRF.
Switch# ntp peer vrf vrf-name ip-host	Configure the NTP peer in the specified VRF.

VRF-lite Configuration Example

The following topology illustrates how to use OSPFv3 for CE-PE routing.

Figure 43-3 VRF-lite Configuration Example

Configuring CE1 Switch

```

ipv6 unicast-routing

Displaying VRF-lite Status

To display information about VRF-lite configuration and status, perform one of the following tasks:

**Note**

For more information about the information in the displays, refer to the *Cisco IOS Switching Services Command Reference* at:

http://www.cisco.com/en/US/docs/ios/ipswitch/command/reference/isw_book.html

To display information about VRF-lite configuration and status, perform one of the following tasks:

Command	Purpose
Switch# show ipv6 route vrf a [X:X:X:X::X/<0-128>] [bgp] [connected] [eigrp] [interface] [isis] [local] [nd] [nsf] [ospf] [repair] [rip] [shortcut] [static] [summary] [tag] [updated] [watch]	Displays routing protocol information associated with a VRF. X:X:X:X::X/<0-128> IPv6 prefix bgp BGP routes connected Connected routes eigrp EIGRP routes interface interface specific routes isis IS-IS routes local Local routes nd ND routes nsf non stop forwarding state ospf OSPFv3 routes repair Routes with Repair paths rip RIPng routes shortcut Routes with Shortcut paths static Static routes summary Summary display tag Route Tag updated Show routes with timestamps watch route watchers
Switch# show ipv6 vrf [brief detail interfaces] [vrf-name]	Displays information about the defined VRF instances. brief Brief VPN Routing/Forwarding instance information detail Detailed VPN Routing/Forwarding instance information interfaces Show VPN Routing/Forwarding interface information

When you configure VRF table “a” with the IPv6 address family and attach the VRF to the interface with IPv6 address 1::2/64, the **show ipv6 route vrf a** command displays the following output:

```
Switch# show ipv6 route vrf a
IPv6 Routing Table - a - 3 entries
Codes: C - Connected, L - Local, S - Static, U - Per-user Static route
        B - BGP, R - RIP, I1 - ISIS L1, I2 - ISIS L2
        IA - ISIS interarea, IS - ISIS summary, D - EIGRP, EX - EIGRP external
        ND - ND Default, NDp - ND Prefix, DCE - Destination, NDr - Redirect
        O - OSPF Intra, OI - OSPF Inter, OE1 - OSPF ext 1, OE2 - OSPF ext 2
        ON1 - OSPF NSSA ext 1, ON2 - OSPF NSSA ext 2
C    1::/64 [0/0]
    via GigabitEthernet7/1, directly connected
L    1::2/128 [0/0]
    via GigabitEthernet7/1, receive
L    FF00::/8 [0/0]
    via Null0, receive
Switch#
```

For further examples, refer to

http://www.cisco.com/en/US/docs/ios/ipv6/command/reference/ipv6_16.html

Configuring IPv6 VRF-lite

Beginning with Release IOS XE 3.5.0E and IOS 15.2(1)E, to support IPv6 VRF-lite, we transition from the **ip vrf** command to the “new” **vrf definition** command.

Configure VRFs

To configure one or more VRFs, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ipv6 routing	Enables IPv6 routing.
Step 3	Switch(config)# vrf definition <i>vrf-name</i>	Names the VRF and enters VRF configuration mode.
Step 4	Switch(config-vrf)# address-family <i>ipv4 ipv6</i>	(Optional) IPv4 by default. Configuration MUST for ipv6.
Step 5	Switch(config-vrf)# rd <i>route-distinguisher</i>	(Optional) Creates a VRF table by specifying a route distinguisher. Enter either an Autonomous System number and an arbitrary number (xxx:y) or an IP address and arbitrary number (A.B.C.D:y).
Step 6	Switch(config-vrf)# route-target { export import both } <i>route-target-ext-community</i>	(Optional) Creates a list of import, export, or import and export route target communities for the specified VRF. Enter either an AS system number and an arbitrary number (xxx:y) or an IP address and an arbitrary number (A.B.C.D:y). Note This command is effective only if BGP is running.
Step 7	Switch(config-vrf)# import map <i>route-map</i>	(Optional) Associates a route map with the VRF.
Step 8	Switch(config-vrf)# interface <i>interface-id</i>	Enters interface configuration mode and specify the Layer 3 interface to be associated with the VRF. The interface can be a routed port or SVI.
Step 9	Switch(config-if)# ip vrf forwarding <i>vrf-name</i>	Associates the VRF with the Layer 3 interface.
Step 10	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 11	Switch# show ip vrf [brief detail interfaces] [<i>vrf-name</i>]	Verifies the configuration. Displays information about the configured VRFs.
Step 12	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to configure VRFs:

```
Switch(config)# vrf definition red
Switch(config-vrf)# rd 100:1
Switch(config-vrf)# address family ipv6
Switch(config-vrf-af)# route-target both 200:1
Switch(config-vrf)# exit-address-family
Switch(config-vrf)# interface Ethernet0/1
Switch(config-if)# vrf forwarding red
Switch(config-if)# ipv6 address 5000::72B/64
```

Associate Interfaces to the Defined VRFs

To associate interface to the defined VRFs, perform this task:

	Command	Purpose
Step 1	Switch(config)# vrf configuration	Enters vrf configuration mode.
Step 1	Switch(config-vrf)# interface <i>interface-id</i>	Enters interface configuration mode and specifies the Layer 3 interface to be associated with the VRF. The interface can be a routed port or SVI.
Step 2	Switch(config-if)# vrf forwarding <i>vrf-name</i>	Associates the VRF with the Layer 3 interface.
Step 3	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 4	Switch# show ipv6 vrf [brief detail interfaces] [<i>vrf-name</i>]	Verifies the configuration. Displays information about the configured VRFs.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to associate an interface to VRFs:

```
Switch(config-vrf)# interface ethernet0/1
Switch(config-if)# vrf forwarding red
Switch(config-if)# ipv6 address 5000::72B/64
```

Populate VRF with Routes via Routing Protocols

Static Route

	Command	Purpose
Step 1	ipv6 route [vrf <i>vrf-name</i>] <i>ipv6-prefix/prefix-length</i> { <i>ipv6-address</i> interface-type <i>interface-number</i> [<i>ipv6-address</i>]}	To configure static routes specific to VRF.

This example shows how to populate VRF with a static route:

```
Switch(config)# ipv6 route vrf v6a 7000::/64 TenGigabitEthernet3/2 4000::2
```

Routing Protocols

OSPFv3

To configure the OSPFv3 router process and the IPv6 address family in OSPFv3, perform the following steps:

	Command	Purpose
Step 1	Switch> enable	Enters privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# router ospfv3 <i>process-id</i>	Enables OSPFv3 router configuration mode for the IPv4 or IPv6 address family.
Step 4	Switch(config-router)# area <i>area-ID</i> [default-cot nssa stub]	Configures the OSPFv3 area.
Step 5	Switch(config-router)# router-id <i>router-id</i>	Use a fixed router ID.
Step 6	Switch(config-router)# address-family ipv6 unicast vrf <i>vrf-name</i> <i>Or</i> Switch(config-router)# address-family ipv4 unicast	Enters IPv6 address family configuration mode for OSPFv3 in VRF <i>vrf-name</i> or Enters IPv4 address family configuration mode for OSPFv3.
Step 7	Switch(config-router)# redistribute source-protocol [<i>process-id</i>] options	Redistributes IPv6 and IPv4 routes from one routing domain into another routing domain.
Step 8	Switch(config-router)# end	Returns to privileged EXEC mode.

This example shows how configure the OSPFv3 router process:

```
Switch(config-router)# router ospfv3 1
Switch(config-router)# router-id 10.1.1.1
Switch(config-router)# address-family ipv6 unicast
Switch(config-router-af)# exit-address-family
```

To enable OSPFv3 on an interface, do the following:

	Command	Purpose
Step 1	Switch> enable	Enters privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# interface <i>type-number</i>	Specifies an interface type and number, and places the switch in interface configuration mode.

	Command	Purpose
Step 4	Switch(config-if)# ospfv3 <i>process-id</i> area <i>area-ID</i> { ipv4 ipv6 } [instance <i>instance-id</i>]	Enables OSPFv3 on an interface with the IPv4 or IPv6 AF.
	Or Switch(config-if)# ipv6 ospf process-id <i>area</i> <i>area-ID</i> [instance <i>instance-id</i>]	or Enables OSPFv3 on an interface.
Step 5	Switch(config-if)# end	Returns to privileged EXEC mode.

This example show how to enable OSPFv3 on an interface:

```
Switch(config)# interface GigabitEthernet2/1
Switch(config-if)# no switchport
Switch(config-if)# ipv6 address 4000::2/64
Switch(config-if)# ipv6 enable
Switch(config-if)# ipv6 ospf 1 area 0
Switch(config-if)# end
```

EIGRP

To configure an EIGRPv6 routing process, perform the following steps:

	Command	Purpose
Step 1	Switch> enable	Enters privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# router eigrp <i>virtual-instance-name</i>	Configures the EIGRP routing process and enters router configuration mode.
Step 4	Switch(config-router)# address-family ipv6 vrf <i>vrf-name</i> autonomous-system <i>autonomous-system-number</i>	Enables EIGRP IPv6 VRF-Lite and enters address family configuration mode.
Step 5	Switch(config-router-af)# topology { base topology-name <i>tid</i> <i>number</i> }	Configures an EIGRP process to route IP traffic under the specified topology instance and enters address family topology configuration mode.
Step 6	Switch(config-router-af-topology)# exit-af-topology	Exits address family topology configuration mode.
Step 7	Switch(config-router)# eigrp router-id <i>ip-address</i>	Enables the use of a fixed router-id.
Step 8	Switch(config-router)# end	Exits router configuration mode.

This example shows how to configure an EIGRP routing process:

```
Switch(config)# router eigrp test
Switch(config-router)# address-family ipv6 unicast vrf b1 autonomous-system 10
Switch(config-router-af)# topology base
Switch(config-router-af-topology)# exit-af-topology
Switch(config-router)# eigrp router-id 2.3.4.5
Switch(config-router)# exit-address-family
```

EBGPv6

To configure EBGPv6, do the following:

	Command	Purpose
Step 1	Switch> enable	Enters privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# router bgp <i>as-number</i>	Enters router configuration mode for the specified routing process.
Step 4	Switch(config-router)# neighbor <i>peer-group-name peer-group</i>	Creates a multiprotocol BGP peer group.
Step 5	Switch(config-router)# neighbor <i>{ip-address ipv6-address[%] peer-group-name}</i> remote-as <i>autonomous-system-number</i> [alternate-as <i>autonomous-system-number ...</i>]	Adds the IPv6 address of the neighbor in the specified autonomous system to the IPv6 multiprotocol BGP neighbor table of the local router.
Step 6	Switch(config-router)# address-family ipv6 [vrf <i>vrf-name</i>] [unicast multicast vpnv6]	Specifies the IPv6 address family, and enters address family configuration mode. <ul style="list-style-type: none"> The unicast keyword specifies the IPv6 unicast address family. By default, the switch is placed in configuration mode for the IPv6 unicast address family if the unicast keyword is not specified with the address-family ipv6 command. The multicast keyword specifies IPv6 multicast address prefixes.
Step 7	Switch(config-router-af)# neighbor <i>ipv6-address peer-group</i> <i>peer-group-name</i>	Assigns the IPv6 address of a BGP neighbor to a peer group.
Step 8	Switch(config-router-af)# neighbor <i>{ip-address peer-group-name ipv6-address[%]}</i> route-map <i>map-name</i> [in out]	Applies a route map to incoming or outgoing routes. <ul style="list-style-type: none"> Changes to the route map will not take effect for existing peers until the peering is reset or a soft reset is performed. Using the clear bgp ipv6 command with the soft and in keywords will perform a soft reset.
Step 9	Switch(config-router-af)# exit	Exits address family configuration mode, and returns the router to router configuration mode.

This example shows how to configure EBRPv6:

```
Switch(config)# router bgp 2
Switch(config-router)# bgp router-id 2.2.2.2
Switch(config-router)# bgp log-neighbor-changes
Switch(config-router)# no bgp default ipv4-unicast
Switch(config-router)# neighbor 2500::1 remote-as 1
Switch(config-router)# neighbor 4000::2 remote-as 3
Switch(config-router)# address-family ipv6 vrf b1
Switch(config-router-af)# network 2500::/64
Switch(config-router-af)# network 4000::/64
Switch(config-router-af)# neighbor 2500::1 remote-as 1
Switch(config-router-af)# neighbor 2500::1 activate
Switch(config-router-af)# neighbor 4000::2 remote-as 3
```

```
Switch(config-router-af)# neighbor 4000::2 activate
Switch(config-router-af)# exit-address-family
```

VPN Co-existence Between IPv4 and IPv6

With Release IOS XE 3.5.0E and IOS 15.2(1)E, we provide backward compatibility between the “older” CLI for configuring IPv4 and the “new” CLI for IPv6. This means that a configuration might contain both CLI. The IPv4 CLI retains the ability to have on the same interface, an IP address defined within a VRF as well as an IPv6 address defined in the global routing table.

For example:

```
vrf definition red
rd 100:1
address family ipv6
route-target both 200:1
exit-address-family
!
ip vrf blue
rd 200:1
route-target both 200:1
!
interface Ethernet0/0
vrf forwarding red
ip address 50.1.1.2 255.255.255.0
ipv6 address 4000::72B/64
!
interface Ethernet0/1
ip vrf forwarding blue
ip address 60.1.1.2 255.255.255.0
ipv6 address 5000::72B/64
```

In this example, all addresses (v4 and v6) defined for Ethernet0/0 refer to VRF red whereas for Ethernet0/1, the IP address refers to VRF blue but the ipv6 address refers to the global IPv6 routing table.

Migrating from the Old to New CLI Scheme

Prior to Release IOS XE 3.5.0E and IOS 15.2(1)E, you used the **ip vrf** command to configure vrf. With Release IOS XE 3.5.0E and IOS 15.2(1)E, you use the new **vrf definition** command.

Henceforward, to incorporate IPv6 VRF configurations in addition to IPv4 configurations, you must *migrate* from the prior VRF CLI scheme using the following command:

```
Switch(config)# vrf upgrade-cli multi-af-mode {common-policies | non-common-policies} [vrf name]
```

This command forces migration from *old* CLI for IPv4 VRF to the *new* VRF multi-AF CLI. It is not nvgen'd because the effect is “one-time” only (see BGP similar command " bgp upgrade-cli ").

Configuring Quality of Service

This chapter describes how to configure quality of service (QoS) with either automatic QoS (auto-QoS) commands or standard QoS commands on a Catalyst 4500 series switch. It describes how to specify QoS configuration on different types of interfaces (access, Layer 2 trunk, Layer 3 routed, Etherchannel) as well as VLANs. It also describes how to specify different QoS configurations on different VLANs on a given interface (per-port per-VLAN QoS).

A switch supports a QoS configuration model known as *MQC* (Modular QoS CLI). Please refer to the appropriate configuration section for the supervisor engine on which QoS will be configured. For more information about MQC, see the “Modular Quality of Service Command-Line Interface” section of the *Cisco IOS Quality of Service Solutions Configuration Guide, Release 12.3*.

This chapter addresses both VSS and non-VSS environments. Sections include:

- [Overview of QoS, page 44-1](#)
- [Configuring VSS QoS, page 44-14](#)
- [Configuring QoS on a Standalone Supervisor Engine 6-E, 6L-E or Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E, page 44-48](#)
- [Configuring VSS Auto-QoS, page 44-82](#)
- [Configuring Auto-QoS on a Standalone Supervisor Engine 6-E/6L-E or Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E, page 44-89](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Overview of QoS

Typically, networks operate on a *best-effort* delivery basis, which means that all traffic has equal priority and an equal chance of being delivered in a timely manner. When congestion occurs, all traffic has an equal chance of being dropped.

QoS selects network traffic (both unicast and multicast), prioritizes it according to its relative importance, and uses congestion avoidance to provide priority-indexed treatment; QoS can also limit the bandwidth used by network traffic. QoS can make network performance more predictable and bandwidth utilization more effective.

This section contains the following subsections:

- [Prioritization, page 44-2](#)
- [QoS Terminology, page 44-3](#)
- [Basic QoS Model, page 44-5](#)
- [Classification, page 44-6](#)

- [Configuring System Queue Limit, page 44-12](#)
- [Configuring QoS with a 40-Gigabit Ethernet Interface, page 44-13](#)

Prioritization

QoS implementation is based on the DiffServ architecture. This architecture specifies that each packet is classified upon entry into the network. The classification is carried in the IP packet header, using 6 bits from the deprecated IP type of service (TOS) field to carry the classification (*class*) information. Classification can also be carried in the Layer 2 frame. These special bits in the Layer 2 frame or a Layer 3 packet are described here and shown in [Figure 44-1](#):

- Prioritization values in Layer 2 frames:

Layer 2 Inter-Switch Link (ISL) frame headers have a 1-byte User field that carries an IEEE 802.1p class of service (CoS) value in the three least-significant bits. On interfaces configured as Layer 2 ISL trunks, all traffic is in ISL frames.

Layer 2 802.1Q frame headers have a 2-byte Tag Control Information field that carries the CoS value in the three most-significant bits, which are called the User Priority bits. On interfaces configured as Layer 2 802.1Q trunks, all traffic is in 802.1Q frames except for traffic in the native VLAN.

Other frame types cannot carry Layer 2 CoS values.

Layer 2 CoS values range from 0 for low priority to 7 for high priority.

- Prioritization bits in Layer 3 packets:

Layer 3 IP packets can carry either an IP precedence value or a Differentiated Services Code Point (DSCP) value. QoS supports the use of either value because DSCP values are backward-compatible with IP precedence values.

IP precedence values range from 0 to 7.

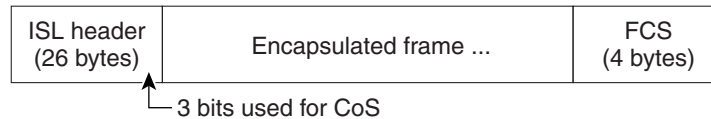

DSCP values range from 0 to 63.

Figure 44-1 QoS Classification Layers in Frames and Packets

Encapsulated Packet

Layer 2 ISL Frame

Layer 2 802.1Q/P Frame

Layer 3 IPv4 Packet

All switches and routers across the Internet rely on the class information to provide the same forwarding treatment to packets with the same class information and different treatment to packets with different class information. The class information in the packet can be assigned by end hosts or by switches or routers along the way, based on a configured policy, detailed examination of the packet, or both. Detailed examination of the packet is expected to happen closer to the edge of the network so that the core switches and routers are not overloaded.

Switches and routers along the path can use the class information to limit the amount of resources allocated per traffic class. The behavior of an individual device when handling traffic in the DiffServ architecture is called per-hop behavior. If all devices along a path provide a consistent per-hop behavior, you can construct an end-to-end QoS solution.

Implementing QoS in your network can be a simple or complex task and depends on the QoS features offered by your internetworking devices, the traffic types and patterns in your network, and the granularity of control you need over incoming and outgoing traffic.

QoS Terminology

The following terms are used when discussing QoS features:

- *Packets* carry traffic at Layer 3.
- *Frames* carry traffic at Layer 2. Layer 2 frames carry Layer 3 packets.
- *Labels* are prioritization values carried in Layer 3 packets and Layer 2 frames:
 - Layer 2 class of service (CoS) values, which range between zero for low priority and seven for high priority:

Layer 2 Inter-Switch Link (ISL) frame headers have a 1-byte User field that carries an IEEE 802.1p CoS value in the three least significant bits.

Layer 2 802.1Q frame headers have a 2-byte Tag Control Information field that carries the CoS value in the three most significant bits, which are called the User Priority bits.

Other frame types cannot carry Layer 2 CoS values.

**Note**

On interfaces configured as Layer 2 ISL trunks, all traffic is in ISL frames. On interfaces configured as Layer 2 802.1Q trunks, all traffic is in 802.1Q frames except for traffic in the native VLAN.

- Layer 3 IP precedence values—The IP version 4 specification defines the three most significant bits of the 1-byte ToS field as IP precedence. IP precedence values range between zero for low priority and seven for high priority.
- Layer 3 differentiated services code point (DSCP) values—The Internet Engineering Task Force (IETF) has defined the six most significant bits of the 1-byte IP ToS field as the DSCP. The per-hop behavior represented by a particular DSCP value is configurable. DSCP values range between 0 and 63.

**Note**

Layer 3 IP packets can carry either an IP precedence value or a DSCP value. QoS supports the use of either value, since DSCP values are backwards compatible with IP precedence values. See [Table 44-1](#).

Table 44-1 IP Precedence and DSCP Values

3-bit IP Precedence	6 MSb ¹ of ToS						6-bit DSCP		3-bit IP Precedence	6 MSb ¹ of ToS						6-bit DSCP
	8	7	6	5	4	3				8	7	6	5	4	3

1. MSb = most significant bit

- *Classification* is the selection of traffic to be marked.
- *Marking*, according to RFC 2475, is the process of setting a Layer 3 DSCP value in a packet; in this publication, the definition of marking is extended to include setting Layer 2 CoS values.
- *Policing* is limiting bandwidth used by a flow of traffic. Policing can mark or drop traffic.

Basic QoS Model

Figure 44-2 illustrates a high-level flow of QoS function.

Figure 44-2 QoS Packet Processing

203973

The QoS model proceeds as follows:

-
- | | |
|---------------|--|
| Step 1 | The incoming packet is classified (based on different packet fields, receive port and/or VLAN) to belong to a traffic class. |
| Step 2 | Depending on the traffic class, the packet is rate-limited/policed and its priority is optionally <i>marked</i> (typically at the edge of the network) so that lower priority packets are dropped or marked with lower priority in the packet fields (DSCP and CoS). |
| Step 3 | After the packet has been marked, it is <i>looked up</i> for forwarding. This action obtains the transmit port and VLAN to transmit the packet. |
| Step 4 | The packet is classified in the output direction based on the transmit port and/or VLAN. The classification takes into account any marking of the packet by input QoS. |
| Step 5 | Depending on the output classification, the packet is policed, its priority is optionally <i>(re-)marked</i> , and the transmit queue for the packet is determined depending on the traffic class. |
| Step 6 | The transmit queue state is dynamically monitored via the AQM (Active Queue Management) algorithm and drop threshold configuration to determine whether the packet should be dropped or enqueued for transmission. |
| Step 7 | If eligible for transmission, the packet is enqueued to a transmit queue. The transmit queue is selected based on output QoS classification criteria. The selected queue provides the desired behavior in terms of latency and bandwidth. |
-

Classification

Classification is the process of distinguishing one kind of traffic from another by examining the fields in the packet. Classification is enabled when a QoS policy-map is attached to an interface.

You specify which fields in the frame or packet that you want to use to classify incoming traffic.

For non-IP traffic, you have the following classification options:

- CoS value in the VLAN tag of the incoming frame is used to classify the packet.
- If the frame does not contain a CoS value, the port's default CoS value ("0") is used for the classification.

Perform the classification based on a configured MAC ACL, which examines the fields in the Layer 2 header.

For IP traffic, you have the following classification options:

- IP DSCP or IP Precedence in the incoming packet is used for classification. DSCP values range from 0 to 63.
- Perform the classification based on a configured IP standard or extended ACL, which examines various fields in the IP header.

Classification Based on QoS ACLs

A packet can be classified for QoS using multiple match criteria, and the classification can specify whether the packet should match all of the specified match criteria or at least one of the match criteria. To define a QoS classifier, you can provide the match criteria using the *match* statements in a class map.

In the 'match' statements, you can specify the fields in the packet to match on, or you can use IP standard or IP extended ACLs or MAC ACLs. For more information, see the [“Classification Based on Class Maps and Policy Maps” section on page 44-7](#).

If the class map is configured to match all the match criteria, then a packet must satisfy all the match statements in the class map before the QoS action is taken. The QoS action for the packet is not taken if the packet does not match even one match criterion in the class map.

If the class map is configured to match at least one match criterion, then a packet must satisfy at least one of the match statements in the class map before the QoS action is taken. The QoS action for the packet is not taken if the packet does not match any match criteria in the class map.

**Note**

When you use the IP standard and IP extended ACLs, the permit and deny ACEs in the ACL have a slightly different meaning in the QoS context.

- If a packet encounters (and satisfies) an ACE with a “permit,” then the packet “matches” the match criterion in the QoS classification.
- If a packet encounters (and satisfies) an ACE with a “deny,” then the packet “does not match” the match criterion in the QoS classification.
- If no match with a permit action is encountered and all the ACEs have been examined, then the packet “does not match” the criterion in the QoS classification.

**Note**

When creating an access list, remember that, by default, the end of the access list contains an implicit deny statement for everything if it did not find a match before reaching the end.

After a traffic class has been defined with the class map, you can create a policy that defines the QoS actions for a traffic class. A policy might contain multiple classes with actions specified for each one of them. A policy might include commands to classify the class as a particular aggregate (for example, assign a DSCP) or rate limit the class. This policy is then attached to a particular port on which it becomes effective.

You implement IP ACLs to classify IP traffic by using the **access-list** global configuration command.

When a class-map is created with the **match-all** keyword, you cannot include both IP and MAC ACLs as match criteria.

Classification Based on Class Maps and Policy Maps

A class map is a mechanism that you use to isolate and name a specific traffic flow (or class) from all other traffic. The class map defines the criterion used to match against a specific traffic flow to further classify it; the criteria can include matching the access group defined by the ACL or matching a specific list of DSCP, IP precedence, or L2 CoS values. If you have more than one type of traffic that you want to classify, you can create another class map and use a different name. After a packet is matched against the class-map criteria, you can specify the QoS actions via a policy map.

A policy map specifies the QoS actions for the traffic classes. Actions can include setting a specific CoS, DSCP, or IP precedence value; policing the traffic to a specified rate; specifying the traffic bandwidth limitations; shaping the traffic to a specified rate. Before a policy map can be effective, you must attach it to an interface.

You create a class map by using the **class-map** global configuration command. When you enter the **class-map** command, the switch enters the class-map configuration mode. In this mode, you define the match criteria for the traffic by using the **match** class-map configuration command.

You create and name a policy map by using the **policy-map** global configuration command. When you enter this command, the switch enters the policy-map configuration mode. In this mode, you specify the actions to take on a specific traffic class by using the **set**, **police**, **bandwidth**, or **shape** policy-map configuration and policy-map class configuration commands. To make the policy map effective, you attach it to an interface by using the **service-policy** interface configuration command.

The policy map can also contain commands that define the policer, (the bandwidth limitations of the traffic) and the action to take if the limits are exceeded. For more information, see the [“Policing and Marking” section on page 44-8](#).

A policy map also has these characteristics:

- A policy map can contain up to 254 class statements.
- You can have different classes within a policy map.

Policing and Marking

Policing involves creating a policer that specifies the bandwidth limits for the traffic. Packets that exceed the limits are *out of profile* or *nonconforming*. Each policer specifies the action to take for packets that are in or out of profile. These actions, carried out by the marker, include passing through the packet without modification, dropping the packet, or marking down the packet with a new DSCP value that is obtained from the configurable policed-DSCP map. You can configure policer within a policy map with the **police** command in policy-map class configuration mode. For information on the policed-DSCP map, see the [“Queueing and Scheduling” section on page 44-8](#).

When configuring policing and policers, keep these items in mind:

- Policers account only for the Layer 2 header length when calculating policer rates. In contrast, shapers account for header length as well as IPG in rate calculations.
- Beginning with Cisco IOS Release 15.0(2)SG (IOS XE 3.2.0), Supervisor Engine 6-E, Supervisor Engine 6L-E, Supervisor Engine 7-E, and Supervisor Engine 7L-E support the **qos account layer-all encapsulation** command, which accounts for Layer 1 headers of 20 bytes (12 bytes preamble + 8 bytes IPG) and Layer 2 headers in policing features.
- Only the average rate and committed burst parameters are configurable.
- After you configure the policy map and policing actions, attach the policy to an ingress or egress interface by using the **service-policy** interface configuration command.
- For 2 rate 3 colors (2r3c) policers, if no explicit violation-action is specified, the exceed-action is used as the violate-action.

Queueing and Scheduling

The Catalyst 4500 series switch supports 8 transmit queues per port. Once the decision has been made to forward a packet out a port, the output QoS classification determines the transmit queue into which the packet must be enqueued.

Queues are assigned when an output policy attached to a port with one or more queuing related actions for one or more classes of traffic. Because there are only eight queues per port, there are at most eight traffic classes (including *class-default*, the reserved class) with queuing action(s). Classes of traffic that do not have any queuing action are referred to as non-queuing classes. Non-queuing class traffic use the queue corresponding to *class-default*.

Active Queue Management

Active queue management (AQM) is the pro-active approach of informing you about congestion before a buffer overflow occurs. AQM is done using Dynamic buffer limiting (DBL). DBL tracks the queue length for each traffic flow in the switch. When the queue length of a flow exceeds its limit, DBL drop packets.

Sharing Link Bandwidth Among Transmit Queues

The eight transmit queues for a transmit port share the available link bandwidth of that transmit port. You can set the link bandwidth to be shared differently among the transmit queues using the **bandwidth** command in the **policy-map class** configuration command in class mode.

With this command, you assign the minimum guaranteed bandwidth for each transmit queue.

By default, all queues are scheduled in a round robin manner.

Strict Priority / Low Latency Queueing

You can only configure one transmit queue on a port as strict priority (termed Low Latency Queue, or LLQ).

LLQ provides strict-priority queuing for a traffic class. It enables delay-sensitive data, such as voice, to be sent before packets in other queues. The priority queue is serviced first until it is empty or until it falls under its shape rate. Only one traffic stream can be destined for the priority queue per class-level policy. You enable the priority queue for a traffic class with the **priority policy-map class** configuration command in class mode.

Traffic Shaping

Traffic Shaping provides the ability to control the rate of outgoing traffic in order to make sure that the traffic conforms to the maximum rate of transmission contracted for it. Traffic that meets certain profile can be shaped to meet the downstream traffic rate requirements to handle any data rate mismatches.

Each transmit queue can be configured to transmit a maximum rate using the **shape** command in the **policy-map class** configuration command in class mode.

The configuration allows you to specify the maximum rate of traffic. Any traffic that exceeds the configured shape rate is queued and transmitted at the configured rate. If the burst of traffic exceeds the size of the queue, packets are dropped to maintain transmission at the configured shape rate.

Packet Modification

A packet is classified, policed, and queued to provide QoS. Packet modifications can occur during this process:

- For IP packets, classification involves assigning a DSCP to the packet. However, the packet is not modified at this stage; only an indication of the assigned DSCP is carried along. The reason for this is that QoS classification and ACL lookup occur in parallel, and it is possible that the ACL specifies that the packet should be denied and logged. In this situation, the packet is forwarded with its original DSCP to the CPU, where it is again processed through ACL software.

- For non-IP packets, classification involves assigning an internal DSCP to the packet, but because there is no DSCP in the non-IP packet, no overwrite occurs. Instead, the internal DSCP is used both for queueing and scheduling decisions and for writing the CoS priority value in the tag if the packet is being transmitted on either an ISL or 802.1Q trunk port.
- During policing, IP and non-IP packets can have another DSCP assigned to them (if they are out of profile and the policer specifies a markdown DSCP). Once again, the DSCP in the packet is not modified, but an indication of the marked-down value is carried along. For IP packets, the packet modification occurs at a later stage.

Per Port Per VLAN QoS

Per-port per-VLAN QoS (PVQoS) offers differentiated quality-of-services to individual VLANs on a trunk port. It enables service providers to rate limit individual VLAN-based services on each trunk port to a business or a residence. In an enterprise Voice-over-IP environment, it can be used to rate limit voice VLAN even if an attacker impersonates an IP phone. A per-port per-VLAN service policy can be separately applied to either ingress or egress traffic. For configuration details see [“Enabling Per-Port Per-VLAN QoS” section on page 44-71](#).

Flow-based QoS

Note

Before reading this section, you should be familiar with implementing Flexible NetFlow ([Chapter 76, “Configuring Flexible NetFlow”](#)) and QoS implementation in this chapter.

Flow based QoS enables microflow policing and marking capability to dynamically learn traffic flows. It also rate limits each unique flow to an individual rate. Flow based QoS is available on a Catalyst 4500 series switch with the built-in NetFlow hardware support. It can be applied to ingress traffic on both switched and routed interfaces with flow masks defined using Flexible NetFlow (FNF). It supports up to 100,000 individual flows in hardware and up to 512 unique policer configuration. Flow based QoS is typically used in environments where per-user, granular rate-limiting required. For example, per-flow outbound and inbound traffic rate might differ. Flow based QoS is also referred to as User Based Rate Limiting (UBRL).

A *flow* is defined as a stream of packets having the same properties as those defined by the key fields in the FNF flow record. A new flow is created when the value of data in packet’s key fields is unique with respect to the flow that already exist.

A flow based QoS policy possesses one or more classmaps matching on a FNF flow record. Such a classmap must be configured as **match-all** to match all the match criteria specified in the classmap. When a flow based QoS policy is attached to a QoS target, ingress traffic on the target is first classified based on the classification rules specified in the class-map. If the classifier has FNF flow record, the key fields specified in the FNF flow record are applied on the classified traffic to create flows provided the flow does not already exist. The corresponding policy actions (policing and marking) are then applied to these individual flows. Flow-based policers (termed *microflow policers*) rate limit each unique flow. Flows are dynamically created and inactive flows are periodically aged out.

Flow based QoS policy can be attached to QoS targets such as port (P), vlan (V), per-port-per-vlan (PV), and EtherChannel but only in the ingress direction.

For details on how to enable FNF, refer to the [“Applying Flow-based QoS Policy” section on page 44-76](#).

Using Metadata in QoS Policy

Beginning with Cisco IOS Release IOS XE 3.3.0SG and IOS 15.1(1)SG, you can configure class-map with metadata filters. A QoS policy that include such classes is termed a *metadata based QoS policy* or *parameterized QoS policy*. It allows you to classify flows based on intuitive and user friendly metadata attributes rather than individual flow 5-tuple and applicable QoS actions.

Software uses mechanisms like MSI and MSI-Proxy to do the following:

- Identify flows
- Glean metadata information from the traffic received at the network edge
- Generate and transport metadata information using RSVP messages hop-by-hop to every network element along the flow path using on-path RSVP signalling mechanism.

For configuration details on Cisco Medianet Metadata, refer to the following URLs:

<http://www.cisco.com/en/US/docs/ios-xml/ios/mdata/configuration/15-mt/metadata-framework.html>

For details on the metadata commands, refer to the following URL:

<http://www.cisco.com/en/US/docs/ios-xml/ios/qos/command/qos-cr-book.html>

For configuration details on Cisco Media Services Proxy, refer to the following URL:

<http://www.cisco.com/en/US/docs/ios-xml/ios/msp/configuration/15-mt/media-ser-prxy.html>

For command details on Cisco Media Services Proxy, refer to the following URL:

<http://www.cisco.com/en/US/docs/ios-xml/ios/msp/command/reference/guide/media-ser-prxy.html>

Restrictions

The following restrictions apply to using a metadata-based QoS policy on a Catalyst 4500 series switch:

- They can only be attached to target in input direction.
- They can only be attached to physical ports and EtherChannel. They cannot be attached to VLANs, port VLANs, and SVI interfaces.
- A policy can have multiple metadata-based classifiers.
- A class-map can have one or more metadata filters with match-any or match-all semantics.
- Policy actions corresponding to metadata class are applied on aggregate traffic. However, if the metadata filter is configured along with Flexible NetFlow record filter, the policy action (like policer) applies on individual flows.
- If there are no flows associated with metadata filter, the software configures an implicit ACL with a deny ACE.
- If the same metadata QoS policy is applied on multiple interfaces, the policy is installed in hardware in separate TCAM entries for each interface; the TCAM entries are not shared by the interfaces.
- When a new flow is associated with a metadata filter, the software installs a new set of TCAM entries that includes the new flow along with other existing previously-discovered flows.

Observing Metadata Filter Statistics

- Although interfaces with the same metadata policy do not share TCAM resources in hardware, the metadata filter statistics observed with the show policy-map interface *ifname* command are reported as though it were shared.
- Only metadata filter statistics are available. The individual flow statistics are not available.

Example

The following example illustrates a metadata-based QoS policy with two classes using metadata filters:

```
class-map c1
  match application telepresence-media

class-map c2
  match access-group name mysubnet

class-map match-any c3
  match application webex-video
  match application webex-audio

policy-map p1
  class c1
    police cir 10m
  class c2
    set dscp cs1
    police cir 2m
  class c3
    police cir 5m
```

Configuring System Queue Limit

Note

This feature is available only from Cisco IOS Release 15.0(2)SG1 and later and Cisco IOS Release XE 3.2.1SG.

With the **hw-module system max-queue-limit** command, the Catalyst 4500 series switch allows you to change the queue limit for all interfaces globally, instead of applying a policy with queue limit to all the interfaces.

To set the queue limit globally, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# hw-module system max-queue-limit max-queue-limit	Sets the queue limit for all interfaces globally. Valid values are from 1024 to 8184. The value must be a multiple of 8.
Step 3	Switch(config)# exit	Returns to privileged EXEC mode.
Step 4	Switch# reload or Switch# redundancy reload shelf Switch# redundancy force-switchover	Reloads standalone supervisor engine. Reloads redundancy supervisor engine in SSO mode. Reloads redundancy supervisor engine in RPR mode. This command must be followed by another redundancy force-switchover.

This is a global configuration command. You can override it with the per port, per class, **queue-limit** command.

For a standalone supervisor engine, you must reboot the engine after applying this command.

For redundant supervisors in SSO mode, you must enter the **redundancy reload shelf** command enforce reboot to both the supervisors. For redundancy supervisors in RPR mode, you must execute two consecutive switchovers to enforce the system queue limit on both the supervisors.

This example shows how to set the queue limit globally to 1024 on a standalone supervisor engine:

```
Switch> enable
Switch# configure terminal
Switch(config)# hw-module system max-queue-limit 1024
Switch(config)# exit
Switch# reload (for standalone supervisors)
Switch# redundancy reload shelf (for redundancy supervisors in SSO mode)
or
Switch# redundancy force-switchover (followed by another redundancy force-switchover, for
redundancy supervisors in RPR mode)
```

Configuring QoS with a 40-Gigabit Ethernet Interface

Starting with Cisco IOS XE 3.10.0E, the 40-GE interface is available with Supervisor Engine 9-E.

After you configure the policy map and policy map actions, you attach the policy to an ingress or egress interface by using the **service-policy** interface configuration command. If the interface you are attaching it to is a 40-Gigabit Ethernet interface, note the following:

- The **percent** keyword is not supported—policing actions such as shaping and bandwidth must be configured only with absolute values and not percent values.
- The reserved class (**class-default**) is required—This class must be present in the policy map, and must be configured with an absolute value.

Note

This 40-GE interface limitation applies to QoS configurations in VSS environments, non-VSS environments, and to auto-QoS configurations.

The following example shows how to configure a class map with match criteria, the class-default configured with a value, and how to attach the corresponding policy map, called “queuing” to a 40-Gigabit Ethernet interface:

```
Switch# configure terminal
Switch(config)# class-map dscp-10
Switch(config-cmap)# match dscp 10
Switch(config-cmap)# exit

Switch(config)# policy-map queuing
Switch(config-pmap)# class dscp-10
Switch(config-pmap-c)# shape average 10m
Switch(config-pmap-c)# exit
Switch(config-pmap)# class class-default
Switch(config-pmap-c)# bandwidth 10000
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit

Switch(config)# interface fortygigabitethernet1/1
Switch(config-if)# service-policy output queuing
Switch(config-if)# end
Switch#
```

Configuring VSS QoS

**Note**

HQoS is not supported on the Catalyst 4500 series switch.

MQC-based QoS Configuration

**Note**

Starting with Cisco IOS Release 12.2(40)SG Catalyst 4500 series switch with Supervisor Engine 6-E or Supervisor Engine 6L-E use the MQC model of QoS.

To apply QoS, you use the Modular QoS Command-Line Interface (MQC), which is a CLI structure that allows you to complete the following tasks:

- Specify the matching criteria used to define a traffic class.
- Create a traffic policy (policy map). The traffic policy defines the QoS policy actions to be taken for each traffic class.
- Apply the policy actions specified in the policy map to an interface, VLAN, or port and VLAN.

For more information about the MQC, see the “Modular Quality of Service Command-Line Interface” section of the *Cisco IOS Quality of Service Solutions Configuration Guide, Release 12.3*.

**Note**

The incoming traffic is considered trusted by default. Only when the *trusted boundary* feature is enabled on an interface can the port enter untrusted mode. In this mode, the switch marks the DSCP value of an IP packet and the CoS value of the VLAN tag on the Ethernet frame as “0”.

Platform-supported Classification Criteria and QoS Features

The following table provides a summary of various classification criteria and actions supported on the Catalyst 4500 series switch. For details, refer to the *Catalyst 4500 Series Switch Command Reference*.

Supported classification actions	Descriptions
match access-group	Configures the match criteria for a class map on the basis of the specified ACL.
match any	Configures the match criteria for a class map to be successful match criteria for all packets.
match cos	Matches a packet based on a Layer 2 class of service (CoS) marking.
match [ip] dscp	Identifies a specific IP differentiated service code point (DSCP) value as a match criterion. Up to eight DSCP values can be included in one match statement.
match [ip] precedence	Identifies IP precedence values as match criteria.
match protocol	Configures the match criteria for a class map on the basis of the specified protocol.
Supported Qos Features	Descriptions
police	Configures traffic policing.
police (percent)	Configures traffic policing on the basis of a percentage of bandwidth available on an interface.
police (two rates)	Configures traffic policing using two rates, the committed information rate (CIR) and the peak information rate (PIR).
set cos	Sets the Layer 2 class of service (CoS) value of an outgoing packet.
set dscp	Marks a packet by setting the differentiated services code point (DSCP) value in the type of service (ToS) byte of IPv4 or traffic class byte of IPv6 packet.
set precedence	Sets the precedence value in the packet header.
table map support	Unconditional marking of one packet field based on another packet field.
priority	Gives priority to a class of traffic belonging to a policy map.
shape	Shapes traffic to the indicated bit rate according to the algorithm specified.
bandwidth	Provides a guaranteed minimum bandwidth to each of the eight queues.
dbl	Dynamic buffer limit.
queue-limit	Specifies the maximum number of packets a transmit queue can hold.

Note

The classification action “match qos-group” is not supported in Cisco Release IOS XE 3.4.0SG and IOS 15.1(2)SG.

Note

The QoS feature “set qos-group” is not supported in Cisco Release IOS XE 3.4.0SG and IOS 15.1(2)SG.

Platform Hardware Capabilities

Qos Actions	Numbers of entries supported
Classification	64k input and 64k output classification entries are supported. A given policy can use at most 24k ACLs
Policing	16K policers are supported. Policers are allocated to given direction in blocks of 2k. For example, 2k policers can be used in for input and 14k policers can be used for output. Single rate policers uses one policer entry. Single Rate Three Color Marker (srTCM) (RFC 2697) and Two Rate Three Color Marker (trTCM) (RFC 2698) uses two policer entries
Marking	Marking of Cos and DSCP/Precedence is supported through two marking tables, each capable of supporting 512 entries. There are separate tables for each direction.
Queuing	The queue size is Configurable with the maximum number of entries configurable per port depending on the chassis and line card type.
DBL	You can enable DBL action on all configured class-maps.

Prerequisites for Applying a QoS Service Policy

Unlike the Switch QoS model, there is no prerequisite for enabling QoS on various targets. Just the attachment of a service policy enables QoS and detachment of that policy disables QoS on that target.

Restrictions for Applying a QoS Service Policy

Traffic marking can be configured on an interface, a VLAN, or a port and VLAN. An interface can be a Layer 2 access port, a Layer 2 switch trunk, a Layer 3 routed port, or an EtherChannel. A policy is attached to a VLAN using *vlan configuration* mode.

Attaching QoS service policy to VLANs and EtherChannel is described in the [“Policy Associations” section on page 44-74](#).

Classification

The supervisor engine supports classification of Layer 2, IP, IPv6 packets, and ARP packets marking performed on input can be matched in the output direction. The previous table lists the full set of capabilities. By default, the switch also supports classification resources sharing. Similarly, when the same policy is attached to a port or a VLAN or on per-port per-vlan targets, ACL entries are shared though QoS actions are unique on each target.

For example:

```

class-map c1
  match ip dscp 50
Policy Map p1
  class c1
    police rate 1 m burst 200000

```

If policy-map p1 is applied to interfaces Gig 1/1 and Gig 1/2, 1 CAM entry is used (one ACE that matches IP packets), but 2 policers are allocated (one per target). So, all IP packets with dscp 50 are policed to 1 mbps on interface Gig 1/1 and packets on interface Gig 1/2 are policed to 1 mbps.

**Note**

With Cisco IOS Release 12.2(46)SG, you can issue the **match protocol arp** command. For details, see the *Catalyst 4500 Series Switch Cisco IOS Command Reference*.

Classification Statistics

The supervisor engine supports only packet based classification statistics and TCAM resource sharing. When a policy-map is applied on multiple targets, the command **show policy-map interface** displays the aggregate classification statistics, not those specific to an interface.

**Note**

To obtain per interface policy-map stats, you should configure a unique policy-map name on each interface.

When a policy-map is attached to a port-channel member ports, classification statistics are not displayed.

Configuring a Policy Map

You can attach only one policy map to an interface. Policy maps can contain one or more policy-map classes, each with different match criteria and actions.

Configure a separate policy-map class in the policy map for each type of traffic that an interface receives. Put all commands for each type of traffic in the same policy-map class. QoS does not attempt to apply commands from more than one policy-map class to matched traffic.

Creating a Policy Map

To create a policy map, enter this command:

Command	Purpose
Switch(config)# [no] policy-map <i>policy_name</i>	Creates a policy map with a user-specified name. Use the no keyword to delete the policy map.

Attaching a Policy Map to an Interface

To create a policy map, enter this command:

Command	Purpose
Switch(config)# interface {vlan <i>vlan_ID</i> { fastethernet gigabitethernet } <i>slot/interface</i> Port-channel <i>number</i> }	Selects the interface to configure.
Switch(config-if)# [no] service-policy input <i>policy_map_name</i>	Attaches a policy map to the input direction of the interface. Use the no keyword to detach a policy map from an interface.

Command	Purpose
Switch(config-if)# end	Exits configuration mode.
Switch# show policy-map interface {vlan vlan_ID { fastethernet gigabitethernet } slot/interface}	Verifies the configuration.

Policing

The supervisor engine supports policers in the following operation modes:

- Single Rate Policer Two Color Marker

This kind of policer is configured with just the committed rate (CIR) and normal burst and it has only conform and exceed actions.
- Single Rate Three Color Marker (srTCM) (RFC 2697)
- Two Rate Three Color Marker (trTCM) (RFC 2698)
- Color Blind Mode

Policing accuracy of 0.75% of configured policer rate.

The engine supports 16384 (16 x 1024, 16K) single rate, single burst policers. 16K policers are organized as 8 banks of 2K policers. The policer banks are dynamically assigned (input or output policer bank) by the software depending on the QoS configuration. So, the 16K policers are dynamically partitioned by software as follows:

- 0 Input Policers and 16K Output Policers
- 2K Input Policers and 14K Output Policers
- 4K Input Policers and 12K Output Policers
- 6K Input Policers and 10K Output Policers
- 8K Input Policers and 8K Output Policers
- 10K Input Policers and 6K Output Policers
- 12K Input Policers and 4K Output Policers
- 14K Input Policers and 2K Output Policers
- 16K Input Policers and 0 Output Policers

These numbers represent individual policer entries in the hardware that support a single rate and burst parameter. Based on this, a switch supports the following number of policers:

- 16K Single Rate Policer with Single Burst (Two Color Marker)
- 8K Single Rate Three Color Marker (srTCM)
- 8K Two Rate Three Color Marker (trTCM)

These policers are partitioned between Input and Output in chunks of 2K policer banks. The different types of policers can all co-exist in the system. However, a given type of policer (srTCM, trTCM etc.) is configurable as a block of 128 policers.

Note

Two policers are reserved for internal use.

How to Implement Policing

For details on how to implement the policing features on a Catalyst 4500 series switch, refer to the Cisco IOS documentation at the following link:

http://www.cisco.com/en/US/docs/ios/12_2/qos/configuration/guide/qcfdpolsh.html

Platform Restrictions

Platform restrictions include the following:

- Multi-policer actions can be specified (setting CoS and IP DSCP is supported).
- When unconditional marking and policer based marking exists on the same field(cos or dscp or precedence), policer-based marking is preferred.
- If policer based service-policy is attached to both a port and a VLAN, port-based policed is preferred by default. To over-ride a specific VLAN policy on a given port, then you must configure a per-port per-vlan policy.
- You should not delete a port-channel with a per-port, per-VLAN QoS policy.

Workaround: Before deleting the port-channel, do the following:

1. Remove any per-port per-VLAN QoS policies, if any.
2. Remove the VLAN configuration on the port-channel with the **no vlan-range** command.

Marking Network Traffic

Marking network traffic allows you to set or modify the attributes of traffic (that is, packets) belonging to a specific class or category. When used in conjunction with network traffic classification, marking network traffic is the foundation for enabling many quality of service (QoS) features on your network. This module contains conceptual information and the configuration tasks for marking network traffic.

Information About Marking Network Traffic

To mark network traffic, you should understand the following concepts:

- [“Purpose of Marking Network Traffic” section on page 44-54](#)
- [“Benefits of Marking Network Traffic” section on page 44-54](#)
- [“Two Methods for Marking Traffic Attributes” section on page 44-55](#)

Purpose of Marking Network Traffic

Traffic marking is used to identify certain traffic types for unique handling, effectively partitioning network traffic into different categories.

After the network traffic is organized into classes by traffic classification, traffic marking allows you to mark (that is, set or change) a value (attribute) for the traffic belonging to a specific class. For instance, you may want to change the class of service (CoS) value from 2 to 1 in one class, or you may want to change the differentiated services code point (DSCP) value from 3 to 2 in another class. In this module, these values are referred to as attributes or marking fields.

Attributes that can be set and modified include the following:

- CoS value of a tagged Ethernet frame
- DSCP/Precedence value in the Type of Service (ToS) byte of IPv4.
- DSCP /Precedence value in the traffic class byte of IPv6

Benefits of Marking Network Traffic

Traffic marking allows you to fine-tune the attributes for traffic on your network. This increased granularity helps isolate traffic that requires special handling, and thus, helps to achieve optimal application performance.

Traffic marking allows you to determine how traffic will be treated, based on how the attributes for the network traffic are set. It allows you to segment network traffic into multiple priority levels or classes of service based on those attributes, as follows:

- Traffic marking is often used to set the IP precedence or IP DSCP values for traffic entering a network. Networking devices within your network can then use the newly marked IP precedence values to determine how traffic should be treated. For example, voice traffic can be marked with a particular IP precedence or DSCP and strict priority can then be configured to put all packets of that marking into that queue. In this case, the marking was used to identify traffic for strict priority queue.
- Traffic marking can be used to identify traffic for any class-based QoS feature (any feature available in policy map class configuration mode, although some restrictions exist).
- Traffic marking can be used to assign traffic to a QoS group within a switch. The switch can use the QoS groups to determine how to prioritize traffic for transmission. The QoS group value is usually used for one of the two following reasons:
 - To leverage a large range of traffic classes. The QoS group value has 64 different individual markings, similar to DSCP.
 - If changing the Precedence or DSCP value is undesirable.

Two Methods for Marking Traffic Attributes

Note

This section describes *Unconditional* marking, which differs from *Policer-based* marking. Unconditional marking is based solely on classification.

Method One: Unconditional Explicit Marking (using the set command)

You specify the traffic attribute you want to change with a set command configured in a policy map. The following table lists the available set commands and the corresponding attribute. For details on the set command, refer to the *Catalyst 4500 Series Switch Command Reference*.

Table 44-2 **set Commands and Applicable Packet Types**

set Commands	Traffic Attribute	Packet Type
set cos	Layer 2 CoS value of the outgoing traffic	Ethernet IPv4, IPv6
set dscp	DSCP value in the ToS byte	IPv4, IPv6
set precedence	precedence value in the packet header	IPv4, IPv6

If you are using individual **set** commands, those set commands are specified in a policy map. The following is a sample of a policy map configured with one of the set commands listed in [Table 44-4](#).

In this sample configuration, the **set cos** command has been configured in the policy map (policy1) to mark the CoS attribute:

```
enable
configure terminal
policy map p1
  class class1
    set cos 3
end
```

For information on configuring a policy map, see the “[Creating a Policy Map](#)” section on page 44-52.

The final task is to attach the policy map to the interface. For information on attaching the policy map to the interface, see the “[Attaching a Policy Map to an Interface](#)” section on page 44-52.

Method Two: Unconditional Tablemap-based Marking

You can create a table map that can be used to mark traffic attributes. A table map is a kind of two-way conversion chart that lists and maps one traffic attribute to another. A table map supports a many-to-one type of conversion and mapping scheme. The table map establishes a to-from relationship for the traffic attributes and defines the change to be made to the attribute. That is, an attribute is set to one value that is taken from another value. The values are based on the specific attribute being changed. For instance, the Precedence attribute can be a number from 0 to 7, while the DSCP attribute can be a number from 0 to 63.

The following is a sample table map configuration:

```
table-map table-map1
map from 0 to 1
map from 2 to 3
exit
```

The following table lists the traffic attributes for which a to-from relationship can be established using the table map.

Table 44-3 Traffic Attributes for Which a To-From Relationship Can Be Established

The "To" Attribute	The "From" Attribute
Precedence	CoS, DSCP, Precedence
DSCP	COS, DSCP, Precedence
CoS	DSCP, CoS, Precedence

The following is an example of a policy map (policy2) configured to use the table map (table-map1) created earlier:

```
Policy map policy
  class class-default
    set cos dscp table table-map
exit
```

In this example, a mapping relationship was created between the CoS attribute and the DSCP attribute as defined in the table map.

For information on configuring a policy map to use a table map, [“Configuring a Policy Map” section on page 44-51](#).

The final task is to attach the policy map to the interface. For information on attaching the policy map to the interface, see the [“Attaching a Policy Map to an Interface” section on page 44-52](#).

Marking Action Drivers

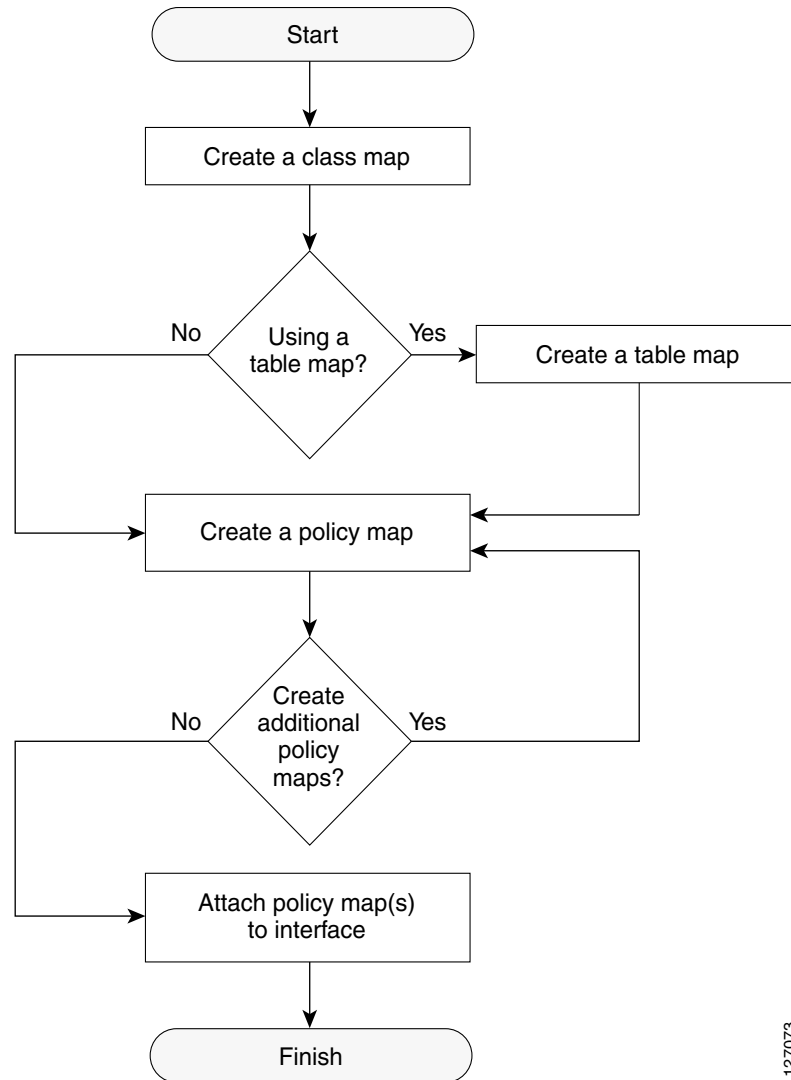

A marking action can be triggered based on one of the two QoS processing steps.

Classification based: In this case, all the traffic matching a class is marked using either explicit or tablemap based method. This method is referred to as *unconditional* marking.

Policer result-based: In this case, a class of traffic is marked differently based on the policer result (conform/exceed/violate) applicable to that packet. This method is referred to as *conditional* marking.

Traffic Marking Procedure Flowchart

[Figure 44-5](#) illustrates the order of the procedures for configuring traffic marking.

Figure 44-3 Traffic marking Procedure Flowchart

127073

Restrictions for Marking Network Traffic

The following restrictions apply to the following packet marking action:

- Only explicit marking is supported for policer-based marking.

Multi-attribute Marking Support

The supervisor engine can mark more than one QoS attribute of a packet matching a class of traffic. For example, DSCP, and CoS can all be set together, using either explicit or tablemap-based marking.

Note

When using unconditional explicit marking of multiple fields or policer-based multi-field, multi-region (conform/exceed/violate) marking the number of table maps that can be setup in TOS or COS marking tables will be less than the maximum supported.

Hardware Capabilities for Marking

Supervisor Engine 6-E, and Supervisor Engine 6L-E provide a 128 entry marking action (Supervisor Engines 9-E, 8L-E, 8-E, 7-LE, and 7-E provide a 256 entry marking action) where each entry specifies the type of marking actions on CoS and DSCP/Precedence fields as well as policer action to transmit/markdown/drop a packet.

One such table is supported for each direction, input and output. This table is used for both unconditional marking as well as policer-based marking. It can be used to support 256 unique marking actions or 64 unique policer-based actions or a combinations of the two.

For each of the marking fields (COS and DSCP), the supervisor engine provides 512 entry marking tables for each direction. These are similar to mapping tables available on supervisor engines that support the switch QoS model. However, these provide an ability to have multiple unique mapping tables that are setup by the user.

For example, the TOS marking table provides marking of DSCP/Precedence fields and can be used as one of the following:

- 64 (32) different tablemaps with each one mapping 8 CoS (16 CoS and CFi) values to DSCP in input (output) direction
- a combination of above two types of tablemaps

Similar mappings are available on the 512 entry COS marking table.

Configuring the Policy Map Marking Action

This section describes how to establish unconditional marking action for network traffic.

As a prerequisites, create a class map (*ipp5*) and a policy map. (Refer to the “[Configuring a Policy Map](#)” section on page 44-51).

Note

The marking action command options have been extended (refer to [Table 44-4 on page 44-55](#) and [Table 44-5 on page 44-56](#)).

Configuring Tablemap-based Unconditional Marking

To configure table-map based unconditional marking, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# table-map name	Configures a tablemap.
Step 3	Switch(config-tablemap)# map from from_value to to_value	Creates a map from a <i>from_value</i> to a <i>to_value</i>
Step 4	Switch(config-tablemap)# exit	Exits table-map configuration mode.
Step 5	Switch(config)# policy-map name	Enters policy-map configuration mode.
Step 6	Switch(config-p)# class name	Selects the class for QoS actions.
Step 7	Switch(config-p-c)# set cos dscp prec cos dscp prec [table name]	Selects the marking action based on an implicit or explicit table-map.
Step 8	Switch(config-p-c)# end	Exits configuration mode.

	Command	Purpose
Step 9	Switch# show policy-map name	Verifies the configuration of the policy-map.
Step 10	Switch# show table-map name	Verifies the configuration of the table-map.

The following example shows how to enable marking action using table-map.

```
Switch(config)# table-map dscp2Cos
Switch(config-tablemap)# map from 8 to 1
Switch(config-tablemap)# exit
Switch(config)# policy-map p1
Switch(config-pmap)# class ipp5
Switch(config-pmap-c)# set cos dscp table dscp2Cos
Switch(config-pmap-c)# end
Switch# show policy-map p1

Policy Map p1
  Class ipp5
    set cos dscp table dscp2Qos

Switch# show table-map dscp2Cos

Table Map dscp2Cos
  from 8 to 1
  default copy
```

Configuring Policer Result-based Conditional Marking

To configure policer result-based conditional marking, setup a single rate or dual rate policer. Refer to the [“How to Implement Policing”](#) section on page 44-53.

This example shows how to configure a two rate three-color policer with explicit actions for each policer region:

```
Switch# configure terminal
Switch(config-pmap-c)# policer cir percent 20 pir percent 30
Switch(config-pmap-c-policer)# conform-action set-cos-transmit 3 set-dscp-transmit 10
Switch(config-pmap-c-policer)# exceed-action set-cos-transmit 4 set-dscp-transmit 20
Switch(config-pmap-c-policer)# violate action drop
Switch# show policy-map p1

Policy Map police
  Class ipp5
    police cir percent 20 pir percent 30
      conform-action set-cos-transmit 3
      conform-action set-dscp-transmit af11
      exceed-action set-cos-transmit 4
      exceed-action set-dscp-transmit af22
      violate-action drop
```

Marking Statistics

The marking statistics indicate the number of packets that are *marked*.

For unconditional marking, the *classification entry* points to an entry in the marking action table that in turn indicates the fields in the packet that are marked. Therefore, the classification statistics by itself indicates the unconditional marking statistics.

For a conditional marking using policer, provided the policer is a packet rate policer, you cannot determine the number packets marked because the policer only provides byte statistics for different policing results.

Shaping, Sharing (Bandwidth), Priority Queuing, Queue-limiting and DBL

Catalyst 4500 series switches support the Classification-based (class-based) mode for transmit queue selection. In this mode, the transmit queue selection is based on the Output QoS classification lookup.

Note

Only output (egress) queuing is supported.

The supervisor engine supports 8 transmit queues per port. Once the forwarding decision has been made to forward a packet out a port, the output QoS classification determines the transmit queue into which the packet needs to be enqueued.

By default, without any service policies associated with a port, there are two queues (a control packet queue and a default queue) with no guarantee as to the bandwidth or kind of prioritization. The only exception is that system generated control packets are enqueued into control packet queue so that control traffic receives some minimum link bandwidth.

Queues are assigned when an output policy attached to a port with one or more queuing related actions for one or more classes of traffic. Because there are only eight queues per port, there can be at most eight classes of traffic (including the reserved class, class-default) with queuing action(s). Classes of traffic that do not have any queuing action are referred to as *non-queuing* classes. Non-queuing class traffic ends up using the queue corresponding to class class-default.

When a queuing policy (a policy with queuing action) is attached, the control packet queue is deleted and the control packets are enqueued into respective queue per their classification. An egress QoS class must be configured to match IP Precedence 6 and 7 traffic, and a bandwidth guarantee must be configured.

Dynamic resizing of queues (queue limit class-map action) is supported through the use of the **queue-limit** command. Based on the chassis and line card type, all eight queues on a port are configured with equal queue size.

Shaping

Shaping enables you to delay out-of-profile packets in queues so that they conform to a specified profile. Shaping is distinct from policing. Policing drops packets that exceed a configured threshold, whereas shaping *buffers* packets so that traffic remains within a given threshold. Shaping offers greater *smoothness* in handling traffic than policing. You enable average-rate traffic shaping on a traffic class with the **policy-map** class configuration command.

The supervisor engine supports a range of 32kbps to 10 gbps for shaping, with a precision of approximately +/- 0.75 per cent.

When a queuing class is configured without any explicit shape configuration, the queue shape is set to the link rate.

To configure class-level shaping in a service policy, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# policy-map <i>policy-map-name</i>	Creates a policy map by entering the policy-map name, and enter policy-map configuration mode. By default, no policy maps are defined.
Step 3	Switch(config-pmap)# class <i>class-name</i>	Specifies the name of the class whose traffic policy you want to create or change, and enter policy-map class configuration mode. By default, no traffic classes are defined.
Step 4	Switch(config-pmap-class)# shape average { <i>cir-bps</i> [<i>optional_postfix</i>] <i>percent percent</i> }	Enables average-rate traffic shaping. You can specify the shaping rate in absolute value or as a percentage: <ul style="list-style-type: none"> For <i>cir-bps</i> [<i>optional_postfix</i>], specify the shaping rate in bps. Range is 32000 to 10000000000 bps. Supply an optional postfix (K, M, G). For <i>percent</i>, specify the percentage of link rate to shape the class of traffic. The range is 1 to 100. By default, average-rate traffic shaping is disabled.
Step 5	Switch(config-pmap-class)# exit	Returns to policy-map configuration mode.
Step 6	Switch(config-pmap)# exit	Returns to global configuration mode.
Step 7	Switch(config)# interface <i>interface-id</i>	Specifies a physical port and enter interface configuration mode.
Step 8	Switch(config-interface)# service-policy output <i>policy-map-name</i>	Specifies the policy-map name, and apply it a physical interface.
Step 9	Switch(config-interface)# end	Returns to privileged EXEC mode.
Step 10	Switch# show policy-map [<i>policy-map-name</i> [<i>class class-map-name</i>]] or Switch# show policy-map interface <i>interface-id</i>	Verifies your entries.
Step 11	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To delete an existing policy map, use the **no policy-map** *policy-map-name* global configuration command. To delete an existing class, use the **no class** *class-name* policy-map configuration command. To disable the average-rate traffic shaping, use the **no shape average** policy-map class configuration command.

This example shows how to configure class-level, average-rate shaping. It limits traffic class class1 to a data transmission rate of 256 kbps:

```
Switch# configure terminal
Switch(config)# policy-map policy1
Switch(config-pmap)# class class1
Switch(config-pmap-c)# shape average 256000
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet1/1
```

```
Switch(config-if)# service-policy output policy1
Switch(config-if)# end
Switch#
```

```
Switch# show policy-map policy1
  Policy Map policy1
    Class class1
      shape average 256000
```

This example shows how to configure class-level, average shape percentage to 32% of link bandwidth for queuing-class traffic:

```
Switch# configure terminal
Switch(config)# policy-map queuing-policy
Switch(config-pmap)# class queuing-class
Switch(config-pmap-c)# shape average percent 32
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# service-policy output queuing-policy1
Switch(config-if)# end
Switch #
```

```
Switch# show policy-map queuing-policy
  Policy Map queuing-policy
    Class queuing-class
      Average Rate Traffic Shaping
        cir 32%
```

Sharing (bandwidth)

The bandwidth assigned to a class of traffic is the minimum bandwidth that is guaranteed to the class during congestion. Transmit Queue Sharing is the process by which output link bandwidth is shared among multiple queues of a given port.

The supervisor engine supports a range of 32 kbps to 10 gbps for sharing, with a precision of approximately +/- 0.75 per cent. The sum of configured bandwidth across all queuing classes should not exceed the link bandwidth.

To configure class-level bandwidth action in a service policy, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# policy-map <i>policy-map-name</i>	Creates a policy map by entering the policy-map name, and enter policy-map configuration mode. By default, no policy maps are defined.
Step 3	Switch(config-pmap)# class <i>class-name</i>	Specifies the name of the class whose traffic policy you want to create or change, and enter policy-map class configuration mode. By default, no traffic classes are defined.

	Command	Purpose
Step 4	Switch(config-pmap-class)# bandwidth { <i>bandwidth-kbps</i> percent <i>percent</i> }	Specifies the minimum bandwidth provided to a class belonging to the policy map when there is traffic congestion in the switch. If the switch is not congested, the class receives more bandwidth than you specify with the bandwidth command. By default, no bandwidth is specified. You can specify the bandwidth in kbps or as a percentage: <ul style="list-style-type: none"> For <i>bandwidth-kbps</i>, specify the bandwidth amount in kbps assigned to the class. The range is 32 to 10000000. For <i>percent</i>, specify the percentage of available bandwidth assigned to the class. The range is 1 to 100. Specify all the class bandwidths in either kbps or in percentages, but not a mix of both.
Step 5	Switch(config-pmap-class)# exit	Returns to policy-map configuration mode.
Step 6	Switch(config-pmap)# exit	Returns to global configuration mode.
Step 7	Switch(config)# interface <i>interface-id</i>	Specifies a physical port and enter interface configuration mode.
Step 8	Switch(config-interface)# service-policy output <i>policy-map-name</i>	Specifies the policy-map name, and apply it a physical interface.
Step 9	Switch(config-interface)# end	Returns to privileged EXEC mode.
Step 10	Switch# show policy-map [<i>policy-map-name</i> [class <i>class-map-name</i>]] or Switch# show policy-map interface <i>interface-id</i>	Verifies your entries.
Step 11	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To delete an existing policy map, use the **no policy-map** *policy-map-name* global configuration command. To delete an existing class, use the **no class** *class-name* policy-map configuration command. To return to the default bandwidth, use the **no bandwidth** policy-map class configuration command.

This example shows how to create a class-level policy map called policy11 for three classes called prec1, prec2, and prec3. In the policy for these classes, 30 percent of the available bandwidth is assigned to the queue for the first class, 20 percent is assigned to the queue for the second class, and 10 percent is assigned to the queue for the third class.

```
Switch # configure terminal
Switch(config)# policy-map policy11
Switch(config-pmap)# class prec1
Switch(config-pmap-c)# bandwidth percent 30
Switch(config-pmap-c)# exit
Switch(config-pmap)# class prec2
Switch(config-pmap-c)# bandwidth percent 20
Switch(config-pmap-c)# exit
Switch(config-pmap)# class prec3
Switch(config-pmap-c)# bandwidth percent 10
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# service-policy output policy11
```

```

Switch(config-if)# end
Switch #

Switch# show policy-map policy11
Policy Map policy11
  Class prec1
    bandwidth percent 30
  Class prec2
    bandwidth percent 20
  Class prec3
    bandwidth percent 10

```

This example shows how to create a class-level policy map called policy11 for three classes called prec1, prec2, and prec3. In the policy for these classes, 300 mbps of the available bandwidth is assigned to the queue for the first class, 200 mbps is assigned to the queue for the second class, and 100 mbps is assigned to the queue for the third class.

```

Switch # configure terminal
Switch(config)# policy-map policy11
Switch(config-pmap)# class prec1
Switch(config-pmap-c)# bandwidth 300000
Switch(config-pmap-c)# exit
Switch(config-pmap)# class prec2
Switch(config-pmap-c)# bandwidth 200000
Switch(config-pmap-c)# exit
Switch(config-pmap)# class prec3
Switch(config-pmap-c)# bandwidth 100000
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# service-policy output policy11
Switch(config-if)# end
Switch #

Switch# show policy-map policy11
Policy Map policy11
  Class prec1
    bandwidth 300000 (kbps)
  Class prec2
    bandwidth 200000 (kbps)
  Class prec3
    bandwidth 100000 (kbps)

```

When a queuing class is configured without any explicit share/bandwidth configuration, because the queue is not guaranteed any minimum bandwidth, the hardware queue is programmed to get a share of any unallocated bandwidth on the port as shown in the following example.

If there is no bandwidth remaining for the new queue or if the unallocated bandwidth is not sufficient to meet the minimum configurable rate (32kbps) for all queues which do not have any explicit share/bandwidth configuration, then the policy association is rejected.

For example, if there are two queues as given below

```

policy-map queue-policy
  class q1
    bandwidth percent 10

  class q2
    bandwidth percent 20

```

then the bandwidth allocation for the queues is as follows

```

q1 = 10%
q2 = 20%

```

```
class-default = 70%
```

Similarly, when another queuing class (say q3) is added without any explicit bandwidth (say, just a shape command), then the bandwidth allocation is

```
q1 = 10%
      q2 = 20%
      q3 = min(35%, q3-shape-rate)
class-default = max(35%, (100 - (q1 + q2 + q3 )))
```

Priority queuing

Only one transmit queue on a port can be configured as *strict priority* (termed Low Latency Queue, or LLQ).

LLQ provides strict-priority queuing for a traffic class. It enables delay-sensitive data, such as voice, to be sent *before* packets in other queues. The priority queue is serviced first until it is empty or until it is under its shape rate. Only one traffic stream can be destined for the priority queue per class-level policy. You enable the priority queue for a traffic class with the **priority policy-map class** configuration command at the class mode.

A LLQ can starve other queues unless it is rate limited. The supervisor engine does not support *conditional policing* where a 2-parameter policer (rate, burst) becomes effective when the queue is *congested* (based on queue length). However, it supports application of an unconditional policer to rate limit packets enqueued to the strict priority queue.

When a priority queue is configured on one class of a policy map, only *bandwidth remaining* is accepted on other classes, guaranteeing a minimum bandwidth for other classes from the remaining bandwidth of what is left after using the priority queue. When a priority queue is configured with a policer, then either *bandwidth* or *bandwidth remaining* is accepted on other classes.

Note

Use *bandwidth* or *bandwidth remaining* on all classes. You cannot apply *bandwidth* on one class and *bandwidth remaining* on another class within a policy map.

To enable class-level priority queuing in a service policy, follow these steps:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# policy-map <i>policy-map-name</i>	Creates a policy map by entering the policy-map name, and enter policy-map configuration mode. By default, no policy maps are defined.
Step 3	Switch(config-pmap)# class <i>class-name</i>	Specifies the name of the class whose traffic policy you want to create or change, and enter policy-map class configuration mode. By default, no traffic classes are defined.
Step 4	Switch(config-pmap-class)# priority	Enables the strict-priority queue, and give priority to a class of traffic. By default, strict-priority queueing is disabled.
Step 5	Switch(config-pmap-class)# exit	Returns to policy-map configuration mode.
Step 6	Switch(config-pmap)# exit	Returns to global configuration mode.
Step 7	Switch(config)# interface <i>interface-id</i>	Specifies a physical port and enter interface configuration mode.

	Command	Purpose
Step 8	Switch(config-interface)# service-policy output <i>policy-map-name</i>	Specifies the policy-map name, and apply it a physical interface.
Step 9	Switch(config-interface)# end	Returns to privileged EXEC mode.
Step 10	Switch# show policy-map [<i>policy-map-name</i> [class <i>class-map-name</i>]] or Switch# show policy-map interface <i>interface-id</i>	Verifies your entries.
Step 11	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To delete an existing policy map, use the **no policy-map** *policy-map-name* global configuration command. To delete an existing class, use the **no class** *class-name* policy-map configuration command. To disable the priority queue, use the **no priority** *policy-map-class* configuration command.

This example shows how to configure a class-level policy called policy1. Class 1 is configured as the priority queue, which is serviced first until it is empty.

```
Switch# configure terminal
Switch(config)# policy-map policy1
Switch(config-pmap)# class class1
Switch(config-pmap-c)# priority
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# service-policy output policy1
Switch(config-if)# end
Switch #

Switch# show policy-map policy1
  Policy Map policy1
    Class class1
      priority
```

Queue-limiting

When a class-based queue is instantiated on a physical port, it is set up with a default size. This size represents the number of queue entries in which packets belonging to that class of traffic can be queued. The scheduler moves packets from the queue that are ready for transmission, based on the queue shape, bandwidth, and priority configuration.

The queue-limit provides the maximum number of packets that can be in the queue at any given time. When the queue is full, an attempt to enqueue any further packets results in tail drop. However, if dynamic buffer limiting (DBL) is enabled on the queue, packets get a probabilistic drop based on the DBL algorithm, even when the queue is not full.

The **queue-limit** command can be configured under a class only when queue scheduling, such as bandwidth, shape, or priority is already configured. The only exception to this requirement is the support of the stand-alone **queue-limit** command on the class-default class.

Queue Memory

The number of queue entries that can be allocated has to be a multiple of 8 and can range from 16 to 8184. When a class-based queue is instantiated on a physical port, it is given a default number of entries. This default queue size is based on the number of slots in the chassis and the number of front-panel ports in each slot.

Supervisor Engine 6-E, and Supervisor Engine 6L-E have 512 K (524,288) queue entries of which the system sets aside 100 K (102,400) queue entries in a free reserve pool. Of the remaining 412 K (421,88), the drop port is provided 8184 entries and the CPU ports are assigned 11704 entries. Supervisor Engine 9-E, 8-E, and 7-E have 1M (1,048,576) queue entries of which the system sets aside 100K (102,400) queue entries in a free reserve pool. Of the remaining queue entries, the drop port is provided 8184 entries, 24576 entries for recirculation ports and the CPU ports are assigned 8656 entries. Supervisor Engine 7L-E has a 512 K queue entries.

The remaining entries are divided equally among the slots in the chassis. In a redundant chassis the two supervisor slots are treated as one for the purpose of this entries distribution. Within each slot the number of queue entries are equally divided among the front-panel ports present on the line card in that slot.

When the user configuration for queue entries on an interface exceeds its dedicated quota, the system attempts to satisfy the configuration from the free reserve pool. The entries from the free reserve pool are allocated to interfaces on a first-come first-served basis.

Service Policy Association

When a QoS service-policy with queuing actions is configured, but no explicit queue-limit command is attached in the egress direction on a physical interface, each of the class-based queues gets the same number of queue entries from within the dedicated quota for that physical port. When a queue is explicitly given a size using the queue-limit command, the switch tries to allocate all the entries from within the dedicated quota for the interface. If the required number of entries is greater than the dedicated quota for the interface, the switch tries to allocate the entries from the free reserve.

The queue entries associated with a queue always have to be consecutive. This requirement can result in fragmentation of the 512K of the queue entries that are shared across the switch. For example, an interface may not have enough entries for a queue in its dedicated quota and thus have to use the free reserve to set up that queue. In this case, the queue entries from the dedicated quota remain unused because they cannot be shared with any other port or slot.

When the QoS service-policy associated with an interface is removed, any queue entries taken from the free reserve are returned to the free reserve pool. The interface queuing configuration reverts to two queues — class-default and the control-packet queue with default shape, bandwidth, and size. The control-packet queue is set up with size 16 whereas the default queue is set up with the maximum size possible based on the dedicated quota for that interface.

Queue Allocation Failure

The switch might not be able to satisfy the explicit queue size required on one or more queues on an interface because of fragmentation of queue memory or lack of enough free reserve entries. In this scenario, the switch logs an error message to notify you of the failure. The QoS service-policy is left configured on the interface. You can fix the error by removing the QoS service-policy and examining the current usage of the queue entries from the free reserve by other ports on the switch.

Note

Do not attach a QoS policy with the maximum queue-limit (8184) to a large number of targets in a VSS system. This will cause continuous reloads on the standby supervisor engine.

To configure class-level queue-limit in a service policy, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# policy-map <i>policy-map-name</i>	Creates a policy map by entering the policy-map name, and enter policy-map configuration mode. By default, no policy maps are defined.
Step 3	Switch(config-pmap)# class <i>class-name</i>	Specifies the name of the class whose traffic policy you want to create or change, and enter policy-map class configuration mode. By default, no traffic classes are defined.
Step 4	Switch(config-pmap-class)# shape average { <i>cir-bps</i> [<i>optional_postfix</i>] percent <i>percent</i> }	Enables average-rate traffic shaping. You can specify the shaping rate in absolute value or as a percentage: <ul style="list-style-type: none"> For <i>cir-bps</i> [<i>optional_postfix</i>], specify the shaping rate in bps. Range is 32000 to 10000000000 bps. Supply an optional postfix (K, M, G). For <i>percent</i>, specify the percentage of link rate to shape the class of traffic. The range is 1 to 100. By default, average-rate traffic shaping is disabled.
Step 5	Switch(config-pmap-class)# queue-limit <i>number-of-packets</i>	Provides an explicit queue size in packets. The size must be a multiple of 8 and ranging from 16 to 8184.
Step 6	Switch(config-pmap-class)# exit	Returns to policy-map configuration mode.
Step 7	Switch(config-pmap)# exit	Returns to global configuration mode.
Step 8	Switch(config)# interface <i>interface-id</i>	Specifies a physical port and enter interface configuration mode.
Step 9	Switch(config-interface)# service-policy output <i>policy-map-name</i>	Specifies the policy-map name, and apply it a physical interface.
Step 10	Switch(config-interface)# end	Returns to privileged EXEC mode.
Step 11	Switch# show policy-map [<i>policy-map-name</i> [class <i>class-map-name</i>]] or Switch# show policy-map interface <i>interface-id</i>	Verifies your entries.
Step 12	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To remove the explicit queue size use the **no queue-limit** command under the class in a policy-map.

This example shows how to configure a class-based queue with an explicit **queue-limit** command. It limits traffic class class1 to a queue of size 4048:

```
Switch# configure terminal
Switch(config)# policy-map policy1
Switch(config-pmap)# class class1
Switch(config-pmap-c)# shape average 256000
```

```

Switch(config-pmap-c) # queue-limit 4048
Switch(config-pmap-c) # exit
Switch(config-pmap) # exit
Switch(config) # interface gigabitethernet1/1
Switch(config-if) # service-policy output policy1
Switch(config-if) # end
Switch#

Switch# show policy-map policy1
  Policy Map policy1
    Class class1
      shape average 256000
      queue-limit 4048
Switch#

```

Active Queue Management (AQM) via Dynamic Buffer Limiting (DBL)

AQM provides buffering control of traffic flows prior to queuing a packet into a transmit queue of a port. This is of significant interest in a shared memory switch, ensuring that certain flows do not hog the switch packet memory.

Note

The supervisor engine supports active switch buffer management via DBL.

Except for the default class of traffic (class class-default), you can configure DBL action only when at least one of the other queuing action is configured.

To configure class-level dbf action along with shaping in a service policy, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config) # policy-map <i>policy-map-name</i>	Creates a policy map by entering the policy-map name, and enter policy-map configuration mode. By default, no policy maps are defined.
Step 3	Switch(config-pmap) # class <i>class-name</i>	Specifies the name of the class whose traffic policy you want to create or change, and enter policy-map class configuration mode. By default, no traffic classes are defined.
Step 4	Switch(config-pmap-class) # shape average <i>cir-bps</i>	Enables average-rate traffic shaping. Specify the committed information rate, the bit rate that traffic is shaped to, in bps. The range is 32000 to 10000000000 bps. By default, average-rate traffic shaping is disabled.
Step 5	Switch(config-pmap-class) # dbf	Enables DBL on the queue associated with this class of traffic
Step 6	Switch(config-pmap-class) # exit	Returns to policy-map configuration mode.
Step 7	Switch(config-pmap) # exit	Returns to global configuration mode.
Step 8	Switch(config) # interface <i>interface-id</i>	Specifies a physical port and enter interface configuration mode.
Step 9	Switch(config-interface) # service-policy output <i>policy-map-name</i>	Specifies the policy-map name, and apply it a physical interface.
Step 10	Switch(config-interface) # end	Returns to privileged EXEC mode.

	Command	Purpose
Step 11	<pre>Switch# show policy-map [<i>policy-map-name</i> [<i>class</i> <i>class-map-name</i>]] or Switch# show policy-map interface <i>interface-id</i></pre>	Verifies your entries.
Step 12	<pre>Switch# copy running-config startup-config</pre>	(Optional) Saves your entries in the configuration file.

To delete an existing policy map, use the **no policy-map** *policy-map-name* global configuration command. To delete an existing class, use the **no class** *class-name* policy-map configuration command. To disable DBL on the associated queue, use the **no db1** policy-map class configuration command.

The following example shows how to configure class-level, DBL action along with average-rate shaping. It enables DBL on the queue associated with traffic-class *class1*.

```
Switch# configure terminal
Switch(config)# policy-map policy1
Switch(config-pmap)# class class1
Switch(config-pmap-c)# shape average 256000
Switch(config-pmap-c)# db1
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitEthernet1/1
Switch(config-if)# service-policy output policy1
Switch(config-if)# end
Switch#

Switch# show policy-map policy1
  Policy Map policy1
    Class class1
      shape average 256000
      db1
```

Transmit Queue Statistics

Transmit queue statistics are visible by entering the **show policy-map interface** command:

```
Switch# show policy-map interface gigabitEthernet 1/1
GigabitEthernet1/1

  Service-policy output: queuing-policy

    Class-map: queuing-class (match-all)
      1833956 packets
      Match: cos 1
      Queueing
        (total drops) 1006239
        (bytes output) 56284756
        shape (average) cir 320000000, bc 1280000, be 1280000
        target shape rate 320000000

    Class-map: class-default (match-any)
      1 packets
      Match: any

        (total drops) 0
        (bytes output) 2104
```

Enabling Per-Port Per-VLAN QoS

The per-port per-VLAN QoS feature enables you to specify different QoS configurations on different VLANs on a given interface. Typically, you use this feature on trunk or voice VLANs (Cisco IP Phone) ports, as they belong to multiple VLANs.

To configure per-port per-VLAN QoS, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface { fastethernet gigabitethernet tengigabitethernet } slot/interface Port-channel <i>number</i>	Selects the interface to configure.
Step 2	Switch(config-if)# vlan-range <i>vlan_range</i>	Specifies the VLANs involved.
Step 3	Switch(config-if-vlan-range)# service-policy { input output } <i>policy-map</i>	Specifies the policy-map and direction.
Step 4	Switch(config-if-vlan-range)# exit	Exits class-map configuration mode.
Step 5	Switch(config-if)# end	Exits configuration interface mode.
Step 6	Switch# show policy-map interface <i>interface_name</i>	Verifies the configuration.

Example 1

Figure 44-6 displays a sample topology for configuring PVQoS. The trunk port gi3/1 is comprised of multiple VLANs (101 and 102). Within a port, you can create your own service policy per VLAN. This policy, performed in hardware, might consist of ingress and egress Policing or giving precedence to voice packet over data.

Figure 44-4 Per-Port Per-VLAN Topology

The following configuration file shows how to perform ingress and egress policing per VLAN using the policy-map P31_QOS applied to port Gigabit Ethernet 3/1:

```
ip access-list 101 permit ip host 1.2.2.2 any
```

```

ip access-list 103 permit ip any any
Class-map match-all RT

match ip access-group 101
Class-map Match all PD

match ip access-group 103
Policy-map P31_QoS

Class RT

Police 200m 16k conform transmit exceed drop

Class PD

Police 100m 16k conform transmit exceed drop

Interface Gigabit 3/1
Switchport
Switchport trunk encapsulation dot1q
Switchport trunk allowed vlan 101-102
  Vlan range 101
    Service-policy input P31_QoS
    Service-policy output P31_QoS
  Vlan range 102
    Service-policy input P32_QoS
    Service-policy output P32_QoS

```

Example 2

Let us assume that interface Gigabit Ethernet 6/1 is a trunk port and belongs to VLANs 20, 300-301, and 400. The following example shows how to apply policy-map p1 for traffic in VLANs 20 and 400 and policy map p2 to traffic in VLANs 300 through 301:

```

Switch# configure terminal
Switch(config)# interface gigabitethernet 6/1
Switch(config-if)# vlan-range 20,400
Switch(config-if-vlan-range)# service-policy input p1
Switch(config-if-vlan-range)# exit
Switch(config-if)# vlan-range 300-301
Switch(config-if-vlan-range)# service-policy output p2
Switch(config-if-vlan-range)# end
Switch#

```

Example 3

The following command shows how to display policy-map statistics on VLAN 20 configured on Gigabit Ethernet interface 6/1:

```

Switch# show policy-map interface gigabitEthernet 6/1 vlan 20

GigabitEthernet6/1 vlan 20

Service-policy input: p1

Class-map: c1 (match-all)
  0 packets
  Match: cos 1
  Match: access-group 100
  police:
    cir 100000000 bps, bc 3125000 bytes

```

```

conformed 0 bytes; actions:
  transmit
exceeded 0 bytes; actions:
  drop
conformed 0000 bps, exceed 0000 bps

Class-map: class-default (match-any)
  0 packets
  Match: any

```

Example 4

The following command shows how to display policy-map statistics on all VLANs configured on Gigabit Ethernet interface 6/1:

```
Switch# show policy-map interface gigabitEthernet 6/1
```

```
GigabitEthernet6/1 vlan 20
```

```
Service-policy input: p1
```

```

Class-map: c1 (match-all)
  0 packets
  Match: cos 1
  Match: access-group 100
  police:
    cir 100000000 bps, bc 3125000 bytes
    conformed 0 bytes; actions:
      transmit
    exceeded 0 bytes; actions:
      drop
    conformed 0000 bps, exceed 0000 bps

```

```

Class-map: class-default (match-any)
  0 packets
  Match: any

```

```
GigabitEthernet6/1 vlan 300
```

```
Service-policy output: p2
```

```

Class-map: c1 (match-all)
  0 packets
  Match: cos 1
  Match: access-group 100
  QoS Set
    dscp 50
  police:
    cir 200000000 bps, bc 6250000 bytes
    conformed 0 bytes; actions:
      transmit
    exceeded 0 bytes; actions:
      drop
    conformed 0000 bps, exceed 0000 bps

```

```

Class-map: class-default (match-any)
  0 packets
  Match: any

```

```
GigabitEthernet6/1 vlan 301
```

```
Service-policy output: p2
```

```

Class-map: c1 (match-all)
  0 packets
  Match: cos 1
  Match: access-group 100
  QoS Set
    dscp 50
  police:
    cir 200000000 bps, bc 6250000 bytes
    conformed 0 bytes; actions:
      transmit
    exceeded 0 bytes; actions:
      drop
    conformed 0000 bps, exceed 0000 bps

```

Policy Associations

The supervisor engine supports per-port, per-VLAN policies. The associated policies are attached to the interface, VLAN, and a specific VLAN on a given port, respectively.

A policy can be associated with a variety of objects. The following table lists the objects and the actions allowed.

Table 44-1 Table QoS Policy Associations

Object	Action
Physical port	Policing, marking, and queuing
VLAN	Policing and marking
Port and VLAN (PV)	Policing and marking
EtherChannel	Policing and marking
EtherChannel member port	Queuing

Qos Action Restrictions

- The same actions cannot be performed multiple times in a given direction on different targets. In other words, it is not possible to police the packets both on port and VLAN in the input direction. However, the user can police on the input port and on the output VLAN.
- Queuing actions are only allowed in the egress direction and only on the physical port.
- Percentage-based actions like policer cannot be configured on a VLAN, Port and VLAN (PV) and EtherChannel.
- Port channel or VLAN configuration can only have a policing or a marking action, not a queueing action.

Qos Policy priorities

- If a policy on a port and a VLAN are configured with conflicting actions (such as policing or marking actions on both a port and VLAN), the port policy is picked.
- If policy on a VLAN on a given port must be over-written, the user can configure PV policy.

Qos Policy merging

Applicable policies are applied to a given packet in given direction. For example, if you configure egress VLAN-based police and marking, followed by selective queuing on the port, then actions from both policies will be applied for this packet.

The following policy-map configuration restrictions are imposed on an EtherChannel:

- only policing and marking actions are supported at the EtherChannel level
- only queuing actions are supported at the physical member port level

A packet can be marked (dscp or cos fields) by the EtherChannel policy. If the physical member port policy uses a classification based on dscp or cos fields, it must be based on the marked (modified) value. To ensure proper operation, the following restriction is placed on the EtherChannel.

The classification criteria for the policy-map on the physical member ports has to be based only on one type of field:

- dscp
- precedence
- cos
- any non marking field (no dscp or cos based classification)

Classification criteria for the policy-map on the physical member ports cannot be based on a combination of fields. This restriction ensures that if the EtherChannel policy is marking down dscp or cos, the marked (modified) value-based classification can be implemented in hardware.

**Note**

Auto-QoS macros with SRND4 generate class-maps with more than one type of match. These class-maps need to be modified to use only with one matching type when applied on EtherChannel member ports.

**Note**

Classification criteria for the policy-map on the physical member ports cannot be modified to add a new type of field.

Auto-QoS is not supported on EtherChannel or its member ports. A physical port configured with Auto-QoS is not allowed to become a member of a physical port.

Software QoS

At the highest level, there are two types of locally sourced traffic (such as control protocol packets, pings, and telnets) from the switch: high priority traffic (typically the control protocol packets like OSPF Hellos and STP) and low priority packets (all other packet types).

The QoS treatment for locally-sourced packets differs for the two types.

The supervisor engine provides a way to apply QoS to packets processed in the software path. The packets that get this QoS treatment in software can be classified into two types: software switched packets and software generated packets.

On reception, software switched packets are sent to the CPU that in turn sends them out of another interface. For such packets, input software QoS provides input marking and output software QoS provides output marking and queue selection.

The software generated packets are the ones locally sourced by the switch. The type of output software QoS processing applied to these packets is the same as the one applied to software switched packets. The only difference in the two is that the software switched packets take input marking of the packet into account for output classification purpose.

High Priority Packets

High priority packets are marked as one of the following:

- internally with PAK_PRIORITY
- with IP Precedence of 6 (for IP packets)
- with CoS of 6 (for VLAN Tagged packets)

These packets behave as follows:

- They are not dropped because of any policing, AQM, drop thresholds (or any feature that can drop a packet) configured as per the egress service policy. However, they might be dropped because of hardware resource constraints (packet buffers, queue full, etc.).
- They are classified and marked as per the marking configuration of the egress service policy that could be a port or VLAN (refer to the [“Policy Associations” section on page 44-74](#)).
- These high priority packets are enqueued to queue on the egress port based on the following criteria:
 - If there is no egress queuing policy on the port, the packet is queued to a control packet queue that is setup separately from the default queue and has 5 percent of the link bandwidth reserved for it.
 - If there is an egress queuing policy on the port, the queue is selected based on the classification criteria applicable to the packet.

Low Priority Packets

Packets that are not considered high priority (as described previously) are considered *unimportant*. These include locally sourced pings, telnet, and other protocol packets. They undergo the same treatment as any other packet that is transiting the given transmit port including egress classification, marking and queuing.

Applying Flow-based QoS Policy

Flow based QoS enables microflow policing and marking capability to dynamically learn traffic flows. It also rate limits each unique flow to an individual rate. Flow based QoS is available with the built-in NetFlow hardware support.

For more overview information, refer to the [“Flow-based QoS” section on page 44-10](#).

The following steps show how to apply Flow based QoS policy to QoS targets:

-
- | | |
|---------------|---|
| Step 1 | Create a FNF flow record by specifying the key fields that identify unique flows. You can use any FNF flow records that are associated with the FNF monitor. |
| Step 2 | Create a class-map to specify the set of match criteria. Include the FNF flow record from Step 1 in the class-map match criteria using the match flow record command. Then, configure the class-map to match all the match criteria with class-map match-all class_name . |
| Step 3 | Create a policy-map and define actions associated with class-map from Step 2. |

Step 4 Attach the policy to one or more QoS targets.

Examples

The following examples illustrate how to configure Flow based QoS policy and apply microflow policers on individual flows.

Example 1

This example assumes there are multiple users (identified by source IP address) on the subnet 192.168.10.*. The configuration below shows how to configure a flow based QoS policy that uses micro policing to limit the per-user traffic with the source address in the range of 192.168.10.*. The microflow policer is configured with a CIR of 1Mbps, “conform action” as transmit, and “exceed action” as drop.

Step 1: Define an ACL to match traffic with specified source address.

```
Switch(config)# ip access-list extended UserGroup1
Switch(config-ext-nacl)# permit ip 192.168.10.0 0.0.0.255 any
Switch(config-ext-nacl)# exit
Switch(config)#
```

Step 2: Define a flow record to create flows with source address as key.

```
Switch(config)# flow record r1
Switch(config-flow-record)# match ipv4 source address
Switch(config-flow-record)# exit
Switch(config)#
```

Step 3: Configure classmap to match on the UserGroup1 and specify flow record definition for flow creation.

```
Switch(config)# class-map match-all c1
Switch(config-cmap)# match access-group name UserGroup1
Switch(config-cmap)# match flow record r1
Switch(config-cmap)# exit
Switch(config)#
```

Step 4: Configure flow based QoS policy-map with microflow policing action for the matching traffic.

```
Switch(config)# policy-map p1
Switch(config-pmap)# class c1
Switch(config-pmap-c)# police cir 1m
Switch(config-pmap-c-police)# conform-action transmit
Switch(config-pmap-c-police)# exceed-action drop
Switch(config-pmap-c-police)# exit
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
```

Step 5: Attach flow QoS policy to the interface.

```
Switch(config)# interface gigabitEthernet3/1
Switch(config-if)# service-policy input p1
Switch(config-if)#
```

Use the **show** commands (described in the policy and marking sections of this chapter) to display the policy-map configuration and interface specific policy-map statistics.

Example 2.

This example assumes there are multiple users (identified by source IP address) on subnets 192.168.10.* and 172.20.55.*. The first requirement is to police with a CIR of 500Kbps and a PIR of 650Kbps on any TCP traffic originating from 192 network to any destination at any given time. The **exceed action** keyword marks down the dscp value to 32. The second requirement is to police per-user traffic originating from 172 network to CIR of 2Mbps and unconditionally mark the traffic with dscp 10.

Step 1: Define an ACL to match traffic with specified source address.

```
Switch(config)# ip access-list extended UserGroup1
Switch(config-ext-nacl)# permit ip 19 2.168.10.0 0.0.0.255 any
Switch(config-ext-nacl)# exit
Switch(config)# ip access-list extended UserGroup2
Switch(config-ext-nacl)# permit ip 172.20.55.0 0.0.0.255 any
Switch(config-ext-nacl)# exit
Switch(config)#
```

Step 2: Define a flow record to create flows with source address as key.

```
Switch(config)# flow record r1
Switch(config-flow-record)# match ipv4 source address
Switch(config-flow-record)# match ipv4 destination address
Switch(config-flow-record)# match transport tcp source-port
Switch(config-flow-record)# match transport tcp destination-port
Switch(config-flow-record)# exit
Switch(config)# flow record r2
Switch(config-flow-record)# match ipv4 source address
Switch(config-flow-record)# exit
Switch(config)#
```

Step 3: Configure classmap to match on the UserGroup1 and specify flow record definition for flow creation.

```
Switch(config)# class-map match-all c1
Switch(config-cmap)# match access-group name UserGroup1
Switch(config-cmap)# match flow record r1
Switch(config-cmap)# exit
Switch(config)# class-map match-all c2
Switch(config-cmap)# match access-group name UserGroup2
Switch(config-cmap)# match flow record r2
Switch(config-cmap)# exit
Switch(config)#
```

Step 4: Configure flow based QoS policy-map with microflow policing action for the matching traffic.

```
Switch(config)# policy-map p1
Switch(config-pmap)# class c1
Switch(config-pmap-c)# police cir 500k pir 650k
Switch(config-pmap-c-police)# conform-action transmit
Switch(config-pmap-c-police)# exceed-action set-dscp-transmit 32
Switch(config-pmap-c-police)# violate-action drop
Switch(config-pmap-c-police)# exit
Switch(config-pmap-c)# exit
Switch(config-pmap)# class c2
Switch(config-pmap-c)# set dscp 10
Switch(config-pmap-c)# police cir 2m
Switch(config-pmap-c-police)# conform-action transmit
Switch(config-pmap-c-police)# exceed-action drop
Switch(config-pmap-c-police)# exit
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
```

Step 5: Attach flow QoS policy to the interface.

```
Switch(config)# interface gigabitEthernet3/1
Switch(config-if)# service-policy input p1
Switch(config-if)# exit
```

Use the show commands described in the QoS section to display the policy-map configuration and interface specific policy-map statistics.

Example 3

Assume that there are two active flows on FastEthernet interface 6/1:

Table 44-2

SrcIp	DStIp	IPProt	SrcL4Port	DstL4Port
192.168.10.10	192.168.20.20	20	6789	81
192.168.10.10	192.168.20.20	20	6789	21

With the following configuration, each flow is policed to 1000000 bps with an allowed 9000 burst value.

```
Switch(config)# flow record r1
Switch(config-flow-record)# match ipv4 source address
Switch(config-flow-record)# match ipv4 destination address
Switch(config-flow-record)# match transport tcp source-port
Switch(config-flow-record)# match transport tcp destination-port
Switch(config-flow-record)# match transport udp source-port
Switch(config-flow-record)# match transport udp destination-port
Switch(config-flow-record)# exit
Switch(config)# class-map match-all c1
Switch(config-cmap)# match flow record r1
Switch(config-cmap)# exit
Switch(config)# policy-map p1
Switch(config-pmap)# class c1
Switch(config-pmap-c)# police 1000000 9000
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface fastEthernet 6/1
Switch(config-if)# service-policy input p1
Switch(config-if)# end
```

Configuration Guidelines

The general guidelines for creating, configuring, modifying, deleting a flow based QoS policy and attaching (and detaching) a flow based QoS policy to a supported target is the same as described in the QoS section. The following description and restriction applies to Flow based QoS policy:

- A classmap can have multiple match statements but only one FNF flow record can be specified in a class-map.
- A flow record must have at least one key field before it can be used in a classmap. Non-key fields can be present in the flow record. However, all the non-key fields are ignored by microflow QoS. Only key-fields are used for flow creation.
- If a FNF flow record is referenced in any class-map, the flow record cannot be modified. Remove the flow record from all classmaps before modifying it.
- A classmap with a FNF flow record must be configured as **match-all**; traffic hitting the class-map must satisfy all match criteria in the class-map.

- A policy can contain multiple classes and each class-map may contain the same or different FNF flow record.
- Flow based QoS policy and FNF monitor both cannot be applied on the same target at the same time.
- When the interface mode changes from switchport to routed port and vice versa, any Flow QoS policy attached to the port remains applied after the mode change.
- There are 3 types of FNF flow records: ipv4, ipv6, and datalink. The datalink flow record is mutually exclusive with the ipv4 and ipv6 flow records; a classmap with the datalink flow record cannot co-exist with classmap having a ipv4 or ipv6 flow record in the same policy and vice-versa.
- Classmap class-default is not editable; it cannot be configured with the match flow record. Instead, you can configure the policy with a class-map that uses a match any filter and the flow record.
- Traffic is classified in the same order in which class-map is defined in a policy. Hence, if a FNF flow record is the only match statement in a class-map, the classifier matches all packets of the type identified by the flow record. This means that any subsequent class-map in the same policy matching on the same traffic type will be redundant and will never be hit.
- Policers associated with classmap having flow record are called *microflow policers*. The CIR and PIR rates for microflow policers cannot be configured using the percent keyword.
- Flow records within the same policy must include appropriate key fields to ensure flows created from different classmaps are unique and distinct. Otherwise, the resulting flows from different classmap cannot be distinguished. In such cases, policy actions corresponding to the classmap which created the first flow in hardware will apply and results will not be always be as expected.
- Flows from traffic received on different QoS targets are distinct even if the same policy is applied to those targets.
- A flow is aged out if it is inactive for more than 5 seconds; there is no traffic matching the flow for a period longer than 5 sec.
- When a flow is aged out, policer state information associated with the flow is also deleted. When a new flow is created, the policer instance for the flow is re-initialized.
- Flows created by flow based QoS policy exist in hardware only and cannot be exported (as with FNF monitor).
- Per-flow statistics are not available for flows created by flow based QoS policy.
- Class-map statistics indicate the number of packets matching the classifier. It does not represent individual flow stats.
- Policer statistics show the aggregate policer statistics of individual flow.
- Information about the flows created by hardware are not available and not displayed in the show commands associated with QoS policy-map. Only class-map and policer statistics are displayed in the output of the **show policy-map** commands.

Configuring CoS Mutation

CoS reflection and CoS mutation are supported on Supervisor Engine 6-E. Below is an example of how to apply CoS reflection.

Let us say that traffic arrives on interface gigabit 2/5 with VLAN 10 and COS 1, 2, We want traffic to egress interface gigabit 2/6 with outer tag VLAN 11 and CoS copied from C-tag, where C-tag is VLAN 10 and COS 1, 2, ...

```
class-map match-all c2
```

```

        match cos 2

class-map match-all c1

    match cos 1

!

policy-map my

class c1

    set cos 1

class c2

    set cos 2

interface GigabitEthernet2/5

switchport mode trunk

switchport vlan mapping 10 dot1q-tunnel 11

spanning-tree bpdupfilter enable

service-policy input my

!

interface GigabitEthernet2/6

switchport mode trunk

```

Configuring System Queue Limit

Note

This feature is available only from Cisco IOS Release 15.0(2)SG1 and later and Cisco IOS Release XE 3.2.1SG.

With the **hw-module system max-queue-limit** command, the Catalyst 4500 series switch allows you to change the queue limit for all interfaces globally, instead of applying a policy with queue limit to all the interfaces.

To set the queue limit globally, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# hw-module system max-queue-limit <i>max-queue-limit</i>	Sets the queue limit for all interfaces globally. Valid values are from 1024 to 8184. The value must be a multiple of 8.

	Command	Purpose
Step 3	Switch(config)# exit	Returns to privileged EXEC mode.
Step 4	Switch# reload	Reloads standalone supervisor engine.
	or	
	Switch# redundancy reload shelf	Reloads redundancy supervisor engine in SSO mode.
	Switch# redundancy force-switchover	Reloads redundancy supervisor engine in RPR mode. This command must be followed by another redundancy force-switchover.

This is a global configuration command. You can override it with the per port, per class, **queue-limit** command.

For a standalone supervisor engine, you must reboot the engine after applying this command.

For redundant supervisors in SSO mode, you must enter the **redundancy reload shelf** command enforce reboot to both the supervisors. For redundancy supervisors in RPR mode, you must execute two consecutive switchovers to enforce the system queue limit on both the supervisors.

This example shows how to set the queue limit globally to 1024 on a standalone supervisor engine:

```
Switch> enable
Switch# configure terminal
Switch(config)# hw-module system max-queue-limit 1024
Switch(config)# exit
Switch# reload (for standalone supervisors)
Switch# redundancy reload shelf (for redundancy supervisors in SSO mode)
or
Switch# redundancy force-switchover (followed by another redundancy force-switchover, for
redundancy supervisors in RPR mode)
```

Configuring QoS on a Standalone Supervisor Engine 6-E, 6L-E or Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E

Note

HQoS is not supported on the Catalyst 4500 series switch.

MQC-based QoS Configuration

Note

Starting with Cisco IOS Release 12.2(40)SG, Catalyst 4500 series switches with Supervisor Engine 6-E or Supervisor Engine 6L-E use the MQC model of QoS.

To apply QoS, you use the Modular QoS Command-Line Interface (MQC), which is a CLI structure that allows you to complete the following tasks:

- Specify the matching criteria used to define a traffic class.
- Create a traffic policy (policy map). The traffic policy defines the QoS policy actions to be taken for each traffic class.
- Apply the policy actions specified in the policy map to an interface, VLAN, or port and VLAN.

For more information about the MQC, see the “Modular Quality of Service Command-Line Interface” section of the *Cisco IOS Quality of Service Solutions Configuration Guide, Release 12.3*.

Note

The incoming traffic is considered trusted by default. Only when the *trusted boundary* feature is enabled on an interface can the port enter untrusted mode. In this mode, the switch marks the DSCP value of an IP packet and the CoS value of the VLAN tag on the Ethernet frame as “0”.

Platform-supported Classification Criteria and QoS Features

The following table provides a summary of various classification criteria and actions supported on the Catalyst 4500 series switch. For details, refer to the *Catalyst 4500 Series Switch Command Reference*.

Supported classification actions	Descriptions
match access-group	Configures the match criteria for a class map on the basis of the specified ACL.
match any	Configures the match criteria for a class map to be successful match criteria for all packets.
match cos	Matches a packet based on a Layer 2 class of service (CoS) marking.
match [ip] dscp	Identifies a specific IP differentiated service code point (DSCP) value as a match criterion. Up to eight DSCP values can be included in one match statement.
match [ip] precedence	Identifies IP precedence values as match criteria.
match protocol	Configures the match criteria for a class map on the basis of the specified protocol.
match qos-group	Identifies a specific QoS group value as a match criterion. Applies only on the egress direction.
Supported Qos Features	Descriptions

Supported classification actions	Descriptions
police	Configures traffic policing.
police (percent)	Configures traffic policing on the basis of a percentage of bandwidth available on an interface.
police (two rates)	Configures traffic policing using two rates, the committed information rate (CIR) and the peak information rate (PIR).
set cos	Sets the Layer 2 class of service (CoS) value of an outgoing packet.
set dscp	Marks a packet by setting the differentiated services code point (DSCP) value in the type of service (ToS) byte of IPv4 or traffic class byte of IPv6 packet.
set precedence	Sets the precedence value in the packet header.
set qos-group	Sets a QoS group identifier (ID) that can be used later to classify packets.
table map support	Unconditional marking of one packet field based on another packet field.
priority	Gives priority to a class of traffic belonging to a policy map.
shape	Shapes traffic to the indicated bit rate according to the algorithm specified.
bandwidth	Provides a guaranteed minimum bandwidth to each of the eight queues.
dbl	Dynamic buffer limit.
queue-limit	Specifies the maximum number of packets a transmit queue can hold.

Platform Hardware Capabilities

Qos Actions	Numbers of entries supported
Classification	64k input and 64k output classification entries are supported. A given policy can use at most 24k ACLs
Policing	16K policers are supported. Policers are allocated to given direction in blocks of 2k. For example, 2k policers can be used in for input and 14k policers can be used for output. Single rate policers uses one policer entry. Single Rate Three Color Marker (srTCM) (RFC 2697) and Two Rate Three Color Marker (trTCM) (RFC 2698) uses two policer entries
Marking	Marking of Cos and DSCP/Precedence is supported through two marking tables, each capable of supporting 512 entries. There are separate tables for each direction.
Queuing	The queue size is Configurable with the maximum number of entries configurable per port depending on the chassis and line card type.
DBL	You can enable DBL action on all configured class-maps.

Prerequisites for Applying a QoS Service Policy

Unlike the Switch QoS model, there is no prerequisite for enabling QoS on various targets. Just the attachment of a service policy enables QoS and detachment of that policy disables QoS on that target.

Restrictions for Applying a QoS Service Policy

Traffic marking can be configured on an interface, a VLAN, or a port and VLAN. An interface can be a Layer 2 access port, a Layer 2 switch trunk, a Layer 3 routed port, or an EtherChannel. A policy is attached to a VLAN using *vlan configuration* mode.

Attaching QoS service policy to VLANs and EtherChannel is described in the [“Policy Associations” section on page 44-74](#).

Classification

The supervisor engine supports classification of Layer 2, IP, IPv6 packets, and ARP packets marking performed on input can be matched in the output direction. The previous table lists the full set of capabilities. By default, the switch also supports classification resources sharing. Similarly, when the same policy is attached to a port or a VLAN or on per-port per-vlan targets, ACL entries are shared though QoS actions are unique on each target.

For example:

```
class-map c1
  match ip dscp 50

Policy Map p1
  class c1
    police rate 1 m burst 200000
```

If policy-map p1 is applied to interfaces Gig 1/1 and Gig 1/2, 1 CAM entry is used (one ACE that matches IP packets), but 2 policers are allocated (one per target). So, all IP packets with dscp 50 are policed to 1 mbps on interface Gig 1/1 and packets on interface Gig 1/2 are policed to 1 mbps.

**Note**

With Cisco IOS Release 12.2(46)SG, you can issue the **match protocol arp** command. For details, see the *Catalyst 4500 Series Switch Cisco IOS Command Reference*.

Classification Statistics

The supervisor engine supports only packet based classification statistics and TCAM resource sharing. When a policy-map is applied on multiple targets, the command **show policy-map interface** displays the aggregate classification statistics, not those specific to an interface.

**Note**

To obtain per interface policy-map stats, you should configure a unique policy-map name on each interface.

When a policy-map is attached to a port-channel member ports, classification statistics are not displayed.

Configuring a Policy Map

You can attach only one policy map to an interface. Policy maps can contain one or more policy-map classes, each with different match criteria and actions.

Configure a separate policy-map class in the policy map for each type of traffic that an interface receives. Put all commands for each type of traffic in the same policy-map class. QoS does not attempt to apply commands from more than one policy-map class to matched traffic.

Creating a Policy Map

To create a policy map, enter this command:

Command	Purpose
Switch(config)# [no] policy-map <i>policy_name</i>	Creates a policy map with a user-specified name. Use the no keyword to delete the policy map.

Attaching a Policy Map to an Interface

To create a policy map, enter this command:

Command	Purpose
Switch(config)# interface {vlan <i>vlan_ID</i> { fastethernet gigabitethernet } <i>slot/interface</i> Port-channel <i>number</i> }	Selects the interface to configure.
Switch(config-if)# [no] service-policy input <i>policy_map_name</i>	Attaches a policy map to the input direction of the interface. Use the no keyword to detach a policy map from an interface.
Switch(config-if)# end	Exits configuration mode.
Switch# show policy-map interface {vlan <i>vlan_ID</i> { fastethernet gigabitethernet } <i>slot/interface</i> }	Verifies the configuration.

Policing

The supervisor engine supports policers in the following operation modes:

- Single Rate Policer Two Color Marker

This kind of policer is configured with just the committed rate (CIR) and normal burst and it has only conform and exceed actions.

- Single Rate Three Color Marker (srTCM) (RFC 2697)
- Two Rate Three Color Marker (trTCM) (RFC 2698)
- Color Blind Mode

Policing accuracy of 0.75% of configured policer rate.

The engine supports 16384 (16 x 1024, 16K) single rate, single burst policers. 16K policers are organized as 8 banks of 2K policers. The policer banks are dynamically assigned (input or output policer bank) by the software depending on the QoS configuration. So, the 16K policers are dynamically partitioned by software as follows:

- 0 Input Policers and 16K Output Policers
- 2K Input Policers and 14K Output Policers
- 4K Input Policers and 12K Output Policers
- 6K Input Policers and 10K Output Policers
- 8K Input Policers and 8K Output Policers

- 10K Input Policers and 6K Output Policers
- 12K Input Policers and 4K Output Policers
- 14K Input Policers and 2K Output Policers
- 16K Input Policers and 0 Output Policers

These numbers represent individual policer entries in the hardware that support a single rate and burst parameter. Based on this, a switch supports the following number of policers:

- 16K Single Rate Policer with Single Burst (Two Color Marker)
- 8K Single Rate Three Color Marker (srTCM)
- 8K Two Rate Three Color Marker (trTCM)

These policers are partitioned between Input and Output in chunks of 2K policer banks. The different types of policers can all co-exist in the system. However, a given type of policer (srTCM, trTCM etc.) is configurable as a block of 128 policers.

**Note**

Two policers are reserved for internal use.

How to Implement Policing

For details on how to implement the policing features on a Catalyst 4500 Series Switch, refer to the Cisco IOS documentation at the following link:

http://www.cisco.com/en/US/docs/ios/12_2/qos/configuration/guide/qcfpolsh.html

Platform Restrictions

Platform restrictions include the following:

- Multi-policer actions can be specified (setting CoS and IP DSCP is supported).
- When unconditional marking and policer based marking exists on the same field(cos or dscp or precedence), policer-based marking is preferred.
- If policer based service-policy is attached to both a port and a VLAN, port-based policed is preferred by default. To over-ride a specific VLAN policy on a given port, then you must configure a per-port per-vlan policy.
- You should not delete a port-channel with a per-port, per-VLAN QoS policy.

Workaround: Before deleting the port-channel, do the following:

1. Remove any per-port per-VLAN QoS policies, if any.
2. Remove the VLAN configuration on the port-channel with the **no vlan-range** command.

Marking Network Traffic

Marking network traffic allows you to set or modify the attributes of traffic (that is, packets) belonging to a specific class or category. When used in conjunction with network traffic classification, marking network traffic is the foundation for enabling many quality of service (QoS) features on your network. This module contains conceptual information and the configuration tasks for marking network traffic.

Information About Marking Network Traffic

To mark network traffic, you should understand the following concepts:

- “Purpose of Marking Network Traffic” section on page 44-54
- “Benefits of Marking Network Traffic” section on page 44-54
- “Two Methods for Marking Traffic Attributes” section on page 44-55

Purpose of Marking Network Traffic

Traffic marking is used to identify certain traffic types for unique handling, effectively partitioning network traffic into different categories.

After the network traffic is organized into classes by traffic classification, traffic marking allows you to mark (that is, set or change) a value (attribute) for the traffic belonging to a specific class. For instance, you may want to change the class of service (CoS) value from 2 to 1 in one class, or you may want to change the differentiated services code point (DSCP) value from 3 to 2 in another class. In this module, these values are referred to as attributes or marking fields.

Attributes that can be set and modified include the following:

- CoS value of a tagged Ethernet frame
- DSCP/Precedence value in the Type of Service (ToS) byte of IPv4.
- QoS group identifier (ID)
- DSCP /Precedence value in the traffic class byte of IPv6

Benefits of Marking Network Traffic

Traffic marking allows you to fine-tune the attributes for traffic on your network. This increased granularity helps isolate traffic that requires special handling, and thus, helps to achieve optimal application performance.

Traffic marking allows you to determine how traffic will be treated, based on how the attributes for the network traffic are set. It allows you to segment network traffic into multiple priority levels or classes of service based on those attributes, as follows:

- Traffic marking is often used to set the IP precedence or IP DSCP values for traffic entering a network. Networking devices within your network can then use the newly marked IP precedence values to determine how traffic should be treated. For example, voice traffic can be marked with a

particular IP precedence or DSCP and strict priority can then be configured to put all packets of that marking into that queue. In this case, the marking was used to identify traffic for strict priority queue.

- Traffic marking can be used to identify traffic for any class-based QoS feature (any feature available in policy map class configuration mode, although some restrictions exist).

Two Methods for Marking Traffic Attributes

Note

This section describes *Unconditional* marking, which differs from *Policer-based* marking. Unconditional marking is based solely on classification.

Method One: Unconditional Explicit Marking (using the set command)

You specify the traffic attribute you want to change with a set command configured in a policy map. The following table lists the available set commands and the corresponding attribute. For details on the set command, refer to the *Catalyst 4500 Series Switch Command Reference*.

Table 44-4 *set Commands and Applicable Packet Types*

set Commands	Traffic Attribute	Packet Type
set cos	Layer 2 CoS value of the outgoing traffic	Ethernet IPv4, IPv6
set dscp	DSCP value in the ToS byte	IPv4, IPv6
set precedence	precedence value in the packet header	IPv4, IPv6
set qos-group	QoS group ID	Ethernet, IPv4, IPv6

If you are using individual **set** commands, those set commands are specified in a policy map. The following is a sample of a policy map configured with one of the set commands listed in [Table 44-4](#).

In this sample configuration, the **set cos** command has been configured in the policy map (policy1) to mark the CoS attribute:

```
enable
configure terminal
policy map p1
  class class1
    set cos 3
end
```

For information on configuring a policy map, see the “[Creating a Policy Map](#)” section on page 44-52.

The final task is to attach the policy map to the interface. For information on attaching the policy map to the interface, see the “[Attaching a Policy Map to an Interface](#)” section on page 44-52.

Method Two: Unconditional Tablemap-based Marking

You can create a table map that can be used to mark traffic attributes. A table map is a kind of two-way conversion chart that lists and maps one traffic attribute to another. A table map supports a many-to-one type of conversion and mapping scheme. The table map establishes a to-from relationship for the traffic attributes and defines the change to be made to the attribute. That is, an attribute is set to one value that is taken from another value. The values are based on the specific attribute being changed. For instance, the Precedence attribute can be a number from 0 to 7, while the DSCP attribute can be a number from 0 to 63.

The following is a sample table map configuration:

```

table-map table-map1
map from 0 to 1
map from 2 to 3
exit

```

The following table lists the traffic attributes for which a to-from relationship can be established using the table map.

Table 44-5 Traffic Attributes for Which a To-From Relationship Can Be Established

The "To" Attribute	The "From" Attribute
Precedence	CoS, QoS group, DSCP, Precedence
DSCP	COS, QoS group, DSCP, Precedence
CoS	DSCP, QoS group, CoS, Precedence

The following is an example of a policy map (policy2) configured to use the table map (table-map1) created earlier:

```

Policy map policy
  class class-default
    set cos dscp table table-map
exit

```

In this example, a mapping relationship was created between the CoS attribute and the DSCP attribute as defined in the table map.

For information on configuring a policy map to use a table map, [“Configuring a Policy Map” section on page 44-51](#).

The final task is to attach the policy map to the interface. For information on attaching the policy map to the interface, see the [“Attaching a Policy Map to an Interface” section on page 44-52](#).

Marking Action Drivers

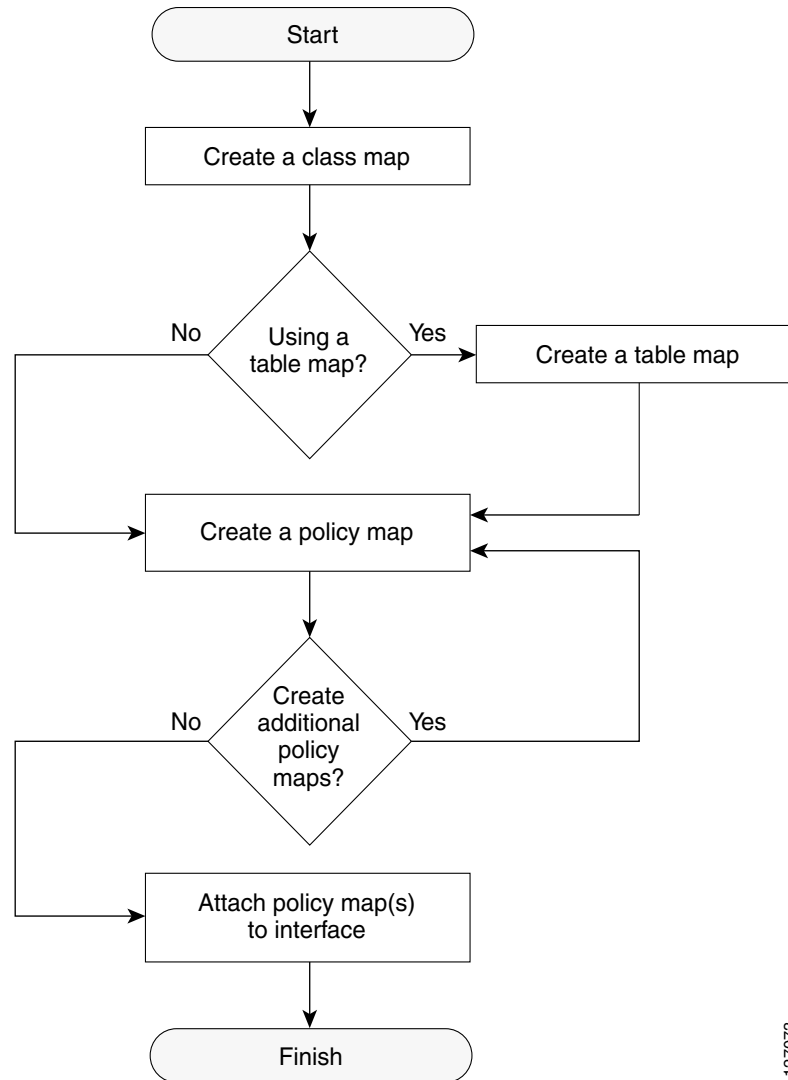

A marking action can be triggered based on one of the two QoS processing steps.

Classification based: In this case, all the traffic matching a class is marked using either explicit or tablemap based method. This method is referred to as *unconditional* marking.

Policer result-based: In this case, a class of traffic is marked differently based on the policer result (conform/exceed/violate) applicable to that packet. This method is referred to as *conditional* marking.

Traffic Marking Procedure Flowchart

[Figure 44-5](#) illustrates the order of the procedures for configuring traffic marking.

Figure 44-5 Traffic marking Procedure Flowchart

127073

Restrictions for Marking Network Traffic

The following restrictions apply to packet marking actions:

- QoS-group can be marked only in the input direction and can only support unconditional explicit marking.
- Only explicit marking is supported for policer-based marking.

Multi-attribute Marking Support

The supervisor engine can mark more than one QoS attribute of a packet matching a class of traffic. For example, DSCP, CoS, and QoS-group can all be set together, using either explicit or tablemap-based marking.

**Note**

When using unconditional explicit marking of multiple fields or policer-based multi-field, multi-region (conform/exceed/violate) marking the number of tablemaps that can be setup in TOS or COS marking tables will be less than the maximum supported.

Hardware Capabilities for Marking

Supervisor Engine 6-E, and Supervisor Engine 6L-E provide a 128 entry marking action (Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E provide a 256 entry marking action) where each entry specifies the type of marking actions on CoS and DSCP/Precedence fields as well as policer action to transmit/markdown/drop a packet.

One such table is supported for each direction, input and output. This table is used for both unconditional marking as well as policer-based marking. It can be used to support 256 unique marking actions or 64 unique policer-based actions or a combinations of the two.

For each of the marking fields (COS and DSCP), the supervisor engine provides 512 entry marking tables for each direction. These are similar to mapping tables available on supervisor engines that support the switch QoS model. However, these provide an ability to have multiple unique mapping tables that are setup by the user.

For example, the TOS marking table provides marking of DSCP/Precedence fields and can be used as one of the following:

- 8 different tablemaps with each mapping the 64 DSCP or qos-group values to another DSCP
- 64 (32) different tablemaps with each one mapping 8 CoS (16 CoS and CFi) values to DSCP in input (output) direction
- a combination of above two types of tablemaps

Similar mappings are available on the 512 entry COS marking table.

Configuring the Policy Map Marking Action

This section describes how to establish unconditional marking action for network traffic.

As a prerequisites, create a class map (*ipp5*) and a policy map. (Refer to the [“Configuring a Policy Map” section on page 44-51](#)).

**Note**

The marking action command options have been extended (refer to [Table 44-4 on page 44-55](#) and [Table 44-5 on page 44-56](#)).

Configuring Tablemap-based Unconditional Marking

To configure table-map based unconditional marking, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# table-map name	Configures a tablemap.
Step 3	Switch(config-tablemap)# map from from_value to to_value	Creates a map from a <i>from_value</i> to a <i>to_value</i>

	Command	Purpose
Step 4	Switch(config-tablemap)# exit	Exits table-map configuration mode.
Step 5	Switch(config)# policy-map <i>name</i>	Enters policy-map configuration mode.
Step 6	Switch(config-p)# class <i>name</i>	Selects the class for QoS actions.
Step 7	Switch(config-p-c)# set cos dscp prec cos dscp prec qos-group [table <i>name</i>]	Selects the marking action based on an implicit or explicit table-map.
Step 8	Switch(config-p-c)# end	Exits configuration mode.
Step 9	Switch# show policy-map <i>name</i>	Verifies the configuration of the policy-map.
Step 10	Switch# show table-map <i>name</i>	Verifies the configuration of the table-map.

The following example shows how to enable marking action using table-map.

```
Switch(config)# table-map dscp2Cos
Switch(config-tablemap)# map from 8 to 1
Switch(config-tablemap)# exit
Switch(config)# policy-map p1
Switch(config-pmap)# class ip5
Switch(config-pmap-c)# set cos dscp table dscp2Cos
Switch(config-pmap-c)# end
Switch# show policy-map p1

Policy Map p1
  Class ip5
    set cos dscp table dscp2Qos

Switch# show table-map dscp2Cos

Table Map dscp2Cos
  from 8 to 1
  default copy
```

Configuring Policer Result-based Conditional Marking

To configure policer result-based conditional marking, setup a single rate or dual rate policer. Refer to the [“How to Implement Policing”](#) section on page 44-53.

This example shows how to configure a two rate three-color policer with explicit actions for each policer region:

```
Switch# configure terminal
Switch(config-pmap-c)# policer cir percent 20 pir percent 30
Switch(config-pmap-c-policer)# conform-action set-cos-transmit 3 set-dscp-transmit 10
Switch(config-pmap-c-policer)# exceed-action set-cos-transmit 4 set-dscp-transmit 20
Switch(config-pmap-c-policer)# violate action drop
Switch# show policy-map p1

Policy Map police
  Class ip5
    police cir percent 20 pir percent 30
      conform-action set-cos-transmit 3
      conform-action set-dscp-transmit af11
      exceed-action set-cos-transmit 4
      exceed-action set-dscp-transmit af22
      violate-action drop
```

Marking Statistics

The marking statistics indicate the number of packets that are *marked*.

For unconditional marking, the *classification entry* points to an entry in the marking action table that in turn indicates the fields in the packet that are marked. Therefore, the classification statistics by itself indicates the unconditional marking statistics.

For a conditional marking using policer, provided the policer is a packet rate policer, you cannot determine the number packets marked because the policer only provides byte statistics for different policing results.

Shaping, Sharing (Bandwidth), Priority Queuing, Queue-limiting and DBL

The Catalyst 4500 series switch supports the Classification-based (class-based) mode for transmit queue selection. In this mode, the transmit queue selection is based on the Output QoS classification lookup.

Note

Only output (egress) queuing is supported.

The supervisor engine supports 8 transmit queues per port. Once the forwarding decision has been made to forward a packet out a port, the output QoS classification determines the transmit queue into which the packet needs to be enqueued.

By default, without any service policies associated with a port, there are two queues (a control packet queue and a default queue) with no guarantee as to the bandwidth or kind of prioritization. The only exception is that system generated control packets are enqueued into control packet queue so that control traffic receives some minimum link bandwidth.

Queues are assigned when an output policy attached to a port with one or more queuing related actions for one or more classes of traffic. Because there are only eight queues per port, there can be at most eight classes of traffic (including the reserved class, class-default) with queuing action(s). Classes of traffic that do not have any queuing action are referred to as *non-queuing* classes. Non-queuing class traffic ends up using the queue corresponding to class class-default.

When a queuing policy (a policy with queuing action) is attached, the control packet queue is deleted and the control packets are enqueued into respective queue per their classification. An egress QoS class must be configured to match IP Precedence 6 and 7 traffic, and a bandwidth guarantee must be configured.

Dynamic resizing of queues (queue limit class-map action) is supported through the use of the **queue-limit** command. Based on the chassis and line card type, all eight queues on a port are configured with equal queue size.

Shaping

Shaping enables you to delay out-of-profile packets in queues so that they conform to a specified profile. Shaping is distinct from policing. Policing drops packets that exceed a configured threshold, whereas shaping *buffers* packets so that traffic remains within a given threshold. Shaping offers greater *smoothness* in handling traffic than policing. You enable average-rate traffic shaping on a traffic class with the **policy-map** class configuration command.

The supervisor engine supports a range of 32kbps to 10 gbps for shaping, with a precision of approximately +/- 0.75 per cent.

When a queuing class is configured without any explicit shape configuration, the queue shape is set to the link rate.

To configure class-level shaping in a service policy, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# policy-map <i>policy-map-name</i>	Creates a policy map by entering the policy-map name, and enter policy-map configuration mode. By default, no policy maps are defined.
Step 3	Switch(config-pmap)# class <i>class-name</i>	Specifies the name of the class whose traffic policy you want to create or change, and enter policy-map class configuration mode. By default, no traffic classes are defined.
Step 4	Switch(config-pmap-class)# shape average { <i>cir-bps</i> [<i>optional_postfix</i>] percent <i>percent</i> }	Enables average-rate traffic shaping. You can specify the shaping rate in absolute value or as a percentage: <ul style="list-style-type: none"> For <i>cir-bps</i> [<i>optional_postfix</i>], specify the shaping rate in bps. Range is 32000 to 10000000000 bps. Supply an optional postfix (K, M, G). For <i>percent</i>, specify the percentage of link rate to shape the class of traffic. The range is 1 to 100. By default, average-rate traffic shaping is disabled.
Step 5	Switch(config-pmap-class)# exit	Returns to policy-map configuration mode.
Step 6	Switch(config-pmap)# exit	Returns to global configuration mode.
Step 7	Switch(config)# interface <i>interface-id</i>	Specifies a physical port and enter interface configuration mode.
Step 8	Switch(config-interface)# service-policy output <i>policy-map-name</i>	Specifies the policy-map name, and apply it a physical interface.
Step 9	Switch(config-interface)# end	Returns to privileged EXEC mode.
Step 10	Switch# show policy-map [<i>policy-map-name</i> [class <i>class-map-name</i>]] or Switch# show policy-map interface <i>interface-id</i>	Verifies your entries.
Step 11	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To delete an existing policy map, use the **no policy-map** *policy-map-name* global configuration command. To delete an existing class, use the **no class** *class-name* policy-map configuration command. To disable the average-rate traffic shaping, use the **no shape average** policy-map class configuration command.

This example shows how to configure class-level, average-rate shaping. It limits traffic class class1 to a data transmission rate of 256 kbps:

```
Switch# configure terminal
Switch(config)# policy-map policy1
Switch(config-pmap)# class class1
Switch(config-pmap-c)# shape average 256000
```

```
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# service-policy output policy1
Switch(config-if)# end
Switch#
```

```
Switch# show policy-map policy1
Policy Map policy1
Class class1
  shape average 256000
```

This example shows how to configure class-level, average shape percentage to 32% of link bandwidth for queuing-class traffic:

```
Switch# configure terminal
Switch(config)# policy-map queuing-policy
Switch(config-pmap)# class queuing-class
Switch(config-pmap-c)# shape average percent 32
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# service-policy output queuing-policy1
Switch(config-if)# end
Switch #
```

```
Switch# show policy-map queuing-policy
Policy Map queuing-policy
Class queuing-class
  Average Rate Traffic Shaping
  cir 32%
```

Sharing(bandwidth)

The bandwidth assigned to a class of traffic is the minimum bandwidth that is guaranteed to the class during congestion. Transmit Queue Sharing is the process by which output link bandwidth is shared among multiple queues of a given port.

The supervisor engine supports a range of 32 kbps to 10 gbps for sharing, with a precision of approximately +/- 0.75 per cent. The sum of configured bandwidth across all queuing classes should not exceed the link bandwidth.

To configure class-level bandwidth action in a service policy, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# policy-map <i>policy-map-name</i>	Creates a policy map by entering the policy-map name, and enter policy-map configuration mode. By default, no policy maps are defined.
Step 3	Switch(config-pmap)# class <i>class-name</i>	Specifies the name of the class whose traffic policy you want to create or change, and enter policy-map class configuration mode. By default, no traffic classes are defined.

	Command	Purpose
Step 4	Switch(config-pmap-class)# bandwidth { <i>bandwidth-kbps</i> percent <i>percent</i> }	Specifies the minimum bandwidth provided to a class belonging to the policy map when there is traffic congestion in the switch. If the switch is not congested, the class receives more bandwidth than you specify with the bandwidth command. By default, no bandwidth is specified. You can specify the bandwidth in kbps or as a percentage: o For <i>bandwidth-kbps</i> , specify the bandwidth amount in kbps assigned to the class. The range is 32 to 10000000. o For <i>percent</i> , specify the percentage of available bandwidth assigned to the class. The range is 1 to 100. Specify all the class bandwidths in either kbps or in percentages, but not a mix of both.
Step 5	Switch(config-pmap-class)# exit	Returns to policy-map configuration mode.
Step 6	Switch(config-pmap)# exit	Returns to global configuration mode.
Step 7	Switch(config)# interface <i>interface-id</i>	Specifies a physical port and enter interface configuration mode.
Step 8	Switch(config-interface)# service-policy output <i>policy-map-name</i>	Specifies the policy-map name, and apply it a physical interface.
Step 9	Switch(config-interface)# end	Returns to privileged EXEC mode.
Step 10	Switch# show policy-map [<i>policy-map-name</i> [class <i>class-map-name</i>]] or Switch# show policy-map interface <i>interface-id</i>	Verifies your entries.
Step 11	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To delete an existing policy map, use the **no policy-map** *policy-map-name* global configuration command. To delete an existing class, use the **no class** *class-name* policy-map configuration command. To return to the default bandwidth, use the **no bandwidth** policy-map class configuration command.

This example shows how to create a class-level policy map called policy11 for three classes called prec1, prec2, and prec3. In the policy for these classes, 30 percent of the available bandwidth is assigned to the queue for the first class, 20 percent is assigned to the queue for the second class, and 10 percent is assigned to the queue for the third class.

```
Switch # configure terminal
Switch(config)# policy-map policy11
Switch(config-pmap)# class prec1
Switch(config-pmap-c)# bandwidth percent 30
Switch(config-pmap-c)# exit
Switch(config-pmap)# class prec2
Switch(config-pmap-c)# bandwidth percent 20
Switch(config-pmap-c)# exit
Switch(config-pmap)# class prec3
Switch(config-pmap-c)# bandwidth percent 10
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# service-policy output policy11
```

```

Switch(config-if)# end
Switch #

Switch# show policy-map policy11
Policy Map policy11
  Class prec1
    bandwidth percent 30
  Class prec2
    bandwidth percent 20
  Class prec3
    bandwidth percent 10

```

This example shows how to create a class-level policy map called policy11 for three classes called prec1, prec2, and prec3. In the policy for these classes, 300 mbps of the available bandwidth is assigned to the queue for the first class, 200 mbps is assigned to the queue for the second class, and 100 mbps is assigned to the queue for the third class.

```

Switch # configure terminal
Switch(config)# policy-map policy11
Switch(config-pmap)# class prec1
Switch(config-pmap-c)# bandwidth 300000
Switch(config-pmap-c)# exit
Switch(config-pmap)# class prec2
Switch(config-pmap-c)# bandwidth 200000
Switch(config-pmap-c)# exit
Switch(config-pmap)# class prec3
Switch(config-pmap-c)# bandwidth 100000
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# service-policy output policy11
Switch(config-if)# end
Switch #

Switch# show policy-map policy11
Policy Map policy11
  Class prec1
    bandwidth 300000 (kbps)
  Class prec2
    bandwidth 200000 (kbps)
  Class prec3
    bandwidth 100000 (kbps)

```

When a queuing class is configured without any explicit share/bandwidth configuration, because the queue is not guaranteed any minimum bandwidth, the hardware queue is programmed to get a share of any unallocated bandwidth on the port as shown in the following example.

If there is no bandwidth remaining for the new queue or if the unallocated bandwidth is not sufficient to meet the minimum configurable rate (32kbps) for all queues which do not have any explicit share/bandwidth configuration, then the policy association is rejected.

For example, if there are two queues as given below

```

policy-map queue-policy
  class q1
    bandwidth percent 10

  class q2
    bandwidth percent 20

```

then the bandwidth allocation for the queues is as follows

```

q1 = 10%
q2 = 20%

```

```
class-default = 70%
```

Similarly, when another queuing class (say q3) is added without any explicit bandwidth (say, just a shape command), then the bandwidth allocation is

```
q1 = 10%
q2 = 20%
q3 = min(35%, q3-shape-rate)
class-default = max(35%, (100 - (q1 + q2 + q3)))
```

Priority queuing

Only one transmit queue on a port can be configured as *strict priority* (termed Low Latency Queue, or LLQ).

LLQ provides strict-priority queuing for a traffic class. It enables delay-sensitive data, such as voice, to be sent *before* packets in other queues. The priority queue is serviced first until it is empty or until it is under its shape rate. Only one traffic stream can be destined for the priority queue per class-level policy. You enable the priority queue for a traffic class with the **priority policy-map class** configuration command at the class mode.

A LLQ can starve other queues unless it is rate limited. The supervisor engine does not support *conditional policing* where a 2-parameter policer (rate, burst) becomes effective when the queue is *congested* (based on queue length). However, it supports application of an unconditional policer to rate limit packets enqueued to the strict priority queue.

When a priority queue is configured on one class of a policy map, only *bandwidth remaining* is accepted on other classes, guaranteeing a minimum bandwidth for other classes from the remaining bandwidth of what is left after using the priority queue. When a priority queue is configured with a policer, then either *bandwidth* or *bandwidth remaining* is accepted on other classes.

Note

Use *bandwidth* or *bandwidth remaining* on all classes. You cannot apply *bandwidth* on one class and *bandwidth remaining* on another class within a policy map.

To enable class-level priority queuing in a service policy, follow these steps:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# policy-map <i>policy-map-name</i>	Creates a policy map by entering the policy-map name, and enter policy-map configuration mode. By default, no policy maps are defined.
Step 3	Switch(config-pmap)# class <i>class-name</i>	Specifies the name of the class whose traffic policy you want to create or change, and enter policy-map class configuration mode. By default, no traffic classes are defined.
Step 4	Switch(config-pmap-class)# priority	Enables the strict-priority queue, and give priority to a class of traffic. By default, strict-priority queueing is disabled.
Step 5	Switch(config-pmap-class)# exit	Returns to policy-map configuration mode.
Step 6	Switch(config-pmap)# exit	Returns to global configuration mode.
Step 7	Switch(config)# interface <i>interface-id</i>	Specifies a physical port and enter interface configuration mode.

	Command	Purpose
Step 8	Switch(config-interface)# service-policy output <i>policy-map-name</i>	Specifies the policy-map name, and apply it a physical interface.
Step 9	Switch(config-interface)# end	Returns to privileged EXEC mode.
Step 10	Switch# show policy-map [<i>policy-map-name</i> [class <i>class-map-name</i>]] or Switch# show policy-map interface <i>interface-id</i>	Verifies your entries.
Step 11	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To delete an existing policy map, use the **no policy-map** *policy-map-name* global configuration command. To delete an existing class, use the **no class** *class-name* policy-map configuration command. To disable the priority queue, use the **no priority** *policy-map-class* configuration command.

This example shows how to configure a class-level policy called policy1. Class 1 is configured as the priority queue, which is serviced first until it is empty.

```
Switch# configure terminal
Switch(config)# policy-map policy1
Switch(config-pmap)# class class1
Switch(config-pmap-c)# priority
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# service-policy output policy1
Switch(config-if)# end
Switch #

Switch# show policy-map policy1
  Policy Map policy1
    Class class1
      priority
```

Queue-limiting

When a class-based queue is instantiated on a physical port, it is set up with a default size. This size represents the number of queue entries in which packets belonging to that class of traffic can be queued. The scheduler moves packets from the queue that are ready for transmission, based on the queue shape, bandwidth, and priority configuration.

The queue-limit provides the maximum number of packets that can be in the queue at any given time. When the queue is full, an attempt to enqueue any further packets results in tail drop. However, if dynamic buffer limiting (DBL) is enabled on the queue, packets get a probabilistic drop based on the DBL algorithm, even when the queue is not full.

The **queue-limit** command can be configured under a class only when queue scheduling, such as bandwidth, shape, or priority is already configured. The only exception to this requirement is the support of the stand-alone **queue-limit** command on the class-default class.

Queue Memory

The number of queue entries that can be allocated has to be a multiple of 8 and can range from 16 to 8184. When a class-based queue is instantiated on a physical port, it is given a default number of entries. This default queue size is based on the number of slots in the chassis and the number of front-panel ports in each slot.

Supervisor Engine 6-E, and Supervisor Engine 6L-E have 512 K (524,288) queue entries of which the system sets aside 100 K (102,400) queue entries in a free reserve pool. Of the remaining 412 K (421,88), the drop port is provided 8184 entries and the CPU ports are assigned 11704 entries. Supervisor Engine 7-E and Supervisor Engine 8-E have 1M (1,048,576) queue entries of which the system sets aside 100K (102,400) queue entries in a free reserve pool. Of the remaining queue entries, the drop port is provided 8184 entries, 24576 entries for recirculation ports and the CPU ports are assigned 8656 entries.

Supervisor Engine 7L-E has a 512 K queue entries.

The remaining entries are divided equally among the slots in the chassis. In a redundant chassis the two supervisor slots are treated as one for the purpose of this entries distribution. Within each slot the number of queue entries are equally divided among the front-panel ports present on the line card in that slot.

When the user configuration for queue entries on an interface exceeds its dedicated quota, the system attempts to satisfy the configuration from the free reserve pool. The entries from the free reserve pool are allocated to interfaces on a first-come first-served basis.

Service Policy Association

When a QoS service-policy with queuing actions is configured, but no explicit queue-limit command is attached in the egress direction on a physical interface, each of the class-based queues gets the same number of queue entries from within the dedicated quota for that physical port. When a queue is explicitly given a size using the queue-limit command, the switch tries to allocate all the entries from within the dedicated quota for the interface. If the required number of entries is greater than the dedicated quota for the interface, the switch tries to allocate the entries from the free reserve.

The queue entries associated with a queue always have to be consecutive. This requirement can result in fragmentation of the 512K of the queue entries that are shared across the switch. For example, an interface may not have enough entries for a queue in its dedicated quota and thus have to use the free reserve to set up that queue. In this case, the queue entries from the dedicated quota remain unused because they cannot be shared with any other port or slot.

When the QoS service-policy associated with an interface is removed, any queue entries taken from the free reserve are returned to the free reserve pool. The interface queuing configuration reverts to two queues — class-default and the control-packet queue with default shape, bandwidth, and size. The control-packet queue is set up with size 16 whereas the default queue is set up with the maximum size possible based on the dedicated quota for that interface.

Queue Allocation Failure

The switch might not be able to satisfy the explicit queue size required on one or more queues on an interface because of fragmentation of queue memory or lack of enough free reserve entries. In this scenario, the switch logs an error message to notify you of the failure. The QoS service-policy is left configured on the interface. You can fix the error by removing the QoS service-policy and examining the current usage of the queue entries from the free reserve by other ports on the switch.

To configure class-level queue-limit in a service policy, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# policy-map <i>policy-map-name</i>	Creates a policy map by entering the policy-map name, and enter policy-map configuration mode. By default, no policy maps are defined.
Step 3	Switch(config-pmap)# class <i>class-name</i>	Specifies the name of the class whose traffic policy you want to create or change, and enter policy-map class configuration mode. By default, no traffic classes are defined.
Step 4	Switch(config-pmap-class)# shape average { <i>cir-bps</i> [<i>optional_postfix</i>] percent <i>percent</i> }	Enables average-rate traffic shaping. You can specify the shaping rate in absolute value or as a percentage: <ul style="list-style-type: none"> For <i>cir-bps</i> [<i>optional_postfix</i>], specify the shaping rate in bps. Range is 32000 to 10000000000 bps. Supply an optional postfix (K, M, G). For <i>percent</i>, specify the percentage of link rate to shape the class of traffic. The range is 1 to 100. By default, average-rate traffic shaping is disabled.
Step 5	Switch(config-pmap-class)# queue-limit <i>number-of-packets</i>	Provides an explicit queue size in packets. The size must be a multiple of 8 and ranging from 16 to 8184.
Step 6	Switch(config-pmap-class)# exit	Returns to policy-map configuration mode.
Step 7	Switch(config-pmap)# exit	Returns to global configuration mode.
Step 8	Switch(config)# interface <i>interface-id</i>	Specifies a physical port and enter interface configuration mode.
Step 9	Switch(config-interface)# service-policy output <i>policy-map-name</i>	Specifies the policy-map name, and apply it a physical interface.
Step 10	Switch(config-interface)# end	Returns to privileged EXEC mode.
Step 11	Switch# show policy-map [<i>policy-map-name</i> [class <i>class-map-name</i>]] or Switch# show policy-map interface <i>interface-id</i>	Verifies your entries.
Step 12	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To remove the explicit queue size use the **no queue-limit** command under the class in a policy-map.

This example shows how to configure a class-based queue with an explicit **queue-limit** command. It limits traffic class class1 to a queue of size 4048:

```
Switch# configure terminal
Switch(config)# policy-map policy1
Switch(config-pmap)# class class1
Switch(config-pmap-c)# shape average 256000
Switch(config-pmap-c)# queue-limit 4048
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# service-policy output policy1
```

```

Switch(config-if)# end
Switch#

Switch# show policy-map policy1
  Policy Map policy1
    Class class1
      shape average 256000
      queue-limit 4048
Switch#

```

Active Queue Management (AQM) via Dynamic Buffer Limiting (DBL)

AQM provides buffering control of traffic flows prior to queuing a packet into a transmit queue of a port. This is of significant interest in a shared memory switch, ensuring that certain flows do not hog the switch packet memory.

Note

The supervisor engine supports active switch buffer management via DBL.

Except for the default class of traffic (class class-default), you can configure DBL action only when at least one of the other queuing action is configured.

To configure class-level dbf action along with shaping in a service policy, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# policy-map <i>policy-map-name</i>	Creates a policy map by entering the policy-map name, and enter policy-map configuration mode. By default, no policy maps are defined.
Step 3	Switch(config-pmap)# class <i>class-name</i>	Specifies the name of the class whose traffic policy you want to create or change, and enter policy-map class configuration mode. By default, no traffic classes are defined.
Step 4	Switch(config-pmap-class)# shape average <i>cir-bps</i>	Enables average-rate traffic shaping. Specify the committed information rate, the bit rate that traffic is shaped to, in bps. The range is 32000 to 10000000000 bps. By default, average-rate traffic shaping is disabled.
Step 5	Switch(config-pmap-class)# dbl	Enables DBL on the queue associated with this class of traffic
Step 6	Switch(config-pmap-class)# exit	Returns to policy-map configuration mode.
Step 7	Switch(config-pmap)# exit	Returns to global configuration mode.
Step 8	Switch(config)# interface <i>interface-id</i>	Specifies a physical port and enter interface configuration mode.
Step 9	Switch(config-interface)# service-policy output <i>policy-map-name</i>	Specifies the policy-map name, and apply it a physical interface.
Step 10	Switch(config-interface)# end	Returns to privileged EXEC mode.

	Command	Purpose
Step 11	<pre>Switch# show policy-map [<i>policy-map-name</i> [<i>class</i> <i>class-map-name</i>]] or Switch# show policy-map interface <i>interface-id</i></pre>	Verifies your entries.
Step 12	<pre>Switch# copy running-config startup-config</pre>	(Optional) Saves your entries in the configuration file.

To delete an existing policy map, use the **no policy-map** *policy-map-name* global configuration command. To delete an existing class, use the **no class** *class-name* policy-map configuration command. To disable DBL on the associated queue, use the **no db1** policy-map class configuration command.

The following example shows how to configure class-level, DBL action along with average-rate shaping. It enables DBL on the queue associated with traffic-class *class1*.

```
Switch# configure terminal
Switch(config)# policy-map policy1
Switch(config-pmap)# class class1
Switch(config-pmap-c)# shape average 256000
Switch(config-pmap-c)# db1
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitEthernet1/1
Switch(config-if)# service-policy output policy1
Switch(config-if)# end
Switch#

Switch# show policy-map policy1
Policy Map policy1
  Class class1
    shape average 256000
    db1
```

Transmit Queue Statistics

Transmit queue statistics are visible by entering the **show policy-map interface** command:

```
Switch# show policy-map interface gigabitEthernet 1/1
GigabitEthernet1/1

Service-policy output: queuing-policy

Class-map: queuing-class (match-all)
  1833956 packets
  Match: cos 1
  Queueing
    (total drops) 1006239
    (bytes output) 56284756
  shape (average) cir 320000000, bc 1280000, be 1280000
  target shape rate 320000000

Class-map: class-default (match-any)
  1 packets
  Match: any

    (total drops) 0
    (bytes output) 2104
```

Enabling Per-Port Per-VLAN QoS

The per-port per-VLAN QoS feature enables you to specify different QoS configurations on different VLANs on a given interface. Typically, you use this feature on trunk or voice VLANs (Cisco IP Phone) ports, as they belong to multiple VLANs.

To configure per-port per-VLAN QoS, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface { fastethernet gigabitethernet tengigabitethernet } slot/interface Port-channel <i>number</i>	Selects the interface to configure.
Step 2	Switch(config-if)# vlan-range <i>vlan_range</i>	Specifies the VLANs involved.
Step 3	Switch(config-if-vlan-range)# service-policy { input output } <i>policy-map</i>	Specifies the policy-map and direction.
Step 4	Switch(config-if-vlan-range)# exit	Exits class-map configuration mode.
Step 5	Switch(config-if)# end	Exits configuration interface mode.
Step 6	Switch# show policy-map interface <i>interface_name</i>	Verifies the configuration.

Example 1

Figure 44-6 displays a sample topology for configuring PVQoS. The trunk port gi3/1 is comprised of multiple VLANs (101 and 102). Within a port, you can create your own service policy per VLAN. This policy, performed in hardware, might consist of ingress and egress Policing or giving precedence to voice packet over data.

Figure 44-6 Per-Port Per-VLAN Topology

The following configuration file shows how to perform ingress and egress policing per VLAN using the policy-map P31_QOS applied to port Gigabit Ethernet 3/1:

```
ip access-list 101 permit ip host 1.2.2.2 any
```

```

ip access-list 103 permit ip any any
Class-map match-all RT

match ip access-group 101
Class-map Match all PD

match ip access-group 103
Policy-map P31_QoS

Class RT

Police 200m 16k conform transmit exceed drop

Class PD

Police 100m 16k conform transmit exceed drop

Interface Gigabit 3/1
Switchport
Switchport trunk encapsulation dot1q
Switchport trunk allowed vlan 101-102
  Vlan range 101
    Service-policy input P31_QoS
    Service-policy output P31_QoS
  Vlan range 102
    Service-policy input P32_QoS
    Service-policy output P32_QoS

```

Example 2

Let us assume that interface Gigabit Ethernet 6/1 is a trunk port and belongs to VLANs 20, 300-301, and 400. The following example shows how to apply policy-map p1 for traffic in VLANs 20 and 400 and policy map p2 to traffic in VLANs 300 through 301:

```

Switch# configure terminal
Switch(config)# interface gigabitEthernet 6/1
Switch(config-if)# vlan-range 20,400
Switch(config-if-vlan-range)# service-policy input p1
Switch(config-if-vlan-range)# exit
Switch(config-if)# vlan-range 300-301
Switch(config-if-vlan-range)# service-policy output p2
Switch(config-if-vlan-range)# end
Switch#

```

Example 3

The following command shows how to display policy-map statistics on VLAN 20 configured on Gigabit Ethernet interface 6/1:

```

Switch# show policy-map interface gigabitEthernet 6/1 vlan 20

GigabitEthernet6/1 vlan 20

Service-policy input: p1

Class-map: c1 (match-all)
  0 packets
  Match: cos 1
  Match: access-group 100
  police:
    cir 100000000 bps, bc 3125000 bytes

```

```

conformed 0 bytes; actions:
  transmit
exceeded 0 bytes; actions:
  drop
conformed 0000 bps, exceed 0000 bps

Class-map: class-default (match-any)
  0 packets
  Match: any

```

Example 4

The following command shows how to display policy-map statistics on all VLANs configured on Gigabit Ethernet interface 6/1:

```
Switch# show policy-map interface gigabitEthernet 6/1
```

```
GigabitEthernet6/1 vlan 20
```

```
Service-policy input: p1
```

```

Class-map: c1 (match-all)
  0 packets
  Match: cos 1
  Match: access-group 100
  police:
    cir 100000000 bps, bc 3125000 bytes
    conformed 0 bytes; actions:
      transmit
    exceeded 0 bytes; actions:
      drop
    conformed 0000 bps, exceed 0000 bps

```

```

Class-map: class-default (match-any)
  0 packets
  Match: any

```

```
GigabitEthernet6/1 vlan 300
```

```
Service-policy output: p2
```

```

Class-map: c1 (match-all)
  0 packets
  Match: cos 1
  Match: access-group 100
  QoS Set
    dscp 50
  police:
    cir 200000000 bps, bc 6250000 bytes
    conformed 0 bytes; actions:
      transmit
    exceeded 0 bytes; actions:
      drop
    conformed 0000 bps, exceed 0000 bps

```

```

Class-map: class-default (match-any)
  0 packets
  Match: any

```

```
GigabitEthernet6/1 vlan 301
```

```
Service-policy output: p2
```

```

Class-map: c1 (match-all)
  0 packets
  Match: cos 1
  Match: access-group 100
  QoS Set
    dscp 50
  police:
    cir 200000000 bps, bc 6250000 bytes
    conformed 0 bytes; actions:
      transmit
    exceeded 0 bytes; actions:
      drop
    conformed 0000 bps, exceed 0000 bps

```

Policy Associations

The supervisor engine supports per-port, per-VLAN policies. The associated policies are attached to the interface, VLAN, and a specific VLAN on a given port, respectively.

A policy can be associated with a variety of objects. The following table lists the objects and the actions allowed.

Table 44-3 Table QoS Policy Associations

Object	Action
Physical port	Policing, marking, and queuing
VLAN	Policing and marking
Port and VLAN (PV)	Policing and marking
EtherChannel	Policing and marking
EtherChannel member port	Queuing

Qos Action Restrictions

- The same actions cannot be performed multiple times in a given direction on different targets. In other words, it is not possible to police the packets both on port and VLAN in the input direction. However, the user can police on the input port and on the output VLAN.
- Queuing actions are only allowed in the egress direction and only on the physical port.
- Percentage-based actions like policer cannot be configured on a VLAN, Port and VLAN (PV) and EtherChannel.
- Port channel or VLAN configuration can only have a policing or a marking action, not a queueing action.

Qos Policy priorities

- If a policy on a port and a VLAN are configured with conflicting actions (such as policing or marking actions on both a port and VLAN), the port policy is picked.
- If policy on a VLAN on a given port must be over-written, the user can configure PV policy.

Qos Policy merging

Applicable policies are applied to a given packet in given direction. For example, if you configure egress VLAN-based police and marking, followed by selective queuing on the port, then actions from both policies will be applied for this packet.

The following policy-map configuration restrictions are imposed on an EtherChannel:

- only policing and marking actions are supported at the EtherChannel level
- only queuing actions are supported at the physical member port level

A packet can be marked (dscp or cos fields) by the EtherChannel policy. If the physical member port policy uses a classification based on dscp or cos fields, it must be based on the marked (modified) value. To ensure proper operation, the following restriction is placed on the EtherChannel.

The classification criteria for the policy-map on the physical member ports has to be based only on one type of field:

- dscp
- precedence
- cos
- any non marking field (no dscp or cos based classification)

Classification criteria for the policy-map on the physical member ports cannot be based on a combination of fields. This restriction ensures that if the EtherChannel policy is marking down dscp or cos, the marked (modified) value-based classification can be implemented in hardware.

Note

Classification criteria for the policy-map on the physical member ports cannot be modified to add a new type of field.

Auto-QoS is not supported on EtherChannel or its member ports. A physical port configured with Auto-QoS is not allowed to become a member of a physical port.

Software QoS

At the highest level, there are two types of locally sourced traffic (such as control protocol packets, pings, and telnets) from the switch: high priority traffic (typically the control protocol packets like OSPF Hellos and STP) and low priority packets (all other packet types).

The QoS treatment for locally-sourced packets differs for the two types.

The supervisor engine provides a way to apply QoS to packets processed in the software path. The packets that get this QoS treatment in software can be classified into two types: software switched packets and software generated packets.

On reception, software switched packets are sent to the CPU that in turn sends them out of another interface. For such packets, input software QoS provides input marking and output software QoS provides output marking and queue selection.

The software generated packets are the ones locally sourced by the switch. The type of output software QoS processing applied to these packets is the same as the one applied to software switched packets. The only difference in the two is that the software switched packets take input marking of the packet into account for output classification purpose.

High Priority Packets

High priority packets are marked as one of the following:

- internally with PAK_PRIORITY
- with IP Precedence of 6 (for IP packets)
- with CoS of 6 (for VLAN Tagged packets)

These packets behave as follows:

- They are not dropped because of any policing, AQM, drop thresholds (or any feature that can drop a packet) configured as per the egress service policy. However, they might be dropped because of hardware resource constraints (packet buffers, queue full, etc.).
- They are classified and marked as per the marking configuration of the egress service policy that could be a port or VLAN (refer to the [“Policy Associations” section on page 44-74](#)).
- These high priority packets are enqueued to queue on the egress port based on the following criteria:
 - If there is no egress queuing policy on the port, the packet is queued to a control packet queue that is setup separately from the default queue and has 5 percent of the link bandwidth reserved for it.
 - If there is an egress queuing policy on the port, the queue is selected based on the classification criteria applicable to the packet.

Low Priority Packets

Packets that are not considered high priority (as described previously) are considered *unimportant*. These include locally sourced pings, telnet, and other protocol packets. They undergo the same treatment as any other packet that is transiting the given transmit port including egress classification, marking and queuing.

Applying Flow-based QoS Policy

Flow based QoS enables microflow policing and marking capability to dynamically learn traffic flows. It also rate limits each unique flow to an individual rate. Flow based QoS is available with the built-in NetFlow hardware support.

For more overview information, refer to the [“Flow-based QoS” section on page 44-10](#).

The following steps show how to apply Flow based QoS policy to QoS targets:

-
- | | |
|---------------|--|
| Step 1 | Create a FNF flow record by specifying the key fields that identify unique flows. You can use any FNF flow records that are associated with the FNF monitor. |
| Step 2 | Create a class-map to specify the set of match criteria. Include the FNF flow record from Step 1 in the class-map match criteria using the match flow record command. Then, configure the class-map to match all the match criteria with class-map match-all <i>class_name</i> . |
| Step 3 | Create a policy-map and define actions associated with class-map from Step 2. |
| Step 4 | Attach the policy to one or more QoS targets. |
-

Examples

The following examples illustrate how to configure Flow based QoS policy and apply microflow policers on individual flows.

Example 1

This example assumes there are multiple users (identified by source IP address) on the subnet 192.168.10.*. The configuration below shows how to configure a flow based QoS policy that uses micro policing to limit the per-user traffic with the source address in the range of 192.168.10.*. The microflow policer is configured with a CIR of 1Mbps, “conform action” as transmit, and “exceed action” as drop.

Step 1: Define an ACL to match traffic with specified source address.

```
Switch(config)# ip access-list extended UserGroup1
Switch(config-ext-nacl)# permit ip 192.168.10.0 0.0.0.255 any
Switch(config-ext-nacl)# exit
Switch(config)#
```

Step 2: Define a flow record to create flows with source address as key.

```
Switch(config)# flow record r1
Switch(config-flow-record)# match ipv4 source address
Switch(config-flow-record)# exit
Switch(config)#
```

Step 3: Configure classmap to match on the UserGroup1 and specify flow record definition for flow creation.

```
Switch(config)# class-map match-all c1
Switch(config-cmap)# match access-group name UserGroup1
Switch(config-cmap)# match flow record r1
Switch(config-cmap)# exit
Switch(config)#
```

Step 4: Configure flow based QoS policy-map with microflow policing action for the matching traffic.

```
Switch(config)# policy-map p1
Switch(config-pmap)# class c1
Switch(config-pmap-c)# police cir 1m
Switch(config-pmap-c-police)# conform-action transmit
Switch(config-pmap-c-police)# exceed-action drop
Switch(config-pmap-c-police)# exit
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
```

Step 5: Attach flow QoS policy to the interface.

```
Switch(config)# interface gigabitEthernet3/1
Switch(config-if)# service-policy input p1
Switch(config-if)#
```

Use the **show** commands (described in the policy and marking sections of this chapter) to display the policy-map configuration and interface specific policy-map statistics.

Example 2.

This example assumes there are multiple users (identified by source IP address) on subnets 192.168.10.* and 172.20.55.*. The first requirement is to police with a CIR of 500Kbps and a PIR of 650Kbps on any TCP traffic originating from 192 network to any destination at any given time. The **exceed action** keyword marks down the dscp value to 32. The second requirement is to police per-user traffic originating from 172 network to CIR of 2Mbps and unconditionally mark the traffic with dscp 10.

Step 1: Define an ACL to match traffic with specified source address.

```
Switch(config)# ip access-list extended UserGroup1
Switch(config-ext-nacl)# permit ip 19 2.168.10.0 0.0.0.255 any
Switch(config-ext-nacl)# exit
Switch(config)# ip access-list extended UserGroup2
Switch(config-ext-nacl)# permit ip 172.20.55.0 0.0.0.255 any
Switch(config-ext-nacl)# exit
Switch(config)#
```

Step 2: Define a flow record to create flows with source address as key.

```
Switch(config)# flow record r1
Switch(config-flow-record)# match ipv4 source address
Switch(config-flow-record)# match ipv4 destination address
Switch(config-flow-record)# match transport tcp source-port
Switch(config-flow-record)# match transport tcp destination-port
Switch(config-flow-record)# exit
Switch(config)# flow record r2
Switch(config-flow-record)# match ipv4 source address
Switch(config-flow-record)# exit
Switch(config)#
```

Step 3: Configure classmap to match on the UserGroup1 and specify flow record definition for flow creation.

```
Switch(config)# class-map match-all c1
Switch(config-cmap)# match access-group name UserGroup1
Switch(config-cmap)# match flow record r1
Switch(config-cmap)# exit
Switch(config)# class-map match-all c2
Switch(config-cmap)# match access-group name UserGroup2
Switch(config-cmap)# match flow record r2
Switch(config-cmap)# exit
Switch(config)#
```

Step 4: Configure flow based QoS policy-map with microflow policing action for the matching traffic.

```
Switch(config)# policy-map p1
Switch(config-pmap)# class c1
Switch(config-pmap-c)# police cir 500k pir 650k
Switch(config-pmap-c-police)# conform-action transmit
Switch(config-pmap-c-police)# exceed-action set-dscp-transmit 32
Switch(config-pmap-c-police)# violate-action drop
Switch(config-pmap-c-police)# exit
Switch(config-pmap-c)# exit
Switch(config-pmap)# class c2
Switch(config-pmap-c)# set dscp 10
Switch(config-pmap-c)# police cir 2m
Switch(config-pmap-c-police)# conform-action transmit
Switch(config-pmap-c-police)# exceed-action drop
Switch(config-pmap-c-police)# exit
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
```

Step 5: Attach flow QoS policy to the interface.

```
Switch(config)# interface gigabitEthernet3/1
Switch(config-if)# service-policy input p1
Switch(config-if)# exit
```

Use the show commands described in the QoS section to display the policy-map configuration and interface specific policy-map statistics.

Example 3

Assume that there are two active flows on FastEthernet interface 6/1:

Table 44-4

SrcIp	DStIp	IPProt	SrcL4Port	DstL4Port
192.168.10.10	192.168.20.20	20	6789	81
192.168.10.10	192.168.20.20	20	6789	21

With the following configuration, each flow is policed to 1000000 bps with an allowed 9000 burst value.

```
Switch(config)# flow record r1
Switch(config-flow-record)# match ipv4 source address
Switch(config-flow-record)# match ipv4 destination address
Switch(config-flow-record)# match transport tcp source-port
Switch(config-flow-record)# match transport tcp destination-port
Switch(config-flow-record)# match transport udp source-port
Switch(config-flow-record)# match transport udp destination-port
Switch(config-flow-record)# exit
Switch(config)# class-map match-all c1
Switch(config-cmap)# match flow record r1
Switch(config-cmap)# exit
Switch(config)# policy-map p1
Switch(config-pmap)# class c1
Switch(config-pmap-c)# police 1000000 9000
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface fastEthernet 6/1
Switch(config-if)# service-policy input p1
Switch(config-if)# end
```

Configuration Guidelines

The general guidelines for creating, configuring, modifying, deleting a flow based QoS policy and attaching (and detaching) a flow based QoS policy to a supported target is the same as described in the QoS section. The following description and restriction applies to Flow based QoS policy:

- A classmap can have multiple match statements but only one FNF flow record can be specified in a class-map.
- A flow record must have at least one key field before it can be used in a classmap. Non-key fields can be present in the flow record. However, all the non-key fields are ignored by microflow QoS. Only key-fields are used for flow creation.
- If a FNF flow record is referenced in any class-map, the flow record cannot be modified. Remove the flow record from all classmaps before modifying it.
- A classmap with a FNF flow record must be configured as **match-all**; traffic hitting the class-map must satisfy all match criteria in the class-map.

- A policy can contain multiple classes and each class-map may contain the same or different FNF flow record.
- Flow based QoS policy and FNF monitor both cannot be applied on the same target at the same time.
- When the interface mode changes from switchport to routed port and vice versa, any Flow QoS policy attached to the port remains applied after the mode change.
- There are 3 types of FNF flow records: ipv4, ipv6, and datalink. The datalink flow record is mutually exclusive with the ipv4 and ipv6 flow records; a classmap with the datalink flow record cannot co-exist with classmap having a ipv4 or ipv6 flow record in the same policy and vice-versa.
- Classmap class-default is not editable; it cannot be configured with the match flow record. Instead, you can configure the policy with a class-map that uses a match any filter and the flow record.
- Traffic is classified in the same order in which class-map is defined in a policy. Hence, if a FNF flow record is the only match statement in a class-map, the classifier matches all packets of the type identified by the flow record. This means that any subsequent class-map in the same policy matching on the same traffic type will be redundant and will never be hit.
- Policers associated with classmap having flow record are called *microflow policers*. The CIR and PIR rates for microflow policers cannot be configured using the percent keyword.
- Flow records within the same policy must include appropriate key fields to ensure flows created from different classmaps are unique and distinct. Otherwise, the resulting flows from different classmap cannot be distinguished. In such cases, policy actions corresponding to the classmap which created the first flow in hardware will apply and results will not be always be as expected.
- Flows from traffic received on different QoS targets are distinct even if the same policy is applied to those targets.
- A flow is aged out if the it is inactive for more than 5 seconds; there is no traffic matching the flow for a period longer than 5 sec.
- When a flow is aged out, policer state information associated with the flow is also deleted. When a new flow is created, the policer instance for the flow is re-initialized.
- Flows created by flow based QoS policy exist in hardware only and cannot be exported (as with FNF monitor).
- Per-flow statistics are not available for flows created by flow based QoS policy.
- Class-map statistics indicate the number of packets matching the classifier. It does not represent individual flow stats.
- Policer statistics show the aggregate policer statistics of individual flow.
- Information about the flows created by hardware are not available and not displayed in the show commands associated with QoS policy-map. Only class-map and policer statistics are displayed in the output of the **show policy-map** commands.

Configuring CoS Mutation

CoS reflection and CoS mutation are supported on Supervisor Engine 6-E. Below is an example of how to apply CoS reflection.

Let us say that traffic arrives on interface gigabit 2/5 with VLAN 10 and COS 1, 2, We want traffic to egress interface gigabit 2/6 with outer tag VLAN 11 and CoS copied from C-tag, where C-tag is VLAN 10 and COS 1, 2, ...

```
class-map match-all c2
```

```
match cos 2

class-map match-all c1

match cos 1

!

policy-map my

class c1

set cos 1

class c2

set cos 2

interface GigabitEthernet2/5

switchport mode trunk

switchport vlan mapping 10 dot1q-tunnel 11

spanning-tree bpdupfilter enable

service-policy input my

!

interface GigabitEthernet2/6

switchport mode trunk
```

Configuring System Queue Limit

Note This feature is available only from Cisco IOS Release 15.0(2)SG1 and later and Cisco IOS Release XE 3.2.1SG.

With the **hw-module system max-queue-limit** command, the Catalyst 4500 series switch allows you to change the queue limit for all interfaces globally, instead of applying a policy with queue limit to all the interfaces.

To set the queue limit globally, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# hw-module system max-queue-limit <i>max-queue-limit</i>	Sets the queue limit for all interfaces globally. Valid values are from 1024 to 8184. The value must be a multiple of 8.

	Command	Purpose
Step 3	Switch(config)# exit	Returns to privileged EXEC mode.
Step 4	Switch# reload	Reloads standalone supervisor engine.
	or	
	Switch# redundancy reload shelf	Reloads redundancy supervisor engine in SSO mode.
	Switch# redundancy force-switchover	Reloads redundancy supervisor engine in RPR mode. This command must be followed by another redundancy force-switchover.

This is a global configuration command. You can override it with the per port, per class, **queue-limit** command.

For a standalone supervisor engine, you must reboot the engine after applying this command.

For redundant supervisors in SSO mode, you must enter the **redundancy reload shelf** command enforce reboot to both the supervisors. For redundancy supervisors in RPR mode, you must execute two consecutive switchovers to enforce the system queue limit on both the supervisors.

This example shows how to set the queue limit globally to 1024 on a standalone supervisor engine:

```
Switch> enable
Switch# configure terminal
Switch(config)# hw-module system max-queue-limit 1024
Switch(config)# exit
Switch# reload (for standalone supervisors)
Switch# redundancy reload shelf (for redundancy supervisors in SSO mode)
or
Switch# redundancy force-switchover (followed by another redundancy force-switchover, for
redundancy supervisors in RPR mode)
```

Configuring VSS Auto-QoS

- [Auto-QoS Overview, page 44-82](#)
- [Auto-QoS Policy and Class Maps, page 44-83](#)
- [Auto-Qos Compact, page 44-88](#)
- [Effects of Auto-QoS and Auto-Qos Compact on Running Configuration, page 44-89](#)

Auto-QoS Overview

Note

Auto-QoS cannot be applied to VLANs or EtherChannel interfaces.

Note

If you have an auto-QoS policy on a port connected to a device that supports CDP, the port is automatically trusted. However, if the device does not support CDP (like legacy Digital Media Player), QoS trust must be applied manually.

You can use the auto-QoS feature to simplify the deployment of QoS features. Auto-QoS determines the network design and enables QoS configurations so that the switch can prioritize different traffic flows. You can also hide all the auto-QoS-generated configuration from the running configuration, by using the auto-QoS compact feature.

The switch employs the MQC model. This means that instead of using certain global configurations (like qos and qos dbf), auto-QoS applied to any interface on a switch configures several global class-maps and policy-maps.

We need QoS in both directions, both on inbound and outbound. Inbound, the switch port needs to trust the DSCP in the packet (done by default). Outbound, the switch port needs to give voice packets "front of line" priority. If voice is delayed too long by waiting behind other packets in the outbound queue, the end host drops the packet because it arrives outside of the receive window for that packet.

Note QoS is a two way street. So, it might work in one direction and not in the other.

Auto-QoS Policy and Class Maps

There are 7 policy maps that must be defined (5 Input, 2 output) on all ports

- AutoQos-4.0-Input-Policy
- AutoQos-VoIP-Input-Cos-Policy
- AutoQos-VoIP-Input-Dscp-Policy
- AutoQos-4.0-Cisco-Phone-Input-Policy
- AutoQos-4.0-Output-Policy
- AutoQos-4.0-Cisco-Softphone-Input-Policy
- AutoQos-VoIP-Output-Policy

The problem with COS is that packets on the native VLAN is marked as zero.

The class maps used for input matching are as follows:

```
! for control traffic between the phone and the callmanager
! and phone to phone [Bearer] DSCP matching

class-map match-all AutoQos-VoIP-Control-Dscp26
  match dscp af31
class-map match-all AutoQos-VoIP-Control-Dscp24
  match dscp cs3
class-map match-all AutoQos-VoIP-Bearer-Dscp
  match dscp ef

! for control traffic and phone to phone [Bearer] COS matching
! Note: Both CS3 and AF31 control traffic maps to COS 3

class-map match-all AutoQos-VoIP-Control-Cos
  match cos 3
class-map match-all AutoQos-VoIP-Bearer-Cos
  match cos 5

! for control traffic between the softphonephone and the callmanager
! and softphone to softphonephone [Bearer] DSCP matching
Class Map match-all AutoQos-4.0-Multimedia-Conf-Classify (id 36)
  Match access-group name AutoQos-4.0-ACL-Multimedia-Conf
Class Map match-all AutoQos-4.0-Signaling-Classify (id 2)
```

```

    Match access-group name AutoQos-4.0-ACL-Signaling
Class Map match-all AutoQos-4.0-Transaction-Classify (id 18)
    Match access-group name AutoQos-4.0-ACL-Transactional-Data
Class Map match-all AutoQos-4.0-Bulk-Data-Classify (id 29)
    Match access-group name AutoQos-4.0-ACL-Bulk-Data
Class Map match-all AutoQos-4.0-Scavenger-Classify (id 1)
    Match access-group name AutoQos-4.0-ACL-Scavenger

! for untrusted interfaces
class-map match-all AutoQos-4.0-Multimedia-Conf-Classify
    match access-group name AutoQos-4.0-ACL-Multimedia-Conf
class-map match-all AutoQos-4.0-Signaling-Classify
    match access-group name AutoQos-4.0-ACL-Signaling
class-map match-all AutoQos-4.0-Transaction-Classify
    match access-group name AutoQos-4.0-ACL-Transactional-Data
class-map match-all AutoQos-4.0-Bulk-Data-Classify
    match access-group name AutoQos-4.0-ACL-Bulk-Data
class-map match-all AutoQos-4.0-Scavenger-Classify
    match access-group name AutoQos-4.0-ACL-Scavenger
    class-map match-all AutoQos-4.0-Default-Classify
    match access-group name AutoQos-4.0-ACL-Default

! for interfaces with video devices
class-map match-any AutoQos-4.0-VoIP
    match dscp ef
    match cos 5
class-map match-all AutoQos-4.0-Broadcast-Vid
    match dscp cs5
class-map match-all AutoQos-4.0-Realtime-Interact
    match dscp cs4
class-map match-all AutoQos-4.0-Network-Ctrl
    match dscp cs7
class-map match-all AutoQos-4.0-Internetwork-Ctrl
    match dscp cs6
class-map match-any AutoQos-4.0-Signaling
    match dscp cs3
    match cos 3
class-map match-all AutoQos-4.0-Network-Mgmt
    match dscp cs2
class-map match-any AutoQos-4.0-Multimedia-Conf
    match dscp af41
    match dscp af42
    match dscp af43
class-map match-any AutoQos-4.0-Multimedia-Stream
    match dscp af31
    match dscp af32
    match dscp af33
class-map match-any AutoQos-4.0-Transaction-Data
    match dscp af21
    match dscp af22
    match dscp af23
class-map match-any AutoQos-4.0-Bulk-Data
    match dscp af11
    match dscp af12
    match dscp af13
class-map match-all AutoQos-4.0-Scavenger
    match dscp cs1

```

The class maps are intended to identify control and data (bearer) voice traffic for either an Layer 2 or Layer 3 interface.

The 2 Input policy maps, one for matching DSCP and one for matching COS, where DSCP and COS are set to an assigned qos-group used in outbound policy-maps are as follows:

```
policy-map AutoQos-VoIP-Input-Dscp-Policy
  class AutoQos-VoIP-Bearer-Dscp
  class AutoQos-VoIP-Control-Dscp26
  class AutoQos-VoIP-Control-Dscp24
```

! Note: For COS, Control traffic only has a single COS value of 3 (versus DSCP which has 2 values to match). So, only 2 class-maps instead of 3 like above.

```
policy-map AutoQos-VoIP-Input-Cos-Policy
  class AutoQos-VoIP-Bearer-Cos
  class AutoQos-VoIP-Control-Cos
```

The input policy maps are as follows:

```
policy-map AutoQos-4.0-Input-Policy
  class AutoQos-4.0-VoIP
  class AutoQos-4.0-Broadcast-Vid
  class AutoQos-4.0-Realtime-Interact
  class AutoQos-4.0-Network-Ctrl
  class AutoQos-4.0-Internetwork-Ctrl
  class AutoQos-4.0-Signaling
  class AutoQos-4.0-Network-Mgmt
  class AutoQos-4.0-Multimedia-Conf
  class AutoQos-4.0-Multimedia-Stream
  class AutoQos-4.0-Transaction-Data
  class AutoQos-4.0-Bulk-Data
  class AutoQos-4.0-Scavenger
  policy-map AutoQos-4.0-Classify-Police-Input-Policy
  class AutoQos-4.0-Multimedia-Conf-Classify
    set dscp af41
    set cos 4
    police cir 5000000 bc 8000
    exceed-action drop
  class AutoQos-4.0-Signaling-Classify
    set dscp cs3
    set cos 3
    police cir 32000 bc 8000
    exceed-action drop
  class AutoQos-4.0-Transaction-Classify
    set dscp af21
    set cos 2
    police cir 10000000 bc 8000
    exceed-action set-dscp-transmit cs1
    exceed-action set-cos-transmit 1
  class AutoQos-4.0-Bulk-Data-Classify
    set dscp af11
    set cos 1
    police cir 10000000 bc 8000
    exceed-action set-dscp-transmit cs1
    exceed-action set-cos-transmit 1
  class AutoQos-4.0-Scavenger-Classify
    set dscp cs1

        exceed-action set-dscp-transmit cs1
        exceed-action set-cos-transmit 1
class class-default
    set dscp default
    set cos 0
policy-map AutoQos-4.0-Classify-Input-Policy
class AutoQos-4.0-Multimedia-Conf-Classify
    set dscp af41
    set cos 4
class AutoQos-4.0-Signaling-Classify
    set dscp cs3
    set cos 3
class AutoQos-4.0-Transaction-Classify
    set dscp af21
    set cos 2
class AutoQos-4.0-Bulk-Data-Classify
    set dscp af11
    set cos 1
class AutoQos-4.0-Scavenger-Classify
    set dscp cs1
    set cos 1
class AutoQos-4.0-Default-Classify
    set dscp default
    set cos 0
!
```

The output policy maps are as follows:

```

policy-map AutoQos-4.0-Output-Policy
class AutoQos-4.0-Scavenger-Queue
    bandwidth remaining percent 1
class AutoQos-4.0-Priority-Queue
    priority
    police cir percent 30 bc 33 ms
class AutoQos-4.0-Control-Mgmt-Queue
    bandwidth remaining percent 10
class AutoQos-4.0-Multimedia-Conf-Queue
    bandwidth remaining percent 10
class AutoQos-4.0-Multimedia-Stream-Queue
    bandwidth remaining percent 10
class AutoQos-4.0-Trans-Data-Queue
    bandwidth remaining percent 10
    dbl
class AutoQos-4.0-Bulk-Data-Queue
    bandwidth remaining percent 4
    dbl
class class-default
    bandwidth remaining percent 25
    dbl
```

The three policy maps are defined as follows:

- **policy-map AutoQos-VoIP-Input-Dscp-Policy**
This policy map is applied as an input service policy on an Layer 3 interface (such as an uplink connection to a neighboring switch) when auto-QoS is configured on the port.
- **policy-map AutoQos-VoIP-Input-Cos-Policy**
This policy map is applied as an input service policy on an Layer 2 interface that could be either an uplink connection or a port hooked to a Cisco IP Phone.
- **policy-map AutoQos-VoIP-Output-Policy**
This policy map is applied as an output policy for any port on which auto-QoS is configured, establishing policy governing egress traffic on the port based on whether it is voice data or control traffic.

The purpose of the input policy maps is to identify voice data or control traffic and mark it as such as it traverses the switch. The output policy map matches the packets on the marking occurring on ingress and then applies egress parameters such as bandwidth, policing and/or priority queuing.

For switch-to-switch connections, the **[no] auto qos voip trust** command is used to apply an input and output service policy on the interface:

```
service-policy input AutoQos-VoIP-Input-Cos-Policy
```

OR

```
service-policy input AutoQos-VoIP-Input-Dscp-Policy
```

AND

```
service-policy output AutoQos-VoIP-Output-Policy
```

The selection of the input policy depends on whether the port is Layer 2 or Layer 3. For Layer 2, the policy trusts the Cos setting in the received packets. For Layer 3 ports, it relies on the DSCP value contained in the packets.

For phone connected ports, the **[no] auto qos voice cisco-phone** command is used to apply the following service policy to the port:

```
qos trust device cisco-phone
```

```
service-policy input AutoQos-VoIP-Input-Cos-Policy
```

AND

```
service-policy output AutoQos-VoIP-Output-Policy
```

It establishes a trusted boundary that recognizes Cisco IP Phones and trusts the Cos setting of the packets from the phone. If a Cisco IP Phone is not detected, the Cos field is ignored and the packets are not classified as voice traffic. Upon detecting a Cisco phone, the ingress packets are marked based on the Cos value in the packets. This marking is used on egress for proper traffic classification and handling.

Auto qos srnd4—Is generated when any new auto qos command is configured on an interface and migrates from legacy CLIs to generate new configurations. This CLI only generates a global configuration if during migration, one or more interfaces has legacy auto-QoS enabled

Auto qos video—Generates QoS configuration for untrusted interfaces. It incorporates a service-policy to classify the traffic coming from untrusted desktops/devices and marks them accordingly.

Auto qos void cisco-softphone—Generate QoS configuration for interfaces connected to PCs running the Cisco IP SoftPhone application and marks as police traffic stemming from such interfaces. Ports configured with this CLI are considered untrusted.

Auto qos classify—Generates QoS configuration for untrusted interfaces. It applies a service-policy to classify the traffic stemming from untrusted desktops or devices and marks them accordingly. The service-policies generated do not police.

Auto-Qos Compact

When you enter an auto-QoS command, the switch goes on to display all the generated commands as if the commands were entered from the CLI. Enable auto-QoS compact if you want to hide auto-QoS generated commands from the running configuration.

To enable auto-Qos compact, enter this command:

Command	Purpose
Switch# configure terminal	Enters global configuration mode.
Switch(config)# auto qos global compact	<p>Enables auto-Qos compact and generates global auto-Qos configurations that are hidden from the running configuration.</p> <p>You can then enter the auto-QoS command you want to configure, in the interface configuration mode. The interface commands that the system generates are also hidden from running configuration.</p> <p>To display the auto-QoS configuration that has been applied, use these the privileged EXEC commands: show derived-config, show policy-map, show policy-map interface, show class-map, show table-map, and show auto-qos, show ip access-list.</p>

To disable auto-QoS compact, first remove all the auto-Qos configuration by entering the **no** form of the corresponding auto-QoS interface configuration command and then enter the **no auto qos global compact** global configuration command. Disabling auto-QoS compact is a required task when have to perform an ISSU from an image where auto-QoS compact is supported to an image where this feature is not available.

The following example shows you how to enable auto-qos compact and configure the **auto qos voip cisco-phone** interface configuration command and then display configuration details:

```
Switch# configure terminal
Switch(config)# auto qos global compact
Switch(config)# interface GigabitEthernet1/2
Switch(config-if)# auto qos voip cisco-phone

Switch(config-if)# show auto-qos
GigabitEthernet1/2
auto qos voip cisco-phone
```

Effects of Auto-QoS and Auto-Qos Compact on Running Configuration

The auto-QoS interface configuration commands and the generated global configurations are added to the running configuration. When you save this configuration, all generated commands and any user-entered configuration that was not overridden, is saved to memory.

If auto-QoS compact is enabled, only the list of auto-QoS commands you have entered are displayed in the running configuration. The generated global and interface configurations are hidden from the running configuration. When you save this configuration, only the auto-QoS commands you have entered are saved (and not the hidden configuration). When you reload the switch, the system detects and re-executes the saved auto-QoS commands, re-sets the values, and generates an auto-QoS SRND4.0 complaint configuration set.

**Note**

Do not make changes to the auto-QoS-generated commands when auto-QoS compact is enabled, because user-modifications are overridden when the switch reloads.

Configuring Auto-QoS on a Standalone Supervisor Engine 6-E/6L-E or Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E

- [Auto-QoS Overview, page 44-89](#)
- [Auto-QoS Policy and Class Maps, page 44-90](#)
- [Auto-QoS Compact, page 44-97](#)
- [Effects of Auto-QoS and Auto-Qos Compact on Running Configuration, page 44-98](#)

Auto-QoS Overview

**Note**

Auto-QoS cannot be applied to VLANs or EtherChannel interfaces.

**Note**

If you have an auto-QoS policy on a port connected to a device that supports CDP, the port is automatically trusted. However, if the device does not support CDP (like legacy Digital Media Player), QoS trust must be applied manually.

You can use the auto-QoS feature to simplify the deployment of QoS features. Auto-QoS determines the network design and enables QoS configurations so that the switch can prioritize different traffic flows. You can also hide all the auto-QoS-generated configuration from the running configuration, by using the auto-QoS compact feature.

The switch employs the MQC model. This means that instead of using certain global configurations (like qos and qos dbl), auto-QoS applied to any interface on a switch configures several global class-maps and policy-maps.

Auto-QoS matches traffic and assigns each matched packet to qos-groups. This allows the output policy map to put specific qos-groups into specific queues, including into the priority queue.

We need QoS in both directions, both on inbound and outbound. Inbound, the switch port needs to trust the DSCP in the packet (done by default). Outbound, the switch port needs to give voice packets "front of line" priority. If voice is delayed too long by waiting behind other packets in the outbound queue, the end host drops the packet because it arrives outside of the receive window for that packet.

Note QoS is a two way street. So, it might work in one direction and not in the other.

Auto-QoS Policy and Class Maps

- There are 7 policy maps that must be defined (5 Input, 2 output)
- AutoQos-4.0-Input-Policy
- AutoQos-VoIP-Input-Cos-Policy
- AutoQos-VoIP-Input-Dscp-Policy
- AutoQos-4.0-Cisco-Phone-Input-Policy
- AutoQos-4.0-Output-Policy
- AutoQos-4.0-Cisco-Softphone-Input-Policy
- AutoQos-VoIP-Output-Policy

On all ports. The problem with COS is that packets on the native VLAN is marked as zero.

The class maps used for input matching are as follows:

```
! for control traffic between the phone and the callmanager
! and phone to phone [Bearer] DSCP matching
! Note: Control traffic can be either AF31 or CS3. So, we match to both values and assign
them to different qos-groups when matching DSCP and only a single group when matching COS.
```

```
class-map match-all AutoQos-VoIP-Control-Dscp26
  match dscp af31
class-map match-all AutoQos-VoIP-Control-Dscp24
  match dscp cs3
class-map match-all AutoQos-VoIP-Bearer-Dscp
  match dscp ef
```

```
! for control traffic and phone to phone [Bearer] COS matching
! Note: Both CS3 and AF31 control traffic maps to COS 3
```

```
class-map match-all AutoQos-VoIP-Control-Cos
  match cos 3
class-map match-all AutoQos-VoIP-Bearer-Cos
  match cos 5
```

```
! for control traffic between the softphonephone and the callmanager
! and softphone to softphonephone [Bearer] DSCP matching
Class Map match-all AutoQos-4.0-Multimedia-Conf-Classify (id 36)
  Match access-group name AutoQos-4.0-ACL-Multimedia-Conf
Class Map match-all AutoQos-4.0-Signaling-Classify (id 2)
  Match access-group name AutoQos-4.0-ACL-Signaling
Class Map match-all AutoQos-4.0-Transaction-Classify (id 18)
  Match access-group name AutoQos-4.0-ACL-Transactional-Data
Class Map match-all AutoQos-4.0-Bulk-Data-Classify (id 29)
  Match access-group name AutoQos-4.0-ACL-Bulk-Data
Class Map match-all AutoQos-4.0-Scavenger-Classify (id 1)
  Match access-group name AutoQos-4.0-ACL-Scavenger
```

```

! for untrusted interfaces
class-map match-all AutoQos-4.0-Multimedia-Conf-Classify
    match access-group name AutoQos-4.0-ACL-Multimedia-Conf
class-map match-all AutoQos-4.0-Signaling-Classify
    match access-group name AutoQos-4.0-ACL-Signaling
class-map match-all AutoQos-4.0-Transaction-Classify
    match access-group name AutoQos-4.0-ACL-Transactional-Data
class-map match-all AutoQos-4.0-Bulk-Data-Classify
    match access-group name AutoQos-4.0-ACL-Bulk-Data
class-map match-all AutoQos-4.0-Scavenger-Classify
    match access-group name AutoQos-4.0-ACL-Scavenger
    class-map match-all AutoQos-4.0-Default-Classify
    match access-group name AutoQos-4.0-ACL-Default

! for interfaces with video devices
class-map match-any AutoQos-4.0-VoIP
    match dscp ef
    match cos 5
class-map match-all AutoQos-4.0-Broadcast-Vid
    match dscp cs5
class-map match-all AutoQos-4.0-Realtime-Interact
    match dscp cs4
class-map match-all AutoQos-4.0-Network-Ctrl
    match dscp cs7
class-map match-all AutoQos-4.0-Internetwork-Ctrl
    match dscp cs6
class-map match-any AutoQos-4.0-Signaling
    match dscp cs3
    match cos 3
class-map match-all AutoQos-4.0-Network-Mgmt
    match dscp cs2
class-map match-any AutoQos-4.0-Multimedia-Conf
    match dscp af41
    match dscp af42
    match dscp af43
class-map match-any AutoQos-4.0-Multimedia-Stream
    match dscp af31
    match dscp af32
    match dscp af33
class-map match-any AutoQos-4.0-Transaction-Data
    match dscp af21
    match dscp af22
    match dscp af23
class-map match-any AutoQos-4.0-Bulk-Data
    match dscp af11
    match dscp af12
    match dscp af13
class-map match-all AutoQos-4.0-Scavenger
    match dscp cs1

```

The class maps are intended to identify control and data (bearer) voice traffic for either an Layer 2 or Layer 3 interface.

The 2 Input policy maps, one for matching DSCP and one for matching COS, where DSCP and COS are set to an assigned qos-group used in outbound policy-maps are as follows:

```

policy-map AutoQos-VoIP-Input-Dscp-Policy
    class AutoQos-VoIP-Bearer-Dscp
        set qos-group 46
    class AutoQos-VoIP-Control-Dscp26
        set qos-group 26
    class AutoQos-VoIP-Control-Dscp24
        set qos-group 24

```

! Note: For COS, Control traffic only has a single COS value of 3 (versus DSCP which has 2 values to match). So, only 2 class-maps instead of 3 like above.

```
policy-map AutoQos-VoIP-Input-Cos-Policy
  class AutoQos-VoIP-Bearer-Cos
    set qos-group 46
  class AutoQos-VoIP-Control-Cos
    set qos-group 24
```

```

Class AutoQos-4.0-Default-Classify
        set dscp default
        set cos 0

```

The class maps used for Output matching are as follows:

```

! Since we assigned matched traffic to a qos-group on input,
! we only need to match the qos-group on output

```

```

! Note: Any other traffic not matched on input and assigned to a qos-group goes into the
class-default queue

```

```

! for control traffic (CS3 and AF31)
class-map match-all AutoQos-VoIP-Control-QosGroup24
    match qos-group 24
class-map match-all AutoQos-VoIP-Control-QosGroup26
    match qos-group 26

```

```

! For phone to phone (Bearer EF) traffic
class-map match-all AutoQos-VoIP-Bearer-QosGroup
    match qos-group 46

```

! For softphone

Class Map match-any AutoQos-4.0-Scavenger-Queue (id 24)

```
    Match qos-group 8
```

```
    Match dscp cs1 (8)
```

Class Map match-all AutoQos-4.0-Priority-Queue (id 3)

```
    Match qos-group 32
```

Class Map match-all AutoQos-4.0-Control-Mgmt-Queue (id 28)

```
    Match qos-group 16
```

Class Map match-all AutoQos-4.0-Multimedia-Conf-Queue (id 10)

```
    Match qos-group 34
```

Class Map match-all AutoQos-4.0-Multimedia-Stream-Queue (id 5)

```
    Match qos-group 26
```

Class Map match-all AutoQos-4.0-Trans-Data-Queue (id 30)

```
    Match qos-group 18
```

Class Map match-all AutoQos-4.0-Bulk-Data-Queue (id 17)

```
    Match qos-group 10
```

**Note**

The previous section listing defines the AutoQoS macros for defining QoS guidelines prior to *Solution Reference Network Design 4.0 (SRND4)*. Starting with Cisco Release XE 3.3.0(SG) and 15.1(1)SG, the Catalyst 4500 series switch supports the **auto qos srnd4** command.

The following classes are required and generated by all SRND4 CLIs.

```
class-map match-all AutoQos-4.0-Priority-Queue
  match qos-group 32
class-map match-all AutoQos-4.0-Control-Mgmt-Queue
  match qos-group 16
class-map match-all AutoQos-4.0-Multimedia-Conf-Queue
  match qos-group 34
class-map match-all AutoQos-4.0-Multimedia-Stream-Queue
  match qos-group 26
class-map match-all AutoQos-4.0-Trans-Data-Queue
  match qos-group 18
class-map match-all AutoQos-4.0-Bulk-Data-Queue
  match qos-group 10
class-map match-any AutoQos-4.0-Scavenger-Queue
  match qos-group 8
  match dscp cs1
```

The output policy maps are as follows:

```
! Each class maps to a different qos-group with
! class-default taking any traffic not assigned to a qos-group
```

! Note: in this example, the outbound policy map drops voice packets when the priority queue exceeds 33% utilization of the link. Each deployment must establish their own upper bound for voice packets.

```
policy-map AutoQos-VoIP-Output-Policy
  class AutoQos-VoIP-Bearer-QosGroup
    set dscp ef
    set cos 5
    priority
    police cir percent 33
  class AutoQos-VoIP-Control-QosGroup26
    set dscp af31
    set cos 3
    bandwidth remaining percent 5
  class AutoQos-VoIP-Control-QosGroup24
    set dscp cs3
    set cos 3
    bandwidth remaining percent 5
  class class-default
    dbl
```

**Note**

There are no default cos-to-dscp or dscp-to-cos mappings on the. Values must be explicitly set for trunks.

```
Policy Map AutoQos-4.0-Output-Policy
  Class AutoQos-4.0-Scavenger-Queue
    bandwidth remaining percent 1
  Class AutoQos-4.0-Priority-Queue
    priority
    police cir percent 30 bc 33 ms
    conform-action transmit
    exceed-action drop
```

```

Class AutoQos-4.0-Control-Mgmt-Queue
  bandwidth remaining percent 10
Class AutoQos-4.0-Multimedia-Conf-Queue
  bandwidth remaining percent 10
Class AutoQos-4.0-Multimedia-Stream-Queue
  bandwidth remaining percent 10
Class AutoQos-4.0-Trans-Data-Queue
  bandwidth remaining percent 10
  dbl
Class AutoQos-4.0-Bulk-Data-Queue
  bandwidth remaining percent 4
  dbl
Class class-default
  bandwidth remaining percent 25
  dbl

```

The three policy maps are defined as follows:

- **policy-map AutoQos-VoIP-Input-Dscp-Policy**
This policy map is applied as an input service policy on an Layer 3 interface (such as an uplink connection to a neighboring switch) when auto-QoS is configured on the port.
- **policy-map AutoQos-VoIP-Input-Cos-Policy**
This policy map is applied as an input service policy on an Layer 2 interface that could be either an uplink connection or a port hooked to a Cisco IP Phone.
- **policy-map AutoQos-VoIP-Output-Policy**
This policy map is applied as an output policy for any port on which auto-QoS is configured, establishing policy governing egress traffic on the port based on whether it is voice data or control traffic.

The purpose of the input policy maps is to identify voice data or control traffic and mark it as such as it traverses the switch. The output policy map matches the packets on the marking occurring on ingress and then applies egress parameters such as bandwidth, policing and/or priority queuing.

For switch-to-switch connections, the **[no] auto qos voip trust** command is used to apply an input and output service policy on the interface:

```
service-policy input AutoQos-VoIP-Input-Cos-Policy
```

OR

```
service-policy input AutoQos-VoIP-Input-Dscp-Policy
```

AND

```
service-policy output AutoQos-VoIP-Output-Policy
```

The selection of the input policy depends on whether the port is Layer 2 or Layer 3. For Layer 2, the policy trusts the Cos setting in the received packets. For Layer 3 ports, it relies on the DSCP value contained in the packets.

For phone connected ports, the **[no] auto qos voice cisco-phone** command is used to apply the following service policy to the port:

```
qos trust device cisco-phone
```

```
service-policy input AutoQos-VoIP-Input-Cos-Policy
```

AND

```
service-policy output AutoQos-VoIP-Output-Policy
```

It establishes a trusted boundary that recognizes Cisco IP Phones and trusts the Cos setting of the packets from the phone. If a Cisco IP Phone is not detected, the Cos field is ignored and the packets are not classified as voice traffic. Upon detecting a Cisco phone, the ingress packets are marked based on the Cos value in the packets. This marking is used on egress for proper traffic classification and handling.

Auto qos srnd4—Is generated when any new auto qos command is configured on an interface and migrates from legacy CLIs to generate new configurations. This CLI only generates a global configuration if during migration, one or more interfaces has legacy auto-QoS enabled

Auto qos video—Generates QoS configuration for untrusted interfaces. It incorporates a service-policy to classify the traffic coming from untrusted desktops/devices and marks them accordingly.

Auto qos void cisco-softphone—Generate QoS configuration for interfaces connected to PCs running the Cisco IP SoftPhone application and marks as police traffic stemming from such interfaces. Ports configured with this CLI are considered untrusted.

Auto qos classify—Generates QoS configuration for untrusted interfaces. It applies a service-policy to classify the traffic stemming from untrusted desktops or devices and marks them accordingly. The service-policies generated do not police.

Auto-QoS Compact

When you enter an auto-QoS command, the switch goes on to display all the generated commands as if the commands were entered from the CLI. Enable auto-QoS compact if you want to hide auto-QoS generated commands from the running configuration.

To enable auto-QoS compact, enter this command:

Command	Purpose
Switch# configure terminal	Enters global configuration mode.
Switch(config)# auto qos global compact	<p>Enables auto-QoS compact and generates global auto-QoS configurations that are hidden from the running configuration.</p> <p>You can then enter the auto-QoS command you want to configure, in the interface configuration mode. The interface commands that the system generates are also hidden from running configuration.</p> <p>To display the auto-QoS configuration that has been applied, use these the privileged EXEC commands: show derived-config, show policy-map, show policy-map interface, show class-map, show table-map, and show auto-qos, show ip access-list.</p>

To disable auto-QoS compact, first remove all the auto-QoS configuration by entering the **no** form of the corresponding auto-QoS interface configuration command and then enter the **no auto qos global compact** global configuration command. Disabling auto-QoS compact is a required task when have to perform an ISSU from an image where auto-QoS compact is supported to an image where this feature is not available.

The following example shows how to enable auto-QoS compact and configure the **auto qos voip cisco-phone** interface configuration command and then display configuration details:

```
Switch# configure terminal
Switch(config)# auto qos global compact
Switch(config)# interface GigabitEthernet1/2
Switch(config-if)# auto qos voip cisco-phone

Switch(config-if)# show auto-qos
GigabitEthernet1/2
auto qos voip cisco-phone
```

Effects of Auto-QoS and Auto-Qos Compact on Running Configuration

The auto-QoS interface configuration commands and the generated global configurations are added to the running configuration. When you save this configuration, all generated commands and any user-entered configuration that was not overridden, is saved to memory.

If auto-QoS compact is enabled, only the list of auto-QoS commands you have entered are displayed in the running configuration. The generated global and interface configurations are hidden from the running configuration. When you save this configuration, only the auto-QoS commands you have entered are saved (and not the hidden configuration). When you reload the switch, the system detects and re-executes the saved auto-QoS commands, re-sets the values, and generates an auto-QoS SRND4.0 complaint configuration set.

Note

Do not make changes to the auto-QoS-generated commands when auto-QoS compact is enabled, because user-modifications are overridden when the switch reloads.

Configuring AVC with DNS-AS

The Application Visibility Control (AVC) with Domain Name System as an Authoritative Source (DNS-AS) feature (AVC with DNS-AS) provides a centralized means of controlling the identification and classification of trusted network traffic in an organization. It accomplishes this by using:

- Network metadata stored in a DNS server that is authoritative to the domain in question, to identify applications
- Modular QoS CLI (MQC), to classify the corresponding traffic and apply suitable policies
- Flexible NetFlow (FNF), to monitor and export application information to an external collector.

Starting with Cisco IOS XE Release 3.9.0E, the feature is available on Catalyst 4500E Series Switches with Supervisor Engine 8-E, 8L-E, 7-E, 7L-E, and Catalyst 4500-X Series Switches.

Starting with Cisco IOS XE Release 3.9.2E, you can export application information using FNF.

Starting with Cisco IOS XE Release 3.10.0E, support is extended to Supervisor Engine 9-E.

Benefits of the feature:

- Application Visibility—Ensuring unambiguous visibility of applications.

The DNS-AS mechanism snoops requests and does not require a CPU-intensive, deep packet inspection (DPI). Since traffic classification is by means of a DNS request and not DPI, this feature is compatible in scenarios where network traffic is encrypted.

- Metadata Driven—Using information about applications.

This enables you to holistically program the network so it behaves like a self-driving car. You now have information about all the required applications in your network, irrespective of whether traffic is encrypted or not.

- Centralized Control—Using a cross-domain application intent policy controller.

The feature leverages an existing, universally available query-response mechanism, to enable local DNS servers within an organization to act as authoritative servers and propagate application classification information to client devices (switches) in an enterprise network.

- Control without Administrative Access—Proving alternatives to controller-based approaches.

The feature supports scenarios where your network may be in the cloud and you may not own it. You can still control network devices across the Internet, even though you may not have administrative control of these devices.

This chapter describes how to configure AVC with DNS-AS. It includes the following major sections:

- [About AVC with DNS-AS, page 45-3](#)
- [Configuring AVC with DNS-AS, page 45-7](#)

- [Monitoring AVC with DNS-AS, page 45-21](#)
- [Troubleshooting AVC with DNS-AS, page 45-25](#)

About AVC with DNS-AS

- [Overview, page 45-3](#)
- [Key Concepts, page 45-3](#)
- [AVC with DNS-AS Process Flow, page 45-5](#)
- [High Availability and ISSU for AVC with DNS-AS, page 45-6](#)
- [Default Configuration, page 45-7](#)

Overview

The process starts with an organization's requirements relating to management and control of network traffic. You begin by assessing—the software applications that run on the various hosts (phones, PCs etc.) in your network, the domains (websites) and applications accessed by these devices, and the business-relevance of these domains and applications in your organization.

The assessment helps you arrive at a list of domains and applications that are “trusted” by your organization - designating all remaining domains and applications as untrusted.

With DNS-AS enabled on your network and the list of trusted domains at hand, the networking devices or DNS-AS clients in your network identify which applications the network traffic belongs to or which domains are being requested. As long as the traffic is part of the trusted list, the switch requests the DNS server for metadata and IP address information. This request is sent in the form of a DNS-query. The response, once received, is cached locally until the Time-to-Live (TTL) for that resource record expires. The response is bound to the traffic and allows the DNS-AS client to now identify, classify, and forward traffic accordingly.

Key Concepts

Metadata (RFC6759)	<p>In the context of the AVC with DNS-AS feature, this includes traffic classification information, application identification information, and business relevance information.</p> <p>Metadata is maintained in the form of TXT records. The following is a sample metadata record in the prescribed format:</p> <p>CISCO-CLS=app-name:example app-class:TD business:YES app-id:CU/28202</p>
Forward look-up	<p>A request for an IP address or a request for an “A” record, originating from a host.</p> <p>Being able to snoop these forward lookups in the network traffic is fundamental to the DNS-AS feature.</p>
Host	<p>A PC or mobile where users run software applications, access websites and so on.</p> <p>Only hosts with a wired connection to the network are considered.</p> <p>Forward look-up requests originate from hosts.</p>

Client or DNS-AS client	<p>Networking devices throughout your network. Host traffic is always routed through such a client.</p> <p>Note This configuration chapter deals with DNS-AS configuration on Cisco Catalyst Switches that are deployed as access switches only. Throughout this document, the term client, DNS-AS client, refers to the switch where AVC with DNS-AS is enabled.</p> <p>DNS-AS Clients receive metadata from an authoritative DNS server and maintain a database of this information in the form of records. How long the record remains in the client's database, is determined by the record's TTL.</p>
Binding table	<p>A table that resides in the client and serves as a database of parsed DNS server responses [TXT records and "A" records].</p> <p>Every client has a binding table of its own.</p>
An "A" record	<p>A record containing the domain name and IP address information [Only IPv4 address]. This is one of the DNS-Server responses (the other being the TXT record) and has a predefined lifespan.</p> <p>A forward lookup request from a host is a request for an "A" record.</p>
TXT DNS-AS resource record or TXT record	<p>A record containing metadata. This is one of the DNS-Server responses (the other being the "A" record) and has a predefined lifespan.</p> <p>A TXT record is limited to 255 characters.</p> <p>For AVC with DNS-AS, the TXT attribute is always CISCO-CLS. Any TXT record that starts with CISCO-CLS= can be recognized as a DNS-AS message.</p> <p>Syntax— CISCO-CLS=<option>:<val>{ <option>:<val> }*</p>
Time-to-Live (TTL)	<p>The lifespan of an "A" record and TXT record in the binding table.</p> <p>TTL values are configured on the DNS server.</p> <p>While a TTL accompanies both TXT and "A" record responses, the DNS client only goes by the "A" record response from the DNS server.</p>
Authoritative DNS server	<p>The go-to DNS server for all client metadata and "A" record requests.</p> <p>Every DNS domain has only one authoritative DNS server.</p> <p>Such a server maintains records of application metadata in the form of a TXT record, and only returns responses to queries about domain names that have been maintained in the required format.</p> <p>The following is a sample metadata record in the prescribed format: CISCO-CLS=app-name:example app-class:TD business:YES app-id:CU/28202</p>

AVC with DNS-AS Process Flow

This involves the DNS snooping process and the DNS-AS client process—both of which are loosely coupled, but independent processes. [Figure 45-1](#) is a representation of both processes.

Part -I: DNS Snooping Process

-
- Step 1** The host initiates an “A” record request.
- A user from your organization is in a meeting room in an office building. The associated DNS-AS client here is a switch (the wired network traffic from this meeting room is routed through this switch). The user looks up a website `www.example.com`, which initiates the request for an “A” record.
- Step 2** The authoritative DNS-server responds with an “A” record response.

Part-II: DNS-AS Client Process

-
- Step 1** The DNS-AS client sends a DNS query (TXT request) to the authoritative DNS server.
- The DNS-AS client, which is constantly snooping for requests (based on the trusted domain list), finds the host’s forward look-up request.
-  **Note** The DNS-AS client receives a copy of the host’s “A” record request, and does not alter the host’s original request in any manner.
-
- Based on the snooped result, the DNS-AS client sends a TXT request to the authoritative DNS server.
- Step 2** The authoritative DNS-server responds with a TXT record response.
- Step 3** A successful TXT response is followed by an “A” record request.
- Step 4** The authoritative DNS-server responds with an “A” record response.
- Step 5** The DNS-AS client parses and saves the response in its binding table.
- The DNS-AS client saves the TXT record and “A” record in its binding table. The response will remain saved in the binding table for the duration specified by the TTL of the “A” record. The system automatically checks and prevents duplicate entries for a fully qualified domain name in the binding table.
- The DNS-AS client applies a QoS policy based on the metadata from the DNS server, and exports application information to a collector, based on how the flow record is configured.
- The DNS-AS client forwards information about identified applications to FNF, enabling you to export this information.

Figure 45-1 AVC with DNS-AS Process Flow

1	Host	3	Authoritative DNS Server
2	DNS-AS Client		

	An “A” record request from the host to the DNS server		An “A” record response from the DNS server to the host
	A copy of the host’s “A” record request that the DNS-AS client saves	—	—
	TXT record and “A” record request from the DNS-AS client to the DNS server		TXT record and “A” record response from the DNS server to the DNS-AS client

High Availability and ISSU for AVC with DNS-AS

The AVC with DNS-AS feature supports High Availability and ISSU.

For High Availability, the binding table database of the active DNS-AS client is synchronized with the standby DNS-AS client. As long as AVC with DNS-AS is enabled, no additional user configuration is required.

The binding table entries are synchronized when:

- The standby comes up (bulk synchronization).
- New entries are added to the binding table database.
- One or more entries are cleared from the database.

Note

AVC with DNS-AS is also supported in the VSS mode, and Quad-Supervisor VSS Mode.

Default Configuration

AVC with DNS-AS is disabled.

Configuring AVC with DNS-AS

- [Prerequisites for Configuring AVC with DNS-AS, page 45-7](#)
- [Restrictions and Guidelines for Configuring AVC with DNS-AS, page 45-7](#)
- [Generating Metadata Streams, page 45-8](#)
- [Configuring a DNS Server as the Authoritative Server, page 45-10](#)
- [Enabling AVC with DNS-AS, page 45-10](#)
- [Making an Entry in the Trusted Domain List, page 45-11](#)
- [Configuring QoS for AVC with DNS-AS, page 45-12](#)
- [Configuring FNF for AVC with DNS-AS, page 45-16](#)

Prerequisites for Configuring AVC with DNS-AS

- The DNS-AS client can snoop forward look-up requests originating from hosts.
- To ensure DNS packet logging or snooping, you must attach the policy map to the interface, by using the **service-policy input** command.
- You have maintained metadata in the authoritative DNS server and reachability exists - before you enable AVC with DNS-AS.

Restrictions and Guidelines for Configuring AVC with DNS-AS

- Only a forward look-up is supported.
- Two DNS servers are supported, in case of a failover. One is considered the primary DNS server and other, the secondary DNS server.
- IPv6 is not supported—AAAA requests, and IPv6 DNS servers are not supported.
- AVC with DNS-AS is supported only on physical interfaces, in the ingress direction.
- AVC with DNS-AS is not supported on wireless traffic.
- Virtual Routing and Forwarding (VRF) is not supported.
- We recommend a maximum of 300 AVC with DNS-AS applications (domain names) in the binding table, because of its effect on the ternary content addressable memory (TCAM). To know how the addition of applications affects the TCAM see the [Troubleshooting AVC with DNS-AS, page 45-25](#) section of this chapter

Generating Metadata Streams

Application metadata is configured and saved on the local, authoritative DNS server. You configure application classification information, for each trusted domain, in a prescribed format (a metadata stream). This is the information that the server propagates to switches when queried for application metadata. When the switch sends a TXT query regarding an application, the DNS server sends the relevant metadata in the TXT response.

To generate metadata streams, perform the following task:

Step 1	Command or Action	Purpose
	<p>Go to the AVC Resource Record Generator at: https://www.dns-as.org/support/avc-r-data</p>	<p>Helps you generate a metadata stream for an application or domain, in a TXT record format.</p> <p>You can specify the following metadata fields:</p> <ul style="list-style-type: none"> • (Optional) Domain Name • (Mandatory) Application Name—A value is mandatory. This can be an existing application name or custom application name. <ul style="list-style-type: none"> – Existing Application Name (app-name:)—Select from the list of standard applications. – Custom Application Name(app-name:)—If you enter a custom application name, you must also maintain the Traffic Class and Business Relevance information in the metadata stream. • (Optional) Selector ID (app-id:)—Consists of a classification engine ID (first eight bits) and a selector ID (the next twenty-four bits). <ul style="list-style-type: none"> – Classification Engine ID—Defines the context for the selector ID. Only these engine IDs are allowed: <ul style="list-style-type: none"> L3—IANA layer 3 protocol number L4—IANA layer 4 well-known port number L7—Cisco global application ID CU—Custom protocol. Use this engine ID for custom application names. – Selector ID—An application identifier, for a given classification engine ID. Enter a numeric value between 1 and 65535. <p>Note When you enter the engine ID and selector ID for existing application names, be sure to align with the Network Based Application Recognition (NBAR) standard. Only then will the FNF exporters report with a common ID and in a consistent manner.</p> <ul style="list-style-type: none"> • (Optional) Port Range (server-port:) • (Optional) Traffic Class (app-class:) • (Optional) Business Relevance (business:)—If you do not select yes or no, the business relevance value is set based on the app-class or app-name — in that order. <p>For information about how traffic class and business relevance fields here map to QoS traffic classification, see Table 45-1app-class and QoS Traffic Mapping.</p> <p>Sample metadata stream: CISCO-CLS=app-name:example app-class:TD business:YES app-id:CU/28202</p>

	Command or Action	Purpose
Step 2	Click Generate predefined	Generate predefined —Generates a predefined metadata stream for standard applications, using best practice defaults.
	OR Click Generate custom	Generate custom —Generates a custom metadata stream for your applications, using the custom values you have entered.
Step 3	Copy metadata into the corresponding TXT Resource Record of the DNS server in charge of the DNS domain that you have marked as a trusted domain.	Copy and paste the metadata stream from the website, to the authoritative DNS server you are using.

Configuring a DNS Server as the Authoritative Server

All DNS-AS clients in the network should be configured to send all DNS queries to one authoritative DNS server. On a Cisco Catalyst switch, perform the following task:

	Command or Action	Purpose
Step 1	configure terminal	Enters global configuration mode.
	Example: Switch# configure terminal	
Step 2	ip name-server server-address	Specifies the address of the authoritative DNS server. The port number is always 53.
	Example: Switch(config)# ip name-server 192.0.2.1 192.0.2.2	You can configure up to two DNS servers, in case of a failover.
		Note The command allows you configure up to six name servers (IPv4 and IPv6). Ensure that at least the first two IP addresses in the sequence are IPv4 addresses, because the AVC with DNS-AS feature will use only these. See the example below, here the first two addresses are IPv4 (192.0.2.1 and 192.0.2.2), the third one (2001:DB8::1) is an IPv6 address. AVC with DNS-AS will use the first two. Switch(config)# ip name-server 192.0.2.1 192.0.2.2 2001:DB8::1

Enabling AVC with DNS-AS

DNS-AS is disabled by default. To enable the feature on a Cisco Catalyst switch, perform the following task:

	Command or Action	Purpose
Step 1	configure terminal Example: Switch# configure terminal	Enters global configuration mode.
Step 2	[no] avc dns-as client enable Example: Switch(config)# avc dns-as client enable	<p>Enables AVC with DNS-AS on the switch (DNS-AS client).</p> <p>The system then creates a binding table where parsed DNS server responses are stored till the TTL expires.</p> <p>Note To ensure DNS packet logging or snooping, you must attach the policy map (containing the relevant class maps that will determine traffic class) to the interface by using the service-policy input command. For more information see Configuring QoS for AVC with DNS-AS, page 45-12.</p>

Making an Entry in the Trusted Domain List

When AVC with DNS-AS is first enabled on the switch, the trusted domain list is empty. You must maintain the list of trusted domains on the switch. The switch snoops only for network traffic that is maintained in this list. To make entries in this list, perform the following task

	Command or Action	Purpose
Step 1	configure terminal Example: Switch# configure terminal	Enters global configuration mode.
Step 2	[no] avc dns-as client trusted-domains Example: Switch(config)# avc dns-as client trusted-domains	Enters the trusted domain configuration mode.
Step 3	[no] domain domain-name Example: Switch(config-trusted-domains)# domain www.example.com	<p>Enter the domain name. This forms part of the list of trusted domains for the DNS-AS client. All remaining domains are ignored and will follow default forwarding behavior.</p> <p>You can enter up to 50 domains.</p> <p>You can use regular expressions to match the domain name. For example, to represent all the domains for an organization, if you enter:</p> <pre>Switch(config-trusted-domains)# domain *.example.*</pre> <p>The DNS-AS client matches www.example.com, ftp.example.org and any other domain that pertains to the organization “example”.</p> <p>But use such an entry at your discretion, because it could increase the size of the binding table considerably.</p>

Configuring QoS for AVC with DNS-AS

In order to isolate and classify trusted traffic as defined in the metadata stream, you must complete this sequence of tasks—create class maps (one for each traffic class), define traffic-class match criteria and business-relevance match criteria, create a policy map, attach the policy map to the interface. This sub-section provides the following information:

- [Class Map Configuration in the Easy QoS Model, page 45-12](#)
- [Policy Map Definitions in the Easy QoS Model, page 45-13](#)
- [App-Class and QoS Traffic Mapping, page 45-13](#)
- [Sample QoS Configuration for AVC with DNS-AS: Classifying Network Control Traffic, page 45-14](#)

For more QoS information, see the [Classification, page 44-6](#) section of the Configuring QoS chapter in this guide.

Class Map Configuration in the Easy QoS Model

In order to determine how many traffic classes should be provisioned, you can use the 12-class Easy QoS Model. This model provides uniform, standards-based recommendations to help ensure that QoS designs and deployments are unified and consistent across an organization.

The following shows the class map configuration for traffic class and business relevance as per the 12-class Easy QoS Model:

```
class-map match-all VOICE
  match protocol attribute traffic-class voip-telephony
  match protocol attribute business-relevance business-relevant
class-map match-all BROADCAST-VIDEO
  match protocol attribute traffic-class broadcast-video
  match protocol attribute business-relevance business-relevant
class-map match-all REAL-TIME-INTERACTIVE
  match protocol attribute traffic-class real-time-interactive
  match protocol attribute business-relevance business-relevant
class-map match-all MULTIMEDIA-CONFERENCING
  match protocol attribute traffic-class multimedia-conferencing
  match protocol attribute business-relevance business-relevant
class-map match-all MULTIMEDIA-STREAMING
  match protocol attribute traffic-class multimedia-streaming
  match protocol attribute business-relevance business-relevant
class-map match-all SIGNALING
  match protocol attribute traffic-class signaling
  match protocol attribute business-relevance business-relevant
class-map match-all NETWORK-CONTROL
  match protocol attribute traffic-class network-control
  match protocol attribute business-relevance business-relevant
class-map match-all NETWORK-MANAGEMENT
  match protocol attribute traffic-class ops-admin-mgmt
  match protocol attribute business-relevance business-relevant
class-map match-all TRANSACTIONAL-DATA
  match protocol attribute traffic-class transactional-data
  match protocol attribute business-relevance business-relevant
class-map match-all BULK-DATA
  match protocol attribute traffic-class bulk-data
  match protocol attribute business-relevance business-relevant
class-map match-all SCAVENGER
  match protocol attribute business-relevance business-irrelevant
```

Policy Map Definitions in the Easy QoS Model

The following sample output displays the policy map definitions, with traffic attribute marking for all the traffic classes in the 12-class Easy QoS Model:

```

policy-map MARKING
class VOICE
  set dscp ef
class BROADCAST-VIDEO
  set dscp cs5
class REAL-TIME-INTERACTIVE
  set dscp cs4
class MULTIMEDIA-CONFERENCING
  set dscp af41
class MULTIMEDIA-STREAMING
  set dscp af31
class SIGNALING
  set dscp cs3
class NETWORK-CONTROL
  set dscp cs6
class NETWORK-MANAGEMENT
  set dscp cs2
class TRANSACTIONAL-DATA
  set dscp af21
class BULK-DATA
  set dscp af11
class SCAVENGER
  set dscp cs1
class class-default
  set dscp default

```

App-Class and QoS Traffic Mapping

The following table shows how the app-class field in the metadata stream maps to the 12-class Easy QoS Model of traffic classification:

Note

The DNS-AS client applies default forwarding behavior in these cases:

- If the match attributes that you specify for the traffic class and business relevance do not match what you have defined in the metadata stream.
- If the binding table entry is no longer active. This refers to the age of the entry. Use the **show avc dns-as client binding-table** command to display the age of an entry

Table 45-1 app-class and QoS Traffic Mapping

app-class: <Long Text>	app-class: <Short text>	Corresponding Traffic Class and Business Relevance Label in the 12-Class Easy QoS Model
app-class: VOIP-TELEPHONY	app-class: VO	Traffic-class = voip-telephony Business-relevance = YES
app-class: BROADCAST-VIDEO	app-class: BV	Traffic-class = broadcast-video Business-relevance = YES

Table 45-1 app-class and QoS Traffic Mapping

app-class: REALTIME-INTERACTIVE	app-class: RTI	Traffic-class = real-time-interactive Business-relevance = YES
app-class: MULTIMEDIA-CONFERENCING	app-class: MMC	Traffic-class = multimedia-conferencing Business-relevance = YES
app-class: MULTIMEDIA-STREAMING	app-class: MMS	Traffic-class = multimedia-streaming Business-relevance = YES
app-class: NETWORK-CONTROL	app-class: NC	Traffic-class = network-control Business-relevance = YES
app-class: SIGNALING	app-class: CS	Traffic-class = Signaling Business-relevance = YES
app-class: OPS-ADMIN-MGMT	app-class: OAM	Traffic-class = ops-admin-mgmt Business-relevance = YES
app-class: TRANSACTIONAL-DATA	app-class: TD	Traffic-class = Transactional-Data Business-relevance = YES
app-class: BULK-DATA	app-class: BD	Traffic-class = bulk-data Business-relevance = YES
app-class: BEST-EFFORT	app-class: BE	Traffic-class = <no change> Business-relevance = default
app-class: SCAVENGER	app-class: SCV	Traffic-Class = <no change> Business-relevance = NO

Sample QoS Configuration for AVC with DNS-AS: Classifying Network Control Traffic

The following example shows how to classify network-control traffic based on the 12-class Easy QoS model. It shows how the DNS-AS client allows “example.org” to be classified under class-map NETWORK-CONTROL.

For this example, the corresponding metadata that should be maintained is:

```
CISCO-CLS=app-name:example|app-class:NC|business:YES
```

Create class maps and match attributes

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# class-map NETWORK-CONTROL
Switch(config-cmap)# match protocol attribute traffic-class network-control
Switch(config-cmap)# match protocol attribute business-relevance business-relevant
Switch(config-cmap)# end
```

Create the policy map, attach the class map to it and specify priority

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# policy-map MARKING
Switch(config-pmap)# class NETWORK-CONTROL
Switch(config-pmap-c)# set dscp ef
Switch(config-pmap-c)# end
Switch#
```

Attach the policy map to an interface

```
Switch# configure terminal  
Enter configuration commands, one per line. End with CNTL/Z.  
Switch(config)# interface tengigabitethernet 1/0/1  
Switch(config-if)# service-policy input MARKING  
Switch(config-if)# end
```

Configuring FNF for AVC with DNS-AS

With FNF, you can gain visibility into the applications running on your network, and use FNF option templates to export application ID, description, and attribute information.

You must configure these FNF settings on the DNS-AS client:

- Configure a flow record to collect nonkey field **application-name**, and the key fields **ipv4 source address** and **ipv4 destination address**
- Configure a flow exporter and the two option templates, to fetch application information.

Option template **application-table**, exports only applications resolved by the DNS-AS client, that is, the application ID and name from the binding table. The corresponding application descriptions come from Network Based Application Recognition (NBAR) definition for standard applications. A constructed help string is used for custom applications.

Option **application-attributes** fetches attribute information by mapping it to the application name. Where standard application names are used, the option template uses standard NBAR attribute definitions; where custom application names are used, user-defined application names and only certain attribute fields are guaranteed to carry values.

- Configure a flow monitor and apply it to an interface to enable network traffic monitoring.

FNF Interaction with DNS-AS—With every flow that is created in the flow table, the DNS-AS client resolves the application name for the flow (if the entry exists in the binding table), by using the destination IP address (and if not available), the source IP address.

At periodic, configured intervals (600 seconds, by default), FNF exports option template data, that is mapped to the corresponding application name, to an external collector.

For more information about FNF, see the [Configuring Flexible NetFlow](#) chapter in this guide.

These sections provide more information:

- [Option Templates](#), page 45-16
- [Sample FNF Configuration for AVC with DNS-AS](#), page 45-18

Option Templates

The **application-table** and **application-attributes** options templates are supported. These templates determine the information that will be exported to an external collector.

option application-table

Exports the application name, application tag, and description to the external collector.

On a device where AVC with DNS-AS is enabled, only applications resolved by the DNS-AS client are exported. But in addition, the application-table template exports two applications called *unclassified* and *unknown*, irrespective of whether the feature is enabled or not.

- **Application Name**—For custom and standard applications, this information is derived from the TXT response (**app-name**;) that is saved in the binding table.
- **Application Tag**—This is same as application ID in the context of the AVC with DNS-AS feature and consists of the engine ID and selector ID.

- **Engine ID or Classification Engine ID**—Defines the context for the selector ID. Only these values are supported:

L3—IANA layer 3 protocol number (IANA_L3_STANDARD, ID: 1)

L4—IANA layer 4 well-known port number (IANA_L4_STANDARD, ID: 3)

L7—Cisco global application ID (CISCO_L7_GLOBAL, ID: 13)

CU—Custom protocol, (NBAR_CUSTOM, ID: 6). For custom applications, the DNS-AS client automatically uses this engine ID.

- Selector ID—Uniquely identifies the application or classification.

For standard applications, the application tag information is derived from these sources, in the given order of precedence:

1. TXT response (**app-id**.)
2. The NBAR definition for standard applications (if the TXT response does not carry a value)

For custom applications, the following applies to application tag information:

1. It is derived only from the TXT response (**app-id**.)
 2. For the engine ID, the DNS-AS client automatically uses CU—Custom protocol, (NBAR_CUSTOM, ID: 6).
 3. For the selector ID, the DNS-AS client allots a custom selector ID. A maximum of 120 custom applications are supported - out of which 110 are available to the DNS-AS client. Starting with selector ID value 243, IDs are assigned in descending order. When there are no remaining IDs to assign, the entry is not saved in the binding table.
- Description—This information is derived from the NBAR definition for standard applications. For custom applications, the DNS-AS client uses: User Defined Protocol <app-name>.

option application-attributes

Enables the collector to map the application names (from the **option application-table**) to their attributes. Attributes are statically assigned to each protocol or application, and are not dependent on traffic.

For standard applications—

- Application Tag—Guidelines that apply this field as part of the option application-table template apply here as well.
- Category—Groups applications based on the first level of categorization for each protocol as the match criteria. Similar applications are grouped together under one category. For example, the email category contains all email applications such as, Internet Mail Access Protocol (IMAP), Simple Mail Transfer Protocol (SMTP), Lotus Notes, and so on.
- Sub-category—Groups applications based on the second level of categorization for each protocol as the match criteria. For example, clearcase, dbase, rda, mysql and other database applications are grouped under the database group.
- Application Group—Groups the same networking applications together. For instance, Example-Messenger, Example-VoIP-messenger, and Example-VoIP-over-SIP are grouped together under the example-messenger-group
- Peer-to-peer (p2p)—Groups protocols based on whether or not they use p2p technology.
- Tunnel—Groups protocols based on whether or not a protocol tunnels the traffic of other protocols. Protocols for which the NBAR does not provide any value are categorized under the unassigned tunnel group. For example, Layer 2 Tunneling Protocols (L2TP).
- Encryption—Groups applications based on the encrypted and nonencrypted status of the applications. Protocols for which the NBAR does not provide any value are categorized under the unassigned encrypted group.

- Traffic class—Groups applications and protocols based on the traffic class they belong to. For example, all applications that have traffic class `TD`.

Traffic class information is derived from these sources, in the given order of precedence:

1. TXT response (**app-class:**)
 2. The NBAR definition for standard applications (if the TXT response does not carry a value)
- Business relevance—Groups applications based on whether or not they have been marked as business-relevant. For example, all applications that have business relevance as `YES`.

Business relevance information is derived from these sources, in the given order of precedence:

1. TXT response (**business:**)
2. The NBAR definition for standard applications (if the TXT response does not carry a value)

For custom applications—

Only these attributes of the application-attributes option template are guaranteed to carry a value:

- Application Tag—See the Application Tag info in section [option application-table, page 45-16](#) above. The same applies here as well.
- Traffic class—This information is derived from the TXT response (**app-class:**)
- Business Relevance—This information is derived from the TXT response (**business:**)

Sample FNF Configuration for AVC with DNS-AS

The following example shows how you can configure FNF for AVC with DNS-AS:

1. Create a flow record. As in the example, you must configure:
 - The source and destination IP addresses as key fields, in order to resolve application names.
 - The use of the application name as a nonkey field in flow record.

Additionally (not mandatory), you can also configure the number of bytes or packets in a flow as a nonkey field, to display the number of applications sent to the collector.

```
Switch# configure terminal
Switch(config)# flow record example-record1
Switch(config-flow-record)# match ipv4 source address
Switch(config-flow-record)# match ipv4 destination address
Switch (config-flow-record)# collect application name
Switch (config-flow-record)# collect counter packets
Switch (config-flow-record)# exit
```

```
Switch# show flow record example-record1
flow record example-record1
match ipv4 source address
match ipv4 destination address
collect application name
collect counter packets
```

2. Create a flow exporter. Also configure the **application-table** and **application-attributes** option templates in the exporter. Without option templates, the collector cannot retrieve meaningful application information. At a minimum we recommend that you configure the application-table option. For attribute information, also configure the application-attribute option.

You can also change the frequency of template export in seconds (the allowed range is 1 to 86400 seconds; the default is 600 seconds)

```
Switch(config)# flow exporter example-exporter1
```

```

Switch(config-flow-exporter)# option application-table
Switch(config-flow-exporter)# option application-attributes
Switch(config-flow-exporter)# template data timeout 500
Switch(config-flow-exporter)# exit

Switch#show flow exporter example-exporter1
Flow Exporter example-exporter1:
  Description:                User defined
  Export protocol:            NetFlow Version 9
  Transport Configuration:
    Destination IP address:    192.0.1.254
    Source IP address:        192.51.100.2
    Transport Protocol:       UDP
    Destination Port:         9995
    Source Port:              54964
    DSCP:                     0x0
    TTL:                      255
    Output Features:          Not Used
  Options Configuration:
    application-table (timeout 500 seconds)
    application-attributes (timeout 500 seconds)

Switch# show flow exporter example-exporter1 statistics
Flow Exporter example-exporter1:
  Packet send statistics (last cleared 00:00:48 ago):
    Successfully sent:         2                               (924 bytes)

  Client send statistics:
    Client: Option options application-name
      Records added:           4
      - sent:                  4
      Bytes added:             332
      - sent:                  332

    Client: Option options application-attributes
      Records added:           2
      - sent:                  2
      Bytes added:             388
      - sent:                  388

```

3. Create a flow monitor and apply it to an interface to perform network traffic monitoring.

The interface you apply the flow monitor to, can also be the same interface you have applied the QoS policy to. This example applies the QoS policy created as part of the sample QoS configuration [Sample QoS Configuration for AVC with DNS-AS: Classifying Network Control Traffic](#), page 45-14.

```

Switch# configure terminal
Switch(config)# flow monitor example-monitor1
Switch(config-flow-monitor)# record example-record1

Monitoring AVC with DNS-AS

To display the various AVC with DNS-AS settings you have configured, use these **show** commands in the privileged EXEC mode:

Table 45-2 AVC with DNS-AS Monitoring Commands

Command	Purpose	Example
show avc dns-as client status	Displays current status of the DNS-AS client—whether AVC with DNS-AS is enabled or not.	Example: show avc dns-as client status
show avc dns-as client trusted-domains	Displays list of trusted domains configured.	Example: show avc dns-as client trusted-domains
show avc dns-as client binding-table and show avc dns-as client binding-table detail	Displays AVC with DNS-AS metadata for the list of trusted domains and resolved entries. You can filter the output by application name, domain name, and so on. Both commands display the same information, in different formats.	Example: show avc dns-as client binding-table detail

Table 45-2 AVC with DNS-AS Monitoring Commands

Command	Purpose	Example
show avc dns-as client statistics	Displays packet logging information—the number of DNS queries sent and the number of responses received.	Example: show avc dns-as client statistics
show avc dns-as client name-server brief	Displays information about the DNS server to which the metadata request was sent.	Example: show avc dns-as client name-server brief
show ip name-server	Displays all the name server IP addresses that have been maintained	Example: show ip name-server

Example: show avc dns-as client status

```
Switch# show avc dns-as client status
DNS-AS client is enabled
```

Troubleshooting AVC with DNS-AS

Problem	Possible Causes and Solutions
There are no entries in the binding table	<p>The binding table may be empty because of one or both of these reasons:</p> <ul style="list-style-type: none"> • Metadata is not maintained in DNS server—complete task Generating Metadata Streams, page 45-8 • The entry is not maintained in the trusted domain list—complete task Making an Entry in the Trusted Domain List, page 45-11
Unsuccessful DNS snooping or packet logging.	To ensure DNS snooping and packet logging, you must attach the policy map (containing the relevant class maps that will determine traffic class) to the interface—See the example in the Configuring QoS for AVC with DNS-AS section.
The DNS server does not return correct values	<p>Verify that the correct DNS-AS metadata is maintained in the DNS system</p> <ul style="list-style-type: none"> • Using Linux dig: <pre>dig TXT +short www.example.org [dns-server-ip] "CISCO-CLS=app-name:example app-class:TD business:YES app-id:CU/28 202"</pre> • Using Windows nslookup: <pre>C:\Windows\system32>NSLookup.exe -q=TXT www.example.org [dns-server-ip] www.example.org text = "CISCO-CLS=app-name:example app-class:TD business:YES app-id:CU/28 202"</pre>
The QoS policy you applied to the port is removed.	<p>When the DNS-AS client recognises an application, along with saving the "A" record response in the binding table, the system utilises the TCAM to save the IP address of the application. A single application can in effect have multiple IP addresses, each utilising additional space in the TCAM. When the TCAM is exhausted, QoS policies cease to be applied.</p> <p>To avoid the problem, monitor TCAM utilisation on a regular basis. Enter the show platform tcam utilisation command in privilege EXEC mode, to display information about TCAM availability.</p>

Configuring Voice Interfaces

This chapter describes how to configure voice interfaces for the Catalyst 4500 series switches.

This chapter includes the following major sections:

- [About Voice Interfaces, page 46-1](#)
- [Configuring a Port to Connect to a Cisco 7960 IP Phone, page 46-2](#)
- [Configuring Voice Ports for Voice and Data Traffic, page 46-3](#)
- [Overriding the CoS Priority of Incoming Frames, page 46-4](#)
- [Configuring Power, page 46-5](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Voice Interfaces

Catalyst 4500 series switches can connect to a Cisco 7960 IP Phone and carry IP voice traffic. If necessary, the switch can supply electrical power to the circuit connecting it to the Cisco 7960 IP Phone.

Because the sound quality of an IP telephone call can deteriorate if the data is unevenly sent, the switch uses quality of service (QoS) based on IEEE 802.1p class of service (CoS). QoS uses classification and scheduling to transmit network traffic from the switch in a predictable manner. See [Chapter 44, “Configuring Quality of Service,”](#) for more information on QoS.

You can configure the Cisco 7960 IP Phone to forward traffic with an 802.1p priority. You can use the CLI to configure a Catalyst 4500 series switch to honor or ignore a traffic priority assigned by a Cisco 7960 IP Phone.

The Cisco 7960 IP Phone contains an integrated three-port 10/100 switch. The ports are dedicated connections as described below:

- Port 1 connects to the Catalyst 4500 series switch or other device that supports voice-over-IP.
- Port 2 is an internal 10/100 interface that carries the phone traffic.
- Port 3 connects to a PC or other device.

[Figure 46-1](#) shows one way to configure a Cisco 7960 IP Phone.

Figure 46-1 Cisco 7960 IP Phone Connected to a Catalyst 4500 Series Switch

Cisco IP Phone Voice Traffic

You can configure an access port with an attached Cisco IP phone to use one VLAN for voice traffic and another VLAN for data traffic from a device attached to the phone. You can configure access ports on the switch to send Cisco Discovery Protocol (CDP) packets that instruct an attached phone to send voice traffic to the switch in any of these ways:

- In the voice VLAN tagged with a Layer 2 CoS priority value
- In the access VLAN tagged with a Layer 2 CoS priority value
- In the access VLAN, untagged (no Layer 2 CoS priority value)

**Note**

In all configurations, the voice traffic carries a Layer 3 IP precedence value (the default is 5 for voice traffic and 3 for voice control traffic).

Cisco IP Phone Data Traffic

The switch can also process tagged data traffic (traffic in IEEE 802.1Q or IEEE 802.1p frame types) from the device attached to the access port on the Cisco IP phone. See [Figure 46-1](#). You can configure Layer 2 access ports on the switch to send CDP packets that instruct the attached phone to configure the phone access port in one of these modes:

- In trusted mode, all traffic received using the access port on the Cisco IP phone passes using the phone unchanged.
- In untrusted mode, all traffic in IEEE 802.1Q or IEEE 802.1p frames received using the access port on the Cisco IP phone receive a configured Layer 2 CoS value. The default Layer 2 CoS value is 0. Untrusted mode is the default.

**Note**

Untagged traffic from the device attached to the Cisco IP phone passes using the phone unchanged, regardless of the trust state of the access port on the phone.

Configuring a Port to Connect to a Cisco 7960 IP Phone

Because a Cisco 7960 IP Phone also supports connection to a PC or another device, an interface connecting a Catalyst 4500 series switch to a Cisco 7960 IP Phone can carry a mix of voice and data traffic.

The three configurations for a port connected to a Cisco 7960 IP Phone are as follows:

- All traffic is transmitted according to the default CoS priority of the port. it is the default.

- Voice traffic is given a higher priority by the phone (CoS priority is always 5), and all traffic is in the same VLAN.
- Voice and data traffic are carried on separate VLANs.

To configure a port to instruct the phone to give voice traffic a higher priority and to forward all traffic using the 802.1Q native VLAN, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch(config)# interface { fastethernet gigabitethernet } <i>slot/port</i>	Specifies the interface to configure.
Step 3	Switch(config-if)# switchport voice vlan dot1p	Instructs the switch to use 802.1p priority tagging for voice traffic and to use VLAN 1 (default native VLAN) to carry all traffic.
Step 4	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 5	Switch# show interface { fastethernet gigabitethernet } <i>slot/port</i> switchport	Verifies the port configuration.

Configuring Voice Ports for Voice and Data Traffic

Because voice and data traffic can travel using the same voice port, you should specify a different VLAN for each type of traffic. You can configure a switch port to forward voice and data traffic on different VLANs.

Note

For information on configuring sticky port security on voice VLANs, see the [“Configuring Port Security on Voice Ports”](#) section on page 55-22.

Note

For information on using 802.1X with voice VLANs, see the [“Using 802.1X with Voice VLAN Ports”](#) section on page 49-21.

To configure a port to receive voice and data traffic from a Cisco IP phone on different VLANs, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch(config)# interface { fastethernet gigabitethernet } <i>slot/port</i>	Specifies the interface to configure.
Step 3	Switch(config-if)# switchport mode access	Configures the interface as an access port. The voice VLAN is active only on access ports.
Step 4	Switch(config-if)# switchport voice vlan <i>vlan_num</i>	Instructs the Cisco IP phone to forward all voice traffic through a specified VLAN. The Cisco IP phone forwards the traffic with an 802.1p priority of 5.
Step 5	Switch(config-if)# switchport access vlan <i>data_vlan_num</i>	Configures the access VLAN (the data VLAN) on the port.

	Command	Purpose
Step 6	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 7	Switch# show interface { fastethernet gigabitethernet } <i>slot/port</i> switchport	Verifies the configuration.

In the following example, VLAN 1 carries data traffic, and VLAN 2 carries voice traffic. In this configuration, you must connect all Cisco IP phones and other voice-related devices to switch ports that belong to VLAN 2.

```
Switch# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch(config)# interface fastEthernet 3/1
Switch(config-if)# switchport mode access
Switch(config-if)# switchport voice vlan 2
Switch(config-if)# switchport access vlan 3
Switch(config-if)# end
Switch# show interfaces fastEthernet 3/1 switchport

Switch#
```

Overriding the CoS Priority of Incoming Frames

A PC or another data device can connect to a Cisco 7960 IP Phone port. The PC can generate packets with an assigned CoS value. You can also use the switch CLI to override the priority of frames arriving on the phone port from connected devices, and you can set the phone port to accept (trust) the priority of frames arriving on the port.

To override the CoS priority setting received from the non-voice port on the Cisco 7960 IP Phone, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch(config)# interface { fastethernet gigabitethernet } <i>slot/port</i>	Specifies the interface to configure.
Step 3	Switch(config-if)# [no] qos trust extend cos 3	Sets the phone port to override the priority received from the PC or the attached device and forward the received data with a priority of 3. Use the no keyword to return the port to its default setting.
Step 4	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 5	Switch# show interface { fastethernet gigabitethernet } <i>slot/port</i> switchport	Verifies the change.

Configuring Power

The Catalyst 4500 series switch recognizes that it is connected to a Cisco 7960 IP Phone. The Catalyst 4500 series switch can supply Power over Ethernet (PoE) to the Cisco 7960 IP Phone if there is no power on the circuit. The Cisco 7960 IP Phone can also be connected to an AC power source and supply its own power to the voice circuit. If there is power on the circuit, the switch does not supply it.

You can configure the switch not to supply power to the Cisco 7960 IP Phone and to disable the detection mechanism. For information on the CLI commands that you can use to supply PoE to a Cisco 7960 IP Phone, see [Chapter 15, “Configuring Power over Ethernet.”](#)

Configuring Private VLANs

This chapter describes how to implement private VLANs (PVLANS) on Catalyst 4500 series switches. It also provides restrictions, procedures, and configuration examples.

This chapter includes the following major sections:

- [About Private VLANs, page 47-1](#)
- [PVLAN Commands, page 47-10](#)
- [Configuring PVLANS, page 47-11](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Private VLANs

The private VLAN (PVLAN) feature addresses two problems that service providers face when using VLANs:

- The switch supports up to 4094 active VLANs. If a service provider assigns one VLAN per customer, this limits the numbers of customers the service provider can support.
- To enable IP routing, each VLAN is assigned a subnet address space or a block of addresses, which can result in wasting the unused IP addresses, and cause IP address management problems.

To configure PVLANS, you need to understand the concepts in these sections:

- [Purpose of a PVLAN, page 47-2](#)
- [PVLAN Terminology, page 47-3](#)
- [PVLANS across Multiple Switches, page 47-5](#)
- [PVLAN Modes Over Gigabit Etherchannel, page 47-8](#)
- [Private-VLAN Interaction with Other Features, page 47-8](#)

Purpose of a PVLAN

Using PVLANs provides scalability and IP address management benefits for service providers and Layer 2 security for customers. PVLANs partition a regular VLAN domain into subdomains. A subdomain is represented by a pair of VLANs: a *primary* VLAN and a *secondary* VLAN. A PVLAN can have multiple VLAN pairs, one pair for each subdomain. All VLAN pairs in a PVLAN share the same primary VLAN. The secondary VLAN ID differentiates one subdomain from another. See [Figure 47-1](#).

Figure 47-1 Private-VLAN Domain

The three types of secondary VLANs are as follows:

- Isolated VLANs—Ports within an isolated VLAN cannot communicate with each other at the Layer 2 level.
- Community VLANs—Ports within a community VLAN can communicate with each other but cannot communicate with ports in other communities at the Layer 2 level.
- Twoway-Community VLANs—Bidirectional VLAN. Ports within a twoway-community VLAN can communicate with each other but not with communities or twoway-communities at the Layer 2 level.

Note

Beginning with Cisco IOS Release 15.0(2)SG, you can use a twoway-community VLAN to apply VACLs or QoS in both directions per-community and per-customer.

A promiscuous port can serve only one primary VLAN, one isolated VLAN, and multiple community (or twoway-community) VLANs. Layer 3 gateways are typically connected to the switch through a promiscuous port.

In a switched environment, you can assign an individual PVLAN and associated IP subnet to each individual or common group of end stations. The end stations need to communicate only with a default gateway to communicate outside the PVLAN.

You can use PVLANs to control access to end stations in these ways:

- Configure selected interfaces connected to end stations as isolated ports to prevent any communication at Layer 2. For example, if the end stations are servers, this configuration prevents Layer 2 communication between the servers.
- Configure interfaces connected to default gateways and selected end stations (such as, backup servers) as promiscuous ports to allow all end stations access to a default gateway.
- Reduce VLAN and IP subnet consumption; you can prevent traffic between end stations even though they are in the same VLAN and IP subnet.

With a promiscuous port, you can connect a wide range of devices as access points to a PVLAN. For example, you can connect a promiscuous port to the server port of a LocalDirector to connect an isolated VLAN or a number of community (or twoway-community) VLANs to the server. LocalDirector can load balance the servers present in the isolated, community, or twoway-community VLANs, or you can use a promiscuous port to monitor or back up all the PVLAN servers from an administration workstation.

PVLAN Terminology

The following table defines the key terms used in this chapter:

Term	Definition
PVLANs	PVLANs are sets of VLAN pairs that share a common primary identifier and provide a mechanism for achieving layer-2 separation between ports while sharing a single layer-3 router port and IP subnet.
Secondary VLAN	A type of VLAN used to implement PVLANs. Secondary VLANs are associated with a primary VLAN, and are used to carry traffic from hosts to other allowed hosts or to routers.
Community Port	A community port is a host port that belongs to a community secondary VLAN. Community ports communicate with other ports in the same community VLAN and with promiscuous ports. These interfaces are isolated at Layer 2 from all other interfaces in other communities and from isolated ports within their PVLAN.
Community VLAN	Community VLAN—A community VLAN is a secondary VLAN that carries upstream traffic from the community ports to the promiscuous port gateways and to other host ports in the same community. You can configure multiple community VLANs in a PVLAN.

Term	Definition
Isolated Port	An isolated port is a host port that belongs to an isolated secondary VLAN. It has complete Layer 2 separation from other ports within the same PVLAN, except for the promiscuous ports. PVLANS block all traffic to isolated ports except traffic from promiscuous ports. Traffic received from an isolated port is forwarded only to promiscuous ports.
Isolated VLAN	Isolated VLAN —A PVLAN has only one isolated VLAN. An isolated VLAN is a secondary VLAN that carries unidirectional traffic upstream from the hosts toward the promiscuous ports and the gateway.
Primary VLAN	Primary VLAN—A PVLAN has only one primary VLAN. Every port in a PVLAN is a member of the primary VLAN. The primary VLAN carries unidirectional traffic downstream from the promiscuous ports to the (isolated and community) host ports and to other promiscuous ports.
PVLAN Trunk Port	A PVLAN trunk port can carry multiple secondary (isolated only) and non-PVLANS. Packets are received and transmitted with secondary or regular VLAN tags on the PVLAN trunk ports. Note Only IEEE 802.1q encapsulation is supported.
Promiscuous Port	A promiscuous port belongs to the primary VLAN and can communicate with all interfaces, including the community and isolated host ports and PVLAN trunk ports that belong to the secondary VLANs associated with the primary VLAN.
Promiscuous Trunk Port	A promiscuous trunk port can carry multiple primary and normal VLANs. Packets are received and transmitted with primary or regular VLAN tags. Other than that, the port behaves just like a promiscuous access port. Note Only IEEE 802.1q encapsulation is supported.
Two-way-Community Ports	A two-way-community port is a host port that belongs to a two-way-community secondary VLAN. Ports within a two-way-community VLAN can communicate with each other but not with ports in other communities or two-way-communities at the Layer 2 level. These interfaces are isolated at Layer 2 from all other interfaces in other two-way communities and from isolated ports within their PVLAN.
Two-way-Community VLANs	A bidirectional VLAN. Ports within a 2-way community VLAN can communicate with each other but cannot communicate with ports in other 2-way communities at the Layer 2 level.

PVLANS across Multiple Switches

This section discusses the following topics:

- [Standard Trunk Ports, page 47-5](#)
- [Isolated PVLAN Trunk Ports, page 47-6](#)
- [Promiscuous PVLAN Trunk Ports, page 47-7](#)

Standard Trunk Ports

As with regular VLANs, PVLANS can span multiple switches. A trunk port carries the primary VLAN and secondary VLANs to a neighboring switch. The trunk port treats the PVLAN as any other VLAN. A feature of PVLANS across multiple switches is that traffic from an isolated port in switch A does not reach an isolated port on Switch B. See [Figure 47-2](#).

To maintain the security of your private-VLAN configuration and to avoid other use of the VLANs configured as PVLANS, configure PVLANS on all intermediate devices, including devices that have no private-VLAN ports.

Note

Trunk ports carry traffic from regular VLANs and also from primary, isolated, community or twoway community VLANs.

Note

You should use standard trunk ports if both switches undergoing trunking support PVLANS.

Figure 47-2 PVLANS across Switches

VLAN 100 = Primary VLAN
 VLAN 201 = Secondary isolated VLAN
 VLAN 202 = Secondary community or Twoway-community VLAN

208745

Because VTP does not support PVLANS, you must manually configure PVLANS on all switches in the Layer 2 network. If you do not configure the primary and secondary VLAN association in some switches in the network, the Layer 2 databases in these switches are not merged. This can result in unnecessary flooding of private-VLAN traffic on those switches.

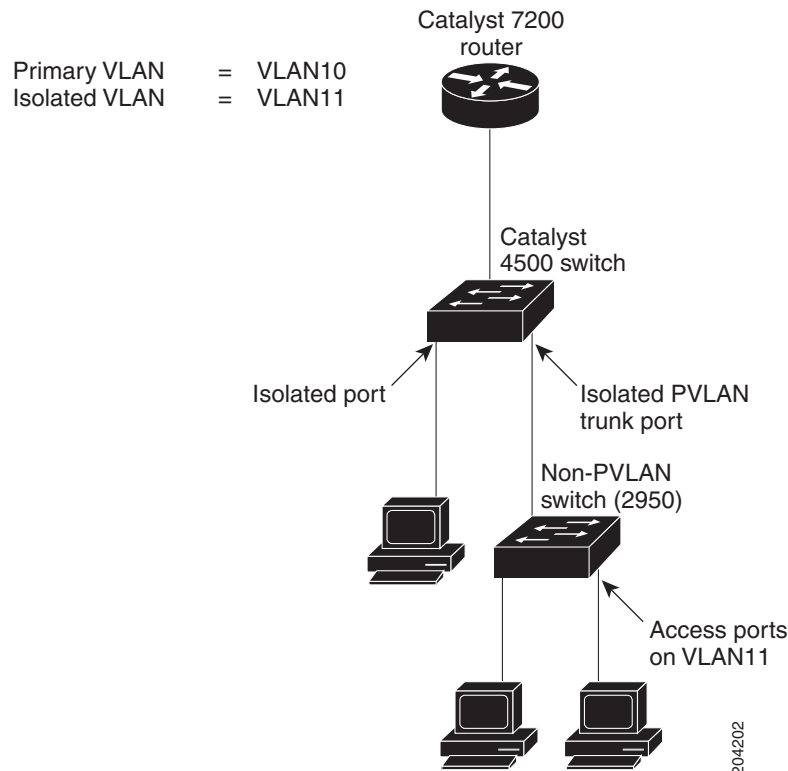

**Note**

PVLANS are supported in VTP v3 under server mode.

Isolated PVLAN Trunk Ports

You would use a isolated PVLAN trunk ports when you would anticipate using PVLAN isolated host ports to carry multiple VLANs, either normal VLANs or for multiple PVLAN domains. This makes it useful for connecting a downstream switch that does not support PVLANS such as Catalyst 2950.

Figure 47-3 **Isolated PVLAN Trunk Ports**

In this illustration, a Catalyst 4500 switch is being used to connect a downstream switch that does not support PVLANS.

Traffic being sent in the downstream direction towards host1 from the router is received by the Catalyst 4500 series switch on the promiscuous port and in the primary VLAN (VLAN 10). The packets are then switched out of the isolated PVLAN trunk. Rather than being tagged with the primary VLAN (VLAN 10), they are transmitted with the isolated VLAN's tag (VLAN 11). In this way, when the packets arrive on the non-PVLAN switch, they can be bridged to the destination hosts' access port.

Traffic in the upstream direction is sent by host1 to the non-PVLAN switch, arriving in VLAN 11. The packets are then transmitted to the switch tagged with that VLAN's tag (VLAN 11) over the trunk port. On the switch, VLAN 11 is configured as the isolated VLAN, and the traffic is forwarded as if it came from an isolated host port.

**Note**

When an isolated trunk is used in this way, Catalyst 4500 series switch provides isolation between the isolated trunk and directly connected hosts (such as host3) but not between hosts connected to the non-PVLAN switch (such as host1 and host2). The non-PVLAN switch must provide isolation between these hosts, using a feature such as protected ports on a Catalyst 2950.

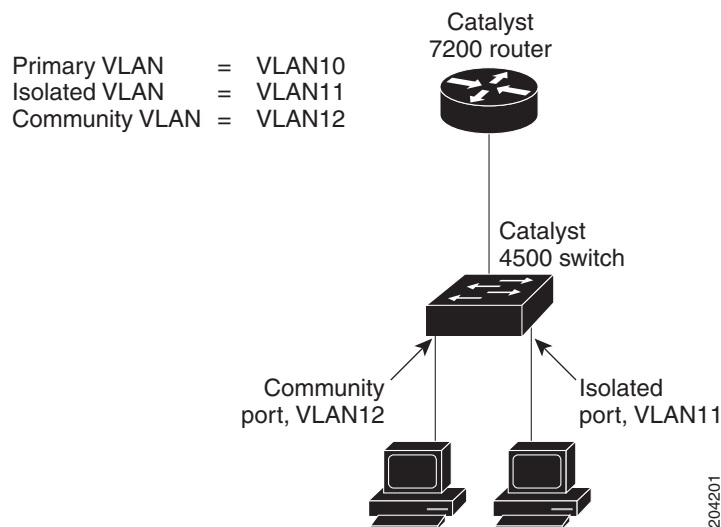

For details on protected ports, see the URL:

http://www.cisco.com/en/US/docs/switches/lan/catalyst2950/software/release/12.1_22_ea11x/configuration/guide/swtrafc.html#wp1158863

Promiscuous PVLAN Trunk Ports

PVLAN promiscuous trunks are used in situations where one would normally use a PVLAN promiscuous host port but where it is necessary to carry multiple VLANs, either normal VLANs or for multiple PVLAN domains. This makes it useful for connecting an upstream router that does not support PVLANs, such as a Cisco 7200.

Figure 47-4 Promiscuous PVLAN Trunk Ports

In [Figure 47-4](#), a Catalyst 4500 series switch connects a PVLAN domain to an upstream router that does not support PVLANs. Traffic being sent upstream by host1 arrives on the switch in the community VLAN (VLAN 12). When this traffic is bridged onto the promiscuous PVLAN trunk towards the router, it is tagged with the primary VLAN (VLAN 10). This way it can be routed using the correct subinterface configured on the router.

Traffic in the downstream direction is received on the promiscuous PVLAN trunk port by the switch in the primary VLAN (VLAN 10), just as if it had been received on a promiscuous host port. It can then be bridged to the destination host as in any PVLAN domain.

PVLAN promiscuous trunks interact with VLAN QoS. Refer to the section [“PVLANs and VLAN ACL/QoS”](#) section on [page 47-8](#).

PVLAN Modes Over Gigabit Etherchannel

Beginning with Cisco IOS Release 15.0(2)SG you can configure PVLAN modes over Etherchannel. These new modes are:

- Host mode - Isolated, Community and 2-way community
- Promiscuous mode
- Secondary Isolated trunks
- Promiscuous trunks

The process of bundling ports has not changed. PVLAN modes are added to already existing modes such as access, trunk, routed, tunneled etc.

Feature interactions include:

- A primary VLAN can be associated with multiple community and twoway-community VLANs, but only one isolated VLAN.
- An isolated or community VLAN or 2-way community VLAN can be associated with only one primary VLAN.
- If you delete a VLAN used in a PVLAN configuration, the PVLAN ports associated with the VLAN become inactive.
- The default native VLAN for promiscuous trunk port is VLAN 1 (management VLAN). All untagged packets are forwarded in the native VLAN. Either the primary VLANs or a regular VLAN can be configured as the native VLAN.
- No default native VLAN set exists on an isolated secondary trunks. All untagged packets are dropped, if no native VLAN is configured.
- Community and twoway-community VLANs cannot be propagated or carried over PVLAN trunks.
- For IGMP Snooping, IGMP reports are learned on the primary VLAN and the platform decides if packet must be forwarded in the primary or secondary VLANs.

For details on configuring PVLANs over EtherChannel, Refer to the section [“Configuring PVLAN over EtherChannel”](#) section on page 47-24.

Private-VLAN Interaction with Other Features

PVLANs have specific interaction with some other features, described in these sections:

- [PVLANs and VLAN ACL/QoS, page 47-8](#)
- [PVLANs and Unicast, Broadcast, and Multicast Traffic, page 47-9](#)
- [PVLANs and SVIs, page 47-10](#)
- [Per-Virtual Port Error-Disable on PVLANs, page 47-10](#)

For details, see the section “PVLAN Configuration Guidelines and Restrictions” on page 12.

PVLANs and VLAN ACL/QoS

PVLAN ports use primary and secondary VLANs, as follows:

- A packet received on a PVLAN host port belongs to the secondary VLAN.

- A packet received on a PVLAN trunk port belongs to the secondary VLAN if the packet is tagged with a secondary VLAN or if the packet is untagged and the native VLAN on the port is a secondary VLAN.

A packet received on a PVLAN host or trunk port and assigned to a secondary VLAN is bridged on the secondary VLAN. Because of this bridging, the secondary VLAN ACL as well as the secondary VLAN QoS (on input direction) apply.

When a packet is transmitted out of a PVLAN host or trunk port, the packet logically belongs to the primary VLAN. This relationship applies even though the packet may be transmitted with the secondary VLAN tagging for PVLAN trunk ports. In this situation, the primary VLAN ACL and the primary VLAN QoS on output apply to the packet.

- Similarly, a packet received on a PVLAN promiscuous access port belongs to primary VLAN.
- A packet received on a PVLAN promiscuous trunk port could belong to the primary VLAN or normal VLAN depending on incoming VLAN.

For traffic flowing in normal VLAN on promiscuous trunk ports, normal VLAN ACL and QoS policies apply. For traffic flowing in a PVLAN domain, a packet received on a promiscuous port is bridged in primary VLAN. The primary VLAN ACL and QoS policies apply on input.

For egress traffic on twoway-community host port, the secondary VLAN ACL and secondary VLAN QoS apply to egress unicast routed traffic stemming from the integrated router port.

When a packet is transmitted out of a promiscuous trunk port, the packet could logically belong to secondary VLAN if received from a secondary port, or in primary VLAN if bridged from another promiscuous port. Because we cannot differentiate between both packets, all VLAN QoS policies are ignored on packets egressing promiscuous trunk ports.

PVLANS and Unicast, Broadcast, and Multicast Traffic

In regular VLANs, devices in the same VLAN can communicate with each other at the Layer 2 level, but devices connected to interfaces in different VLANs must communicate at the Layer 3 level. In PVLANS, the promiscuous ports are members of the primary VLAN, while the host ports belong to secondary VLANs. Because the secondary VLAN is associated to the primary VLAN, members of these VLANs can communicate with each other at the Layer 2 level.

In a regular VLAN, broadcasts are forwarded to all ports in that VLAN. PVLAN broadcast forwarding depends on the port sending the broadcast:

- An isolated port sends a broadcast only to the promiscuous ports or trunk ports.
- A community port sends a broadcast to all promiscuous ports, trunk ports, and ports in the same community VLAN.
- A promiscuous port sends a broadcast to all ports in the PVLAN (other promiscuous ports, trunk ports, isolated ports, and community ports).

Multicast traffic is routed or bridged across private-VLAN boundaries and within a single community VLAN. Multicast traffic is not forwarded between ports in the same isolated VLAN or between ports in different secondary VLANs.

Transmitting Multicast traffic through secondary private VLAN where the multicast source is located is not supported. This might result in software switching of the packets and thereby causing significantly lower forwarding rate and packet loss.

PVLANS and SVIs

In a Layer 3 switch, a switch virtual interface (SVI) represents the Layer 3 interface of a VLAN. Layer 3 devices communicate with a PVLAN only using the primary VLAN and not through secondary VLANs. Configure Layer 3 VLAN interfaces (SVIs) only for primary VLANs. You cannot configure Layer 3 VLAN interfaces for secondary VLANs. SVIs for secondary VLANs are inactive while the VLAN is configured as a secondary VLAN.

- If you try to configure a VLAN with an active SVI as a secondary VLAN, the configuration is not allowed until you disable the SVI.
- If you try to create an SVI on a VLAN that is configured as a secondary VLAN and the secondary VLAN is already mapped at Layer 3, the SVI is not created, and an error is returned. If the SVI is not mapped at Layer 3, the SVI is created, but it is automatically shut down.

When the primary VLAN is associated with and mapped to the secondary VLAN, any configuration on the primary VLAN is propagated to the secondary VLAN SVIs. For example, if you assign an IP subnet to the primary VLAN SVI, this subnet is the IP subnet address of the entire PVLAN.

Per-Virtual Port Error-Disable on PVLANS

For PVLANS, per-virtual port error-disable behavior is defined as follows:

- On a PVLAN promiscuous or promiscuous trunk ports, if a violation occurs on the primary VLAN, it is error-disabled.
- On a PVLAN host or trunk port, if a violation occurs on the secondary VLAN, the associated primary VLAN is error-disabled.
- On a standard trunk port that carries both primary and secondary VLANs, if a violation occurs on the primary VLAN, this VLAN and all its associated secondary VLANs are error-disabled. If a violation occurs on a secondary VLAN, the associated primary VLAN and all its associated secondary VLANs are error-disabled.

PVLAN Commands

This table lists the commands most commonly used with PVLANS.

Command	Purpose	Location
private-vlan { community twoway-community isolated primary }	Configures a VLAN as a PVLAN.	Configuring a VLAN as a PVLAN, page 47-15
private-vlan association { <i>secondary_vlan_list</i> add <i>secondary_vlan_list</i> remove <i>secondary_vlan_list</i> }	Associates the secondary VLAN with the primary VLAN. The list can contain only one isolated VLAN ID; it can also contain multiple community VLAN IDs.	Associating a Secondary VLAN with a Primary VLAN, page 47-16
show vlan private-vlan [type]	Verifies the configuration.	Configuring a VLAN as a PVLAN, page 47-15 Associating a Secondary VLAN with a Primary VLAN, page 47-16

Command	Purpose	Location
show interface private-vlan mapping	Verifies the configuration.	Permitting Routing of Secondary VLAN Ingress Traffic, page 47-23
switchport mode private-vlan {host promiscuous trunk promiscuous trunk [secondary]}	Configures a Layer 2 interface as a PVLAN port.	Configuring PVLANS, page 47-11
switchport private-vlan mapping [trunk] <i>primary_vlan_ID</i> { <i>secondary_vlan_list</i> add <i>secondary_vlan_list</i> remove <i>secondary_vlan_list</i> }	Maps the PVLAN promiscuous port to a primary VLAN and to selected secondary VLANs.	Configuring a Layer 2 Interface as a PVLAN Promiscuous Port, page 47-17 Configuring a Layer 2 Interface as a Promiscuous PVLAN Trunk Port, page 47-21
Switch(config-if)# switchport private-vlan host-association <i>primary_vlan_ID secondary_vlan_ID</i>	Associates the Layer 2 interface with a PVLAN. Note You can associate only one primary-secondary VLAN pair to the isolated port.	Configuring a Layer 2 Interface as a PVLAN Host Port, page 47-18
switchport private-vlan association trunk <i>primary_vlan_ID</i> <i>secondary_vlan_ID</i>	Configures association between primary VLANs and secondary VLANs the PVLAN trunk port with a PVLAN. Note You can configure the isolated trunk port with multiple primary-secondary pair.	Configuring a Layer 2 Interface as an Isolated PVLAN Trunk Port, page 47-19
switchport private-vlan trunk allowed vlan <i>vlan_list</i> all none [add remove except] <i>vlan_atom</i> [, <i>vlan_atom</i> ...]	Configures a list of allowed normal VLANs on a PVLAN trunk port.	Configuring a Layer 2 Interface as an Isolated PVLAN Trunk Port, page 47-19
switchport private-vlan trunk native vlan <i>vlan_id</i>	Configures a VLAN to which untagged packets (as in IEEE 802.1Q tagging) are assigned on a PVLAN trunk port.	Configuring a Layer 2 Interface as an Isolated PVLAN Trunk Port, page 47-19

Configuring PVLANS

These sections describe how to configure PVLANS:

- [Basic PVLAN Configuration Procedure, page 47-12](#)
- [Default Private-VLAN Configuration, page 47-12](#)
- [PVLAN Configuration Guidelines and Restrictions, page 47-12](#)
- [Configuring a VLAN as a PVLAN, page 47-15](#)
- [Associating a Secondary VLAN with a Primary VLAN, page 47-16](#)
- [Configuring a Layer 2 Interface as a PVLAN Promiscuous Port, page 47-17](#)
- [Configuring a Layer 2 Interface as a PVLAN Host Port, page 47-18](#)

- [Configuring a Layer 2 Interface as an Isolated PVLAN Trunk Port](#), page 47-19
- [Configuring a Layer 2 Interface as a Promiscuous PVLAN Trunk Port](#), page 47-21
- [Permitting Routing of Secondary VLAN Ingress Traffic](#), page 47-23
- [Configuring PVLAN over EtherChannel](#), page 47-24

Basic PVLAN Configuration Procedure

To configure a PVLAN, follow these basic steps:

-
- Step 1** Set VTP mode to transparent. See the [“VLAN Trunking Protocol”](#) section on page 17-7.
 - Step 2** Create the secondary VLANs. See the [“Configuring a VLAN as a PVLAN”](#) section on page 47-15.
 - Step 3** Create the primary VLAN. See the [“Configuring a VLAN as a PVLAN”](#) section on page 47-15.
 - Step 4** Associate the secondary VLAN to the primary VLAN. See the [“Associating a Secondary VLAN with a Primary VLAN”](#) section on page 47-16.

Note Only one isolated VLAN can be mapped to a primary VLAN, but more than one community (or twoway-community) VLAN can be mapped to a primary VLAN.

- Step 5** Configure an interface as an isolated or community host or trunk port. See the [“Configuring a Layer 2 Interface as a PVLAN Host Port”](#) section on page 47-18 and [“Configuring a Layer 2 Interface as an Isolated PVLAN Trunk Port”](#) section on page 47-19.
 - Step 6** Associate the isolated port or community port to the primary-secondary VLAN pair. See the [“Associating a Secondary VLAN with a Primary VLAN”](#) section on page 47-16.
 - Step 7** Configure an interface as a promiscuous port. See the [“Configuring a Layer 2 Interface as a PVLAN Promiscuous Port”](#) section on page 47-17.
 - Step 8** Map the promiscuous port to the primary-secondary VLAN pair. See the [“Configuring a Layer 2 Interface as a PVLAN Promiscuous Port”](#) section on page 47-17.
 - Step 9** If you plan to use inter-VLAN routing, configure the primary SVI, and map secondary VLANs to the primary. See the [“Permitting Routing of Secondary VLAN Ingress Traffic”](#) section on page 47-23.
 - Step 10** Verify private-VLAN configuration. See the [“Switch#”](#) section on page 47-24.
-

Default Private-VLAN Configuration

No PVLANS are configured.

PVLAN Configuration Guidelines and Restrictions

When using (or configuring) PVLANS, consider these guidelines and restrictions:

- To configure a PVLAN correctly, enable VTP in transparent mode in VTP version 1 and VTP version 2. (VTP version 3 enables you to create it in server mode).

You cannot change the VTP mode to client or server for PVLANS.

- Do not include VLAN 1 or VLANs 1002 through 1005 in PVLANS.
- Use only PVLAN commands to assign ports to primary, isolated, community VLANs, or twoway-community VLANs.

Layer 2 interfaces on primary, isolated, community VLANs, or twoway-community VLANs are inactive in PVLANS. Layer 2 trunk interfaces remain in the STP forwarding state.
- You cannot configure Layer 3 VLAN interfaces for secondary VLANs.

Layer 3 VLAN interfaces for isolated and community (secondary) VLANs are inactive while the VLAN is configured as an isolated or community VLAN.
- Do not apply dynamic access control entries (ACEs) to primary VLANs.

Cisco IOS dynamic ACL configuration applied to a primary VLAN is inactive while the VLAN is part of the PVLAN configuration.
- To prevent spanning tree loops due to misconfigurations, enable PortFast on the PVLAN trunk ports with the **spanning-tree portfast trunk** command.
- Any VLAN ACL configured on a secondary VLAN is effective in the input direction, and any VLAN ACL configured on the primary VLAN associated with the secondary VLAN is effective in the output direction. Exception case is given below.
- On twoway-community host ports, secondary VLAN ACL and QoS are applied on egress unicast routed traffic stemming from the integrated router port
- You can stop Layer 3 switching on an isolated or community VLAN by deleting the mapping of that VLAN with its primary VLAN.
- PVLAN ports can be on different network devices as long as the devices are trunk-connected and the primary and secondary VLANs remain associated with the trunk
- Isolated ports on two different devices cannot communicate with each other, but community VLAN ports can.
- PVLANS support the following SPAN features:
 - You can configure a PVLAN port as a SPAN source port.
 - To monitor egress or ingress traffic separately, you can use VLAN-based SPAN (VSPAN) on primary, isolated, community VLANs, twoway-community VLANs, or use SPAN on only one VLAN.

For more information about SPAN, see [Chapter 69, “Configuring SPAN and RSPAN.”](#)

- Although a PVLAN contains more than one VLAN, only one Spanning Tree Protocol (STP) instance runs for the entire PVLAN. When a secondary VLAN is associated with the primary VLAN, the STP parameters of the primary VLAN are propagated to the secondary VLAN. A separate STP instance exists for each of the primary and secondary VLANs.
- A primary VLAN can be associated with multiple community VLANs, or twoway-community VLANs, but only one isolated VLAN.
- An isolated or community VLAN can be associated with only one primary VLAN.
- If you delete a VLAN used in a PVLAN configuration, the PVLAN ports associated with the VLAN become inactive.
- VTP does not support PVLANS. You must configure PVLANS on each device in which you plan to use PVLAN ports.
- To maintain the security of your PVLAN configuration and avoid other use of VLANs configured as PVLANS, configure PVLANS on all intermediate devices, even if the devices have no PVLAN ports.

- Prune the PVLANS from trunks on devices that carry no traffic in the PVLANS.
- With port ACLS functionality available, you can apply Cisco IOS ACLs to secondary VLAN ports and Cisco IOS ACLs to PVLANS (VACLs). For more information on VACLs, see [Chapter 62, “Configuring Network Security with ACLs.”](#)
- You can apply different quality of service (QoS) configurations to primary, isolated, community VLANs, and twoway-community VLANs. See [Chapter 44, “Configuring Quality of Service.”](#) Cisco IOS ACLs applied to the Layer 3 VLAN interface of a primary VLAN automatically apply to the associated isolated, community VLANs, and twoway-community VLANs.
- On a PVLAN trunk port a secondary VLAN ACL is applied on ingress traffic and a primary VLAN ACL is applied on egress traffic.
- On a promiscuous port the primary VLAN ACL is applied on ingress traffic.
- Both PVLAN secondary and promiscuous trunk ports support only IEEE 802.1q encapsulation.
- Community VLANs cannot be propagated or carried over PVLAN trunks.
- ARP entries learned on Layer 3 PVLAN interfaces are termed “sticky” ARP entries (we recommend that you display and verify PVLAN interface ARP entries).
- For security reasons, PVLAN port sticky ARP entries do not age out. Connecting a device with a different MAC address but with the same IP address generates an error message and the ARP entry is not created.
- Because PVLAN port sticky ARP entries do not age out, you must manually remove the entries if you change the MAC address. To overwrite a sticky ARP entry, first delete the entry with the **no arp** command, then overwrite the entry with the **arp** command.
- In a DHCP environment, if you shut down your PC, it is not possible to give your IP address to someone else. To solve this problem, the Catalyst 4500 series switch supports the **no ip sticky-arp** command. This command promotes IP address overwriting and reuse in a DHCP environment.
- Normal VLANs can be carried on a promiscuous or isolated trunk port.
- The default native VLAN for promiscuous trunk port is VLAN 1, the management VLAN. All untagged packets are forwarded in the native VLAN. Either the primary VLANs or a regular VLAN can be configured as native VLAN.
- Promiscuous trunks cannot be configured to carry secondary VLANs. If a secondary VLAN is specified in the allowed VLAN list, the configuration is accepted but the port is not operational/forwarding in the secondary VLAN. This includes even those VLANs that are of secondary but not associated with any primary VLAN on given port.
- On a promiscuous trunk port, the primary VLAN ACL and QoS are applied on ingress traffic coming in primary VLANs.
- On a promiscuous trunk port, no VLAN ACL or QoS is applied to the egress traffic. It is because for upstream direction, traffic in PVLAN logically flows in the secondary VLAN. Due to VLAN translation in hardware, information about received secondary VLANs has been lost. No policies are applied. This restriction also applies to traffic bridged from other ports in the same primary VLANs.
- Do not configure port security on PVLAN promiscuous trunk port and vice versa.
If port security is enabled on a promiscuous trunk port, that port may behave in an unpredictable manner because this functionality is not supported.
- Do not configure IEEE 802.1X on a PVLAN promiscuous trunk port.

**Note**

Community or twoway-community PVLAN trunk ports are not supported.

Configuring a VLAN as a PVLAN

To configure a VLAN as a PVLAN, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch(config)# vlan <i>vlan_ID</i>	Enters VLAN configuration mode.
Step 3	Switch(config-vlan)# private-vlan { community twoway-community isolated primary }	Configures a VLAN as a PVLAN. <ul style="list-style-type: none"> This command does not take effect until you exit VLAN configuration submode. You can use the no keyword to clear PVLAN status.
Step 4	Switch(config-vlan)# end	Exits VLAN configuration mode.
Step 5	Switch# show vlan private-vlan [<i>type</i>]	Verifies the configuration.

This example shows how to configure VLAN 202 as a primary VLAN and verify the configuration:

```
Switch# configure terminal
Switch(config)# vlan 202
Switch(config-vlan)# private-vlan primary
Switch(config-vlan)# end
Switch# show vlan private-vlan
Primary Secondary Type Interfaces
-----
202                primary
```

This example shows how to configure VLAN 303 as a community VLAN and verify the configuration:

```
Switch# configure terminal
Switch(config)# vlan 303
Switch(config-vlan)# private-vlan community
Switch(config-vlan)# end
Switch# show vlan private-vlan
Primary Secondary Type Interfaces
-----
202                primary
                303 community
```

This example shows how to configure VLAN 440 as an isolated VLAN and verify the configuration:

```
Switch# configure terminal
Switch(config)# vlan 440
Switch(config-vlan)# private-vlan isolated
Switch(config-vlan)# end
Switch# show vlan private-vlan
Primary Secondary Type Interfaces
-----
202                primary
                303 community
                440 isolated
```

This example shows how to configure VLAN 550 as a twoway-community VLAN and verify the configuration:

```
Switch# configure terminal
Switch(config)# vlan 550
Switch(config-vlan)# private-vlan twoway-community
Switch(config-vlan)# end
Switch# show vlan private-vlan
```

```
Primary Secondary Type Interfaces
-----
202                primary
303             community
440             isolated
550    twoway-community
```

Associating a Secondary VLAN with a Primary VLAN

To associate secondary VLANs with a primary VLAN, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch(config)# vlan <i>primary_vlan_ID</i>	Enters VLAN configuration mode for the primary VLAN.
Step 3	Switch(config-vlan)# private-vlan association { <i>secondary_vlan_list</i> add <i>secondary_vlan_list</i> remove <i>secondary_vlan_list</i> }	Associates the secondary VLAN with the primary VLAN. The list can contain only one isolated VLAN ID; it can also contain multiple community or twoway-community VLAN IDs. You can use the no keyword to clear all secondary associations.
Step 4	Switch(config-vlan)# end	Exits VLAN configuration mode.
Step 5	Switch# show vlan private-vlan [<i>type</i>]	Verifies the configuration.

When you associate secondary VLANs with a primary VLAN, note the following:

- The *secondary_vlan_list* parameter cannot contain spaces. It can contain multiple comma-separated items. Each item can be a single PVLAN ID or a hyphenated range of PVLAN IDs.
- The *secondary_vlan_list* parameter can contain multiple community or twoway-community VLAN IDs.
- The *secondary_vlan_list* parameter can contain only one isolated VLAN ID.
- Enter a *secondary_vlan_list* or use the **add** keyword with a *secondary_vlan_list* to associate secondary VLANs with a primary VLAN.
- Use the **remove** keyword with a *secondary_vlan_list* to clear the association between secondary VLANs and a primary VLAN.
- The command does not take effect until you exit VLAN configuration submode.

This example shows how to associate community VLANs 303 through 307 and 309, twoway-community VLANs 550 through 552, and isolated VLAN 440 with primary VLAN 202 and verify the configuration:

```
Switch# configure terminal
Switch(config)# vlan 202
Switch(config-vlan)# private-vlan association 303-307,309,440
Switch(config-vlan)# end
Switch# show vlan private-vlan
```

Primary	Secondary	Type	Interfaces
202	303	community	
202	304	community	
202	305	community	
202	306	community	
202	307	community	
202	309	community	
202	440	isolated	
202	550	twoway-community	
202	551	twoway-community	
202	552	twoway-community	
	308	community	

**Note**

The secondary VLAN 308 has no associated primary VLAN.

Configuring a Layer 2 Interface as a PVLAN Promiscuous Port

To configure a Layer 2 interface as a PVLAN promiscuous port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface {fastethernet gigabitethernet tengigabitethernet} slot/port	Specifies the LAN interface to configure.
Step 3	Switch(config-if)# switchport mode private-vlan {host promiscuous trunk promiscuous trunk [secondary]}	Configures a Layer 2 interface as a PVLAN promiscuous port.
Step 4	Switch(config-if)# [no] switchport private-vlan mapping [trunk] primary_vlan_ID {secondary_vlan_list add secondary_vlan_list remove secondary_vlan_list}	Maps the PVLAN promiscuous port to a primary VLAN and to selected secondary VLANs.
Step 5	Switch(config-if)# end	Exits configuration mode.
Step 6	Switch# show interfaces {fastethernet gigabitethernet tengigabitethernet} slot/port switchport	Verifies the configuration.

**Note**

The maximum number of unique PVLAN pairs supported by the **switchport private-vlan mapping** command is 1000.

When you configure a Layer 2 interface as a PVLAN promiscuous port, note the following:

- The *secondary_vlan_list* parameter cannot contain spaces. It can contain multiple comma-separated items. Each item can be a single PVLAN ID or a hyphenated range of PVLAN IDs.
- Enter a *secondary_vlan_list* or use the **add** keyword with a *secondary_vlan_list* to map the secondary VLANs to the PVLAN promiscuous port.

- Use the **remove** keyword with a *secondary_vlan_list* to clear the mapping between secondary VLANs and the PVLAN promiscuous port.

This example shows how to configure interface FastEthernet 5/2 as a PVLAN promiscuous port, map it to a PVLAN, and verify the configuration:

```
Switch# configure terminal
Switch(config)# interface fastethernet 5/2
Switch(config-if)# switchport mode private-vlan promiscuous
Switch(config-if)# switchport private-vlan mapping 200 2
Switch(config-if)# end
Switch# show interfaces fastethernet 5/2 switchport
Name:Fa5/2
Switchport:Enabled
Administrative Mode:private-vlan promiscuous
Operational Mode:private-vlan promiscuous
Administrative Trunking Encapsulation:negotiate
Operational Trunking Encapsulation:native
Negotiation of Trunking:Off
Access Mode VLAN:1 (default)
Trunking Native Mode VLAN:1 (default)
Voice VLAN:none
Administrative Private VLAN Host Association:none
Administrative Private VLAN Promiscuous Mapping:200 (VLAN0200) 2 (VLAN0002)
Private VLAN Trunk Native VLAN:none

    200 (VLAN0200) 2 (VLAN0002)
Trunking VLANs Enabled:ALL
Pruning VLANs Enabled:2-1001
Capture Mode Disabled
Capture VLANs Allowed:ALL
```

Configuring a Layer 2 Interface as a PVLAN Host Port

To configure a Layer 2 interface as a PVLAN host port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch(config)# interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i>	Specifies the LAN port to configure.
Step 3	Switch(config-if)# switchport mode private-vlan { host promiscuous trunk promiscuous trunk [secondary] }	Configures a Layer 2 interface as a PVLAN host port.
Step 4	Switch(config-if)# [no] switchport private-vlan host-association <i>primary_vlan_ID secondary_vlan_ID</i>	Associates the Layer 2 interface with a PVLAN. You can use the no keyword to delete all associations from the primary VLAN.
Step 5	Switch(config-if)# end	Exits configuration mode.
Step 6	Switch# show interfaces { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i> switchport	Verifies the configuration.

This example shows how to configure interface FastEthernet 5/1 as a PVLAN host port and verify the configuration:

```
Switch# configure terminal
Switch(config)# interface fastethernet 5/1
Switch(config-if)# switchport mode private-vlan host
Switch(config-if)# switchport private-vlan host-association 202 440
Switch(config-if)# end

Switch# show interfaces fastethernet 5/1 switchport
Name: Fa5/1
Switchport: Enabled
Administrative Mode: private-vlan host
Operational Mode: private-vlan host
Administrative Trunking Encapsulation: negotiate
Operational Trunking Encapsulation: native
Negotiation of Trunking: Off
Access Mode VLAN: 1 (default)
Trunking Native Mode VLAN: 1 (default)
Voice VLAN: none

  Host Association: 202 (VLAN0202) 440 (VLAN0440)
  Promiscuous Mapping: none
  Trunk encapsulation : dot1q
  Trunk vlans:
Operational private-vlan(s):
  202 (VLAN0202) 440 (VLAN0440)
Trunking VLANs Enabled: ALL
Pruning VLANs Enabled: 2-1001
Capture Mode Disabled
Capture VLANs Allowed: ALL
```

Configuring a Layer 2 Interface as an Isolated PVLAN Trunk Port

To configure a Layer 2 interface as an isolated PVLAN trunk port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i>	Specifies the LAN port to configure.
Step 3	Switch(config-if)# switchport mode private-vlan { host promiscuous trunk promiscuous trunk [secondary] }	Configures a Layer 2 interface as a PVLAN trunk port.

	Command	Purpose
Step 4	Switch(config-if)# [no] switchport private-vlan association trunk <i>primary_vlan_ID</i> <i>secondary_vlan_ID</i>	Configures association between primary VLANs and secondary VLANs the PVLAN trunk port with a PVLAN. Note Multiple PVLAN pairs can be specified using this command so that a PVLAN trunk port can carry multiple secondary VLANs. If an association is specified for the existing primary VLAN, the existing association is replaced. If there is no trunk association, any packets received on secondary VLANs are dropped. You can use the no keyword to delete all associations from the primary VLAN.
Step 5	Switch(config-if)# [no] switchport private-vlan trunk allowed vlan <i>vlan_list</i> all none [add remove except] <i>vlan_atom[,vlan_atom...]</i>	Configures a list of allowed normal VLANs on a PVLAN trunk port. You can use the no keyword to remove all allowed normal VLANs on a PVLAN trunk port.
Step 6	Switch(config-if)# switchport private-vlan trunk native vlan <i>vlan_id</i>	Configures a VLAN to which untagged packets (as in IEEE 802.1Q tagging) are assigned on a PVLAN trunk port. If there is no native VLAN configured, all untagged packets are dropped. If the native VLAN is a secondary VLAN and the port does not have the association for the secondary VLAN, the untagged packets are dropped. You can use the no keyword to remove all native VLANs on a PVLAN trunk port.
Step 7	Switch(config-if)# end	Exits configuration mode.
Step 8	Switch# show interfaces { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i> switchport	Verifies the configuration.

This example shows how to configure interface FastEthernet 5/2 as a secondary trunk port, and verify the configuration:

```
Switch# configure terminal
Switch(config)# interface fastethernet 5/2
Switch(config-if)# switchport mode private-vlan trunk secondary
Switch(config-if)# switchport private-vlan trunk native vlan 10
Switch(config-if)# switchport private-vlan trunk allowed vlan 10. 3-4
Switch(config-if)# switchport private-vlan association trunk 3 301
Switch(config-if)# end
Switch# show interfaces fastethernet 5/2 switchport
Name: Fa5/2
  Switchport: Enabled
Administrative Mode: private-vlan trunk secondary
Operational Mode: private-vlan trunk secondary
Administrative Trunking Encapsulation: negotiate

```

Configuring a Layer 2 Interface as a Promiscuous PVLAN Trunk Port

To configure a Layer 2 interface as a promiscuous PVLAN trunk port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i>	Specifies the LAN interface to configure.
Step 3	Switch(config-if)# switchport mode private-vlan { host promiscuous trunk promiscuous trunk [secondary] }	Configures a Layer 2 interface as a PVLAN promiscuous trunk port.
Step 4	Switch(config-if)# [no] switchport private-vlan mapping [trunk] <i>primary_vlan_ID</i> { <i>secondary_vlan_list</i> add <i>secondary_vlan_list</i> remove <i>secondary_vlan_list</i> }	Maps the promiscuous PVLAN port to a primary VLAN and to selected secondary VLANs. This command offers 3 levels of removal. See the examples that follow this table.
Step 5	Switch(config-if)# end	Exits configuration mode.
Step 6	Switch# show interfaces { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i> switchport	Verifies the configuration.

Note

The maximum number of unique PVLAN pairs supported by the **switchport private-vlan mapping trunk** command is 500. For example, 500 isolated secondary VLANs could map to 500 primary VLANs, because only one isolated VLAN association per primary VLAN is supported. Or, 500 community secondary VLANs could map to one primary VLAN. Or, 250 community secondary VLANs could map to 1 primary VLAN, and another 250 community secondary VLANs could map to another primary VLAN for a total of 500 pairs.

Note

By default, when you configure the mode to PVLAN trunk **promiscuous**, the native VLAN is set to 1.

The **[no] switchport private-vlan mapping** command provides the following three levels of removal:

- Remove one or more secondary VLANs from the list. For example:
Switch(config-if)# **switchport private-vlan mapping trunk 2 remove 222**
- Remove the entire mapping of PVLAN promiscuous trunk port to the specified primary VLAN (and all of its selected secondary VLANs). For example:
Switch(config-if)# **no switchport private-vlan mapping trunk 2**
- Remove the mapping of a PVLAN promiscuous trunk port to all previously configured primary VLANs (and all of their selected secondary VLANs). For example:
Switch(config-if)# **no switchport private-vlan mapping trunk**

When you configure a Layer 2 interface as a PVLAN promiscuous port, note the following:

- Multiple PVLAN pairs can be specified using the **switchport private-vlan mapping trunk** command so that a promiscuous trunk port can carry multiple primary VLANs.
- The *secondary_vlan_list* parameter cannot contain spaces. It can contain multiple comma-separated items. Each item can be a single PVLAN ID or a hyphenated range of PVLAN IDs.
- Enter a *secondary_vlan_list* or use the **add** keyword with a *secondary_vlan_list* to map the secondary VLANs to the PVLAN promiscuous port.
- Use the **remove** keyword with a *secondary_vlan_list* to clear the mapping between secondary VLANs and the PVLAN promiscuous port.

This example shows how to configure interface FastEthernet 5/2 as a promiscuous trunk port and to verify the configuration:

```
Switch# configure terminal
Switch(config)# interface fastethernet 5/2
Switch(config-if)# switchport mode private-vlan trunk promiscuous
Switch(config-if)# switchport private-vlan trunk native vlan 10
Switch(config-if)# switchport private-vlan trunk allowed vlan 10, 3-4
Switch(config-if)# switchport private-vlan mapping trunk 3 301, 302
Switch(config-if)# end
Switch# show interfaces fastethernet 5/2 switchport
Name: Fa5/2
Switchport: Enabled
Administrative Mode: private-vlan trunk promiscuous
Operational Mode: private-vlan trunk promiscuous
Administrative Trunking Encapsulation: negotiate
Operational Trunking Encapsulation: dot1q
Negotiation of Trunking: On
Access Mode VLAN: 1 (default)
Trunking Native Mode VLAN: 1 (default)
Administrative Native VLAN tagging: enabled
Voice VLAN: none
Administrative private-vlan host-association: none
Administrative private-vlan mapping: none
Administrative private-vlan trunk native VLAN: 10
Administrative private-vlan trunk Native VLAN tagging: enabled
Administrative private-vlan trunk encapsulation: dot1q
Administrative private-vlan trunk normal VLANs: 3-4,10
Administrative private-vlan trunk associations: none
Administrative private-vlan trunk mappings:
    3 (VLAN0003) 301 (VLAN0301) 302 (VLAN0302)
Operational private-vlan:
    3 (VLAN0003) 301 (VLAN0301) 302 (VLAN0302)
Trunking VLANs Enabled: ALL
Pruning VLANs Enabled: 2-1001
```

```

Capture Mode Disabled
Capture VLANs Allowed: ALL

Unknown unicast blocked: disabled
Unknown multicast blocked: disabled
Appliance trust: none

```

Permitting Routing of Secondary VLAN Ingress Traffic

Note

Isolated, community VLANs, and twoway-community VLANs are called secondary VLANs.

To permit routing of secondary VLAN ingress traffic, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface vlan <i>primary_vlan_ID</i>	Enters interface configuration mode for the primary VLAN.
Step 3	Switch(config-if)# [no] private-vlan mapping <i>primary_vlan_ID</i> { <i>secondary_vlan_list</i> add <i>secondary_vlan_list</i> remove <i>secondary_vlan_list</i> }	To permit routing on the secondary VLAN ingress traffic, map the secondary VLAN to the primary VLAN. You can use the no keyword to delete all associations from the primary VLAN.
Step 4	Switch(config-if)# end	Exits configuration mode.
Step 5	Switch# show interface private-vlan mapping	Verifies the configuration.

When you permit routing on the secondary VLAN ingress traffic, note the following:

- The **private-vlan mapping** interface configuration command only affects PVLAN ingress traffic that is Layer 3 switched.
- The *secondary_vlan_list* parameter cannot contain spaces. It can contain multiple comma-separated items. Each item can be a single PVLAN ID or a hyphenated range of PVLAN IDs.
- Enter a *secondary_vlan_list* parameter or use the **add** keyword with a *secondary_vlan_list* parameter to map the secondary VLANs to the primary VLAN.
- Use the **remove** keyword with a *secondary_vlan_list* parameter to clear the mapping between secondary VLANs and the primary VLAN.

This example shows how to permit routing of secondary VLAN ingress traffic from PVLANS 303 through 307, 309, and 440 and verify the configuration:

```

Switch# configure terminal
Switch(config)# interface vlan 202
Switch(config-if)# private-vlan mapping add 303-307,309,440
Switch(config-if)# end
Switch# show interfaces private-vlan mapping
Interface Secondary VLAN Type
-----
vlan202    303          community
vlan202    304          community
vlan202    305          community
vlan202    306          community
vlan202    307          community

```

```
vlan202 309 community
vlan202 440 isolated

Switch#
```

Configuring PVLAN over EtherChannel

After creating a Layer 2 Etherchannel, you can configure it with any of the four PVLAN port modes (promiscuous host, secondary host, isolated trunk, promiscuous trunk).

This section includes the following topics:

- [Configuring a Layer 2 EtherChannel, page 47-24](#)
- [Configuring a Layer 2 Etherchannel as a PVLAN Promiscuous Port, page 47-24](#)
- [Configuring a Layer 2 EtherChannel as a PVLAN Host Port, page 47-26](#)
- [Configuring a Layer 2 EtherChannel as an Isolated PVLAN Trunk Port, page 47-27](#)
- [Configuring a Layer 2 Etherchannel as a Promiscuous PVLAN Trunk Port, page 47-28](#)

Configuring a Layer 2 EtherChannel

Do the following:

-
- Step 1** Configure a VLAN as a PVLAN.
Refer to the URL:
<http://www.cisco.com/en/US/docs/switches/lan/catalyst4500/12.2/01xo/configuration/guide/pvlans.html#wp1174853>
- Step 2** Associate a secondary VLAN with a primary VLAN.
Refer to the URL:
<http://www.cisco.com/en/US/docs/switches/lan/catalyst4500/12.2/01xo/configuration/guide/pvlans.html#wp1121802>
- Step 3** Configuring a Layer 2 EtherChannel.
Refer to the URL
<http://www.cisco.com/en/US/docs/switches/lan/catalyst4500/12.2/01xo/configuration/guide/channel.html#wp1020670>
-

Configuring a Layer 2 Etherchannel as a PVLAN Promiscuous Port

Perform the following task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface port-channel <i>interface-number</i>	Specifies the LAN interface to configure.

	Command	Purpose
Step 3	Switch(config-if)# switchport mode private-vlan { host promiscuous trunk promiscuous trunk [secondary]}	Configures a Layer 2 Etherchannel as a PVLAN promiscuous port.
Step 4	Switch(config-if)# [no] switchport private-vlan mapping [trunk] <i>primary_vlan_ID</i> { <i>secondary_vlan_list</i> add <i>secondary_vlan_list</i> }	(Maps the PVLAN promiscuous port to a primary VLAN and to selected secondary VLANs.
Step 5	Switch(config-if)# end	Exits configuration mode.
Step 6	Switch# show interface port-channel <i>interface-number</i> switchport	Verifies the configuration.

**Note**

The maximum number of unique PVLAN pairs supported by the **switchport private-vlan mapping** command is 1000.

When you configure a Layer 2 Etherchannel as a PVLAN promiscuous port, note the following:

- The *secondary_vlan_list* parameter cannot contain spaces. It can contain multiple comma-separated items. Each item can be a single PVLAN ID or a hyphenated range of PVLAN IDs.
- Enter a *secondary_vlan_list* or use the **add** keyword with a *secondary_vlan_list* to map the secondary VLANs to the PVLAN promiscuous port.
- Use the **remove** keyword with a *secondary_vlan_list* to clear the mapping between secondary VLANs and the PVLAN promiscuous port.

This example shows how to configure interface port channel 63 as a PVLAN promiscuous port, map it to a PVLAN, and verify the configuration:

```
Switch# configure terminal
Switch(config)# interface port-channel 63
Switch(config-if)# switchport mode private-vlan promiscuous
Switch(config-if)# switchport private-vlan mapping 200 2
Switch(config-if)# end
Switch# show interfaces port-channel 63 switchport
Name: Po63
Switchport: Enabled
Administrative Mode: private-vlan promiscuous
Operational Mode: private-vlan promiscuous
Administrative Trunking Encapsulation: negotiate
Operational Trunking Encapsulation: native
Negotiation of Trunking: Off
Access Mode VLAN: 1 (default)
Trunking Native Mode VLAN: 1 (default)
Voice VLAN: none
Administrative Private VLAN Host Association: none
Administrative Private VLAN Promiscuous Mapping: 200 (VLAN0200) 2 (VLAN0002)
Private VLAN Trunk Native VLAN: none
Administrative Private VLAN Trunk Encapsulation: dot1q
Administrative Private VLAN Trunk Normal VLANs: none
Administrative Private VLAN Trunk Private VLANs: none
Operational Private VLANs:
    200 (VLAN0200) 2 (VLAN0002)
Trunking VLANs Enabled: ALL
Pruning VLANs Enabled: 2-1001
Capture Mode Disabled
Capture VLANs Allowed: ALL
```

Configuring a Layer 2 EtherChannel as a PVLAN Host Port

To configure a Layer 2 EtherChannel as a PVLAN host port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface port-channel <i>interface-number</i>	Specifies the LAN interface to configure.
Step 3	Switch(config-if)# switchport mode private-vlan {host promiscuous trunk promiscuous trunk [secondary]}	Configures a Layer 2 Etherchannel as a PVLAN host port.
Step 4	Switch(config-if)# [no] switchport private-vlan host-association <i>primary_vlanb_ID</i> <i>secondary_vlan_ID</i>	Associates the Layer 2 interface with a PVLAN. You can use the no keyword to delete all associations from the primary VLAN.
Step 5	Switch(config-if)# end	Exits configuration mode.
Step 6	Switch# show interface port-channel <i>interface-number</i> switchport	Verifies the configuration.

This example shows how to configure interface port channel 63 as a PVLAN host port and to verify the configuration:

```
Switch# configure terminal
Switch(config)# interface port-channel 63
Switch(config-if)# switchport mode private-vlan host
Switch(config-if)# switchport private-vlan host-association 202 440
Switch(config-if)# end
Switch# show interfaces port-channel 63 switchport
Name: Po63
Switchport: Enabled
Administrative Mode: private-vlan host
Operational Mode: private-vlan host
Administrative Trunking Encapsulation: negotiate
Operational Trunking Encapsulation: native
Negotiation of Trunking: Off
Access Mode VLAN: 1 (default)
Trunking Native Mode VLAN: 1 (default)
Voice VLAN: none
Appliance trust: none
Administrative Private Vlan
  Host Association: 202 (VLAN0202) 440 (VLAN0440)
  Promiscuous Mapping: none
  Trunk encapsulation : dot1q
  Trunk vlans:
Operational private-vlan(s):
  202 (VLAN0202) 440 (VLAN0440)
Trunking VLANs Enabled: ALL

Capture Mode Disabled
Capture VLANs Allowed: ALL
```

Configuring a Layer 2 EtherChannel as an Isolated PVLAN Trunk Port

To configure a Layer 2 EtherChannel as an isolated PVLAN trunk port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface port-channel <i>interface-number</i>	Specifies the LAN interface to configure.
Step 3	Switch(config-if)# switchport mode private-vlan { host promiscuous trunk promiscuous trunk [secondary]}	Configures a Layer 2 Etherchannel as a PVLAN trunk port.
Step 4	Switch(config-if)# [no] switchport private-vlan association trunk <i>primary_vlanb_ID</i> <i>secondary_vlan_ID</i>	<p>(Configures association between primary VLANs and secondary VLANs the PVLAN trunk port with a PVLAN.</p> <p>Note Multiple PVLAN pairs can be specified using this command so that a PVLAN trunk port can carry multiple secondary VLANs. If an association is specified for the existing primary VLAN, the existing association is replaced. If there is no trunk association, any packets received on secondary VLANs are dropped.</p> <p>You can use the no keyword to delete all associations from the primary VLAN.</p>
Step 5	Switch(config-if)# [no] switchport private-vlan trunk allowed vlan <i>vlan_list</i> [all none [add remove except] <i>vlan_atom</i> [, <i>vlan_atom</i> ...]	<p>(Configures a list of allowed normal VLANs on a PVLAN trunk port</p> <p>You can use the no keyword to remove all allowed normal VLANs on a PVLAN trunk port.</p>
Step 6	Switch(config-if)# switchport private-vlan trunk native vlan <i>vlan_id</i>	<p>(Configures a VLAN to which untagged packets (as in IEEE 802.1Q tagging) are assigned on a PVLAN trunk port.</p> <p>If there no native VLAN is configured, all untagged packets are dropped.</p> <p>If the native VLAN is a secondary VLAN and the port does not have the association for the secondary VLAN, the untagged packets are dropped.</p> <p>You can use the no keyword to remove all native VLANs on a PVLAN trunk port.)</p>
Step 7	Switch(config-if)# end	Exits configuration mode.
Step 8	Switch# show interfaces Port-channel <i>interface-number</i> switchport	Verifies the configuration.

This example shows how to configure interface port channel 63 as a secondary trunk port, and to verify the configuration:

```
Switch# configure terminal
Switch(config)# interface port-channel 63
Switch(config-if)# switchport mode private-vlan trunk secondary
Switch(config-if)# switchport private-vlan trunk native vlan 10
Switch(config-if)# switchport private-vlan trunk allowed vlan 10. 3-4
Switch(config-if)# switchport private-vlan association trunk 3 301
Switch(config-if)# end
Switch# show interfaces port-channel 63 switchport
Name: Po63
Switchport: Enabled
Administrative Mode: private-vlan trunk secondary
Operational Mode: private-vlan trunk secondary
Administrative Trunking Encapsulation: negotiate
Operational Trunking Encapsulation: dot1q
Negotiation of Trunking: On
Access Mode VLAN: 1 (default)

Administrative private-vlan mapping: none
Administrative private-vlan trunk native VLAN: 10
Administrative private-vlan trunk Native VLAN tagging: enabled
Administrative private-vlan trunk encapsulation: dot1q
Administrative private-vlan trunk normal VLANs: none
Administrative private-vlan trunk associations:
    3 (VLAN0003) 301 (VLAN0301)
Administrative private-vlan trunk mappings: none
Operational private-vlan: none
Operational Normal VLANs: none
Trunking VLANs Enabled: ALL
Pruning VLANs Enabled: 2-1001
Capture Mode Disabled Capture VLANs Allowed: ALL
Unknown unicast blocked: disabled
Unknown multicast blocked: disabled
Appliance trust: none
```

Configuring a Layer 2 Etherchannel as a Promiscuous PVLAN Trunk Port

To configure a Layer 2 Etherchannel as a promiscuous PVLAN trunk port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface port-channel <i>interface-number</i>	Specifies the LAN interface to configure.
Step 3	Switch(config-if)# switchport mode private-vlan {host promiscuous trunk promiscuous trunk [secondary]}	Configures a Layer 2 Etherchannel as a PVLAN promiscuous trunk port.
Step 4	Switch(config-if)# [no] switchport private-vlan mapping [trunk] primary_vlan_ID {secondary_vlan_list add secondary_vlan_list remove secondary_vlan_list}	Maps the promiscuous PVLAN port to a primary VLAN and to the selected secondary VLANs. This command offers 3 levels of removal.

	Command	Purpose
Step 5	Switch(config-if)# end	Exits configuration mode.
Step 6	Switch# show interfaces port-channel <i>interface-number</i> switchport	Verifies the configuration.

**Note**

The maximum number of unique PVLAN pairs supported by the switchport private-vlan mapping trunk command is 500. For example, 500 isolated secondary VLANs could map to 500 primary VLANs, because only one isolated VLAN association per primary VLAN is supported. Or, 500 community secondary VLANs could map to one primary VLAN. Or, 250 community secondary VLANs could map to 1 primary VLAN, and another 250 community secondary VLANs could map to another primary VLAN for a total of 500 pairs.

**Note**

By default, when you configure the mode to private VLAN trunk promiscuous, the native VLAN is set to 1.

The [no] **switchport private-vlan mapping** command provides the following three levels of removal:

- Remove one or more secondary VLANs from the list.

For example:

```
Switch(config-if)# switchport private-vlan mapping trunk 2 remove 222
```

- Remove the entire mapping of PVLAN promiscuous trunk port to the specified primary VLAN (and all of its selected secondary VLANs).

For example:

```
Switch(config-if)# no switchport private-vlan mapping trunk 2
```

- Remove the mapping of a PVLAN promiscuous trunk port to all previously configured primary VLANs (and all of their selected secondary VLANs).

For example:

```
Switch(config-if)# no switchport private-vlan mapping trunk
```

When you configure a Layer 2 etherchannel as a PVLAN promiscuous trunk port, observe that multiple private VLAN pairs can be specified with the **switchport private-vlan mapping trunk** command so that a promiscuous trunk port can carry multiple primary VLANs.

- The *secondary_vlan_list* parameter cannot contain spaces. It can contain multiple comma-separated items. Each item can be a single PVLAN ID or a hyphenated range of PVLAN IDs.
- Enter a *secondary_vlan_list* or use the **add** keyword with a *secondary_vlan_list* to map the secondary VLANs to the PVLAN promiscuous port.
- Use the **remove** keyword with a *secondary_vlan_list* to clear the mapping between secondary VLANs and the PVLAN promiscuous port.

This example shows how to configure interface Port-channel 63 as a promiscuous trunk port and to verify the configuration:

```
Switch# configure terminal
Switch(config)# interface port-channel 63
Switch(config-if)# switchport mode private-vlan trunk promiscuous
```

```

Configuring MACsec Encryption

This chapter describes how to configure Media Access Control Security (MACsec) encryption on the Catalyst 4500 series switch.

MACsec is the IEEE 802.1AE standard for authenticating and encrypting packets between two MACsec-capable devices. The Catalyst 4500 series switch supports 802.1AE encryption with MACsec Key Agreement (MKA) on downlink ports for encryption between the switch and host devices. The switch also supports MACsec link layer switch-to-switch security by using Cisco TrustSec Network Device Admission Control (NDAC) and the Security Association Protocol (SAP) key exchange. Link layer security can include both packet authentication between switches and MACsec encryption between switches (encryption is optional).

Note

MACsec is supported on the Catalyst 4500 series switch universal k9 image. It is not supported with the NPE license or with a LAN Base service image.

All downlink ports on a switch can run Cisco TrustSec MACsec link layer switch-to-switch security.

Table 1 **MACsec Support on Switch Ports**

Interface	Connections	MACsec support
User-facing downlink ports	Switch-to-host	MKA MACsec encryption
Switchports connected to other switches	Switch-to-switch	Cisco TrustSec NDAC MACsec MKA MACsec encryption

Cisco TrustSec and Cisco SAP are meant only for switch-to-switch links and are not supported on switch ports connected to end hosts, such as PCs or IP phones. MKA is supported on both switch-to-host facing links, and switch-to-switch links as well. Host-facing links typically use flexible authentication ordering for handling heterogeneous devices with or without IEEE 802.1X, and can optionally use MKA encryption. Cisco NDAC and SAP are mutually exclusive with Network Edge Access Topology (NEAT), which is used for compact switches to extend security outside the wiring closet.

This chapter includes the following major sections:

- [Understanding Media Access Control Security and MACsec Key Agreement, page 48-2](#)
- [Configuring MACsec and MACsec Key Agreement, page 48-7](#)
- [Understanding MKA MACsec with EAP-TLS, page 48-12](#)
- [Understanding Cisco TrustSec MACsec, page 48-20](#)
- [Configuring Cisco TrustSec MACsec, page 48-22](#)

**Note**

For more information, refer to the *Cisco TrustSec Switch Configuration Guide*:

<http://www.cisco.com/en/US/docs/switches/lan/trustsec/configuration/guide/trustsec.html>

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Understanding Media Access Control Security and MACsec Key Agreement

MACsec, defined in 802.1AE, provides MAC-layer encryption over wired networks by using out-of-band methods for encryption keying. The MACsec Key Agreement (MKA) Protocol provides the required session keys and manages the required encryption keys. MKA and MACsec are implemented after successful authentication using the 802.1X Extensible Authentication Protocol (EAP) and EAP-Transport Layer Security (EAP-TLS) framework. MKA MACsec supports both host facing links (links between network access devices and endpoint devices such as a PC or IP phone) and switch-to-switch links, beginning in Cisco IOS Release 15.2(5)E and Cisco IOS XE Release 3.9.0E.

A switch using MACsec accepts either MACsec or non-MACsec frames, depending on the policy associated with the client. MACsec frames are encrypted and protected with an integrity check value (ICV). When the switch receives frames from the client, it decrypts them and calculates the correct ICV by using session keys provided by MKA. The switch compares that ICV to the ICV within the frame. If they are not identical, the frame is dropped. The switch also encrypts and adds an ICV to any frames sent over the secured port (the access point used to provide the secure MAC service to a client) using the current session key.

The MKA Protocol manages the encryption keys used by the underlying MACsec protocol. The basic requirements of MKA are defined in 802.1X-2010. The MKA Protocol extends 802.1X to allow peer discovery with confirmation of mutual authentication and sharing of MACsec secret keys to protect data exchanged by the peers.

Pre-shared keys (PSKs) are used to generate Connectivity Association Keys (CAKs). In symmetric cryptography, PSK means a key or a shared secret. This key is shared between parties before it is used. The PSK is used to generate the Key Encryption Key (KEK) and the integrity check value (ICV) Key (ICK).

**Note**

PSK does not support Security Group Tagging and AES-GCM-256 encryption.

In a switch-to-switch connection using the PSK, there is no concept of the authenticator, because of the EAP authentication on the switch. So the switch with highest priority becomes the Key Server (KS). In the current implementation, MKA can act as a non-KS without much change, except for accepting the PSK instead of the CAK.

The EAP framework implements MKA as a newly defined EAP-over-LAN (EAPOL) packet. EAP authentication produces a master session key (MSK) shared by both partners in the data exchange. Entering the EAP session ID generates a secure connectivity association key name (CKN). Because the switch is the authenticator, it is also the key server, generating a random 128-bit secure association key

(SAK), which it sends it to the client partner. The client is never a key server and can only interact with a single MKA entity, the key server. After key derivation and generation, the switch sends periodic transports to the partner at a default interval of 2 seconds.

The CAK and CKN will be derived from the configured PSK name and value

The packet body in an EAPOL Protocol Data Unit (PDU) is referred to as a MACsec Key Agreement PDU (MKPDU). MKA sessions and participants are deleted when the MKA lifetime (6 seconds) passes with no MKPDU received from a participant. For example, if a client disconnects, the participant on the switch continues to operate MKA until 6 seconds have elapsed after the last MKPDU is received from the client.

These sections provide more details:

- [MKA Policies, page 48-3](#)
- [Key Lifetime and Hitless Key Rollover, page 48-3](#)
- [Encryption Algorithms for MKA Control Packets, page 48-4](#)
- [Virtual Ports, page 48-4](#)
- [MACsec, page 48-5](#)
- [MACsec, MKA, and 802.1X Host Modes, page 48-5](#)
- [MKA Statistics, page 48-6](#)

MKA Policies

By default, the MKA protocol default policy is enabled on an interface. However, you can apply a defined MKA policy to an interface. Removing the MKA policy configures the default MKA policy on that interface.

You can configure these options:

- Policy name, not to exceed 16 ASCII characters.
- Confidentiality (encryption) offset of 0, 30, or 50 bytes for each physical interface.
- Replay protection. You can configure MACsec window size, as defined by the number of out-of-order frames that are accepted. This value is used while installing the security associations in the MACsec. A value of 0 means that frames are accepted only in the correct order.

Note

MKA is not supported in the Virtual Switching System (VSS) mode.

Key Lifetime and Hitless Key Rollover

A MACsec key chain (MKA) can have multiple pre-shared keys (PSKs) each configured with a key ID and an optional lifetime. A key lifetime specifies the time period the key is valid. In the absence of a lifetime configuration, the default lifetime is unlimited. MKA rolls over to the next configured valid pre-shared key in the key chain, when a valid key expires. Time zone of the key can be local or UTC. Default time zone is UTC.

MKA rolls over to the next configured valid pre-shared key in the key chain, when a valid key expires.

Use the **key chain** *key-chain-name* **macsec** to configure the MACsec key chain.

To roll over to the next key within the same key chain, configure a second key in the key chain, and a lifetime for the first key. When the lifetime of the first key expires, it automatically rolls over to the next key in the list. If the same key is configured on both sides of the link at the same time, then the key rollover is hitless, that is, key rolls over without traffic interruption.

**Note**

The lifetime of the keys need to be overlapped to achieve hitless key rollover.

Encryption Algorithms for MKA Control Packets

Cryptographic algorithm selection for MKA control protocol packets encryption is as follows:

- The cryptographic algorithm to encrypt MKA control protocol packets is configured as part of the key chain. There can be only one cryptographic algorithm configured per key chain.
- A key server uses the configured MKA cryptographic algorithm from the key chain.
- All nonkey servers must use the same cryptographic algorithm as the key server.

If an MKA cryptographic algorithm is not configured, a default cryptographic algorithm of AES-CMAC-128 (Cipher-based Message Authentication Code with 128-bit Advanced Encryption Standard) is used.

The following is a sample encryption algorithm for data packets:

```
Switch(config)# mka policy p1
Switch(config-mka-policy)# macsec-cipher-suite gsm-aes-256
```

The following is a sample encryption algorithm for MKA control packets:

```
Switch(config)# key chain key-chain-name macsec
Switch(config-keychain-macsec)# key 01
Switch(config-keychain-macsec-key)# key-string 0001
Switch(config-keychain-macsec-key)# cryptographic-algorithm [aes-128-cmac | aes-256-cmac]
Switch(config-keychain-macsec-key)# end
```

Virtual Ports

You use virtual ports for multiple secured connectivity associations on a single physical port. Each connectivity association (pair) represents a virtual port, with a maximum of two virtual ports per physical port. Only one of the two virtual ports can be part of a data VLAN; the other must externally tag its packets for the voice VLAN. You cannot simultaneously host secured and unsecured sessions in the same VLAN on the same port. Because of this limitation, 802.1X multiple authentication mode is not supported.

The exception to this limitation is in multiple-host mode when the first MACsec supplicant is successfully authenticated and connected to a hub that is connected to the switch. A non-MACsec host connected to the hub can send traffic without authentication because it is in multiple-host mode. We do not recommend using multi-host mode because after the first successful client, authentication is not required for other clients.

Virtual ports represent an arbitrary identifier for a connectivity association and have no meaning outside the MKA Protocol. A virtual port corresponds to a separate logical port ID. Valid port IDs for a virtual port are 0x0002 to 0xFFFF. Each virtual port receives a unique secure channel identifier (SCI) based on the MAC address of the physical interface concatenated with a 16-bit port ID.

MACsec

A Catalyst 4500 series switch supervisor running MACsec maintains the configuration files that show which ports on the switch support MACsec. The supervisor-engine performs these functions:

- Processes secure channel and secure association creation and deletion.
- Programs the hardware with the derived secure association key (SAK) for encryption and decryption.

MACsec, MKA, and 802.1X Host Modes

You can use MACsec and the MKA Protocol with 802.1X single-host mode, multiple-host mode, or Multi Domain Authentication (MDA) mode.

Single-Host Mode

Figure 48-1 shows how a single EAP authenticated session is secured by MACsec using MKA.

Figure 48-1 *MACsec in Single-Host Mode with a Secured Data Session*

Multiple-Host Mode

In standard (not 802.1X-2010) 802. multiple-host mode, a port is open or closed based on a single authentication. If one user, the primary secured client services client host, is authenticated, the same level of network access is provided to any host connected to the same port. If a secondary host is a MACsec supplicant, it cannot be authenticated and traffic would no flow. A secondary host that is a non-MACsec host can send traffic to the network without authentication because it is in multiple-host mode. See Figure 48-2.

Figure 48-2 *MACsec in Standard Multiple-Host Mode - Unsecured*

We do not recommend using multi-host mode because after the first successful client, authentication is not required for other clients, which is not secure.

MKA Statistics

Some MKA counters are aggregated globally, while others are updated both globally and per session. You can also obtain information about the status of MKA sessions.

This is an example of the **show mka statistics** command output:

```

Switch# show mka statistics

Configuring MACsec and MACsec Key Agreement

- [Default MKA MACsec Configuration, page 48-7](#)
- [Configuring an MKA Policy, page 48-7](#)
- [Configuring MACsec on an Interface, page 48-9](#)
- [Configuring MKA Pre-Shared Key, page 48-10](#)

Default MKA MACsec Configuration

MACsec is disabled. No MACsec Key Agreement (MKA) policies are configured.

Configuring an MKA Policy

To create an MKA Protocol policy, perform this task. Note that MKA also requires that you enable 802.1X.

	Command	Purpose
Step 1	configure terminal	Enters global configuration mode.
Step 2	mka policy <i>policy-name</i>	Identifies an MKA policy, and enter MKA policy configuration mode. The maximum policy name length is 16 characters.

	Command	Purpose
Step 3	replay-protection window-size <i>frames</i>	Enables replay protection, and configure the window size in number of frames. The range is from 0 to 4294967295. The default window size is 0. Entering a window size of 0 is not the same as entering the no replay-protection command. Configuring a window size of 0 uses replay protection with a strict ordering of frames. Entering no replay-protection turns off MACsec replay-protection.
Step 4	end	Returns to privileged EXEC mode.
Step 5	show mka policy	Verifies your entries.
Step 6	copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example configures the MKA policy *relay-policy*:

```
Switch(config)# mka policy relay-policy
Switch(config-mka-policy)# replay-protection window-size 300
Switch(config-mka-policy)# end
```

Let's say that we configure an MKA policy as follows:

```
Switch# conf terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# mka policy poll
Switch(config-mka-policy)# replay-protection window-size 1000
Switch(config-mka-policy)# confidentiality-offset 50
Switch(config-mka-policy)# end
```

We observe the following:

- The payload starting from the SA (source MAC address) + 50 bytes offset is encrypted.
- Replay protect is YES with a window size of 1000. If the frame received has a packet number (PN) of 1020, for example, all frames with a PN of 20 to 1020 can come out of order (i.e, frame with PN 900 can come first and frame with PN 800 can come later). However, if a frame with a PN of 1021 is received first, followed by a frame with a PN of 20, the frame with PN of 20 is dropped. In this scenario, the expected PN is 1022 and the window size is 1000, so the acceptable PN number is anything greater than or equal to (expected PN - window size) = 22. So, any frame with PN < 22 is dropped.

By default, the MKA protocol default policy is enabled on an interface, if no MKA policies are applied. All the values in the policy (such as confidentiality, offset, and replay protection) take the default values. For example,

- Confidentialityoffset is 0—Encrypts the payload that is immediately after the SA (source MAC address).
- Replay protect is YES with window size 0—Frames cannot come out of order.

Configuring MACsec on an Interface

To configure MACsec on an interface with one MACsec session for voice and one for data, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>interface interface-id</code>	Identifies the MACsec interface, and enter interface configuration mode. The interface must be a physical interface.
Step 3	<code>switchport access vlan vlan-id</code>	Configures the access VLAN for the port.
Step 4	<code>switchport mode access</code>	Configures the interface as an access port.
Step 5	<code>macsec</code>	Enables 802.1ae MACsec on the interface.
Step 6	<code>authentication event linksec fail action authorize vlan vlan-id</code>	(Optional) Specifies that the switch processes authentication link-security failures resulting from unrecognized user credentials by authorizing a restricted VLAN on the port after a failed authentication attempt.
Step 7	<code>authentication host-mode multi-domain</code>	Configures authentication manager mode on the port to allow both a host and a voice device to be authenticated on the 802.1X-authorized port. If not configured, the default host mode is single.
Step 8	<code>authentication linksec policy must-secure</code>	Sets the LinkSec security policy to secure the session with MACsec if the peer is available. If not set, the default is <i>should secure</i> .
Step 9	<code>authentication port-control auto</code>	Enables 802.1X authentication on the port. The port changes to the authorized or unauthorized state based on the authentication exchange between the switch and the client
Step 10	<code>mka policy policy-name</code>	Applies an existing MKA protocol policy to the interface, and enable MKA on the interface. If no MKA policy was configured (by entering the mka policy global configuration command), you must apply the MKA default policy to the interface by entering the mka default-policy interface configuration command.
Step 11	<code>dot1x pae authenticator</code>	Configures the port as an 802.1X port access entity (PAE) authenticator.
Step 12	<code>spanning-tree portfast</code>	Enables spanning tree Port Fast on the interface in all its associated VLANs. When Port Fast feature is enabled, the interface changes directly from a blocking state to a forwarding state without making the intermediate spanning-tree state changes.
Step 13	<code>end</code>	Returns to privileged EXEC mode.
Step 14	<code>show authentication session interface interface-id</code>	Verifies the authorized session security status.
Step 15	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

This is an example of configuring and verifying MACsec on an interface:

```
Switch(config)# interface GigabitEthernet1/0/25
Switch(config-if)# switchport access vlan 10
Switch(config-if)# switchport mode access
Switch(config-if)# macsec
Switch(config-if)# authentication event linksec fail action authorize vlan 2
Switch(config-if)# authentication host-mode multi-domain
Switch(config-if)# authentication linksec policy must-secure
Switch(config-if)# authentication port-control auto
```

```

Switch(config-if)# mka policy replay-policy
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# spanning-tree portfast
Switch(config-if)# end
Switch# show authentication sessions interface gigabitethernet1/0/25
Interface: GigabitEthernet1/0/25
MAC Address: 001b.2140.ec3c
IP Address: 10.1.1.103
User-Name: ms1
Status: Authz Success
Domain: DATA
Security Policy: Must Secure &--- New
Security Status: Secured &--- New
Oper host mode: multi-domain
Oper control dir: both

Vlan Policy: 10
Session timeout: 3600s (server), Remaining: 3567s
Timeout action: Reauthenticate
Idle timeout: N/A
Common Session ID: 0A05783B00000001700448BA8
Acct Session ID: 0x00000019
Handle: 0x06000017
Runnable methods list:
Method State
dot1x Authc Success

```

Configuring MKA Pre-Shared Key

To configure MACsec Key Agreement (MKA) pre-shared key, perform this task:

	Command	Purpose
Step 1	configure terminal	Enters global configuration mode.
Step 2	key chain <i>key-chain-name</i> [macsec]	Configures a key chain and enters keychain MACsec configuration mode. <div>  Note The key ID and the key string should not be all zeros. </div>
Step 3	key <i>hex-string</i>	Configures a key and enters keychain-MACsec key configuration mode. <ul style="list-style-type: none"> The key ID must be an even-digit-sized hex-string. <div>  Note Ensure that key is a non-zero value. If key is set to 00, validation failure occurs and the following message is displayed: MKA Session bring-up failure: FSM (Derive KEK /ICK) - Zero CKN input </div>
Step 4	cryptographic-algorithm [aes-128-cmac aes-256-cmac]	Sets the cryptographic encryption algorithm. <div>  Note Cisco Catalyst 4500-X Series Switches do not support AES-256 encryption. </div>

Command	Purpose
Step 5 <code>key-string {[0 6] pre-shared-key 7 pre-shared-key}</code>	Sets the pre-shared key for a key string. <ul style="list-style-type: none"> The key-string should be a 32 or 64-digit hex-string, that is in sync with the cryptographic algorithm that is configured. <div>  Note </div> Ensure that key-string is a non-zero value. If key-string is set to 00, validation failure occurs and the following message is displayed: MKA Session bring-up failure: FSM (Derive KEK /ICK) - Zero CAK input
Step 6 <code>lifetime {local hh:mm:ss hh:mm:ss} day month year {duration seconds hh:mm:ss day month infinite}</code>	<div>  Note </div> Sets a lifetime for the MACsec key.
Step 7 <code>end</code>	Returns to privileged EXEC mode.
Step 8 <code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

This example shows how to configure MKA pre-shared key:

```
Switch# configure terminal
Switch(config)# key chain keychain1 macsec
Switch(config-keychain-macsec)# key 0001
Switch(config-keychain-macsec-key)# cryptographic-algorithm aes-128-cmac
Switch(config-keychain-macsec-key)# key-string 0 pwd
Switch(config-keychain-macsec-key)# lifetime local 16:00:00 Nov 9 2014 duration 6000
Switch(config-keychain-macsec-key)# end
Switch# copy running-config startup-config
```

Example: Connectivity Association Key Rekey

The connectivity Association Key (CAK) is a long-lived master key that is used to generate all other keys needed for MKA/MACsec.

The CAK rekey happens in the following cases:

- When moving from Key 01 to Key 02 within the Key Chain K1.
- When moving from one Key Chain K1 to another Key Chain K2.

Note

We recommend that you configure keys such that there is an overlap between the lifetime of the keys so that CAK rekey is successful and there is a seamless transition between the keys/CA (without any traffic loss or session restart.)

```
Switch# show key chain k1
```

```
Key-chain k1:
```

```
MacSEC key chain
```

```
key 01 - text "c890433a1e05ef42d723a6b58af8fdbf7a25f42b3cda6a5eeb5ae4bf3a0a679f"
lifetime (00:00:00 UTC Oct 29 2014) - (12:10:00 UTC Oct 29 2014)
key 02 - text "14d9167d538819405c0ff78c655141ed4b3c7242562c0fb0f7a56f780bf29e52"
lifetime (12:00:00 UTC Oct 29 2014) - (18:05:00 UTC Oct 29 2014)
key 03 - text "88d971cb19d9f2598ad76edc562ade2e7e91e3ed70524f5c3c4d8d9599d0670e"
lifetime (18:00:00 UTC Oct 29 2014) - (18:10:00 UTC Oct 29 2014)
```

```
key 04 - text "75474bce819b49ad7e5bd06236bc0c944c69892f71e942e2f9812b7d3a7b2a5f"
lifetime (18:10:00 UTC Oct 29 2014) - (infinite)
```

!In this case, Key 01, 02, 03 have overlapping time, but not key 04. Here is the sequence, how this works:

```
@00:00:00 - A new MKA session is Secured with key 01
@12:00:00 - CAK Rekey triggers with key 02 and upon success goes to Secured state
@18:00:00 - CAK Rekey triggers with key 03 and upon success goes to Secured state
@18:10:00 - Key 03 dies, hence MKA session using this key is brought down
@18:10:00 - Key 04 becomes active and a new MKA session is triggered with this key. Upon
success, session will be Secured and UP for infinite time.
```

Understanding MKA MACsec with EAP-TLS

Beginning in Cisco IOS XE Release 3.9.0E, MKA MACsec is supported on switch-to-switch links on Cisco Catalyst 4500-X series switches and Cisco Catalyst 4500-E series switches with Supervisor Engine 8-E. Beginning in Cisco IOS XE Release 3.10.0E, support is extended to Supervisor Engine 9-E.

Using IEEE 802.1X Port-based Authentication with Extensible Authentication Protocol (EAP-TLS), you can configure MKA MACsec between device uplink ports. EAP-TLS allows mutual authentication and obtains an MSK (master session key) from which the connectivity association key (CAK) is derived for MKA operations. Device certificates are carried, using EAP-TLS, for authentication to the AAA server.

Note

MKA MACsec is not supported on multi-point to multi-point links.

Prerequisites for MKA MACsec with EAP-TLS

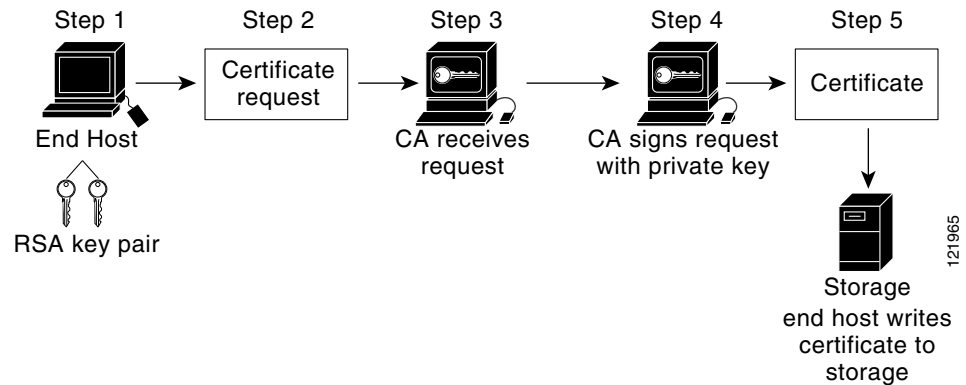

- Ensure that you have a Certificate Authority (CA) server configured for your network.
- Generate a CA certificate.
- We recommend that you configure Cisco Identity Services Engine (ISE) Release 2.0.
- Ensure that both the participating devices, the CA server, and Cisco Identity Services Engine (ISE) are synchronized using Network Time Protocol (NTP).
- Ensure that 802.1x authentication and AAA are configured on your device.

Limitations for MKA MACsec with EAP-TLS

- MKA is not supported on port-channels.
- MKA is not supported with High Availability and local authentication.
- MKA supports encryption using AES-GCM-128 encryption only. MKA does not support Security Group Tagging and AES-GCM-256 encryption.
- WS-C4510R+E chassis that runs IOS XE 3.11.xE supports only TLS 1.0. Later versions of TLS (like 1.1 or 1.2) are not supported.

Understanding Certificate Enrollment

Certificate enrollment is the process of obtaining a certificate from a Certificate Authority (CA). Each end host that wants to participate in the Cisco IOS public key infrastructure (PKI) must obtain a certificate. Certificate enrollment occurs between the end host requesting the certificate and the CA. The figure below and the following steps describe the certificate enrollment process.

1. The end host generates an RSA key pair.
2. The end host generates a certificate request and forwards it to the CA.
3. The CA receives the certificate enrollment request, and, depending on your network configuration, one of the following options occurs:
 - Manual intervention is required to approve the request.
 - The end host is configured to automatically request a certificate from the CA. Thus, operator intervention is no longer required at the time the enrollment request is sent to the CA server.

Note

If you configure the end host to automatically request certificates from the CA, you should have an additional authorization mechanism.

4. After the request is approved, the CA signs the request with its private key and returns the completed certificate to the end host.
5. The end host writes the certificate to a storage area such as NVRAM.

Generating RSA Key Pairs

To generate RSA key pairs, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>crypto key generate rsa label <i>label</i> name <i>general-keys</i> modulus <i>size</i></code>	Generates a RSA key pair for signing and encryption. You can also assign a label to each key pair using the label keyword. The label is referenced by the trustpoint that uses the key pair. If you do not assign a label, the key pair is automatically labeled <Default-RSA-Key>. If you do not use additional keywords this command generates one general purpose RSA key pair. If the modulus is not specified, the default key modulus of 1024 is used. You can specify other modulus sizes with the modulus keyword.
Step 3	<code>end</code>	Returns to privileged EXEC mode.
Step 4	<code>show crypto key mypubkey rsa</code>	(Optional) Displays the RSA public keys of your device. This step allows you to verify that the RSA key pair has been successfully generated.
Step 5	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Configuring Enrollment using SCEP

Simple Certificate Enrollment Protocol (SCEP) is a Cisco-developed enrollment protocol that uses HTTP to communicate with the certificate authority (CA) or registration authority (RA). SCEP is the most commonly used method for sending and receiving requests and certificates.

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>crypto pki trustpoint <i>server name</i></code>	Declares the trustpoint and a given name and enters ca-trustpoint configuration mode.
Step 3	<code>enrollment url <i>url name pem</i></code>	Specifies the URL of the CA on which your device should send certificate requests. An IPv6 address can be added in the URL enclosed in brackets. For example: <code>http:// [2001:DB8:1:1::1]:80</code> . The pem keyword adds privacy-enhanced mail (PEM) boundaries to the certificate request.
Step 4	<code>rsa keypair <i>label</i></code>	Specifies which key pair to associate with the certificate.
Step 5	<code>serial-number none</code>	The none keyword specifies that a serial number will not be included in the certificate request.
Step 6	<code>ip-address none</code>	The none keyword specifies that no IP address should be included in the certificate request.
Step 7	<code>revocation-check <i>crl</i></code>	Specifies CRL as the method to ensure that the certificate of a peer has not been revoked.

	Command	Purpose
Step 8	<code>auto-enroll percent regenerate</code>	<p>Enables auto-enrollment, allowing the client to automatically request a rollover certificate from the CA.</p> <p>If auto-enrollment is not enabled, the client must be manually re-enrolled in your PKI upon certificate expiration.</p> <p>By default, only the Domain Name System (DNS) name of the device is included in the certificate.</p> <p>Use the percent argument to specify that a new certificate will be requested after the percentage of the lifetime of the current certificate is reached.</p> <p>Use the regenerate keyword to generate a new key for the certificate even if a named key already exists.</p> <p>If the key-pair being rolled over is exportable, the new key pair will also be exportable. The following comment will appear in the trustpoint configuration to indicate whether the key pair is exportable: “! RSA key pair associated with trustpoint is exportable.”</p> <p>It is recommended that a new key pair be generated for security reasons.</p>
Step 9	<code>crypto pki authenticate name</code>	Retrieves the CA certificate and authenticates it.
Step 10	<code>exit</code>	Exits Global Configuration mode.
Step 11	<code>show crypto pki certificate trustpoint name</code>	Displays information about the certificate for the trust point.

Configuring Manual Enrollment

If your CA does not support SCEP or if a network connection between the router and CA is not possible. Perform the following task to set up manual certificate enrollment:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>crypto pki trustpoint server name</code>	Declares the trustpoint and a given name and enters ca-trustpoint configuration mode.
Step 3	<code>enrollment terminal</code>	<p>Specifies the manual cut-and-paste certificate enrollment method.</p> <p>The certificate request will be displayed on the console terminal so that it may be manually copied (or cut).</p> <p>The pem keyword configures the trustpoint to generate PEM-formatted certificate requests to the console terminal.</p>
Step 4	<code>rsakeypair label</code>	Specifies which key pair to associate with the certificate.
Step 5	<code>serial-number none</code>	The none keyword specifies that a serial number will not be included in the certificate request.
Step 6	<code>ip-address none</code>	The none keyword specifies that no IP address should be included in the certificate request.
Step 7	<code>revocation-check crl</code>	Specifies CRL as the method to ensure that the certificate of a peer has not been revoked.

	Command	Purpose
Step 8	<code>exit</code>	Exits ca-trustpoint configuration mode and returns to global configuration mode.
Step 9	<code>crypto pki authenticate name</code>	Retrieves the CA certificate and authenticates it.
Step 10	<code>crypto pki enroll name</code>	<p>Generates certificate request and displays the request for copying and pasting into the certificate server.</p> <p>Enter enrollment information when you are prompted. For example, specify whether to include the device FQDN and IP address in the certificate request.</p> <p>You are also given the choice about displaying the certificate request to the console terminal.</p> <p>The base-64 encoded certificate with or without PEM headers as requested is displayed.</p>
Step 11	<code>crypto pki import name certificate</code>	<p>Imports a certificate via TFTP at the console terminal, which retrieves the granted certificate.</p> <p>The device attempts to retrieve the granted certificate via TFTP using the same filename used to send the request, except the extension is changed from “.req” to “.crt”. For usage key certificates, the extensions “-sign.crt” and “-encr.crt” are used.</p> <p>The device parses the received files, verifies the certificates, and inserts the certificates into the internal certificate database on the router.</p> <p>Note Some CAs ignore the usage key information in the certificate request and issue general purpose usage certificates. If your CA ignores the usage key information in the certificate request, only import the general purpose certificate. The device will not use one of the two key pairs generated.</p>
Step 12	<code>exit</code>	Exits Global Configuration mode.
Step 13	<code>show crypto pki certificate trustpoint name</code>	Displays information about the certificate for the trust point.
Step 14	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Ensure that you enroll both the participating devices and the RADIUS server to the PKI infrastructure.

For more information on PKI configuration, see the [Public Key Infrastructure Configuration Guide](#).

Configuring MKA MACsec Using EAP-TLS

To configure MACsec with MKA on point-to-point links, perform these tasks:

- Configure an Authentication Policy
- Configure EAP-TLS Profiles and IEEE 802.1x Credentials
- Configure 802.1x and MKA MACsec using EAP-TLS on Interfaces

Configuring EAP-TLS and 802.1x Credentials

To configure EAP-TLS and 802.1x credentials, perform the following task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>dot1x credentials <i>profile</i></code>	Creates 802.1x credentials profile. This must be attached to the port that is configured as supplicant.
Step 3	<code>username <i>name</i></code>	Creates a username.
Step 4	<code>password <i>password</i></code>	Creates a password.
Step 5	<code>exit</code>	Exits dot1x-creden configuration mode and returns to global configuration mode.
Step 6	<code>eap profile <i>name</i></code>	Configures the EAP profile, and enters eap-profile configuration mode.
Step 7	<code>method tls</code>	Configures the EAP-TLS method.
Step 8	<code>pki trustpoint <i>name</i></code>	Configures the default PKI trustpoint.
Step 9	<code>exit</code>	Exits eap-profile configuration mode and enters global configuration mode.
Step 10	<code>service-template <i>name</i></code>	Creates a service template and enters service template configuration mode.
Step 11	<code>linksec policy must-secure</code>	Sets a data link layer security policy. The must-secure keyword specifies that the device port must be authorized only if a secure MACsec session is established.
Step 12	<code>exit</code>	Exits service-template configuration mode and returns to global configuration mode.
Step 13	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Configuring an Authentication Policy

To configure an authentication policy, perform the following task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>exit</code>	Exits service-template configuration mode and returns to global configuration mode.
Step 3	<code>policy-map type control subscriber <i>control-policy-name</i></code>	Defines a control policy for subscriber sessions and enters control policy-map event configuration mode.
Step 4	<code>event <i>event-name</i> match-all</code>	Specifies that the session-started event triggers actions in a control policy if conditions are met. match-all is the default behavior.
Step 5	<code><i>priority-number</i> class always do-until-failure</code>	Associates a priority with an action in the control policy.
Step 6	<code><i>action-number</i> authenticate using dot1x both</code>	Initiates the authentication of a subscriber session using the IEEE 802.1x method as both a supplicant and an authenticator.
Step 7	<code>event authentication-failure match-all</code>	Specifies that the authentication-failure event triggers actions in a control policy if conditions are met. match-all is the default behavior.

	Command	Purpose
Step 8	<code>priority-number class always do-until-failure</code>	Associates a priority with an action in the control policy.
Step 9	<code>action-number terminate dot1x</code>	Terminates the authentication of a subscriber session using the IEEE 802.1x method
Step 10	<code>action-number authentication-restart seconds</code>	Sets a timer to restart the authentication process after an authentication or authorization failure.
Step 11	<code>exit</code>	Exits control policy-map event configuration mode and returns to global configuration mode.
Step 12	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Applying the 802.1x and MKA MACsec Configuration on Interfaces

To apply 801.1x and MKA MACsec using EAP-TLS to interfaces, perform the following task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>interface interface-id</code>	Identifies the MACsec interface, and enter interface configuration mode. The interface must be a physical interface.
Step 3	<code>macsec network-link</code>	Enables MKA MACsec using EAP-TLS, on the interface.
Step 4	<code>authentication periodic</code>	Enables reauthentication for this port.
Step 5	<code>authentication timer reauthenticate interval</code>	Sets the reauthentication interval.
Step 6	<code>access-session host-mode multi-host</code>	Allows hosts to gain access to the interface.
Step 7	<code>access-session closed</code>	Prevents preauthentication access on the interface.
Step 8	<code>access-session port-control auto</code>	Sets the authorization state of a port.
Step 9	<code>dot1x pae both</code>	Configures the port as an 802.1X port access entity (PAE) supplicant and authenticator.
Step 10	<code>dot1x credentials profile</code>	Assigns a 802.1x credentials profile to the interface.
Step 11	<code>dot1x supplicant eap profile name</code>	Assigns the EAP-TLS profile to the interface.
Step 12	<code>service-policy type control subscriber control-policy name</code>	Applies a subscriber control policy to the interface.
Step 13	<code>exit</code>	Returns to privileged EXEC mode.
Step 14	<code>show access-session interface interface-id</code>	(Optional) Displays the active MKA sessions for the interface, and verifies your MKA MACsec configuration.
Step 15	<code>show mka session interface interface-id</code>	
Step 16	<code>show macsec interface interface-id</code>	
Step 17	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Example: MKA MACsec Switch-to-Switch Configuration

```
Switch# configure terminal
Switch(config)# crypto key generate rsa label mkaioscarsa mod 2048
The name for the keys will be: mkaioscarsa
```

```
% The key modulus size is 2048 bits
% Generating 2048 bit RSA keys, keys will be non-exportable...
[OK] (elapsed time was 2 seconds)
```

```
Switch(config)# crypto pki trustpoint POLESTAR-IOS-CA
Switch(ca-trustpoint)# subject-name CN=catdevice@polestar.com, C=IN, ST=KA,
OU=ENG,O=Polestar
Switch(ca-trustpoint)# revocation-check none
Switch(ca-trustpoint)# rsakeypair mkaioscarsa
Switch(ca-trustpoint)# storage nvram:
Switch(ca-trustpoint)# end
Switch# configure terminal
Switch(config)# crypto pki authenticate POLESTAR-IOS-CA
```

```
Enter the base 64 encoded CA certificate.
End with a blank line or the word "quit" on a line by itself
```

```
!!PASTE THE CERTIFICATE CONTENT HERE AND END WITH ENTER!!
```

```
% Do you accept this certificate? [yes/no]: Yes
Trustpoint CA certificate accepted.
% Certificate successfully imported
Switch(config)# end
Switch# show crypto pki certificate POLESTAR-IOS-CA
```

```
CA Certificate
Status: Available
Certificate Serial Number (hex): 01
Certificate Usage: Signature
Issuer:
  cn=POLESTAR-DHCP-CM.polestar.com
  ou=ENG
Subject:
  cn=POLESTAR-DHCP-CM.polestar.com
  ou=ENG
Validity Date:
  start date: 09:39:53 IST Apr 13 2016
  end   date: 09:39:53 IST Apr 13 2017
Associated Trustpoints: POLESTAR-IOS-CA
```

```
Switch# configure terminal
Switch(config)# crypto pki enroll POLESTAR-IOS-CA
% Start certificate enrollment ..
```

```
% The subject name in the certificate will include: CN=catdevice@polestar.com, C=IN,
ST=KA, OU=ENG,O=Polestar
% The subject name in the certificate will include: Device.polestar.com
% Include the router serial number in the subject name? [yes/no]: no
% Include an IP address in the subject name? [no]: no
Display Certificate Request to terminal? [yes/no]: yes
Certificate Request follows:
```

```

Understanding Cisco TrustSec MACsec

Table 48-2 summarizes the Cisco TrustSec features supported on the switch. For more detailed explanations, see the *Cisco TrustSec Switch Configuration Guide*:

http://www.cisco.com/en/US/docs/switches/lan/trustsec/configuration/guide/arch_over.html#wp1054561

Table 48-2 Cisco TrustSec Features

Cisco TrustSec Feature	Description
802.1AE Encryption (MACsec)	<p>Protocol for 802.1AE-based wire-rate hop-to-hop Layer 2 encryption.</p> <p>Between MACsec-capable devices, packets are encrypted on egress from the sending device, decrypted on ingress to the receiving device, and in the clear within the devices.</p> <p>This feature is only available between 802.1AE-capable devices.</p>
Network Device Admission Control (NDAC)	<p>NDAC is an authentication process by which each network device in the TrustSec domain can verify the credentials and trustworthiness of its peer device. NDAC uses an authentication framework based on IEEE 802.1X port-based authentication and uses Extensible Authentication Protocol Flexible Authentication via Secure Tunnel (EAP-FAST) as its EAP method. Authentication and authorization by NDAC results in Security Association Protocol negotiation for 802.1AE encryption.</p>
Security Association Protocol (SAP)	<p>SAP is a Cisco proprietary key exchange protocol between switches. After NDAC switch-to-switch authentication, SAP automatically negotiates keys and the cipher suite for subsequent switch-to-switch MACsec encryption between TrustSec peers. The protocol description is available under a nondisclosure agreement.</p>
Security Group Tag (SGT)	<p>An SGT is a 16-bit single label showing the security classification of a source in the TrustSec domain. It is appended to an Ethernet frame or an IP packet.</p>
Note SGT is not supported in this release.	
SGT Exchange Protocol (SXP), including SXPv2	<p>With SXP, devices that are not TrustSec-hardware capable can receive SGT attributes for authenticated users or devices from the Cisco Access Control System (ACS). The devices then forward the source IP-to-SGT binding to a TrustSec-hardware capable device for tagging and security group ACL (SGACL) enforcement.</p>

When both ends of a link support 802.1AE MACsec, SAP negotiation occurs. An EAPOL-key exchange occurs between the supplicant and the authenticator to negotiate a cipher suite, exchange security parameters, and manage keys. Successful completion of these tasks results in the establishment of a security association (SA).

Depending on your software version and licensing and link hardware support, SAP negotiation can use one of these modes of operation:

- Galois Counter Mode (GCM)—authentication and encryption
- GCM authentication (GMAC)— GCM authentication, no encryption
- No Encapsulation—no encapsulation (clear text)
- Null—encapsulation, no authentication or encryption

Cisco TrustSec uses AES-128 GCM and GMAC and is compliant with the 802.1AE standard. GCM is not supported on switches running the NPE or the LAN Base image.

Cisco TrustSec NDAC SAP is supported on trunk ports because it is intended only for network device to network device links, that is, switch-to-switch links. It is not supported on:

- Host facing access ports (these ports support MKA MACsec)
- Switch virtual interfaces (SVIs)
- SPAN destination ports

The switch also does not support security group ACLs.

You must set the Cisco TrustSec credentials to create the Cisco TrustSec network.

You can configure Cisco TrustSec link layer security in 802.1X mode or manual mode.

Configuring Cisco TrustSec MACsec

- Following topics are discussed:
- [Configuring Cisco TrustSec Credentials on the Switch, page 48-22](#)
 - [Configuring Cisco TrustSec Switch-to-Switch Link Security in 802.1X Mode, page 48-23](#)
 - [Configuring Cisco TrustSec Switch-to-Switch Link Security in Manual Mode, page 48-24](#)
 - [Cisco TrustSec Switch-to-Switch Link Security Configuration Example, page 48-25](#)

Note

The sample configuration in the last section shows the AAA and the RADIUS configuration. Use this example to configure RADIUS and AAA before configuring switch-to-switch security.

Configuring Cisco TrustSec Credentials on the Switch

To enable Cisco TrustSec features, you must create Cisco TrustSec credentials on the switch to use in other TrustSec configurations.

To configure Cisco TrustSec credentials, perform this task:

	Command	Purpose
Step 1	<code>cts credentials id device-id password cts-password</code>	Specifies the Cisco TrustSec credentials for this switch to use when authenticating with other Cisco TrustSec devices with EAP-FAST. <ul style="list-style-type: none">• id device-id—Specifies a Cisco TrustSec device ID for the switch. The device-id argument has a maximum length of 32 characters and is case sensitive.• password cts-password—Specifies the Cisco TrustSec password for the device.
Step 2	<code>show cts credentials</code>	(Optional) Displays Cisco TrustSec credentials configured on the switch.
Step 3	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

To delete the Cisco TrustSec credentials, enter the **clear cts credentials** privileged EXEC command.

This example shows how to create Cisco TrustSec credentials:

```
Switch# cts credentials id trustsec password mypassword
CTS device ID and password have been inserted in the local keystore. Please make
sure that the same ID and password are configured in the server database.

Switch# show cts credentials
CTS password is defined in keystore, device-id = trustsecchange-password  Initiate
password change with AAA server
```

**Note**

Before you configure Cisco TrustSec MACsec authentication, you should configure Cisco TrustSec seed and non-seed devices. For 802.1X mode, you must configure at least one seed device, that device closest to the access control system (ACS). See this section in the *Cisco TrustSec Switch Configuration Guide*:

<http://www.cisco.com/en/US/docs/switches/lan/trustsec/configuration/guide/trustsec.html>

Configuring Cisco TrustSec Switch-to-Switch Link Security in 802.1X Mode

You enable Cisco TrustSec link layer switch-to-switch security on an interface that connects to another Cisco TrustSec device. When configuring Cisco TrustSec in 802.1X mode on an interface, follow these guidelines:

- To use 802.1X mode, you must globally enable 802.1X on each device.
- If you select GCM as the SAP operating mode, you must have a MACsec encryption software license from Cisco.

**Note**

MACsec is supported on the Catalyst 4500 series switch universal k9 image. It is not supported with the NPE license or with a LAN Base service image.

If you select GCM without the required license, the interface is forced to a link-down state.

To configure Cisco TrustSec switch-to-switch link layer security with 802.1X, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>interface interface-id</code>	Enters interface configuration mode.
Step 3	<code>cts dot1x</code>	Configures the interface to perform NDAC authentication.
Step 4	<code>sap mode-list mode1 [mode2 [mode3 [mode4]]]</code>	<p>(Optional) Configures the SAP operation mode on the interface. The interface negotiates with the peer for a mutually acceptable mode. Enter the acceptable modes in your order of preference.</p> <p>Choices for <i>mode</i> are:</p> <ul style="list-style-type: none"> • gcm-encrypt—Authentication and encryption <p>Note Select this mode for MACsec authentication and encryption if your software license supports MACsec encryption.</p> <ul style="list-style-type: none"> • gmac—Authentication, no encryption • no-encap—No encapsulation • null—Encapsulation, no authentication or encryption <p>Note If the interface is not capable of data link encryption, no-encap is the default and the only available SAP operating mode. SGT is not supported.</p>

**Note**

Although visible in the CLI help, the **timer reauthentication** and **propagate sgt** keywords are not supported. However, the **no propagate sgt** keyword is supported (refer to Step 5 in the next section).

	Command	Purpose
Step 5	exit	Exits Cisco TrustSec 802.1X interface configuration mode.
Step 6	end	Returns to privileged EXEC mode.
Step 7	show cts interface [<i>interface-id</i> / brief / summary]	(Optional) Verifies the configuration by displaying TrustSec-related interface characteristics.
Step 8	copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to enable Cisco TrustSec authentication in 802.1X mode on an interface using GCM as the preferred SAP mode:

```
Switch# configure terminal
Switch(config)# interface tengigabitethernet 1/1/2
Switch(config-if)# cts dot1x
Switch(config-if-cts-dot1x)# sap mode-list gcm-encrypt null no-encap
Switch(config-if-cts-dot1x)# exit
Switch(config-if)# end
```

Configuring Cisco TrustSec Switch-to-Switch Link Security in Manual Mode

If your switch does not have access to an authentication server or if 802.1X authentication is not needed, you can manually configure Cisco TrustSec on an interface. You must manually configure the interface on each end of the connection.

When manually configuring Cisco TrustSec on an interface, consider these usage guidelines and restrictions:

- If no SAP parameters are defined, neither encryption nor MACsec Encapsulation are performed.
- If you select GCM as the SAP operating mode, you must have a MACsec Encryption software license from Cisco. If you select GCM without the required license, the interface is forced to a link-down state.
- These protection levels are supported when you configure SAP pairwise master key (**sap pmk**):
 - SAP is not configured—no protection.
 - **sap mode-list gcm-encrypt gmac no-encap**—protection desirable but not mandatory.
 - **sap mode-list gcm-encrypt gmac**—confidentiality preferred and integrity required. The protection is selected by the supplicant according to supplicant preference.
 - **sap mode-list gmac**—integrity only.
 - **sap mode-list gcm-encrypt**—confidentiality required.
 - **sap mode-list gmac gcm-encrypt**—integrity required and preferred, confidentiality optional.

To manually configure Cisco TrustSec on an interface to another Cisco TrustSec device, perform this task:

	Command	Purpose
Step 1	configure terminal	Enters global configuration mode.
Step 2	interface <i>interface-id</i>	Enters interface configuration mode.
Step 3	cts manual	Enters Cisco TrustSec manual configuration mode.

	Command	Purpose
Step 4	<code>sap pmk key [mode-list mode1 [mode2 [mode3 [mode4]]]]</code>	<p>(Optional) Configures the SAP pairwise master key (PMK) and operation mode. SAP is disabled by default in Cisco TrustSec manual mode.</p> <ul style="list-style-type: none"> <i>key</i>—A hexadecimal value with an even number of characters and a maximum length of 32 characters. <p>The SAP operation <i>mode</i> options:</p> <ul style="list-style-type: none"> gcm-encrypt—Authentication and encryption <p>Note Select this mode for MACsec authentication and encryption if your software license supports MACsec encryption.</p> <ul style="list-style-type: none"> gmac—Authentication, no encryption no-encap—No encapsulation null—Encapsulation, no authentication or encryption <p>Note If the interface is not capable of data link encryption, no-encap is the default and the only available SAP operating mode. SGT is not supported.</p>
Step 5	<code>no propagate sgt</code>	<p>Prevents the interface from transmitting the SGT to the peer and is required in manual mode.</p> <p>Use the no form of this command when the peer is incapable of processing a SGT.</p>
Step 6	<code>exit</code>	Exits Cisco TrustSec 802.1X interface configuration mode.
Step 7	<code>end</code>	Returns to privileged EXEC mode.
Step 8	<code>show cts interface [interface-id brief summary]</code>	(Optional) Verifies the configuration by displaying TrustSec-related interface characteristics.
Step 9	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

This example shows how to configure Cisco TrustSec authentication in manual mode on an interface:

```
Switch# configure terminal
Switch(config)# interface tengigabitethernet 1/1/2
Switch(config-if)# cts manual
Switch(config-if-cts-manual)# sap pmk 1234abcdef mode-list gcm-encrypt null no-encap
Switch(config-if-cts-manual)# no propagate sgt
Switch(config-if-cts-manual)# exit
Switch(config-if)# end
```

Cisco TrustSec Switch-to-Switch Link Security Configuration Example

This example shows the configuration necessary for a seed and non-seed device for Cisco TrustSec switch-to-switch security. You must configure the AAA and RADIUS for link security. In this example, *ACS-1* through *ACS-3* can be any server names and *cts-radius* is the Cisco TrustSec server.

Seed Device Configuration:

```
Switch(config)# aaa new-model
Switch(config)# radius server ACS-1 address ipv4 10.5.120.12 auth-port 1812 acct-port 1813
pac key cisco123
```

```

Switch(config)# radius server ACS-2 address ipv4 10.5.120.14 auth-port 1812 acct-port 1813
pac key cisco123
Switch(config)# radius server ACS-3 address ipv4 10.5.120.15 auth-port 1812 acct-port 1813
pac key cisco123
Switch(config)# aaa group server radius cts-radius
Switch(config-sg-radius)# server name ACS-1
Switch(config-sg-radius)# server name ACS-2
Switch(config-sg-radius)# server name ACS-3
Switch(config-sg-radius)# exit
Switch(config)# aaa authentication login default none
Switch(config)# aaa authentication dot1x default group cts-radius
Switch(config)# aaa authentication network cts-radius group radius
Switch(config)# aaa session-id common
Switch(config)# cts authorization list cts-radius
Switch(config)# dot1x system-auth-control

Switch(config)# interface g1/1/2
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# cts dot1x
Switch(config-if-cts-dot1x)# sap mode-list gcm-encrypt gmac
Switch(config-if-cts-dot1x)# exit
Switch(config-if)# exit

Switch(config)# interface g1/1/4
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# cts manual
Switch(config-if-cts-dot1x)# sap pmk 033445AABBCCDDEEFF mode-list gcm-encrypt gmac
Switch(config-if-cts-dot1x)# no propagate sgt
Switch(config-if-cts-dot1x)# exit
Switch(config-if)# exit

Switch(config)# radius-server vsa send authentication
Switch(config)# end
Switch# cts credentials id cts-36 password trustsec123

```

Non-Seed Device:

```

Switch(config)# aaa new-model
Switch(config)# aaa session-id common
Switch(config)# dot1x system-auth-control

Switch(config)# interface g1/1/2
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# shutdown
Switch(config-if)# cts dot1x
Switch(config-if-cts-dot1x)# sap mode-list gcm-encrypt gmac
Switch(config-if-cts-dot1x)# exit
Switch(config-if)# exit

Switch(config)# interface g1/1/4
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# shutdown
Switch(config-if)# cts manual
Switch(config-if-cts-dot1x)# sap pmk 033445AABBCCDDEEFF mode-list gcm-encrypt gmac
Switch(config-if-cts-dot1x)# no propagate sgt
Switch(config-if-cts-dot1x)# exit
Switch(config-if)# exit
Switch(config)# radius-server vsa send authentication
Switch(config)# end

```

```
Switch# cts credentials id cts-72 password trustsec123
```

Configuring 802.1X Port-Based Authentication

This chapter describes how to configure IEEE 802.1X port-based authentication on the Catalyst 4500 series switch to prevent unauthorized client devices from gaining access to the network.

This chapter includes the following major sections:

- [About 802.1X Port-Based Authentication, page 49-1](#)
- [Configuring 802.1X Port-Based Authentication, page 49-26](#)
- [Controlling Switch Access with RADIUS, page 49-97](#)
- [Configuring Device Sensor, page 49-117](#)
- [Displaying 802.1X Statistics and Status, page 49-126](#)
- [Displaying Authentication Details, page 49-126](#)
- [Cisco IOS Security Features, page 49-131](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About 802.1X Port-Based Authentication

802.1X defines 802.1X port-based authentication as a client-server based access control and authentication protocol that restricts unauthorized clients from connecting to a LAN through publicly accessible ports. An authentication server validates each supplicant (client) connected to an authenticator (network access switch) port before making available any services offered by the switch or the LAN.

Note

802.1X support requires an authentication server that is configured for Remote Authentication Dial-In User Service (RADIUS). 802.1X authentication does not work unless the network access switch can route packets to the configured RADIUS server. To verify that the switch can route packets, you must ping the server from the switch.

Until a client is authenticated, only Extensible Authentication Protocol over LAN (EAPOL) traffic is allowed using the port to which the client is connected. After authentication succeeds, normal traffic can pass using the port.

To configure 802.1X port-based authentication, you need to understand the concepts in these sections:

- [Device Roles, page 49-2](#)
- [802.1X and Network Access Control, page 49-3](#)
- [Authentication Initiation and Message Exchange, page 49-4](#)
- [Ports in Authorized and Unauthorized States, page 49-5](#)
- [802.1X Host Mode, page 49-6](#)
- [802.1X Violation Mode, page 49-9](#)
- [Using MAC Move, page 49-9](#)
- [Using MAC Replace, page 49-9](#)
- [Using 802.1X with VLAN Assignment, page 49-10](#)
- [Using 802.1X for Guest VLANs, page 49-11](#)
- [Using 802.1X with MAC Authentication Bypass, page 49-12](#)
- [Using 802.1X with Web-Based Authentication, page 49-14](#)
- [Using 802.1X with Inaccessible Authentication Bypass, page 49-14](#)
- [Using 802.1X with Unidirectional Controlled Port, page 49-15](#)
- [Using 802.1X with VLAN User Distribution, page 49-16](#)
- [Using 802.1X with Authentication Failed VLAN Assignment, page 49-17](#)
- [Using 802.1X with Port Security, page 49-19](#)
- [Using 802.1X Authentication with ACL Assignments and Redirect URLs, page 49-19](#)
- [Using 802.1X with RADIUS-Provided Session Timeouts, page 49-20](#)

- [How 802.1X Fails on a Port, page 49-24](#)
- [Supported Topologies, page 49-25](#)

Device Roles

With 802.1X port-based authentication, network devices have specific roles. [Figure 49-1](#) shows the role of each device, which is described below.

Figure 49-1 802.1X Device Roles

- **Client**—The workstation that requests access to the LAN, and responds to requests from the switch. The workstation must be running 802.1X-compliant client software.
- **Authenticator**—Controls physical access to the network based on the authentication status of the client. The Catalyst 4500 series switch acts as an intermediary between the client and the authentication server, requesting identity information from the client, verifying that information with the authentication server, and relaying a response to the client. The switch encapsulates and decapsulates the Extensible Authentication Protocol (EAP) frames and interacts with the RADIUS authentication server.

When the switch receives EAPOL frames and relays them to the authentication server, the Ethernet header is stripped and the remaining EAP frame is reencapsulated in the RADIUS format. The EAP frames are not modified or examined during encapsulation, and the authentication server must support EAP within the native frame format. When the switch receives frames from the authentication server, the frame header is removed from the server, leaving the EAP frame, which is then encapsulated for Ethernet and sent to the client.

**Note**

The Catalyst 4500 series switches must be running software that supports the RADIUS client and 802.1X.

- **Authentication server**—Performs the actual authentication of the client. The authentication server validates the identity of the client and notifies the switch that the client is authorized to access the LAN and switch services. (The only supported authentication server is the RADIUS authentication server with EAP extensions; it is available in Cisco Secure Access Control Server version 3.2 and later releases.)

802.1X and Network Access Control

Network Access Control is a feature that allows port access policies to be influenced by the antivirus posture of the authenticating device.

Antivirus posture includes such elements as the operating system running on the device, the operating system version, whether antivirus software is installed and what version of antivirus signatures is available. If the authenticating device has a NAC-aware 802.1X supplicant and the authentication server is configured to support NAC using 802.1X, antivirus posture information is automatically included as part of the 802.1X authentication exchange.

For information on NAC, refer to the URL:

<http://www.cisco.com/en/US/products/ps6128/index.html>

Authentication Initiation and Message Exchange

The switch or the client can initiate authentication. If you enable authentication on a port by using the **authentication port-control auto** interface configuration command (**dot1x port-control auto** command in Cisco IOS Release 12.2(46)SG and earlier releases), the switch must initiate authentication when it determines that the port link state has changed. It then sends an EAP-request/identity frame to the client to request its identity (typically, the switch sends an initial identity/request frame followed by one or more requests for authentication information). Upon receipt of the frame, the client responds with an EAP-response/identity frame.

However, if during bootup, the client does not receive an EAP-request/identity frame from the switch, the client can initiate authentication by sending an EAPOL-start frame, which prompts the switch to request the client's identity.

If 802.1X is not enabled or supported on the network access switch, any EAPOL frames from the client are dropped. If the client does not receive an EAP-request/identity frame after three attempts to start authentication, the client transmits frames as if the port is in the authorized state. A port in the authorized state means that the client was successfully authenticated. When the client supplies its identity, the switch begins its role as the intermediary, passing EAP frames between the client and the authentication server until authentication succeeds or fails. If the authentication succeeds, the switch port becomes authorized.

The specific exchange of EAP frames depends on the authentication method being used. [Figure 49-2](#) shows a message exchange that is initiated by the client using the One-Time Password (OTP) authentication method with an authentication server.

Figure 49-2 Message Exchange

Ports in Authorized and Unauthorized States

The switch port state determines whether the client is granted access to the network. The port starts in the unauthorized state. While in this state, the port disallows all ingress and egress traffic except for 802.1X protocol packets. When a client is successfully authenticated, the port transitions to the authorized state, allowing all traffic for the client to flow normally.

If a non-802.1X capable client is connected to an unauthorized 802.1X port, the switch requests the client's identity. In this situation, the client does not respond to the request, the port remains in the unauthorized state, and the client is not granted access to the network. If a guest VLAN is configured on a port that connects to a client that does not support 802.1X, the port is placed in the configured guest VLAN and in the authorized state. For more information, see the [“Using 802.1X for Guest VLANs” section on page 49-11](#).

In contrast, when an 802.1X-enabled client connects to a port that is not running the 802.1X protocol, the client initiates the authentication process by sending the EAPOL-start frame. When no response is received, the client sends the request a fixed number of times. Because no response is received, the client begins sending frames as if the port is in the authorized state.

You can control the port authorization state by using the **authentication port-control** interface configuration command (**dot1x port-control auto** command in Cisco IOS Release 12.2(46)SG and earlier releases) and these keywords:

- **force-authorized**—Disables 802.1X authentication and causes the port to transition to the authorized state without requiring authentication exchange. The port transmits and receives normal traffic without 802.1X-based authentication of the client. This setting is the default.
- **force-unauthorized**—Causes the port to remain in the unauthorized state, ignoring all attempts by the client to authenticate. The switch cannot provide authentication services to the client using the interface.
- **auto**—Allows 802.1X authentication and causes the port to begin in the unauthorized state, allowing only EAPOL frames to be sent and received using the port. The authentication process begins when the link state of the port transitions from down to up or when an EAPOL-start frame is received. The switch requests the identity of the client and begins relaying authentication messages between the client and the authentication server. The switch can uniquely identify each client attempting to access the network by the client's MAC address.

If the client is successfully authenticated (receives an Accept frame from the authentication server), the port state changes to authorized, and all frames from the authenticated client are allowed using the port. If authentication fails, the port remains in the unauthorized state, but authentication can be retried. If the authentication server cannot be reached, the switch can retransmit the request. If no response is received from the server after the specified number of attempts, authentication fails and network access is not granted.

If the link state of a port transitions from up to down, or if an EAPOL-logoff frame is received by the port, the port returns to the unauthorized state.

If Multidomain Authentication (MDA) is enabled on a port, this flow can be used with some exceptions that are applicable to voice authorization. For more information on MDA, see the [“Using Multiple Domain Authentication and Multiple Authentication” section on page 49-22](#).

Figure 49-3 shows the authentication process.

Figure 49-3 Authentication Flowchart

802.1X Host Mode

The 802.1X port's host mode determines whether more than one client can be authenticated on the port and how authentication is enforced. You can configure an 802.1X port to use any of the five host modes described in the following sections. In addition, each mode can be modified to allow preauthentication open access:

- [Single-Host Mode, page 49-7](#)
- [Multiple-Hosts Mode, page 49-7](#)
- [Multidomain Authentication Mode, page 49-7](#)
- [Multiauthentication Mode, page 49-8](#)

- [Pre-authentication Open Access, page 49-8](#)

Single-Host Mode

You can configure an 802.1X port for single-host or multiple-hosts mode. In single-host mode (see [Figure 49-1 on page 49-3](#)), only one client can be connected to the 802.1X-enabled switch port. The switch detects the client by sending an EAPOL frame when the port link state changes to the up state. If a client leaves or is replaced with another client, the switch changes the port link state to down, and the port returns to the unauthorized state.

Multiple-Hosts Mode

In multiple-hosts mode, you can attach multiple hosts to a single 802.1X-enabled port. [Figure 49-4 on page 49-7](#) shows 802.1X port-based authentication in a wireless LAN. In this mode, only one of the attached clients must be authorized for all clients to be granted network access. If the port becomes unauthorized (reauthentication fails or an EAPOL-logout message is received), the switch denies network access to all of the attached clients. In this topology, the wireless access point is responsible for authenticating the clients attached to it, and it also acts as a client to the switch.

Note

Wired guest access does not work on Supervisor Engine 8-E, 9-E, in multiple-host mode or in multi-authentication mode.

Figure 49-4 Multiple Host Mode Example

Multidomain Authentication Mode

Beginning with Cisco IOS Release 12.2(37)SG, Catalyst 4500 series switches support Multidomain Authentication (MDA), which allows an IP phone (Cisco or third-party) and a single host behind the IP phone to authenticate independently, using 802.1X, MAC authentication bypass (MAB) or (for the host only) web-based authentication. In this application, *multidomain* refers to two domains — data and voice — and only two MAC addresses are allowed per-port. A switch can place the host in the data VLAN and the IP phone in the voice VLAN, even though they appear on the same switch port. The data VLAN and the voice VLAN can be specified in the CLI configuration. The devices are identified as either data or voice depending on the vendor-specific-attributes (VSAs) received from the authentication, authorization, and accounting (AAA) server. The data and voice VLANs can also be obtained from the VSAs received from the (AAA) server during authentication.

Figure 49-5 Multidomain Authentication Mode Example

Figure 49-5 shows a typical MDA application with a single host behind an IP phone connected to the 802.1X-enabled port. Because the client is not directly connected to the switch, the switch cannot detect a loss of port link if the client is disconnected. To prevent another device from using the established authentication of the disconnected client later, Cisco IP phones send a Cisco Discovery Protocol (CDP) host presence type length value (TLV) to notify the switch of changes in the attached client's port link state.

**Note**

Cisco IP phones that are connected to an authenticated port do not work in voice domain if the port is configured in either single-host mode or multi-host mode.

For details on how to configure MDA, see the [“Using Multiple Domain Authentication and Multiple Authentication”](#) section on page 49-22.

Multiauthentication Mode

Available starting in Cisco IOS Release 12.2(50)SG, multiauthentication mode allows one client on the voice VLAN and multiple authenticated clients on the data VLAN. When a hub or access point is connected to an 802.1X port, multiauthentication mode provides enhanced security over multiple-hosts mode by requiring authentication of each connected client. For non-802.1X devices, you can use MAB or web-based authentication as the fallback method for individual host authentications, allowing you to authenticate different hosts through different methods on a single port.

Multiauthentication also supports MDA functionality on the voice VLAN by assigning authenticated devices to either a data or voice VLAN depending on the VSAs received from the authentication server.

Pre-authentication Open Access

Beginning with Cisco IOS Release 12.2(50)SG, any of the four host modes can be additionally configured to allow a device to gain network access before authentication. This preauthentication open access is useful in an application such as the Pre-boot eXecution Environment (PXE), where a device must access the network to download a bootable image containing an authentication client.

Enable preauthentication open access by entering the **authentication open** command after host mode configuration. It acts as an extension to the configured host mode. For example, if preauthentication open access is enabled with single-host mode, then the port allows only one MAC address. When preauthentication open access is enabled, initial traffic on the port is restricted only by whatever other access restriction, independent of 802.1X, is configured on the port. If no access restriction other than 802.1X is configured on the port, then a client device has full access on the configured VLAN.

802.1X Violation Mode

You can use the **authentication violation** interface configuration command to configure the violation mode: restrict, shutdown, and replace.

In single-host mode, a security violation is triggered when more than one device are detected on the data vlan. In multidomain authentication mode, a security violation is triggered when more than one device are detected on the data or voice VLAN.

Security violation cannot be triggered in multiple-host mode or multiauthentication mode.

When security violation occurs, the port is protected depending on the configured violation action:

Shutdown—Errdisables the port; the default behavior on a port.

Restrict—The port state is unaffected. However the platform is notified to restrict the traffic from offending MAC-address.

Replace—Replaces existing host with the new host, instead of error-disabling or restricting the port.

For more information see [“Configuring Violation Action” section on page 49-58](#).

Using MAC Move

Hosts should be able to move across ports within a switch on the same or different VLAN without restriction, as if they had moved to a port on another switch.

Prior to Cisco IOS Release 12.2(54)SG, when a MAC address is authenticated on one switch port, that address is not allowed on another 802.1X switch port. If the switch detects that same MAC address on another 802.1X port, the address is not allowed.

Beginning with Cisco IOS Release 12.2(54)SG, you can move a MAC address to another port on the same switch. it is not pertinent for directly connected hosts or for hosts behind Cisco phones, where a port-down event or proxy EAPoL-Logoff/CDP TLV is received when the initial host disconnects. It is pertinent for hosts that disconnect from behind a hub, third party phone, or legacy Cisco phone, causing the session to remain up. With MAC move you can disconnect the host from such a device and connect it directly to another port on the same switch.

You can globally enable MAC move so that the device is reauthenticated on the new port. When a host moves to a second port, the session on the first port is deleted, and the host is reauthenticated on the new port.

MAC move is supported on all host modes. (The authenticated host can move to any port on the switch, for any host mode enabled on that port.)

For more information see [“Configuring MAC Move” section on page 49-56](#).

Using MAC Replace

Beginning with Cisco IOS Release 12.2(54)SG, you can allow new hosts to connect to abandoned ports. If the configured violation action is *replace*, the existing host is replaced by the new host, instead of err-disabling or restricting the port (as happens for single-host and MDA modes).

it is not an issue for directly connected hosts or for hosts behind Cisco phones, where a port-down event or proxy EAPoL-Logoff/CDP TLV is received when the initial host disconnects. It is an issue where a host disconnects from behind a hub, third party phone, or legacy Cisco phone, causing the session to remain up. New hosts connecting to this port violate the host-mode, triggering a violation. When the

violation action is *replace*, the NAD (switch) terminates the initial session and resets the authentication sequence based on the new MAC. This applies to single-host and MDA host modes. In multiple-auth mode, no attempt is made to remove an existing session on the same port.

For more information see the [“Configuring MAC Replace” section on page 49-57](#).

Using 802.1X with VLAN Assignment

You can use the VLAN assignment to limit network access for certain users. With the VLAN assignment, 802.1X-authenticated ports are assigned to a VLAN based on the username of the client connected to that port. The RADIUS server database maintains the username-to-VLAN mappings. After successful 802.1X authentication of the port, the RADIUS server sends the VLAN assignment to the switch. The VLAN can be a standard VLAN or a PVLAN.

On platforms that support PVLANS, you can isolate hosts by assigning ports into PVLANS.

When configured on the switch and the RADIUS server, 802.1X with VLAN assignment has these characteristics:

- If no VLAN is supplied by the RADIUS server, the port is configured in its access VLAN or isolated PVLAN when authentication succeeds.
- If the authentication server provides invalid VLAN information, the port remains unauthorized. This situation prevents ports from appearing unexpectedly in an inappropriate VLAN due to a configuration error.
- Starting with Cisco IOS Release 15.0(2)SG, if multi-authentication mode is enabled on an 802.1X port, VLAN Assignment occurs successfully for the first authenticated host. Subsequent authorized (based on user credentials) data hosts, are considered successfully authenticated, provided either they have no VLAN assignment or have a VLAN assignment matching the first successfully authenticated host on the port. This ensures that all successfully authenticated hosts on a port are members of the same VLAN. Flexibility of VLAN assignment is only provided to the first authenticated host.
- If the authentication server provides valid VLAN information, the port is authorized and placed in the specified VLAN when authentication succeeds.
- If the multiple-hosts mode is enabled, all hosts are in the same VLAN as the first authenticated user.
- If 802.1X is disabled on the port, the port is returned to the configured access VLAN.
- A port must be configured as an access port (which can be assigned only into “regular” VLANs), or as a PVLAN host port (which can be assigned only into PVLANS). Configuring a port as a PVLAN host port implies that all hosts on the port are assigned into PVLANS, whether their posture is compliant or non-compliant. If the type of the VLAN named in the Access-Accept does not match the type of VLAN expected to be assigned to the port (regular VLAN to access port, secondary PVLAN to PVLAN host port), the VLAN assignment fails.
- If a guest VLAN is configured to handle non-responsive hosts, the type of VLAN configured as the guest VLAN must match the port type (that is, guest VLANs configured on access ports must be standard VLANs, and guest VLANs configured on PVLAN host ports must be PVLANS). If the guest VLAN’s type does not match the port type, non-responsive hosts are treated as if no guest VLAN is configured (that is, they are denied network access).
- To assign a port into a PVLAN, the named VLAN must be a secondary PVLAN. The switch determines the implied primary VLAN from the locally configured secondary-primary association.

**Note**

If you change the access VLAN or PVLAN host VLAN mapping on a port that is already authorized in a RADIUS assigned VLAN, the port remains in the RADIUS assigned VLAN.

To configure VLAN assignment you need to perform these tasks:

- Enable AAA authorization by using the **network** keyword to allow interface configuration from the RADIUS server. For an illustration of how to apply the **aaa authorization network group radius** command, refer to the section “Enabling 802.1X Authentication” on page 28.
- Enable 802.1X. (The VLAN assignment feature is automatically enabled when you configure 802.1X on an access port.)
- Assign vendor-specific tunnel attributes in the RADIUS server. To ensure proper VLAN assignment, the RADIUS server must return these attributes to the switch:
 - Tunnel-Type = VLAN
 - Tunnel-Medium-Type = 802
 - Tunnel-Private-Group-ID = VLAN NAME

Using 802.1X for Guest VLANs

You can use guest VLANs to enable non-802.1X-capable hosts to access networks that use 802.1X authentication. For example, you can use guest VLANs while you are upgrading your system to support 802.1X authentication.

Guest VLANs are supported on a per-port basis, and you can use any VLAN as a guest VLAN as long as its type matches the type of the port. If a port is already forwarding on the guest VLAN and you enable 802.1X support on the network interface of the host, the port is immediately moved out of the guest VLAN and the authenticator waits for authentication to occur.

Enabling 802.1X authentication on a port starts the 802.1X protocol. If the host fails to respond to packets from the authenticator within a certain amount of time, the authenticator brings the port up in the configured guest VLAN.

If the port is configured as a PVLAN host port, the guest VLAN must be a secondary PVLAN. If the port is configured as an access port, the guest VLAN must be a regular VLAN. If the guest VLAN configured on a port is not appropriate for the type of the port, the switch behaves as if no guest VLAN is configured (that is, non-responsive hosts are denied network access).

For details on how to configure guest VLANs, see the [“Configuring 802.1X with Guest VLANs” section on page 49-58](#).

Usage Guidelines for Using 802.1X Authentication with Guest VLANs

When using 802.1X authentication with guest VLANs, consider these guidelines:

- When you reconfigure a guest VLAN to a different VLAN, any authentication failed ports are also moved and the ports stay in their current authorized state.
- When you shut down or remove a guest VLAN from the VLAN database, any authentication failed ports are immediately moved to an unauthorized state and the authentication process is restarted.

**Note**

No periodic reauthentication is allowed with guest VLANs.

Usage Guidelines for Using 802.1X Authentication with Guest VLANs on Windows-XP Hosts

When using 802.1X authentication with guest VLANs on Windows-XP hosts, consider these guidelines:

- If the host fails to respond to the authenticator, the port attempts to connect three times (with a 30 second timeout between each attempt). After this time, the login/password window does not appear on the host, so you must unplug and reconnect the network interface cable.
- Hosts responding with an incorrect login/password fail authentication. Hosts failing authentication are not put in the guest VLAN. The first time that a host fails authentication, the quiet-period timer starts, and no activity occurs for the duration of the quiet-period timer. When the quiet-period timer expires, the host is presented with the login and password window. If the host fails authentication for the second time, the quiet-period timer starts again, and no activity occurs for the duration of the quiet-period timer. The host is presented with the login and password window a third time. If the host fails authentication the third time, the port is placed in the unauthorized state, and you must disconnect and reconnect the network interface cable.

Using 802.1X with MAC Authentication Bypass

The 802.1X protocol has 3 entities: client (supplicant), authenticator, and authentication server. Typically, the host PC runs the supplicant software and tries to authenticate itself by sending its credentials to the authenticator which in turn relays that info to the authentication server for authentication.

However, not all hosts may have supplicant functionality. Devices that cannot authenticate themselves using 802.1X but still need network access can use MAC Authentication Bypass (MAB), which uses the connecting device's MAC address to grant or deny network access.

Typically, you use this feature on ports where devices such as printers are connected. Such devices do not have 802.1X supplicant functionality.

In a typical deployment, the RADIUS server maintains a database of MAC addresses that require access. When this feature detects a new MAC address on a port, it generates a RADIUS request with both username and password as the device's MAC address. After authorization succeeds, the port is accessible to the particular device using the same code path that 802.1X authentication would take when processing an 802.1X supplicant. If authentication fails, the port moves to the guest VLAN if configured, or it remains unauthorized.

The Catalyst 4500 series switch also supports reauthentication of MACs on a per-port level. Be aware that the reauthentication functionality is provided by 802.1X and is not MAB specific. In the reauthentication mode, a port stays in the previous RADIUS-sent VLAN and tries to re-authenticate itself. If the reauthentication succeeds, the port stays in the RADIUS-sent VLAN. Otherwise, the port becomes unauthorized and moves to the guest VLAN if one is configured.

For details on how to configure MAB, see the [“Configuring 802.1X with MAC Authentication Bypass” section on page 49-62](#).

Feature Interaction

This section lists feature interactions and restrictions when MAB is enabled. If a feature is not listed, assume that it interacts seamlessly with MAB (such as Unidirectional Controlled Port).

- MAB can only be enabled if 802.1X is configured on a port. MAB functions as a fall back mechanism for authorizing MACs. If you configure both MAB and 802.1X on a port, the port attempts to authenticate using 802.1X. If the host fails to respond to EAPOL requests and MAB is configured, the 802.1X port is opened up to listen to packets and to grab a MAC address, rather than attempt to authenticate endlessly.

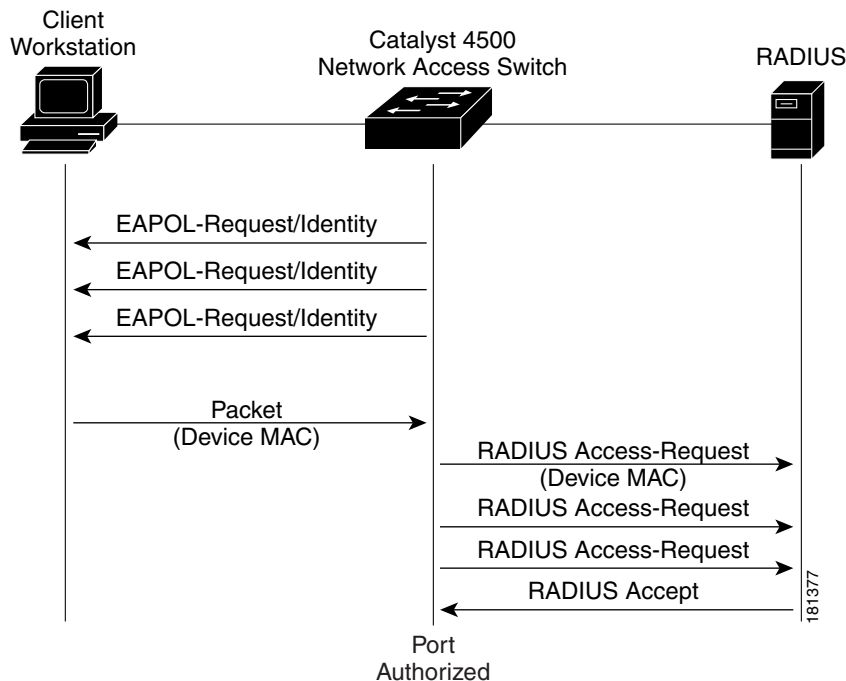

Based on the default 802.1X timer values, the transition between mechanisms takes approximately 90 seconds. You can shorten the time by reducing the value of the transmission period time, which affects the frequency of EAPOL transmission. A smaller timer value results in sending EAPOLs during a shorter time interval. With MAB enabled, after 802.1X performs one full set of EAPOLs, the learned MAC address is forwarded to the authentication server for processing.

The MAB module performs authorization for the first MAC address detected on the wire. The port is considered authorized once a valid MAC address is received that RADIUS approves of.

802.1X authentication can re-start if an EAPOL packet is received on a port that was initially authorized as a result of MAB.

Figure 49-6 shows the message exchange during MAB.

Figure 49-6 Message Exchange during MAC Authentication Bypass

- The authentication-failed VLAN is used only with dot1x-authentication-failed users. MAB is not attempted with dot1x-authentication-failed users. If 802.1X authentication fails, a port moves to the authentication-failed VLAN (if configured) whether MAB is configured or not.

- When both MAB and guest VLAN are configured and no EAPOL packets are received on a port, the 802.1X state-machine is moved to a MAB state where it opens the port to listen to traffic and grab MAC addresses. The port remains in this state forever waiting to see a MAC on the port. A detected MAC address that fails authorization causes the port to be moved to the guest VLAN if configured.

While in a guest VLAN, a port is open to all traffic on the specified guest VLAN. Non-802.1X supplicants that normally would be authorized but are in guest VLAN due to the earlier detection of a device that failed authorization, would remain in the guest VLAN indefinitely. However, loss of link or the detection of an EAPOL on the wire causes a transition out of the guest VLAN and back to the default 802.1X mode.

- Catalyst 4500 series switch supports MAB with VVID, with the restriction that the MAC address appears on a port data VLAN only. All IP phone MACs learned using CDP are allowed on voice VLANs.
- MAB and VMPS are mutually exclusive because their functionality overlaps.

Using 802.1X with Web-Based Authentication

The web-based authentication feature, known as Web Authentication Proxy, allows you to authenticate end users on host systems that do not run the IEEE 802.1X supplicant.

When configuring web-based authentication, consider these guidelines:

- Fallback to web-based authentication is configured on switch ports in access mode. Ports in trunk mode are not supported.
- Fallback to web-based authentication is not supported on EtherChannels or EtherChannel members.
- Although fallback to web-based authentication is an interface-specific configuration, the web-based authentication fallback behavior is defined in a global fallback profile. If the global fallback configuration changes, the new profile is not used until the next instance of authentication fallback.

For detailed information on configuring web-based authentication, see [Chapter 53, “Configuring Web-Based Authentication.”](#)

Using 802.1X with Inaccessible Authentication Bypass

When a switch cannot reach the configured RADIUS servers and clients (supplicants) cannot be authenticated, you can configure a switch to allow network access to hosts connected to *critical* ports that are enabled for Inaccessible Authentication Bypass.

When Inaccessible Authentication Bypass is enabled, a switch monitors the status of the configured RADIUS servers. If no RADIUS servers are available, clients that fail authentication due to server unavailability are authorized. Inaccessible Authentication Bypass can be enabled for data clients and voice clients. For data clients, you can specify an Inaccessible Authentication Bypass VLAN on a per-port basis. For voice clients they are authorized in the configured voice vlan. Inaccessible Authentication Bypass for voice clients can activate in Multiple Domain Authentication and Multiple Authentication modes, in which authentication is enforced for voice devices.

Note

Inaccessible Authentication Bypass allows a voice client to access configured voice VLAN when RADIUS becomes unavailable. For the voice device to operate properly, it must learn the voice VLAN ID through other protocols such as CDP, LLDP, or DHCP, wherever appropriate. When a RADIUS server is unavailable, it may not be possible for a switch to recognize a MAC address as that of a voice device.

Therefore, when Inaccessible Authentication Bypass is configured for voice devices, it should also be configured for data. Voice devices may be authorized on both critical data and voice VLANs. If port security is enabled, this may affect the maximum port security entries enforced on the port.

By default, data clients that were already authorized when RADIUS becomes unavailable are unaffected by Inaccessible Authentication Bypass. To reauthenticate all authorized data clients on the port when RADIUS becomes unavailable, use the **authentication server dead action reinitialize vlan** interface configuration command. This command is intended for multiauthentication mode and is mutually exclusive with the **authentication server dead action authorize vlan** command.

**Note**

In multiauthentication mode, you cannot use the **authentication server dead action authorize vlan** command to enable Inaccessible Authentication Bypass for data clients; it has no effect. Instead, use the **authentication server dead action reinitialize vlan** *vlan-id* command.

When RADIUS becomes available, critically authorized ports can be configured to automatically reauthenticate themselves.

**Note**

To properly detect RADIUS server availability, the **test username** *name* option should be enabled in the **radius server host** command. For details on how to configure RADIUS server, see the [“Configuring Switch-to-RADIUS-Server Communication”](#) section on page 49-32.

Inaccessible Authentication Bypass cannot activate after a port falls back to Web-based authentication. For details on how to configure Web-based authentication, see [Chapter 53, “Configuring Web-Based Authentication.”](#)

For details on how to configure Inaccessible Authentication Bypass, see [Chapter 53, “Configuring Web-Based Authentication”](#).

Using 802.1X with Unidirectional Controlled Port

Unidirectional Controlled Port is a combined hardware and software feature that allows dormant PCs to be powered on based on the receipt of a specific Ethernet frame, known as the *magic packet*. Generally, Unidirectional Controlled Port is used in environments where administrators plan to manage remote systems during off-hours, when the systems usually have been powered down.

Use of Unidirectional Controlled Port with hosts attached through 802.1X ports presents a unique problem: when the host powers down, a 802.1X port becomes unauthorized. In this state, the port allows the receipt and transmission of EAPoL packets only. The Unidirectional Controlled Port magic packet cannot reach the host; without powering up, the PC cannot authenticate and open the port.

Unidirectional Controlled Port solves this problem by allowing packets to be transmitted on unauthorized 802.1X ports.

**Note**

Unidirectional Controlled Port only works when Spanning Tree PortFast is enabled on the port.

For details on how to configure 802.1X with Unidirectional Controlled Port, see the [“Configuring 802.1X with Unidirectional Controlled Port”](#) section on page 49-68.

Unidirectional State

A unidirectional controlled port is typically configured when a connected host might enter a sleeping mode or power-down state. When either occurs, the host does not exchange traffic with other devices in the network. A host connected to the unidirectional port cannot send traffic to the network; it can only receive traffic from other devices in the network.

When you configure a port as unidirectional (with the **authentication control-direction in** interface configuration command), the port will receive traffic in VLANs on that port, but it is not put into a spanning-tree forwarding state. If a VLAN contains only unauthenticated ports, any SVI on that VLAN will be in a down state, during which packets will not be routed into the VLAN. For the SVI to be up, and so enable packets to be routed into the VLAN, at least one port in the VLAN must either be authenticated or in the spanning-tree forwarding state.

Bidirectional State

When you configure a port as bidirectional by using the **authentication control-direction both** interface configuration command (or the **dot1x control-direction both** interface configuration command for Cisco IOS Release 12.2(46) or earlier), the port is access-controlled in both directions. In this state, except for EAPOL packets, a switch port does not receive or send packets.

Using 802.1X with VLAN User Distribution

An alternative to dynamically assigning a VLAN ID or a VLAN name is to assign a VLAN group name. The 802.1X VLAN User Distribution feature allows you to distribute users belonging to the same group (and characterized by a common VLAN group name) across multiple VLANs. You usually do this to avoid creating an overly large broadcast domain.

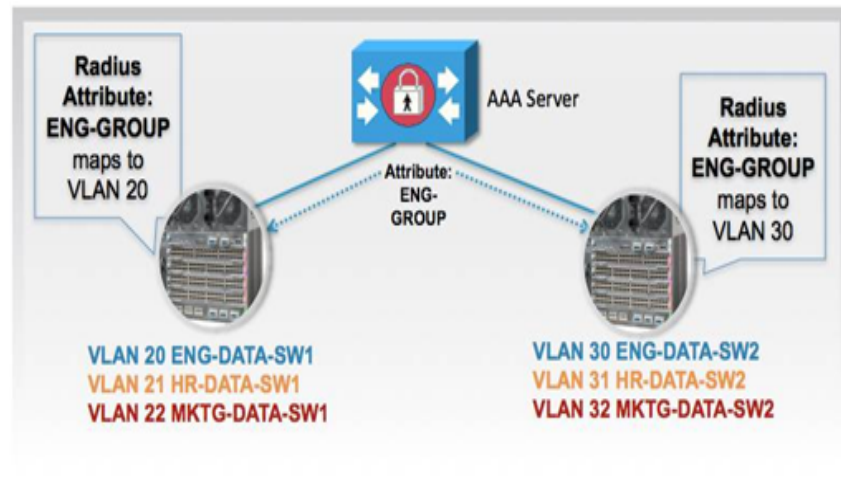

For example, with this feature, you can download a common VLAN group name (similar to ENG-Group, for all the users belonging to the engineering organization) from the authentication server to all the access-layer switches. The VLAN group name is then individually mapped to a different VLAN on each access-layer switch. The same VLAN number need not be spanned across separate switches. Similarly, the VLANs does not need to be renamed at the edge devices.

When the authentication server returns more than one VLAN group name or VLANs, this feature attempts to distribute users evenly across those groups. It internally maintains the count of users assigned to each VLAN on that switch by authentication or port security. Based on this information, this feature assigns a newly authenticated user to the least loaded VLAN on that switch among all the VLANs or VLAN group names obtained from the RADIUS server.

This VLAN distribution considers the load of all the valid VLANs only during initial user authentication, and not during reassignment. When some of the existing authenticated users are removed, the feature does not attempt to redistribute the remaining authenticated users. Group distribution does not guarantee perfect load distribution all the time.

Deployment Example

In a large campus LAN design, you might want to design the VLAN infrastructure without large Layer 2 domain. For the same employee VLAN, customers might have different VLANs at different campus access switches. When you deploy 802.1X with VLAN assignment, it does not assign one employee VLAN to all employees. You have to know the real VLANs configured on the switch. User distribution allows you to send a list of VLAN or VLAN group name(s) to the switch. Your switch can then do a local mapping to the corresponding VLAN. ([Figure 49-7](#)).

Figure 49-7 802.1X with VLAN User Distribution

For details on how to configure VLAN User Distribution, see the “[Configuring 802.1X with VLAN User Distribution](#)” section on page 49-69.

Using 802.1X with Authentication Failed VLAN Assignment

You can use authentication-failed VLAN assignment on a per-port basis to provide access for authentication failed users. Authentication failed users are end hosts that are 802.1X- capable but do not have valid credentials in an authentication server or end hosts that do not give any username and password combination in the authentication pop-up window on the user side.

If a user fails the authentication process, that port is placed in the authentication-failed VLAN. The port remains in the authentication-failed VLAN until the reauthentication timer expires. When the reauthentication timer expires the switch starts sending the port reauthentication requests. If the port fails reauthentication it remains in the authentication-failed VLAN. If the port is successfully reauthenticated, the port is moved either to the VLAN sent by RADIUS server or to the newly authenticated ports configured VLAN; the location depends on whether RADIUS is configured to send VLAN information.

Note

When enabling periodic reauthentication (see the “[Enabling Periodic Reauthentication](#)” section on page 49-83), only local reauthentication timer values are allowed. You cannot use a RADIUS server to assign the reauthentication timer value.

You can set the maximum number of authentication attempts that the authenticator sends before moving a port into the authentication-failed VLAN. The authenticator keeps a count of the failed authentication attempts for each port. A failed authentication attempt is either an empty response or an EAP failure. The authenticator tracks any mix of failed authentication attempts towards the authentication attempt count. After the maximum number of attempts is reached the port is placed in the authentication-failed VLAN until the reauthentication timer expires again.

Note

RADIUS can send a response without an EAP packet in it when it does not support EAP, and sometimes third-party RADIUS servers also send empty responses. When this behavior occurs, the authentication attempt counter is incremented.

For details on how to configure Authentication Failed VLAN Assignment, see the [“Configuring 802.1X with Authentication Failed” section on page 49-72](#).

Usage Guidelines for Using Authentication Failed VLAN Assignment

Usage guidelines include the following:

- You should enable reauthentication. The ports in authentication-failed VLANs do not receive reauthentication attempts if reauthentication is disabled. To start the reauthentication process the authentication-failed VLAN must receive a link-down event or an EAP logoff event from the port. If the host is behind a hub, you may never get a link-down event and may not detect the new host until the next reauthentication occurs.
- EAP failure messages are not sent to the user. If the user fails authentication the port is moved to an authentication-failed VLAN and a EAP success message is sent to the user. Because the user is not notified of the authentication failure there may be confusion as to why there is restricted access to the network. A EAP Success message is sent for the following reasons:
 - If the EAP Success message is not sent, the user tries to authenticate every 60 seconds (by default) by sending an EAP-start message.
 - In some cases, users have configured DHCP to EAP-Success and unless the user sees a success, DHCP does not work on the port.
- Sometimes a user caches an incorrect username and password combination after receiving a EAP success message from the authenticator and reuses that information in every reauthentication. Until the user passes the correct username and password combination the port remains in the authentication-failed VLAN.
- When an authentication failed port is moved to an unauthorized state the authentication process is restarted. If you should fail the authentication process again the authenticator waits in the held state. After you have correctly reauthenticated all 802.1X ports are reinitialized and treated as normal 802.1X ports.
- When you reconfigure an authentication-failed VLAN to a different VLAN, any authentication failed ports are also moved and the ports stay in their current authorized state.
- When you shut down or remove an authentication-failed VLAN from the VLAN database, any authentication failed ports are immediately moved to an unauthorized state and the authentication process is restarted. The authenticator does not wait in a held state because the authentication-failed VLAN configuration still exists. While the authentication-failed VLAN is inactive, all authentication attempts are counted, and as soon as the VLAN becomes active the port is placed in the authentication-failed VLAN.
- If you reconfigure the maximum number of authentication failures allowed by the VLAN, the change takes affect after the reauthentication timer expires.
- Internal VLANs that are used for Layer 3 ports cannot be configured as authentication-failed VLANs.
- The authentication-failed VLAN is supported only in single-host mode (the default port mode).
- When a port is placed in an authentication-failed VLAN the user's MAC address is added to the mac-address-table. If a new MAC address appears on the port, it is treated as a security violation.
- When an authentication failed port is moved to an authentication-failed VLAN, the Catalyst 4500 series switch does not transmit a RADIUS-Account Start Message as it does for standard 802.1X authentication.

Using 802.1X with Port Security

We do not recommend enabling port security when IEEE 802.1x is enabled. IEEE 802.1x enforces a single MAC address per port (or per VLAN when MDA is configured for IP telephony). Therefore port security is redundant and in some cases may interfere with the expected IEEE 802.1x operations.

Using 802.1X Authentication with ACL Assignments and Redirect URLs

Beginning with Cisco IOS Release 12.2(50)SG, you can download per-host policies such as ACLs and redirect URLs to the switch from the RADIUS server during 802.1X or MAB authentication of the host. ACL download is also supported with web authentication after a fallback from 802.1X or MAB.

When the 802.1X host mode of the port is either single-host, MDA, or multiple authentication, the downloaded ACLs (DACLS) are modified to use the authenticated hosts' IP address as the source address. When the host mode is multiple-hosts, the source address is configured as ANY, and the downloaded ACLs or redirects apply to all devices on the port.

If no ACLs are provided during the authentication of a host, the static default ACL configured on the port is applied to the host. On a voice VLAN port, only the static default ACL of the port is applied to the phone.

This section includes these topics:

- [Cisco Secure ACS and AV Pairs for URL-Redirect, page 49-19](#)
- [ACLs, page 49-20](#)

For details on how to configure downloadable ACL and URL redirect, refer to the [“Configuring 802.1X Authentication with ACL Assignments and Redirect URLs” section on page 49-37](#).

Cisco Secure ACS and AV Pairs for URL-Redirect

When downloadable ACL is enabled, Cisco Secure ACS provides AAA services through RADIUS.

You can set these Attribute-Value (AV) pairs on the Cisco Secure ACS with RADIUS *cisco-av-pair* vendor-specific attributes (VSAs):

- CiscoSecure-Defined-ACL specifies the names of the DACLS on the Cisco Secure ACS. The switch receives the ACL name using the CiscoSecure-Defined-ACL AV pair in the format:

#ACL#-IP-name-number

name is the ACL name and *number* is the version number (similar to 3f783768).

The Auth-Manager code verifies whether the access control entries (ACEs) of the specified downloadable ACL were previously downloaded. If not, the Auth-Manager code sends an AAA request with the downloadable ACL name as the username so that the ACEs are downloaded. The downloadable ACL is then created as a named ACL on the switch. This ACL has ACEs with a source address of any and does not have an implicit deny statement at the end. When the downloadable ACL is applied to an interface after authentication completes, the source address changes from any to the host source IP address depending on the host mode of the interface. The ACEs are prepended to the downloadable ACL applied to the switch interface to which the endpoint device is connected. If traffic matches the CiscoSecure-Defined-ACL ACEs, the appropriate actions are taken.

- url-redirect and url-redirect-acl specify the local URL policy on the switch. The switches use these cisco-av-pair VSAs as follows:

- url-redirect = <HTTP or HTTPS URL>
- url-redirect-acl = switch ACL name or number

These AV pairs enable the switch to intercept an HTTP or HTTPS request from the endpoint device and forward the client web browser to the specified redirect address from which the latest antivirus files can be downloaded. The url-redirect AV pair on the Cisco Secure ACS contains the URL to which the web browser is redirected. The url-redirect-acl AV pair contains the name or number of an ACL that specifies the HTTP or HTTPS traffic to be redirected. Traffic that matches a permit entry in the redirect ACL is redirected.

**Note**

The redirect or default ACL must be defined on the switch.

When redirect ACLs are used, we recommend that you configure a dynamic ACL that has an explicit permit statement for the IP address to which the traffic should be redirected.

ACLs

If downloadable ACL is configured for a particular client on the authentication server, you must configure a default port ACL on a client-facing switch port.

If the default ACL is configured on the switch and the Cisco Secure ACS sends a host access policy to the switch, it applies the policy to traffic from the host connected to a switch port. If the policy does not apply, the switch applies the default ACL. If the Cisco Secure ACS sends the switch a downloadable ACL, this ACL takes precedence over the default ACL already configured on the switch port. However, if the switch receives a host access policy from the Cisco Secure ACS, but the default ACL is not configured, the authorization failure is declared.

For details on how to configure a downloadable policy, refer to the [“Configuring a Downloadable Policy” section on page 49-45](#).

Using 802.1X with RADIUS-Provided Session Timeouts

You can specify whether a switch uses a locally configured or a RADIUS-provided reauthentication timeout. If the switch is configured to use the local timeout, it reauthenticates the host when the timer expires.

If the switch is configured to use the RADIUS-provided timeout, it scans the RADIUS Access-Accept message for the Session-Timeout and optional Termination-Action attributes. The switch uses the value of the Session-Timeout attribute to determine the duration of the session, and it uses the value of the Termination-Action attribute to determine the switch action when the session's timer expires.

If the Termination-Action attribute is present and its value is RADIUS-Request, the switch reauthenticates the host. If the Termination-Action attribute is not present, or its value is Default, the switch terminates the session.

**Note**

The supplicant on the port detects that its session was terminated and attempts to initiate a new session. Unless the authentication server treats this new session differently, the client may see only a brief interruption in network connectivity as the switch sets up a new session.

If the switch is configured to use the RADIUS-supplied timeout, but the Access-Accept message does not include a Session-Timeout attribute, the switch never reauthenticates the supplicant. This behavior is consistent with Cisco's wireless access points.

For details on how to configure RADIUS-provided session timeouts, see the [“Configuring RADIUS-Provided Session Timeouts” section on page 49-55](#).

Using 802.1X with Voice VLAN Ports

A voice VLAN port is a special access port associated with two VLAN identifiers:

- Voice VLAN ID (VVID) to carry voice traffic to and from the IP phone. The VVID is used to configure the IP phone connected to the port.
- Port VLAN ID (PVID) to carry the data traffic to and from the workstation connected to the switch using the IP phone. The PVID is the native VLAN of the port.

Each port that you configure for a voice VLAN is associated with a VVID and a PVID. This configuration allows voice traffic and data traffic to be separated onto different VLANs.

A voice VLAN port becomes active when a link exists whether the port is AUTHORIZED or UNAUTHORIZED. All traffic exiting the voice VLAN is obtained correctly and appears in the MAC address table. Cisco IP phones do not relay CDP messages from other devices. If several Cisco IP phones are connected in a series, the switch recognizes only the one directly connected to it. When 802.1X is enabled on a voice VLAN port, the switch drops packets from unrecognized Cisco IP phones more than one hop away.

When 802.1X is enabled on a port, you cannot configure a PVID that is equal to a VVID. For more information about voice VLANs, see [Chapter 46, “Configuring Voice Interfaces.”](#)

Observe the following feature interactions:

- 802.1X VLAN assignment cannot assign to the port the same VLAN as the voice VLAN; otherwise, the 802.1X authentication fails. The same holds true for dynamic VLAN assignment.
- 802.1X guest VLAN works with the 802.1X voice VLAN port feature. However, the guest VLAN cannot be the same as the voice VLAN.
- You cannot use the 802.1X voice VLAN port feature with 802.1X port security’s sticky MAC address configuration and statically configured MAC address configuration.
- 802.1X accounting is unaffected by the 802.1X voice VLAN port feature.
- When 802.1X is configured on a port, you cannot connect multiple IP phones to a Catalyst 4500 series switch through a hub.
- Because voice VLANs cannot be configured as PVLAN host ports, and because only PVLANs can be assigned to PVLAN host ports, VLAN assignment cannot assign a PVLAN to a port with a voice VLAN configured.

For details on how to configure 802.1X with voice VLANs, see the [“Configuring 802.1X with Voice VLAN” section on page 49-74](#).

Using Voice Aware 802.1x Security

You use the voice aware 802.1x security feature to configure the switch to disable only the VLAN on which a security violation occurs, whether it is a data or voice VLAN. In previous releases, when an attempt to authenticate the data client caused a security violation, the entire port shut down, resulting in a complete loss of connectivity.

You can use this feature in IP phone deployments where a PC is connected to the IP phone. A security violation found on the data VLAN results in the shutdown of only the data VLAN. The traffic on the voice VLAN flows through the switch without interruption.

For information on configuring voice aware 802.1x security, see the [“Configuring Voice Aware 802.1x Security” section on page 49-75](#)

Using Multiple Domain Authentication and Multiple Authentication

Multiple Domain Authentication (MDA) allows both a data device and a voice device, such as an IP phone (Cisco or third party non-Cisco), to authenticate on the same switch port, which is divided into a data domain and a voice domain.

Multi Auth allows multiple data devices and a voice device. When a voice VLAN is configured on a multiple- authentication port, the port can perform authentication in the voice domain as on an MDA port.

MDA does not enforce the order of device authentication. For best results, however, you should authenticate a voice device before you authenticate a data device on an MDA-enabled port.

When configuring MDA, consider the following guidelines.

Note

The same guidelines also apply for Multiple Authentication when voice VLAN is configured.

- We recommend that you enable CoPP on an MDA-enabled port to protect against a DoS attack. Refer to [Chapter 57, “Configuring Control Plane Policing and Layer 2 Control Packet QoS.”](#)
- To configure a switch port for MDA or Multiple Authentication, see the [“Configuring Multiple Domain Authentication and Multiple Authorization” section on page 49-33](#).
- You must configure the voice VLAN for the IP phone when the host mode is set to multidomain. For more information, see [Chapter 46, “Configuring Voice Interfaces.”](#)
- To authorize a voice device, the AAA server must be configured to send a Cisco Attribute-Value (AV) pair attribute with a value of device-traffic-class=voice. Without this value, the switch treats the voice device as a data device.
- You must configure the attribute device-traffic-class=voice on all authenticated phones. If not configured, authenticated phones may not work correctly.
- The guest VLAN and restricted VLAN features only apply to the data devices on an MDA-enabled port. The switch treats a voice device that fails authorization as a data device.
- If more than one device attempts authorization on either the voice or the data domain of a port, it is error-disabled.
- Until a device is authorized, the port drops its traffic. Non-Cisco IP phones or voice devices are allowed into both the data and voice VLANs. The data VLAN allows the voice device to contact a DHCP server to obtain an IP address and acquire the voice VLAN information. After the voice device starts sending on the voice VLAN, its access to the data VLAN is blocked. A security violation may occur in MDA if the voice device continues to send traffic on the data VLAN.
- MDA can use MAC authentication bypass as a fallback mechanism to allow the switch port to connect to devices that do not support 802.1X authentication. It is especially useful for third party phones without 802.1X supplicant. For more information, see the [“Using 802.1X with MAC Authentication Bypass” section on page 49-12](#).
- When a data or a **voice** device is detected on a port, its MAC address is blocked until authorization succeeds. If the authorization fails, the MAC address remains blocked for 5 minutes.
- If more than one device is detected on the data VLAN or more than one voice device is detected on the voice VLAN while a port is unauthorized, the port is error-disabled.

- When a port host mode is changed from single- or multihost to multidomain mode, an authorized data device remains authorized on the port. However, a Cisco IP phone that was allowed on the port in the voice VLAN is automatically removed and must be reauthenticated on that port.
- Active fallback mechanisms such as guest VLAN and restricted VLAN remain configured after a port changes from single- or multihost mode to multidomain mode.
- Switching a port host mode from multidomain to single- or multihost mode removes all authorized devices from the port.
- If a data domain is authorized first and placed in the guest VLAN, non-802.1X-capable voice devices need to tag their packets on the voice VLAN to trigger authentication.
- We do not recommend per-user ACLs with an MDA-enabled port. An authorized device with a per-user ACL policy might impact traffic on both the voice and data VLANs of the port. If used, only one device on the port should enforce per-user ACLs.

**Note**

Multi-Authentication per user VLAN is not supported on Catalyst 4500 Series Switch.

Limiting Login for Users

The Limiting Login feature helps Network administrators to limit the login attempt of users to a network. When a user fails to successfully login to a network within a configurable number of attempts within a configurable time limit, the user can be blocked. This feature is enabled only for local users and not for remote users. You need to configure the **aaa authentication rejected** command in global configuration mode to enable this feature.

802.1X Supplicant and Authenticator Switches with Network Edge Access Topology

The Network Edge Access Topology (NEAT) feature extends identity to areas outside the wiring closet (such as conference rooms).

You can enable any authentication host mode on the authenticator switch interface that connects to a supplicant switch. Once the supplicant switch authenticates successfully, the port mode changes from access to trunk. To ensure that NEAT works on all host modes, use the **dot1x supplicant force-multicast** global configuration command on the supplicant switch. If the access VLAN is configured on the authenticator switch, it becomes the native VLAN for the trunk port after successful authentication.

**Note**

MAB is not supported or recommended for use with NEAT. Only use 802.1X to authenticate the supplicant switch.

**Note**

The Catalyst 4500 series switch only supports authenticator ports.

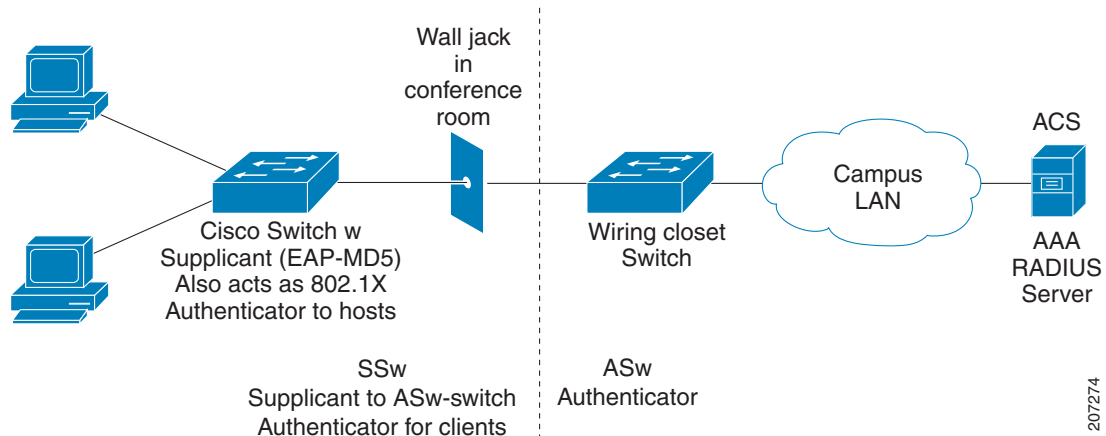

Deployment

NEAT is intended for deployment scenarios where a switch acting as 802.1X authenticator to end-hosts (PC or Cisco IP-phones) is placed in an unsecured location (outside wiring closet).

Because of this topology, the authenticator switch cannot always be trusted. For example, compact switches (8-port Catalyst 3560 and Catalyst 2960) are generally deployed outside the wiring closet. This enables hacker devices to swamp them to gain access to the network, compromising security. An edge switch must be able to authenticate itself against another switch, referred to as Network Edge Authentication Topology (NEAT).

Figure 49-8 illustrates a typical NEAT topology.

Figure 49-8 Typical NEAT Topology

NEAT facilitates the following functionality in such scenarios:

Host Authorization— Ensures that only traffic from authorized hosts (connecting to the switch with a supplicant) is allowed on the network. The switches use Client Information Signalling Protocol (CISP) to send the MAC addresses connecting the supplicant switch to the authenticator switch.

Auto enablement—Automatically enables trunk configuration on the authenticator switch, allowing user traffic from multiple VLANs arising from supplicant switches. At the ACS, you must configure the Cisco AV pair as device-traffic-class=switch. For details on how to do this, see the [“Configuring an Authenticator and a Supplicant Switch with NEAT”](#) section on page 49-89.

How 802.1X Fails on a Port

802.1X may fail on a port in three ways: timeout, explicit failure, and protocol timeout.

Timeout—A switch attempts 802.1X at link up but the attached endpoint is not 802.1X-capable. After the configured number of retries and timeouts, the switch attempts the next authentication method if one is configured (like MAB). If MAB fails, the switch deploys the Guest VLAN (also called the no-response VLAN), if configured. The Guest VLAN is configured with the **authentication event no-response** interface command.

Explicit Failure—A switch and the endpoint perform the entire 802.1X authentication sequence and the result is an explicit failure (usually indicated by an Access-Reject from the RADIUS server to the switch and an EAP-Failure sent from the switch to the endpoint). In this case, the switch attempts MAB (if “authentication event failure action next-method” is configured) or deploy the AuthFail VLAN (if “authentication event failure action authorize vlan” is configured).

Protocol Timeout—A switch and the endpoint start the 802.1X authentication process but do not complete it. For example, the endpoint may send an 802.1X EAPoL-Start message and then stop responding to the switch (perhaps, because the endpoint lacks a credential or because it is waiting for end user to enter some information). In this case, the switch knows that the connected device is EAPoL-capable, so it will not deploy the Guest VLAN after timing out. Instead, it restarts authentication after a timeout. The switch continues to label the port as EAPoL-capable until a physical link down event is detected. To force the switch to deploy the Guest VLAN in the case of a protocol timeout, configure **dot1x guest-vlan supplicant** globally. If the port is configured for hostmode multi-domain authentication, the switch behaves as if **dot1x guest-vlan supplicant** is configured.

Supported Topologies

The 802.1X port-based authentication supports two topologies:

- Point-to-point
- Wireless LAN

In a point-to-point configuration (see [Figure 49-1 on page 49-3](#)), only one client can be connected to the 802.1X-enabled switch port when the multiple-host mode is not enabled (the default). The switch detects the client when the port link state changes to the up state. If a client leaves or is replaced with another client, the switch changes the port link state to down, and the port returns to the unauthorized state.

For 802.1X port-based authentication in a wireless LAN ([Figure 49-9](#)), you must configure the 802.1X port as a multiple-host port that is authorized as a wireless access point once the client is authenticated. (See the [“Resetting the 802.1X Configuration to the Default Values”](#) section on page 49-96.) When the port is authorized, all other hosts that are indirectly attached to the port are granted access to the network. If the port becomes unauthorized (reauthentication fails or an EAPoL-logoff message is received), the switch denies access to the network for all wireless access point-attached clients. In this topology, the wireless access point is responsible for authenticating clients attached to it, and the wireless access point acts as a client to the switch.

Figure 49-9 Wireless LAN Example

Configuring 802.1X Port-Based Authentication

To configure 802.1X, follow this procedure:

-
- | | |
|---------------|---|
| Step 1 | Enable 802.1X authentication. See the “Enabling 802.1X Authentication” section on page 49-28. |
| Step 2 | Configure switch to RADIUS server communication. See the “Configuring Switch-to-RADIUS-Server Communication” section on page 49-32. |
| Step 3 | Adjust the 802.1X timer values. See the “Changing the Quiet Period” section on page 49-86. |
| Step 4 | Configure optional features. See the “Configuring RADIUS-Provided Session Timeouts” section on page 49-55. |
-

These sections describe how to configure 802.1X:

Default 802.1X Configuration

Table 49-1 shows the default 802.1X configuration.

Table 49-1 **Default 802.1X Configuration**

Feature	Default Setting
Authentication, authorization, and accounting (AAA)	Disabled
RADIUS server <ul style="list-style-type: none"> • IP address • UDP authentication port • Key 	<ul style="list-style-type: none"> • None specified • 1645 • None specified
Per-interface 802.1X protocol enable state	Force-authorized The port transmits and receives normal traffic without 802.1X-based authentication of the client.
Periodic reauthentication	Disabled
Time between reauthentication attempts	3600 sec
Quiet period	60 sec Number of seconds that the switch remains in the quiet state following a failed authentication exchange with the client.
Retransmission time	30 sec Number of seconds that the switch should wait for a response to an EAP request/identity frame from the client before retransmitting the request.
Maximum retransmission number	2 Number of times that the switch sends an EAP-request/identity frame before restarting the authentication process.
Multiple host support	Disabled

Table 49-1 **Default 802.1X Configuration (continued)**

Feature	Default Setting
Client timeout period	30 sec When relaying a request from the authentication server to the client, the amount of time that the switch waits for a response before retransmitting the request to the client.
Authentication server timeout period	30 sec When relaying a response from the client to the authentication server, the amount of time that the switch waits for a reply before retransmitting the response to the server. This setting is not configurable.

802.1X Configuration Guidelines

Guidelines for configuring 802.1X authentication include the following:

- The 802.1X protocol is supported only on Layer 2 static access, PVLAN host ports, and Layer 3 routed ports. You cannot configure 802.1X for any other port modes.
- If you are planning to use VLAN assignment, be aware that the features use general AAA commands. For information on how to configure AAA, refer to the “[Enabling 802.1X Authentication](#)” section on page 49-28. Alternatively, you can refer to the Cisco IOS security documentation at this location:

http://www.cisco.com/en/US/products/ps6586/products_ios_technology_home.html

Note

802.1x and MAB authentication session for a client installs only one IPv4 IP-to-MAC binding at a time (while an IP Device Tracking session can maintain multiple IP-to-MAC bindings). This limitation of the 802.1x and MAB authentication session can cause issues with traffic to devices that maintain multiple IP-to-MAC bindings.

Enabling 802.1X Authentication

To enable 802.1X port-based authentication, you first must enable 802.1X globally on your switch, then enable AAA and specify the authentication method list. A method list describes the sequence and authentication methods that must be queried to authenticate a user.

The software uses the first method listed in the method list to authenticate users; if that method fails to respond, the software selects the next authentication method in the list. This process continues until there is successful communication with a listed authentication method or until all defined methods are exhausted. If authentication fails at any point in this cycle, the authentication process stops, and no other authentication methods are attempted.

Note

To allow VLAN assignment, you must enable AAA authorization to configure the switch for all network-related service requests.

To configure 802.1X port-based authentication, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# dot1x system-auth-control	Enables 802.1X on your switch. To disable 802.1X globally on the switch, use the no dot1x system-auth-control command.
Step 3	Switch(config)# aaa new-model	Enables AAA. To disable AAA, use the no aaa new-model command.
Step 4	Switch(config)# aaa authentication dot1x {default} method1 [method2...]	Creates an 802.1X AAA authentication method list. To create a default list that is used when a named list is not specified in the authentication command, use the default keyword followed by the methods that are to be used in default situations. The default method list is automatically applied to all interfaces. Enter at least one of these keywords: <ul style="list-style-type: none"> • group radius—Use the list of all RADIUS servers for authentication. • none—Use no authentication. The client is automatically authenticated by the switch without using the information supplied by the client. To disable 802.1X AAA authentication, use the no aaa authentication dot1x {default list-name} method1 [method2...] global configuration command.
Step 5	Switch(config)# aaa authorization network {default} group radius	(Optional) Configures the switch for user RADIUS authorization for all network-related service requests, such as VLAN assignment.
Step 6	Switch(config)# interface interface-id	Enters interface configuration mode and specifies the interface to be enabled for 802.1X authentication.
Step 7	Switch(config-if)# switchport mode access	Specifies a nontrunking, nontagged single VLAN Layer 2 interface.
Step 8	Switch(config-if)# dot1x pae authenticator	Enables 802.1X authentication on the port with default parameters. Refer to the “Default 802.1X Configuration” section on page 49-27.
Step 9	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# authentication port-control auto Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x port-control auto	Enables 802.1X authentication on the interface.
Step 10	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 11	Switch # show dot1x interface interface-id details	Verifies your entries. Check the PortControl row in the 802.1X port summary section of this display. The PortControl value is set to auto .
Step 12	Switch# show running-config	Verifies your entries.
Step 13	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

**Note**

Enabling Spanning Tree PortFast ensures that a port comes up immediately after authorization.

**Note**

Whenever you configure any 802.1X parameter on a port, a dot1x authenticator is automatically created on the port. As a result, **dot1x pae authenticator** appears in the configuration, ensuring that dot1x authentication still works on legacy configurations without manual intervention.

This example shows how to enable 802.1X and AAA on Fast Ethernet port 2/1, and how to verify the configuration:

Cisco IOS Release 12.2(50)SG and later

```
Switch# configure terminal
Switch(config)# dot1x system-auth-control
Switch(config)# aaa new-model
Switch(config)# aaa authentication dot1x default group radius
Switch(config)# interface fastethernet2/1
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
Switch(config-if)# end
```

```
Switch# show authentication sessions interface f9/2

```

Configuring Switch-to-RADIUS-Server Communication

A RADIUS security server is identified by its host name or IP address, host name and specific UDP port number, or IP address and specific UDP port numbers. The combination of the IP address and UDP port number creates a unique identifier, which enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service (for example, authentication), the second host entry configured acts as the failover backup to the first one. The RADIUS host entries are tried in the order they were configured.

To configure the RADIUS server parameters on the switch, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# radius server host { <i>hostname</i> <i>ip-address</i> } auth-port <i>port-number</i> [acct-port <i>port-number</i>] [test username <i>name</i>] [ignore-auth-port] [ignore-acct-port] [idle-time <i>min</i>] key <i>string</i>	<p>Configures the RADIUS server parameters on the switch.</p> <p>For <i>hostname</i> <i>ip-address</i>, specify the hostname or IP address of the remote RADIUS server.</p> <p>To delete the specified RADIUS server, use the no radius server host {<i>hostname</i> <i>ip-address</i>} global configuration command.</p> <p>auth-port <i>port-number</i>—Specifies the UDP destination port for authentication requests. The default is 1645.</p> <p>acct-port <i>port-number</i>—Specifies the UDP destination port for accounting requests. The default is 1646.</p> <p>Use test username <i>name</i> to enable automated RADIUS server testing, and to detect the RADIUS server going up and down. The name parameter is the username used in the test access request sent to the RADIUS server; it does not need to be a valid user configured on the server. The ignore-auth-port and ignore-acct-port options disable testing on the authentication and accounting ports respectively.</p> <p>The idle-time <i>min</i> parameter specifies the number of minutes before an idle RADIUS server is tested to verify that it is still up. The default is 60 minutes.</p> <p>The key <i>string</i> specifies the authentication and encryption key used between the switch and the RADIUS daemon running on the RADIUS server. The key is a text string that must match the encryption key used on the RADIUS server.</p> <p>Note Always configure the key as the last item in the radius server host command syntax because leading spaces are ignored, but spaces within and at the end of the key are used. If you use spaces in the key, do not enclose the key in quotation marks unless the quotation marks are part of the key. This key must match the encryption used on the RADIUS daemon.</p> <p>If you want to use multiple RADIUS servers, use this command multiple times.</p>
Step 3	Switch(config)# radius-server deadtime <i>min</i>	(Optional) Configures the number of minutes before a dead RADIUS server is tested to check whether it has come back up. The default is 1 minute.

	Command	Purpose
Step 4	Switch(config)# radius-server dead-criteria <i>time seconds tries num</i>	(Optional) Configures the criteria used to decide whether a RADIUS server is dead. The time parameter specifies the number of seconds after which a request to the server is unanswered before it is considered dead. The tries parameter specifies the number of times a request to the server is unanswered before it is considered dead. The recommended values for these parameters are tries equal to radius-server retransmit and time equal to radius-server retransmit x radius-server timeout .
Step 5	Switch(config)# ip radius source-interface <i>m/p</i>	Establishes the IP address to be used as the source address for all outgoing RADIUS packets.
Step 6	Switch(config)# end	Returns to privileged EXEC mode.
Step 7	Switch# show running-config	Verifies your entries.
Step 8	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to specify the server with IP address 172.120.39.46 as the RADIUS server. The first command specifies port 1612 as the authorization port, sets the encryption key to rad123.

The second command dictates that key matches are performed on the RADIUS server:

```
Switch# configure terminal
Switch(config)# radius server host 172.120.39.46 auth-port 1612 key rad123
Switch(config)# ip radius source-interface g3/2
Switch(config)# end
Switch#
```

You can globally configure the timeout, retransmission, and encryption key values for all RADIUS servers by using the **radius server host** global configuration command. If you want to configure these options on a per-server basis, use the **radius-server timeout**, **radius-server retransmit**, and the **radius-server key** global configuration commands.

You also need to create a AAA client setting on the RADIUS server. These settings include the IP address of the switch and the key string to be shared by both the server and the switch.

Configuring Multiple Domain Authentication and Multiple Authorization

Note

Multiple Authorization requires Cisco IOS Release 12.2(50)SG and later releases.

To configure Multiple Domain Authentication (MDA) and Multiple Authorization, perform this task.

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# radius-server vsa send authentication	Configures the network access server to recognize and use vendor-specific attributes (VSAs).
Step 3	Switch(config)# interface interface-id	Specifies the port to which multiple hosts are indirectly attached, and enters interface configuration mode.

	Command	Purpose
Step 4	<p>Cisco IOS Release 12.2(50)SG and later</p> <pre>Switch(config-if)# [no] authentication host-mode {single-host multi-host multi-domain} multi-auth</pre> <p>Cisco IOS Release 12.2(46)SG or earlier releases</p> <pre>Switch(config-if)# [no] dot1x host-mode {single-host multi-host multi-domain}</pre>	<p>The keywords allow the following:</p> <ul style="list-style-type: none"> • single-host—Single-host (client) on an IEEE 802.1X-authorized port. • multi-host—Multiple-hosts on an 802.1X-authorized port after authenticating a single host. • multi-domain—Both a host and a voice device (such as an IP phone, Cisco or non-Cisco), to authenticate on an IEEE 802.1X-authorized port. <p>Note You must configure a voice VLAN for an IP phone when the host mode is set to multi-domain. For more information, see Chapter 46, “Configuring Voice Interfaces.”</p> <ul style="list-style-type: none"> • multi-auth—Allows multiple hosts and a voice device, such as an IP phone (Cisco or non-Cisco), to be authenticated on an IEEE 802.1x-authorized port. This keyword requires Cisco IOS Release 12.2(50)SG or a later release. <p>Ensure that the dot1x port-control interface configuration command is set to auto for the specified interface.</p> <p>To disable multiple hosts on the port, use the no authentication host-mode {multi-host multi-domain multi-auth} interface configuration command (for earlier releases, use the no dot1x host-mode {multi-host multi-domain} interface configuration command).</p>
Step 5	<pre>Switch(config-if)# switchport voice vlan vlan-id</pre>	(Optional) Configures the voice VLAN.
Step 6	<pre>Switch(config-if)# end</pre>	Returns to privileged EXEC mode.
Step 7	<pre>Switch# show dot1x interface interface-id [detail]</pre>	Verifies your entries.
Step 8	<pre>Switch# copy running-config startup-config</pre>	(Optional) Saves your entries in the configuration file.

This example shows how to enable 802.1X authentication and to allow multiple hosts:

Cisco IOS Release 12.2(50)SG and later

```
Switch(config)# interface gigabitethernet2/1
Switch(config-if)# authentication port-control auto
Switch(config-if)# authentication host-mode multi-host
Switch(config-if)# end
```

Cisco IOS Release 12.2(46)SG or earlier

```
Switch(config)# interface gigabitethernet2/1
Switch(config-if)# dot1x port-control auto
Switch(config-if)# dot1x host-mode multi-host
Switch(config-if)# end
```

This example shows how to enable MDA and to allow both a host and a 802.1X voice device (a Cisco or third-party phone with 802.1X supplicant) on the port:

Cisco IOS Release 12.2(50)SG and later

```
Switch# conf terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface FastEthernet3/1
Switch(config-if)# shut
Switch(config-if)# switchport access vlan 12
Switch(config-if)# switchport mode access
Switch(config-if)# switchport voice vlan 10
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
Switch(config-if)# authentication host-mode multi-domain
Switch(config-if)# no shut
Switch(config-if)# end
```

Cisco IOS Release 12.2(46)SG or earlier

```
Switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface FastEthernet3/1
Switch(config-if)# shut
Switch(config-if)# switchport access vlan 12
Switch(config-if)# switchport mode access
Switch(config-if)# switchport voice vlan 10
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# dot1x port-control auto
Switch(config-if)# dot1x host-mode multi-domain
Switch(config-if)# no shut
Switch(config-if)# end
```

This example shows how to enable MDA and to allow both a host and a non-802.1X voice device on the port:

Cisco IOS Release 12.2(50)SG and later

```
Switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface FastEthernet3/1
Switch(config-if)# shut
Switch(config-if)# switchport access vlan 12
Switch(config-if)# switchport mode access
Switch(config-if)# switchport voice vlan 10
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
Switch(config-if)# authentication host-mode multi-domain
Switch(config-if)# mab eap
Switch(config-if)# no shut
Switch(config-if)# end
```

Cisco IOS Release 12.2(46)SG or earlier

```
Switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface FastEthernet3/1
Switch(config-if)# shut
Switch(config-if)# switchport access vlan 12
Switch(config-if)# switchport mode access
Switch(config-if)# switchport voice vlan 10
Switch(config-if)# dot1x pae authenticator
```

```
Switch(config-if)# dot1x port-control auto
Switch(config-if)# dot1x host-mode multi-domain
Switch(config-if)# dot1x mac-auth-bypass
Switch(config-if)# no shut
Switch(config-if)# end
```

This example shows how to verify the dot1x MDA settings on interface FastEthernet3/1:

```
Switch# show dot1x interface FastEthernet3/1 detail
```

```

Switch#
```

This example shows how to enable MDA and to authentication of multiple hosts and a voice device on an IEEE 802.1x-authorized port:

Note This example applies to Cisco IOS Release 12.2(50)SG and later releases.

```
Switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface FastEthernet3/1
Switch(config-if)# shut
Switch(config-if)# switchport access vlan 12
Switch(config-if)# switchport mode access
Switch(config-if)# switchport voice vlan 10
Switch(config-if)# dot1x pae authenticator
```

```

Switch(config-if)# authentication port-control auto
Switch(config-if)# authentication host-mode multi-auth
Switch(config-if)# map eap
Switch(config-if)# no shut
Switch(config-if)# end

```

Configuring Limiting Login for Users

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# aaa new-model	Enables the authentication, authorization, and accounting (AAA) access control model.
Step 3	Switch(config)# aaa authentication login default local	Sets the authentication, authorization, and accounting (AAA) authentication by using the default authentication methods.
Step 4	Switch(config)# aaa authentication rejected n in m ban x	Configures the time period for which an user is blocked, if the user fails to successfully login within the specified time and login attempts. <ul style="list-style-type: none"> <i>n</i>—Specifies the number of times a user can try to login. <i>m</i>—Specifies the number of seconds within which an user can try to login. <i>x</i>—Specifies the time period an user is banned if the user fails to successfully login.
Step 5	Switch(config)# end	Exits from global configuration mode and returns to privileged EXEC mode.
Step 6	Switch# show aaa local user blocked	Displays the list of local users who were blocked.
Step 7	Switch# clear aaa local user blocked username username	Clears the information about the blocked local user.

Configuring 802.1X Authentication with ACL Assignments and Redirect URLs

This section includes these topics:

- [Downloadable ACL, page 49-37](#)
- [URL-Redirect, page 49-43](#)
- [Configuring a Downloadable Policy, page 49-45](#)

Downloadable ACL

The downloadable ACL (DACL) feature allows you to download device specific authorization policies from the authentication server. These policies activate after authentication succeeds for the respective client and the client's IP address was populated in the IP device tracking table. (Downloadable ACL is applied on the port, once the port is authenticated and the IP device tracking table has the host IP address entry).

Starting IOS XE Release 3.11.1E, IPv6 DACL is supported and DACL is defined on the ISE Server.

The following sections describe the configuration that is necessary to complement the related authentication (802.1X or MAB) configuration. (No unique configuration is required on the switch. All of the configuration is on the ACS.) After authentication succeeds, enter the **show ip access-list** command to display the downloadable ACLs.

Configuring the Switch for Downloadable ACL

To configure the switch for downloadable ACL, follow these steps:

Step 1 Configure the IP device tracking table.

```
Switch(config)# ip device tracking
```

Step 2 Configure RADIUS VSA to forward authentication.

```
Switch(config)# radius-server vsa send authentication
```

Step 3 Configure static ACL for the interface.

```
Switch(config)# int g2/9
Switch(config-if)# ip access-group pacl-4 in
```

For an IPv6 interface, add the following command:

```
Switch(config-if)# ipv6 traffic-filter PORT_IPV6_ACL in
```

Interface Configuration Example

```
Switch# show running-configuration interface g2/9
Building configuration...

Current configuration : 617 bytes
!
interface GigabitEthernet2/9
 switchport
 switchport access vlan 29
 switchport mode access
 switchport voice vlan 1234
 access-group mode prefer port
 ip access-group pacl-4 in
 ipv6 traffic-filter PORT_IPV6_ACL in
 speed 100
 duplex full
 authentication event fail action authorize vlan 111
 authentication event server dead action authorize vlan 333
 authentication event server alive action reinitialize
 authentication host-mode multi-auth
 authentication order dot1x
 authentication port-control auto
 authentication timer restart 100
 authentication timer reauthenticate 20
 authentication timer inactivity 200
 mab eap
 dot1x pae authenticator
end

Switch#
Switch# show ip access-list pacl-4
 10 permit ip host 10.1.1.1 host 2.2.2.2
```

```

20 permit icmp host 10.1.1.1 host 2.2.2.2
Switch#
Switch#show ipv6 access-list PORT_IPV6_ACL
deny ipv6 any 2110:10:10::/64 log
deny ipv6 any 2120:10:10::/64 log
deny ipv6 any 2130:10:10::/64 log
permit ipv6 any 2010:10:10::/64 log
permit ipv6 any 2020:10:10::/64 log
permit ipv6 any 2030:10:10::/64 log
permit ipv6 any 2001:10:10::/64 log
permit ipv6 any 2002:10:10::/64 log
permit ipv6 any 2003:10:10::/64 log

```

Debug Commands for DACL

The IP device tracking table contains the host IP address learned through ARP or DHCP.

The following command displays the constraints on the IP device tracking table:

```

Switch# show ip device tracking all
IP Device Tracking = Enabled
IP Device Tracking Probe Count = 3
IP Device Tracking Probe Interval = 30
-----
  IP Address      MAC Address      Interface      STATE
-----
50.0.0.12        0015.60a4.5e84   GigabitEthernet2/9   ACTIVE

```

The following **show authentication sessions** command displays the authentication sessions that contains the downloadable ACL obtained from ACS:

Note

The **show epm** command will be deprecated, displaying a warning message when used. Use the **show authentication sessions** command instead.

```

Switch-2033# show authentication sessions interface g2/9 details
Interface: GigabitEthernet2/9
MAC Address: 2c54.2d6a.0345
IPv6 Address: Unknown
IPv4 Address: 8.8.8.11
User-Name: 2C-54-2D-6A-03-45
Status: Authorized
Domain: DATA
Oper host mode: multi-auth
Oper control dir: both
Session timeout: N/A
Common Session ID: 0404040400000610081AA183
Acct Session ID: 0x000006F2
Handle: 0x760005B9
Current Policy: POLICY_Gi2/9

Server Policies:
ACS ACL: xACSAClX-IP-PERMIT_ALL_TRAFFIC-51de4498

Method status list:
Method      State
mab         Authc Success

```

The **show authentication sessions interface *interface-name* policy** displays session information in the form of Local Policies(features defined locally on the box), Server policies(features downloaded from radius) and Resultant Policies(the one with higher precedence when both local and server policies are present). By default, server policies have higher precedence than those defined locally.

AUTH# **show authentication sessions interface e0/0 policy**

```

Interface: Ethernet0/0
MAC Address: aabb.cc01.ff00
IPv6 Address: Unknown
IPv4 Address: Unknown
User-Name: gupn
Status: Authorized

```

The following command displays the contents of the downloadable ACL:

```

Switch# show ip access-lists xACSACLx-IP-auth-48b79b6e
Extended IP access list xACSACLx-IP-auth-48b79b6e (per-user)
  10 permit udp any any
Switch(config)#

```

Cisco ACS Configuration for DACL

To ensure correct functioning of the ACS configuration required for DACL, follow these steps:

- Step 1** Configure a downloadable IP ACL on the window that appears when you select **Radius Shared Profile > Downloadable IP ACL Content** (Figure 49-10).

Figure 49-10 Shared Profile Components

Shared Profile Components

Edit

Downloadable IP ACL Content

Name:

ACL Definitions
permit ip any host 10.10.10.10

- Step 2** Attach this downloadable ACL with the USER on the window that appears when you select **User > DACLs** (Figure 49-11).

Figure 49-11 Downloadable ACLs

Downloadable ACLs

☒ Assign IP ACL:

Cisco IOS/PIX 6.x RADIUS Attributes

Cisco ISE Configuration for DACL

Note

Starting IOS XE 3.11.1E, DACL can be configured on the Identity Services Engine (ISE) server. IPv6 DACL is supported starting ISE 2.6 release. IPv4 DACL is supported on all releases of ISE.

To ensure correct functioning of the ISE configuration required for DACL, follow these steps on the ISE server:

- Step 1** From the home page, select **Policy > Policy Elements > Results**.

- Step 2** Select **Authorization > Downloadable ACLs** on the left pane of the window. Click **Add** to create a downloadable IP ACL. Fill the required fields - **Name**, **Description**, **IPv6** or **IPv4**, and **DACL** content.
- Step 3** Click **Submit**.

Figure 49-12 Downloadable ACLs Configuration on ISE

The screenshot shows the Cisco Identity Services Engine (ISE) configuration interface. The left sidebar has a navigation menu with 'Authorization' selected. The main area displays the 'Downloadable ACL' configuration form. The form includes the following fields and options:

- Name:** IPv6_DACL_1
- Description:** (empty text box)
- IP version:** IPv6 (selected), IPv4, Agnostic
- DACL Content:** A list of IP addresses: 1234567, 8910111, 2131415, 1617181, 9202122, 2324252, 6272829, 3031323, 3343536.
- Buttons:** Submit, Cancel

- Step 4** Bind the created IPv6 downloadable ACL to an Authorization Profile on the window that appears when you select **Authorization > Authorization Profiles > auth_profile**.

Figure 49-13 Bind IPv6 DACL

The screenshot shows the Cisco Identity Services Engine (ISE) configuration interface for an Authorization Profile. The left sidebar has a navigation menu with 'Authorization' selected. The main area displays the 'Authorization Profile' configuration form. The form includes the following fields and options:

- Name:** CORP13
- Description:** (empty text box)
- Access Type:** ACCESS_ACCEPT
- Network Device Profile:** Cisco
- Service Template:** (checkbox, unchecked)
- Track Movement:** (checkbox, unchecked)
- Passive Identity Tracking:** (checkbox, unchecked)
- Common Tasks:**
 - DACL Name:** (checkbox, unchecked)
 - IPv6 DACL Name:** (checkbox, checked) - IPv6_DACL_1

URL-Redirect

To configure URL-direct, you need to configure it on the ACS, and on the switch.

Starting Cisco IOS XE 3.11.1E, you can use ISE server to configure URL-direct.

Configuring ACS

To configure two Cisco-AV pairs, add the following statements under the user or group Cisco IOS/PIX 6x RADIUS attributes:

```
url-redirect-acl=urlacl
url-redirect=http://www.cisco.com
```

Note A default port ACL must be configured on the interface.

Configuring the Switch

To configure the switch for URL redirect, follow these steps:

-
- Step 1** Configure the IP device tracking table.
Switch(config)# **ip device tracking**
 - Step 2** Configure RADIUS by using the **send authentication** command.
Switch(config)# **radius-server vsa send authentication**
 - Step 3** Configure the URL redirect ACL (URLACL).
Switch# **ip access-list urlacl**
10 permit tcp any any
Switch#
 - Step 4** Configure static ACL (PACL) for the interface.
Switch(config)# **int g2/9**
Switch(config-if)# **ip access-group pacl-4 in**

For an IPv6 interface, add the following command:

```
Switch(config-if)# ipv6 traffic-filter PORT_IPV6_ACL in
```

Interface Configuration Example

```
Switch# show running-configuration int g2/9  
Building configuration...
```

```
Current configuration : 617 bytes  
!  
interface GigabitEthernet2/9  
  switchport  
  switchport access vlan 29  
  switchport mode access  
  switchport voice vlan 1234  
  access-group mode prefer port  
  ip access-group pacl-4 in
```

```

ipv6 traffic-filter PORT_IPV6_ACL in
speed 100
duplex full
authentication event fail action authorize vlan 111
authentication event server dead action authorize vlan 333
authentication event server alive action reinitialize
authentication host-mode multi-auth
authentication order dot1x
authentication port-control auto
authentication timer restart 100
authentication timer reauthenticate 20
authentication timer inactivity 200
mab
dot1x pae authenticator
end

Switch#

Switch# show access-list pacl-4
 10 permit ip host 10.1.1.1 host 2.2.2.2
 20 permit icmp host 10.1.1.1 host 2.2.2.2
Switch#

```

Verify URL-redirect by using the following commands.

The **show ip device tracking** command displays the constraints on the IP device tracking table:

```

Switch(config)# show ip device tracking all
IP Device Tracking = Enabled
IP Device Tracking Probe Count = 3
IP Device Tracking Probe Interval = 30
-----
  IP Address      MAC Address      Interface      STATE
-----
50.0.0.12        0015.60a4.5e84   GigabitEthernet2/9    ACTIVE

```

The **show authentication sessions interface details** command displays the URL-redirect-acl and URL-redirect URL information that downloads from the ACS:

```

Switch-2033# show authentication sessions int G1/0/7 details
Interface: GigabitEthernet1/0/7
MAC Address: 2c54.2d6a.0344
IPv6 Address: Unknown
IPv4 Address: 7.7.7.17
User-Name: 2C-54-2D-6A-03-44
Status: Authorized
Domain: DATA
Oper host mode: multi-auth
Oper control dir: both
Session timeout: N/A
Common Session ID: 0A4046D50000009502F03C4B
Acct Session ID: 0x000000D9
Handle: 0x0700005A
Current Policy: POLICY_Et0/0

Local Policies:

Server Policies:
  URL Redirect: www.cisco.com
  URL Redirect ACL: urlacl

Method status list:

  Method      State

```

```
mab                               Authc Success
```

For more information about AV pairs that are supported by Cisco IOS software, see the ACS configuration and command reference documentation about the software releases running on the AAA clients.

Guideline for DACL and URL Redirect

For downloadable ACL or URL redirect, the ACL source must be ANY (permit TCP ANY host 10.1.1.1 eq 80 or permit TCP ANY host 10.1.1.1 eq 443).

Configuring a Downloadable Policy

To configure downloadable policies, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# access-list <i>access-list-number</i> { deny permit } <i>source</i> [<i>source-wildcard</i>] [log]	Defines the default port ACL through a source address and wildcard. The <i>access-list-number</i> is a decimal from 1 to 99 or 1300 to 1999. Enter deny or permit to specify whether to deny or permit access if conditions match. <i>source</i> is the address of the network or host from which the packet is sent, specified as follows: <ul style="list-style-type: none"> The 32-bit quantity in dotted-decimal format The keyword any as an abbreviation for source and source-wildcard value of 0.0.0.0 255.255.255.255 You do not need a source-wildcard value. The keyword host as an abbreviation for source and source-wildcard of source 0.0.0.0. (Optional) Applies the source-wildcard wildcard bits to the source. (Optional) Enters log to cause an informational logging message about the packet that matches the entry to be sent to the console.
Step 3	Switch(config-if)# interface <i>interface-id</i>	Enters interface configuration mode.
Step 4	Switch(config-if)# ip access-group { <i>access-list-number</i> <i>name</i> } in	Controls access to the specified interface. This step is mandatory for a functioning downloaded policy.
Step 5	Switch(config)# exit	Returns to global configuration mode.
Step 6	Switch(config)# aaa new-model	Enables AAA.
Step 7	Switch(config)# aaa authorization network default local	Sets the authorization method to local. To remove the authorization method, use the no aaa authorization network default local command.

	Command	Purpose
Step 8	Switch(config)# ip device tracking	Enables the IP device tracking table. To disable the IP device tracking table, use the no ip device tracking global configuration commands. Note Starting from Cisco IOS XE Release 3.10.1E, the following IPDT commands are deprecated; there are no replacement commands: [no] ip device tracking probe count [no] ip device tracking probe delay . For more related information, see the <i>Configuring SISF-Based Device Tracking</i> chapter in this guide.
Step 9	Switch(config)# radius-server vsa send authentication	Configures the network access server to recognize and use vendor-specific attributes. Note The downloadable ACL must be operational.
Step 10	Switch(config)# end	Returns to privileged EXEC mode.
Step 11	Switch# show ip device tracking { all interface interface-id ip ip-address mac mac-address }	Displays information about the entries in the IP device tracking table.
Step 12	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

The following example illustrates how to configure a switch for downloadable policy:

```
Switch# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# aaa new-model
Switch(config)# aaa authorization network default local
Switch(config)# ip device tracking
Switch(config)# ip access-list extended default_acl
Switch(config-ext-nacl)# permit ip any any
Switch(config-ext-nacl)# exit
Switch(config)# radius-server vsa send authentication
Switch(config)# int fastEthernet 2/13
Switch(config-if)# ip access-group default_acl in
Switch(config-if)# exit
```

Configuring 802.1X Authentication with Per-User ACL and Filter-ID ACL

This section includes the following topics:

- [Per-User ACL and Filter-ID ACL, page 49-46](#)
- [Configuring a Per-User ACL and Filter-ID ACL, page 49-54](#)

Per-User ACL and Filter-ID ACL

Prior to Cisco IOS Release 12.2(52)SG, the Catalyst 4500 platform only supported downloadable ACLs, which work with the Cisco ACS server but not with third-party AAA servers. With Cisco IOS Release 12.2(52)SG, the Catalyst 4500 switch offers the Filter-ID/Per-user-acl enhancement, which allows ACL policy enforcement using a third-party AAA server.

The Filter-ID feature provides the following capabilities:

Filter-ID option allows an administrator to define the ACL name on the AAA server using IETF standard RADIUS attribute. The ACL itself must be preconfigured locally on the switch.

The Per-user-acl feature provides the following capabilities:

Per-user ACL allows an administrator to define the per-user ACL on the AAA server using Cisco RADIUS AV pairs. This action allows a third-party AAA server to interoperate by loading the Cisco RADIUS dictionary, which has Cisco Radius AV pairs configured as a VSA.

Note The RADIUS vendor-specific attributes (VSAs) allow vendors to support their own proprietary RADIUS attributes that are not included in standard RADIUS attributes.

Configuring the Switch

To configure the switch for per-user ACL and filter-ID ACL:

Step 1 Configure the IP device tracking table.

```
Switch(config)# ip device tracking
```

Step 2 Configure static ACL for the interface.

```
Switch(config)# int g2/9
Switch(config-if)# ip access-group pacl-4 in
```

For an IPv6 interface, add the following command:

```
Switch(config-if)# ipv6 traffic-filter PORT_IPV6_ACL in
```

Interface Configuration Example

```
Switch# show running-configuration interface g2/9
Building configuration...

Current configuration : 617 bytes
!
interface GigabitEthernet2/9
 switchport
 switchport access vlan 29
 switchport mode access
 switchport voice vlan 1234
 access-group mode prefer port
 ip access-group pacl-4 in
 speed 100
 duplex full
 authentication event fail action authorize vlan 111
 authentication event server dead action authorize vlan 333
 authentication event server alive action reinitialize
 authentication host-mode multi-auth
 authentication order dot1x
 authentication port-control auto
 authentication timer restart 100
 authentication timer reauthenticate 20
 authentication timer inactivity 200
 mab eap
 dot1x pae authenticator
end
```

```
Switch#
Switch# show ip access-list pacl-4
    10 permit ip host 10.1.1.1 host 2.2.2.2
    20 permit icmp host 10.1.1.1 host 2.2.2.2
Switch#
```

Per-User ACL Configuration in ACS

In the Group/User Setting page, scroll down to the Cisco IOS/PIX 6.x RADIUS Attributes section. Select the box next to [009\001 cisco-av-pair] and enter the elements of the per-user ACL. Per-user ACLs take this format:

`protocol_#:inacl# sequence number=ACE`

protocol Either `ip` (for IP-based ACLs) or `mac` (for MAC-based ACLs)

Figure 49-14 shows how members of the group you are configuring are denied all access to the 10.100.60.0 subnet, are denied HTTP access to the server at 10.100.10.116, and are permitted everywhere else.

Figure 49-14 Define the ACEs for the Per-User ACL

The screenshot shows the Cisco ACS Group Setup page. On the left is a navigation pane with icons for User Setup, Group Setup, Shared Profile Components, Network Configuration, System Configuration, Interface Configuration, Administration Control, External User Databases, Posture Validation, Network Access Profiles, Reports and Activity, and Online Documentation. The main content area has a 'Jump To' dropdown menu set to 'Access Restrictions'. Below this are two sections: 'IP Assignment' and 'Cisco IOS/PIX 6.x RADIUS Attributes'. The 'IP Assignment' section has three radio buttons: 'No IP address assignment', 'Assigned by dialup client' (which is selected), and 'Assigned from AAA Client pool'. Below the radio buttons is an empty text box. The 'Cisco IOS/PIX 6.x RADIUS Attributes' section has a list of attributes. The first attribute, '[009\001] cisco-av-pair', is selected with a checkbox. Its value is entered in a text box as:

```
ip:inacl#10=deny ip any
10.100.60.0 0.0.0.255
ip:inacl#20=deny tcp any host
10.100.10.116 eq www
ip:inacl#30=permit ip any any
```

 Below this are four other attributes, each with an unchecked checkbox and an empty text box: '[009\101] cisco-h323-credit-amount', '[009\102] cisco-h323-credit-time', '[009\103] cisco-h323-return-code', and '[009\104] cisco-h323-prompt-id'. At the bottom of the page are three buttons: 'Submit', 'Submit + Restart', and 'Cancel'.

274490

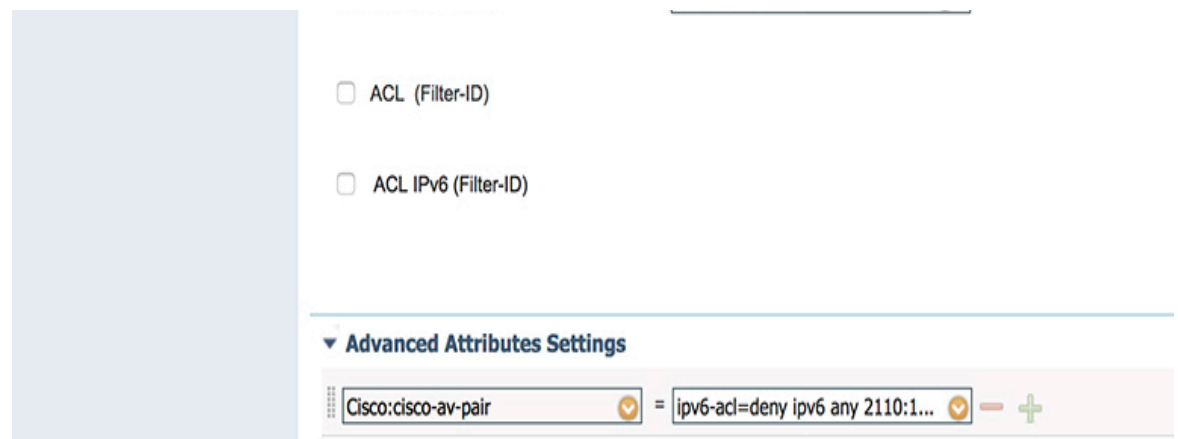

**Note**

Outbound ACLs (OUTACL) are not supported.

Per-User ACL Configuration in ISE

- Step 1** Select an authorization profile from the **Authorization > Authorization Profiles** page.
- Step 2** Select **cisco-av-pair** under **Advanced Attribute Settings** and enter the elements of Per-User ACL.
Cisco:cisco-av-pair = ipv6:inacl#1=deny ipv6 any 2110:10:10:10::64

Figure 49-15 Define ACEs for Per-User Configuration

Filter-Id Configuration in ACS

In the Group/User Setting page, scroll down to the IETF RADIUS Attributes section. Select the box next to Filter-Id and enter the ACL to apply for members of this group (Figure 49-16).

The Filter-Id ia in this format:

ACL_#.in

ACL Number of the ACL that was previously configured on the switch

Figure 49-16 Configuring the Filter-ID Attribute

The screenshot shows the Cisco Group Setup configuration window. On the left is a navigation pane with icons for User Setup, Group Setup, Shared Profile Components, Network Configuration, System Configuration, Interface Configuration, Administration Control, External User Databases, Posture Validation, Network Access Profiles, Reports and Activity, and Online. The main area is titled 'Group Setup' and has a 'Jump To' dropdown menu set to 'Access Restrictions'. Below this is a section titled 'IETF RADIUS Attributes' with a help icon. It contains several attributes with checkboxes and input fields:

- ☐ [006] Service-Type: Authenticate only (dropdown)
- ☐ [007] Framed-Protocol: Ascend MPP (dropdown)
- ☐ [009] Framed-IP-Netmask: 0.0.0.0 (text box)
- ☐ [010] Framed-Routing: None (dropdown)
- ☒ [011] Filter-ID: 100.in (text box)

At the bottom are three buttons: Submit, Submit + Restart, and Cancel. The number 274491 is visible in the bottom right corner.

**Note**

Outbound ACLs (for example, 100.out) are not supported.

Filter-Id Configuration in ISE

- Step 1** From the home page, select **Policy > Policy Elements > Results**.
- Step 2** Select **Authorization > Authorization Profiles > auth_profile**. Check the **ACL Filter-ID** checkbox and enter the name of the IPv6 Filter-ID.

Debug Commands for Per-User ACL and Filter-ID ACL

The IP device tracking table contains the host IP address learned through ARP or DHCP. The following command displays the constraints on the IP device tracking table:

```
Switch# show ip device tracking all
IP Device Tracking = Enabled
IP Device Tracking Probe Count = 3
IP Device Tracking Probe Interval = 30
-----
IP Address MAC Address Interface STATE
```

```
-----
50.0.0.12 0015.60a4.5e84 GigabitEthernet2/9 ACTIVE
```

The following command shows authentication sessions that contains the Filter-Id 100:

```
Switch-2033# show authentication sessions interface G2/9 details
      Interface: GigabitEthernet2/9
      MAC Address: 2c54.2d6a.0344
      IPv6 Address: Unknown
      IPv4 Address: 7.7.7.19
      User-Name: 2C-54-2D-6A-03-44
      Status: Authorized
      Domain: DATA
      Oper host mode: multi-auth
      Oper control dir: both

      Filter-ID: 100

Method status list:
      Method      State
      mab         Authc Success
```

The following command displays the contents of the per-user-acl (note that per-user-acl are shown above as the default port ACL configured on the interface, 151 is the default port ACL in the following example):

```
Switch# show access-list
151

      deny ip host 20.20.0.3 host 20.20.10.10

      10 permit ip any any (57 estimate matches)
```

The following command displays the number of sessions:

```
RouterRP# show authentication sessions

Interface    MAC Address    Method  Domain  Status Fg Session ID
Gi2/9        aabb.cc00.5600 mab      VOICE   Auth    0D0102340000000CEDF12589

Session count = 1

Key to Session Events Status Flags:

A - Applying Policy (multi-line status for details)
D - Awaiting Deletion
F - Final Removal in progress
I - Awaiting IIF ID allocation
P - Pushed Session (non-transient state)
R - Removing User Profile (multi-line status for details)
U - Applying User Profile (multi-line status for details)
X - Unknown Blocker
```

The following command displays authentication sessions that contains the per-user-acl:

```
S2049# show authentication sessions int gi 2/9 det
```

```

Interface: GigabitEthernet2/9
MAC Address: cdd.aabb.0001
IPv6 Address: Unknown
IPv4 Address: 6.6.65.66
User-Name: ccddaabb0001
Status: Authorized
Domain: DATA
Oper host mode: multi-auth
Oper control dir: both
Session timeout: N/A
Common Session ID: 0D0202010000003D04147B45
Acct Session ID: 0x0000004A
Handle: 0x7900002A
Current Policy: POLICY_Gi2/9

Local Policies:
  arp-probe-timeout: yes

Server Policies:
  Per-User ACL: GigabitEthernet1/0/23#v4#7C1C4AC
                : permit ip any host 10.1.1.20

Method status list:
  Method      State
  mab         Authc Success

```

The following command displays the contents of the per-user-acl (note that per-user-acl are shown above as the default port ACL configured on the interface, 151 is the default port ACL in the preceding example below):

```

Switch# show access-list
151

deny ip host 20.20.0.3 host 20.20.10.10

10 permit ip any any (57 estimate matches)
..
..
..(check for the mac access-list created)..
..
Extended MAC access list PerUser_MAC_ACL-589079192 (per-user)
  deny any host 0000.aaaa.aaaa
..

```

The following command shows that the Policy Enforced Module (EPM) session contains the Filter-Id 155 from ACS:

Note

The 156 IP extended ACL is to be preconfigured on the switch, so that the policy enforcement can happen.

```

Switch# show ip access-list 156
Extended IP access list 156
  10 deny ip any host 155.155.155.156
  20 deny ip any 156.100.60.0 0.0.0.255
  30 deny tcp any host 156.100.10.116 eq www

```

The following command shows authentication sessions that contains the Filter-Id TEST-ACL. TEST-ACL has been defined locally:

```

Switch-2033# show authentication sessions interface Gi2/9 details

```

```

Interface: GigabitEthernet2/9
MAC Address: 2c54.2d6a.0344
IPv6 Address: Unknown
IPv4 Address: 7.7.7.19

```

The following command displays the contents of the Filter-Id applied on the interface:

```

Switch# show ip access-list interface gi6/3
deny ip host 20.20.0.2 host 155.155.155.156
deny ip host 20.20.0.2 156.100.60.0 0.0.0.255
deny tcp host 20.20.0.2 host 156.100.10.116 eq www

```

Guidelines for Per-User ACL and Filter-ID ACL

- For per user ACL and Filter-ID ACL, the ACL source must be ANY (permit TCP ANY host 10.1.1.1 eq 80 or permit TCP ANY host 10.1.1.1 eq 443).
- Do not create per-user ACL in Cisco Identity Services Engine (ISE) with a duplicate sequence number. It results in a duplicate sequence number error on the console. It also results in partial policy configuration (only the last ACE/ACL of the same sequence number is applied).

Configuring a Per-User ACL and Filter-ID ACL

To configure per-user ACL and Filter-ID ACL, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# access-list <i>access-list-number</i> { deny permit } <i>source</i> [<i>source-wildcard</i>] [log]	<p>Defines the default port ACL through a source address and wildcard. The <i>access-list-number</i> is a decimal from 1 to 99 or 1300 to 1999.</p> <p>Enter deny or permit to specify whether to deny or permit access if conditions match.</p> <p><i>source</i> is the address of the network or host from which the packet is sent, specified as follows:</p> <ul style="list-style-type: none"> The 32-bit quantity in dotted-decimal format The keyword any as an abbreviation for source and source-wildcard value of 0.0.0.0 255.255.255.255 <p>You do not need a source-wildcard value.</p> <ul style="list-style-type: none"> The keyword host as an abbreviation for source and source-wildcard of source 0.0.0.0. <p>(Optional) Applies the source-wildcard wildcard bits to the source.</p> <p>(Optional) Enters log to cause an informational logging message about the packet that matches the entry to be sent to the console.</p>
Step 3	Switch(config-if)# interface <i>interface-id</i>	Enters interface configuration mode.
Step 4	Switch(config-if)# ip access-group { <i>access-list-number</i> <i>name</i> } in	<p>Controls access to the specified interface.</p> <p>This step is mandatory for a functioning downloaded policy.</p>
Step 5	Switch(config)# exit	Returns to global configuration mode.
Step 6	Switch(config)# aaa new-model	Enables AAA.
Step 7	Switch(config)# aaa authorization network default local	Sets the authorization method to local. To remove the authorization method, use the no aaa authorization network default local command.
Step 8	Switch(config)# ip device tracking	<p>Enables the IP device tracking table.</p> <p>To disable the IP device tracking table, use the no ip device tracking global configuration commands.</p> <p>Note Starting from Cisco IOS XE Release 3.10.1E, the following IPDT commands are deprecated; there are no replacement commands:</p> <p>[no] ip device tracking probe count</p> <p>[no] ip device tracking probe delay. For more related information, see the <i>Configuring SISF-Based Device Tracking</i> chapter in this guide.</p>
Step 9	Switch(config)# end	Returns to privileged EXEC mode.
Step 10	Switch# show ip device tracking { all interface <i>interface-id</i> ip <i>ip-address</i> mac <i>mac-address</i> }	Displays information about the entries in the IP device tracking table.
Step 11	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

The following example illustrates how to configure a switch for downloadable policy:

```
Switch# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# aaa new-model
Switch(config)# aaa authorization network default local
Switch(config)# ip device tracking
Switch(config)# ip access-list extended default_acl
Switch(config-ext-nacl)# permit ip any any
Switch(config-ext-nacl)# exit
Switch(config)# int fastEthernet 2/13
Switch(config-if)# ip access-group default_acl in
Switch(config-if)# exit
```

Configuring RADIUS-Provided Session Timeouts

You can configure the Catalyst 4500 series switch to use a RADIUS-provided reauthentication timeout.

To configure RADIUS-provided timeouts, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode.
Step 3	Switch(config-if)# switchport mode access	Specifies a nontrunking, nontagged single VLAN Layer 2 interface.
Step 4	Switch(config-if)# dot1x pae authenticator	Enables 802.1X authentication on the port with default parameters. Refer to the “ Default 802.1X Configuration ” section on page 49-27.
Step 5	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# authentication timer reauthenticate {interface server} Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x timeout reauth-attempts {interface server}	Sets the reauthentication period (seconds).
Step 6	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 7	Switch# show dot1x interface <i>interface-id details</i>	Verifies your entries.
Step 8	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to configure a switch to derive the reauthentication period from the server and to verify the configuration:

Cisco IOS Release 12.2(50):

```
Switch# configure terminal
Switch(config)# interface f7/1
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication timer reauthenticate server
Switch(config-if)# end
Switch# show dot1x interface f7/1 det
```

```

Switch#

```

Configuring MAC Move

MAC move allows an authenticated host to move from one switch port to another.

Note

You should remove port security before configuring MAC move.

To globally enable MAC move on the switch, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# authentication mac-move permit	Enable MAC move globally.
Step 3	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 4	Switch# show run	Verifies your entries.
Step 5	Switch # copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to globally enable MAC move on a switch:

```
Switch# configure terminal
Switch(config)# authentication mac-move permit
```

The following syslog messages displays when MAC-move happens:

```
%AUTHMGR-5-SECUREMACMOVE: <mac-addr> moved from <interface-name> to <interface-name>
```

Configuring MAC Replace

MAC replace allows new users to connect to abandoned ports.

If a user disconnects but the switch has not received the EAPoL-Logoff, the session will remain up. For single or multiple- domain modes, no new hosts can connect to that port. If a new host tries to connect, a violation is triggered on the port. Where the violation action is configured as replace, the desired behavior is for the NAD (switch) to terminate the initial session and reset the authentication sequence based on the new MAC.

To enable MAC replace on a switch, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface interface-id	Enters interface configuration mode.
Step 3	Switch(config-if)# authentication violation [restrict shutdown replace]	Tears down the old session and authenticates the new host, when a new host is seen in single or multiple- domain modes.
Step 4	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 5	Switch# show run	Verifies your entries.
Step 6	Switch # copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to globally enable MAC replace on a switch:

```
Switch# configure terminal
Switch(config)# interface f7/1
Switch(config-if)# authentication violation replace
```

The following syslog messages displays when MAC-replace occurs:

%AUTHMGR-5-SECUREMACREPLACE: <mac-addr> replaced <mac-addr> on <interface-name>

Configuring Violation Action

You can configure 802.1X security violation behavior as either shutdown, restrict, or replace mode, based on the response to the violation.

To configure the violation action, performing the following task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode.
Step 3	Switch(config-if)# authentication violation [restrict shutdown replace]	(Optional) Configures the disposition of the port if a security violation occurs. The default action is to shut down the port. If the restrict keyword is configured, the port does not shut down. When a new host is seen in single or multiple- domain modes, replace mode tears down the old session and authenticates the new host.
Step 4	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 5	Switch# show run	Verifies your entries.
Step 6	Switch # copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to configure the violation mode shutdown on a switch:

```
Switch# configure terminal
Switch(config)# authentication violation shutdown
```

A port is error-disabled when a security violation triggers on shutdown mode. The following syslog messages displays:

```
%AUTHMGR-5-SECURITY_VIOLATION: Security violation on the interface <interface name>, new
MAC address <mac-address> is seen.
%PM-4-ERR_DISABLE: security-violation error detected on <interface name>, putting
<interface name> in err-disable state
```

Configuring 802.1X with Guest VLANs

You can configure a guest VLAN for each 802.1X port on the Catalyst 4500 series switch to provide limited services to clients, such as downloading the 802.1X client. These clients might be upgrading their system for 802.1X authentication, and some hosts, such as Windows 98 systems, might not be 802.1X-capable.

When you enable a guest VLAN on an 802.1X port, the Catalyst 4500 series switch assigns clients to a guest VLAN, provided one of the following apply:

- The authentication server does not receive a response to its EAPOL request or identity frame.
- The EAPOL packets are not sent by the client.

Beginning with Cisco IOS Release 12.2(25)EWA, the Catalyst 4500 series switch maintains the EAPOL packet history. If another EAPOL packet is detected on the interface during the lifetime of the link, network access is denied. The EAPOL history is reset upon loss of the link.

Any number of 802.1X-incapable clients are allowed access when the switch port is moved to the guest VLAN. If an 802.1X-capable client joins the same port on which the guest VLAN is configured, the port is put into the unauthorized state in the user-configured access VLAN, and authentication is restarted.

Guest VLANs are supported on 802.1X ports in single-host or multiple-hosts mode.

**Note**

When a port is put into a guest VLAN, it is automatically placed into multihost mode, and an unlimited number of hosts can connect using the port. Changing the multihost configuration does not effect a port in a guest VLAN.

**Note**

Except for an RSPAN VLAN or a voice VLAN, you can configure any active VLAN as an 802.1X guest VLAN.

To configure 802.1X with guest VLAN on a port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode and specifies the interface to be enabled for 802.1X authentication.
Step 3	Switch(config-if)# switchport mode access or Switch(config-if)# switchport mode private-vlan host	Specifies a nontrunking, nontagged single VLAN Layer 2 interface. Specifies that the ports with a valid PVLAN trunk association become active host PVLAN trunk ports.
Step 4	Switch(config-if)# dot1x pae authenticator	Enables 802.1X authentication on the port with default parameters. Refer to the “Default 802.1X Configuration” section on page 49-27.
Step 5	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# authentication event no-response action authorize vlan <i>vlan-id</i> Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x guest-vlan <i>vlan-id</i>	Enables a guest VLAN on a particular interface. To disable the guest VLAN feature on a particular port, use the no authentication event no-response action authorize vlan interface configuration command (for earlier releases, use the no dot1x guest-vlan interface configuration command).
Step 6	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# authentication port-control auto Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x port-control auto	Enables 802.1X authentication on the interface.
Step 7	Switch(config-if)# end	Returns to configuration mode.
Step 8	Switch(config)# end	Returns to privileged EXEC mode.

This example shows how to enable regular VLAN 50 on Fast Ethernet 4/3 as a guest VLAN on a static access port:

Cisco IOS Release 12.2(50)SG and later

```
Switch# configure terminal
Switch(config)# interface fa4/3
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication event no-response action authorize vlan 50
Switch(config-if)# authentication port-control auto
Switch(config-if)# end
Switch#
```

Cisco IOS Release 12.2(46)SG or earlier

```
Switch# configure terminal
Switch(config)# interface fa4/3
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# dot1x guest-vlan 50
Switch(config-if)# dot1x port-control auto
Switch(config-if)# end
Switch#
```

This example shows how to enable a secondary PVLAN 100 as a guest VLAN on a PVLAN host port:

Cisco IOS Release 12.2(50)SG and later

```
Switch# configure terminal
Switch(config)# interface fa4/3
Switch(config-if)# switchport mode private-vlan host
Switch(config-if)# authentication port-control auto
Switch(config-if)# authentication event no-response action authorize vlan 100
Switch(config-if)# end
Switch#
```

Cisco IOS Release 12.2(46)SG or earlier

```
Switch# configure terminal
Switch(config)# interface fa4/3
Switch(config-if)# switchport mode private-vlan host
Switch(config-if)# dot1x port-control auto
Switch(config-if)# dot1x guest-vlan 100
Switch(config-if)# end
Switch#
```

To allow supplicants into a guest VLAN on a switch, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch# dot1x guest-vlan supplicant	(Optional) Enables supplicants to be allowed into the guest VLANs globally on the switch. Note Although not visible in the CLI for Cisco IOS Release 12.3(31)SG, legacy configurations that include the dot1x guest-vlan supplicant command still work. We do not recommend that you use this command. However, because the authentication failed VLAN option makes it unnecessary. To disable the supplicant guest VLAN feature on a switch, use the no dot1x guest-vlan supplicant global configuration command.
Step 3	Switch(config)# interface interface-id	Enters interface configuration mode and specifies the interface to be enabled for 802.1X authentication.
Step 4	Switch(config-if)# switchport mode access or Switch(config-if)# switchport mode private-vlan host	Specifies a nontrunking, nontagged single VLAN Layer 2 interface. Specifies that the ports with a valid PVLAN trunk association become active host PVLAN trunk ports.
Step 5	Switch(config-if)# dot1x pae authenticator	Enables 802.1X authentication on the port with default parameters. Refer to the “Default 802.1X Configuration” section on page 49-27 .
Step 6	Switch(config-if)# dot1x guest-vlan vlan-id	Specifies an active VLAN as an 802.1X guest VLAN. The range is 1 to 4094.
Step 7	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# authentication port-control auto Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x port-control auto	Enables 802.1X authentication on the interface.
Step 8	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 9	Switch# show dot1x interface interface-id	Verifies your entries.
Step 10	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to enable the guest VLAN feature and to specify VLAN 5 as a guest VLAN:

Cisco IOS Release 12.2(50)SG and later

```
Switch# configure terminal
Switch(config)# dot1x guest-vlan supplicant
Switch(config)# interface gigabitethernet5/9
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication event no-response action authorize vlan 5
Switch(config-if)# authentication port-control auto
Switch(config-if)# end
Switch#
```

Cisco IOS Release 12.2(46)SG or earlier

```

Switch# configure terminal
Switch(config)# dot1x guest-vlan supplicant
Switch(config)# interface gigabitethernet5/9
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# dot1x guest-vlan 5
Switch(config-if)# dot1x port-control auto
Switch(config-if)# end
Switch#

```

Configuring 802.1X with MAC Authentication Bypass

To enable MAC Authentication Bypass (MAB), perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Specifies the port to be configured, and enters interface configuration mode.
Step 3	Switch(config-if)# switchport mode access or Switch(config-if)# switchport mode private-vlan host	Specifies a nontrunking, nontagged single VLAN Layer 2 interface. Specifies that the ports with a valid PVLAN trunk association become active host PVLAN trunk ports.
Step 4	Switch(config-if)# dot1x pae authenticator	Enables 802.1X authentication on the port with default parameters. Refer to the “Default 802.1X Configuration” section on page 49-27.
Step 5	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# authentication port-control auto Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x port-control auto	Enables 802.1X authentication on the interface.
Step 6	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# mab [eap] Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x mac-auth-bypass [eap]	Enables MAB on a switch. The eap option specifies that a complete EAP conversation should be used, as opposed to standard RADIUS Access-Request, Access-Accept conversation. By default, the eap option is not enabled for MAB.
Step 7	Switch(config)# end	Returns to privileged EXEC mode.
Step 8	Switch# show mab interface <i>interface-id</i> details	(Optional) Verifies your entries.
Step 9	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Note

Removing a 802.1X MAB configuration from a port does not impact the authorized or authenticated state of the port. If the port is in an unauthenticated state, it remains in that state. If the port is in an authenticated state because of MAB, the switch reverts to the 802.1X Authenticator. If the port was

already authorized with a MAC address and the MAB configuration was removed, the port remains in an authorized state until reauthentication occurs. At that time, if an 802.1X supplicant is detected on the wire, the MAC address is removed.

This example shows how to enable MAB on Gigabit Ethernet interface 3/3 and to verify the configuration:

Cisco IOS Release 12.2(50)SG and later

```
Switch# configure terminal
Switch(config)# interface gigabitethernet3/3
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
Switch(config-if)# mab
Switch(config-if)# end
Switch# show mab int g3/3 details

Configuring 802.1X with Inaccessible Authentication Bypass

Caution

You must configure the switch to monitor the state of the RADIUS server as described in the section [Configuring Switch-to-RADIUS-Server Communication, page 49-32](#) for Inaccessible Authentication Bypass to work properly. Specifically, you must configure the RADIUS test username, idle-time, deadtime and dead-criteria. Failure to do so results in the switch failing to detect that the RADIUS server has gone down, or prematurely marking a dead RADIUS server as alive again.

To configure a port as a critical port and to enable the Inaccessible Authentication Bypass feature, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# dot1x critical eapol	(Optional) Configures whether to send an EAPOL-Success packet when a port is critically authorized partway through an EAP exchange. Note Some supplicants require this. The default is not to send EAPOL-Success packets when a port is critically authorized partway through an EAP exchange. If there is no ongoing EAP exchange at the time when a port is critically authorized, EAPOL-Success packet is always sent out regardless of this option.
Step 3	Supervisor Engine 6-E, 6L-E—Cisco IOS Release 12.2(50)SG and later; Supervisor Engine 7-E, 7L-E, 8-E—Cisco IOS Release 15.0(1)X and later; Supervisor Engine 9-E—Cisco IOS XE Release 3.10.0E Switch(config)# authentication critical recovery delay msec Cisco IOS Release 12.2(46)SG or earlier releases Switch(config)# dot1x critical recovery delay msec	(Optional) Specifies a throttle rate for the reinitialization of critically authorized ports when the RADIUS server becomes available. The default throttle rate is 100 milliseconds. This means that 10 ports reinitialize per second.
Step 4	Switch(config)# interface interface-id	Specifies the port to be configured and enters interface configuration mode.
Step 5	Switch(config-if)# switchport mode access or Switch(config-if)# switchport mode private-vlan host	Specifies a nontrunking, nontagged single VLAN Layer 2 interface. Specifies that the ports with a valid PVLAN trunk association become active host PVLAN trunk ports.
Step 6	Switch(config-if)# dot1x pae authenticator	Enables 802.1X authentication on the port with default parameters. Refer to the “Default 802.1X Configuration” section on page 49-27.

	Command	Purpose
Step 7	<code>Switch(config-if)# authentication port-control auto</code>	Enables 802.1X authentication on the interface.
Step 8	<p>Supervisor Engine 6-E, 6L-E—Cisco IOS Release 12.2(50)SG and later Supervisor Engine 7-E, 7L-E, 8-E—Cisco IOS Release 15.0(1)XO and later Supervisor Engine 9-E—Cisco IOS XE Release 3.10.0E and later</p> <p><code>Switch(config-if)# authentication event server dead action authorize [vlan vlan-id]</code></p> <p>Cisco IOS Release 12.2(46)SG or earlier releases</p> <p><code>Switch(config-if)# dot1x critical</code></p> <p>OR</p> <p>Supervisor Engine 6-E, 6L-E—Cisco IOS Release 15.0(2)SG and later Supervisor Engine 7-E, 7L-E, 8-E—Cisco IOS Release XE 3.2.0SG and later Supervisor Engine 9-E—Cisco IOS XE Release 3.10.0E and later</p> <p><code>Switch(config-if)# [no] authentication event server dead action reinitialize [vlan vlan-id]</code></p>	<p>Enables the Inaccessible Authentication Bypass feature for data clients on the port and specifies a VLAN into which data clients are assigned. If no VLAN is specified, data clients are assigned into the configured data VLAN on the port.</p> <p>To disable the feature, use the no authentication event server dead action authorize vlan interface configuration command (for earlier releases, use the no dot1x critical interface configuration command).</p> <p>Alternatively, starting with Cisco IOS Release 15.0(2)SG you can enable Inaccessible Authentication Bypass for data clients using the authentication event server dead action reinitialize vlan interface configuration command which forces all authorized data clients to be reauthenticated when RADIUS becomes unavailable and a client attempts to authenticate. This only applies to data devices. Voice devices are unaffected.</p> <p>To disable it, use the no authentication event server dead action reinitialize vlan interface configuration command.</p>
Step 9	<p>Supervisor Engine 6-E, 6L-E—Cisco IOS Release 15.0(2)SG and later Supervisor Engine 7-E, 7L-E, 8-E—Cisco IOS Release XE 3.2.0SG and later Supervisor Engine 9-E—Cisco IOS XE Release 3.10.0E and later</p> <p><code>Switch(config-if)# authentication event server dead action authorize voice</code></p>	<p>(Optional) Enables Inaccessible Authentication Bypass for voice clients on the port. This command applies to Multiple Domain Authentication and Multiple Authentication modes.</p> <p>To disable the feature, use the no authentication event server dead action authorize voice interface configuration command.</p>
Step 10	<p>Supervisor Engine 6-E, 6L-E—Cisco IOS Release 12.2(50)SG and later Supervisor Engine 7-E, 7L-E, 8-E—Cisco IOS Release 15.0(1)XO and later Supervisor Engine 9-E—Cisco IOS XE Release 3.10.0E and later</p> <p><code>Switch(config-if)# authentication event server alive action reinitialize</code></p> <p>Cisco IOS Release 12.2(46)SG or earlier releases</p> <p><code>Switch(config-if)# dot1x critical recovery action reinitialize</code></p>	<p>(Optional) Specifies that the port should be reinitialized if it is critically authorized and RADIUS becomes available.</p> <p>The default is not to reinitialize the port.</p>

	Command	Purpose
Step 11	Switch(config)# end	Returns to privileged EXEC mode.
Step 12	Switch# show dot1x interface interface-id details	(Optional) Verifies your entries.
Step 13	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

The following example shows a full configuration of 802.1X with Inaccessible Authentication Bypass, including required AAA and RADIUS configuration as specified in the [“Enabling 802.1X Authentication”](#) section on page 49-28 and [“Configuring Switch-to-RADIUS-Server Communication”](#) section on page 49-32.

The RADIUS server configured is at IP address 10.1.2.3, using port 1645 for authentication and 1646 for accounting. The RADIUS secret key is mykey. The username used for the test server probes is randomuser. The test probes for both living and dead servers are generated once per minute. The interface FastEthernet 3/1 is configured to critically authenticate into VLAN 17 when AAA becomes unresponsive, and to reinitialize automatically when AAA becomes available again.

Switch#

Configuring 802.1X with Unidirectional Controlled Port

To configure unidirectional controlled port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Specifies the port to be configured and enters interface configuration mode.
Step 3	Switch(config-if)# switchport mode access or Switch(config-if)# switchport mode private-vlan host	Specifies a nontrunking, nontagged single VLAN Layer 2 interface. Specifies that the ports with a valid PVLAN trunk association become active host PVLAN trunk ports.
Step 4	Switch(config-if)# dot1x pae authenticator	Enables 802.1X authentication on the port with default parameters. Refer to the “ Default 802.1X Configuration ” section on page 49-27.
Step 5	Switch(config-if)# authentication port-control auto	Enables 802.1X authentication on the interface.
Step 6	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# authentication control-direction {in both} Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x control-direction {in both}	Enables unidirectional port control on each port.
Step 7	Switch(config)# end	Returns to privileged EXEC mode.
Step 8	Switch# show dot1x interface <i>interface-id details</i>	(Optional) Verifies your entries.
Step 9	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Note

Unidirectional controlled port only works when Spanning Tree PortFast is enabled on the port. Unidirectional controlled port and Spanning Tree PortFast should be configured on a switch port that connects to a host. If two such ports are connected together with an Ethernet cable, high CPU utilization may result because host learning will be flapping between the two ports.

This example shows how to enable unidirectional port control:

Cisco IOS Release 12.2(50)SG and later

```
Switch# configure terminal
Switch(config)# interface gigabitEthernet3/3
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
Switch(config-if)# authentication control-direction in
Switch(config-if)# end
Switch# show dot1x int g3/3

Switch#

```

Configuring 802.1X with VLAN User Distribution

You will need to configure the switch and ACS to configure 802.1X with VLAN user distribution.

Configuring the Switch

To configure the switch, follow these steps:

Step 1 Create a VLAN group on the switch.

Enter the following commands to create a VLAN group and assign some VLANs to the VLAN group. The following example creates the VLAN group **eng-group** and maps VLANs 20 to 24 to that group:

```

Switch# configure terminal
Switch(config)# vlan group eng-group vlan-list 20-24
Switch(config)# end
Switch# show vlan group group-name eng-group

```

```
Group Name VLANs Mapped
-----
eng-group      20-24
```

Note

Ensure that the VLANs you specify as part of the VLAN group are enabled on the switch. Only specified VLANs are considered for assignment.

Step 2

Configure the individual ports for multidomain, single-host or multiple- host.
For details, refer to the [“Enabling 802.1X Authentication” section on page 49-28](#).

show commands

Use the following **show** commands to display the member VLANs in a VLAN group:

show command	Purpose
show vlan group all	Displays the member VLANs for all the VLAN groups configured on the device.
show vlan group group-name <i>vlan-group-name</i>	Displays the member VLANs in a VLAN group with the given VLAN group name.
show vlan group group-name <i>vlan-group-name</i> user-count	Displays the user count for each of the member VLANs of the specified VLAN group This feature counts only authenticated users and MAC addresses added through port security for distribution. It does not consider other learned MAC addresses. As of Cisco IOS Release 12.2(54)SG, the user count for a VLAN is incremented when a host is learned through port security, 802.1X, MAB, or fallback authentication on that VLAN.

The following examples show outputs of the **show vlan group** command:

```
Switch# show vlan group all
Group Name VLANs Mapped
-----
eng-dept      3-4

Switch# show vlan group group-name my_group user-count
      VLAN :    Count
-----
      3      :    1
      4      :    0
      5      :    2
      7      :    0
      9      :    0
Switch#
```

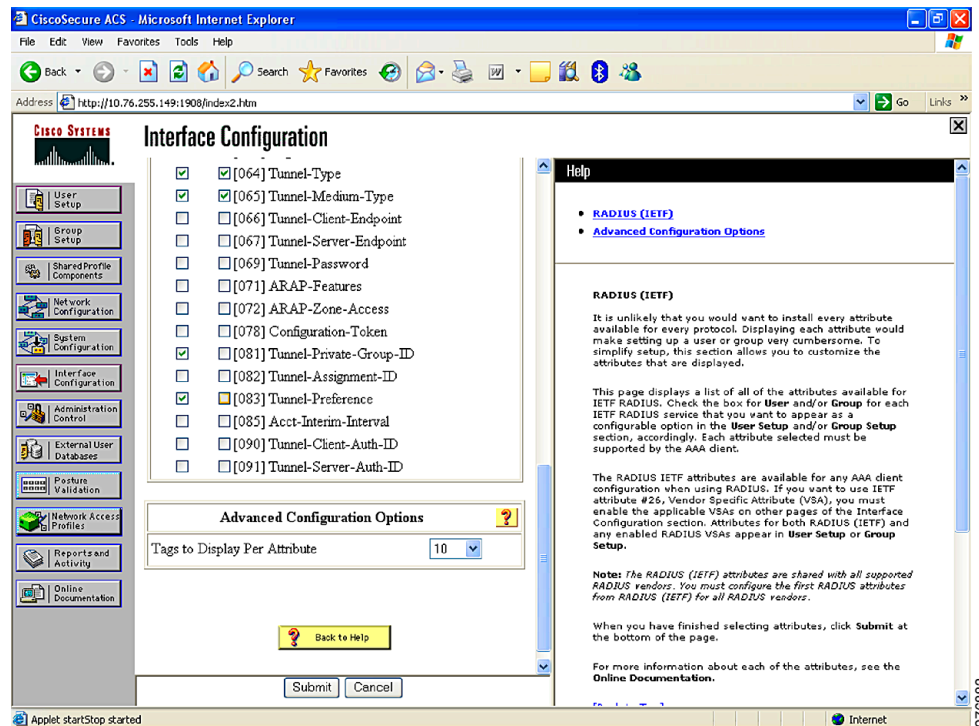

In this example, VLANs 3,4, 5, 7, and 9 are members of the VLAN group *my group*.

ACS Configuration

After configuring the switch, you must provide the VLAN group name in the ACS configuration.

By default, ACS sends only one VLAN name or group per user. However, you can configure ACS to send more than one tag per attribute. To do this, you must modify the configuration in ACS for user or group. (See the example shown in [Figure 49-17](#).)

Figure 49-17 VLAN User Distribution on ACS: Interface Configuration to Modify Tags per Attribute

After you add the number of tags required per attribute, the user or group set up presents multiple fields to be filled with values from the RADIUS server ([Figure 49-18](#)).

Figure 49-18 VLAN User Distribution on ACS: Multiple VLAN Numbers Configured per User

After you complete these two tasks and receive authorization, ACS sends the configured VLAN group to the switch. The switch is alerted to the list of VLANs configured under the VLAN group, and the least loaded valid VLAN in the group is assigned to the port.

Configuring 802.1X with Authentication Failed

By configuring authentication-failed VLAN alignment on any Layer 2 port on the Catalyst 4500 series switch, you can provide limited network services to clients that fail the authentication process.

Note

You can use authentication-failed VLAN assignment with other security features, such as Dynamic ARP Inspection (DAI), Dynamic Host Configuration Protocol (DHCP) snooping, and IP Source Guard. Each of these features can be enabled and disabled independently on the authentication-failed VLAN.

To configure 802.1X with authentication-failed VLAN assignment, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode and specifies the interface to be enabled for 802.1X authentication.
Step 3	Switch(config-if)# switchport mode access	Specifies a nontrunking, nontagged single VLAN Layer 2 interface.
Step 4	Switch(config-if)# authentication port-control auto	Enables 802.1X authentication on the interface.

	Command	Purpose
Step 5	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# authentication event fail action authorize vlan <i>vlan-id</i> Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x auth-fail vlan <i>vlan-id</i>	Enables authentication-failed VLAN on a particular interface. To disable the authentication-failed VLAN feature on a particular port, use the no authentication event fail action authorize vlan interface configuration command.
Step 6	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# authentication event fail retry <i>max-attempts</i> action [authorize vlan <i>vlan-id</i> next-method] Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x auth-fail max-attempts <i>max-attempts</i>	Configure a maximum number of attempts before the port is moved to authentication-failed VLAN. Default is 3 attempts.
Step 7	Switch(config-if)# end	Returns to configuration mode.
Step 8	Switch(config)# end	Returns to privileged EXEC mode.
Step 9	Switch# show dot1x interface <i>interface-id</i> details	(Optional) Verifies your entries.
Step 10	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to enable a regular VLAN 40 on Fast Ethernet 4/3 as a authentication-failed VLAN on a static access port:

Cisco IOS Release 12.2(50)SG and later

```
Switch# configure terminal
Switch(config)# interface gigabitEthernet3/1
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
Switch(config-if)# authentication event fail retry 5 action authorize vlan 40
Switch(config-if)# end
Switch# show dot1x all

Configuring 802.1X with Voice VLAN

Note

You must configure 802.1X and voice VLAN simultaneously.

Note

You cannot configure an authentication-failed VLAN and a voice VLAN on the same port. When you try to configure these two features on the same port, a syslog message appears.

To enable 802.1X with voice VLAN, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode.
Step 3	Switch(config-if)# switchport access vlan <i>vlan-id</i>	Sets the VLAN for a switched interface in access mode.
Step 4	Switch(config-if)# switchport mode access	Specifies a nontrunking, nontagged single VLAN Layer 2 interface.
Step 5	Switch(config-if)# switchport voice vlan <i>vlan-id</i>	Sets the voice VLAN for the interface.

	Command	Purpose
Step 6	Switch(config-if)# dot1x pae authenticator	Enables 802.1X authentication on the port with default parameters. Refer to the “ Default 802.1X Configuration ” section on page 49-27.
Step 7	Cisco IOS Release 12.2(50)SG and later and later Switch(config-if)# authentication port-control auto Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x port-control auto	Enables 802.1X authentication on the interface.
Step 8	Switch(config-if)# end	Returns to configuration mode.
Step 9	Switch(config)# end	Returns to privileged EXEC mode.
Step 10	Switch# show dot1x interface interface-id details	(Optional) Verifies your entries.
Step 11	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to enable 802.1X with voice VLAN feature on Fast Ethernet interface 5/9:

Cisco IOS Release 12.2(50)SG and later

```
Switch# configure terminal
Switch(config)# interface fastethernet5/9
Switch(config-if)# switchport access vlan 2
Switch(config-if)# switchport mode access
Switch(config-if)# switchport voice vlan 10
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
Switch(config-if)# end
Switch(config)# end
Switch#
```

Cisco IOS Release 12.2(46)SG or earlier

```
Switch# configure terminal
Switch(config)# interface fastethernet5/9
Switch(config-if)# switchport access vlan 2
Switch(config-if)# switchport mode access
Switch(config-if)# switchport voice vlan 10
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# dot1x port-control auto
Switch(config-if)# end
Switch(config)# end
Switch#
```

Configuring Voice Aware 802.1x Security

You use the voice aware 802.1x security feature on the switch to disable only the VLAN on which a security violation occurs, whether it is a data or voice VLAN. You can use this feature in IP phone deployments where a PC is connected to the IP phone. A security violation found on the data VLAN results in the shutdown of only the data VLAN. The traffic on the voice VLAN flows through the switch without interruption.

Follow these guidelines to configure voice aware 802.1x voice security on the switch:

- You enable voice aware 802.1x security by entering the **errdisable detect cause security-violation shutdown vlan** global configuration command. You disable voice aware 802.1x security by entering the **no** version of this command. This command applies to all 802.1x-configured ports in the switch.

Note

If you do not include the **shutdown vlan** keywords, the entire port is shut down when it enters the error-disabled state.

- If you use the **errdisable recovery cause security-violation** global configuration command to configure error-disabled recovery, the port is automatically re-enabled. If error-disabled recovery is not configured for the port, you re-enable it with the **shutdown** and **no-shutdown** interface configuration commands.
- You can re-enable individual VLANs with the **clear errdisable interface interface-id vlan [vlan-list]** privileged EXEC command. If you do not specify a range, all VLANs on the port are enabled.

To enable voice aware 802.1x security, follow these steps, beginning in privileged EXEC mode:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# errdisable detect cause security-violation shutdown vlan	Shuts down any VLAN on which a security violation error occurs. Note If the shutdown vlan keywords are not included, the entire port enters the error-disabled state and shuts down.
Step 3	Switch(config)# errdisable recovery cause security-violation	(Optional) Enables automatic per-VLAN error recovery.
Step 4	Switch(config)# errdisable recovery interval interval	(Optional) Sets a recovery interval (in sec). The <i>interval</i> range is 30 to 86400. The default is 300 sec.
Step 5	Switch(config)# end	Enters exec mode.
Step 6	Switch# clear errdisable interface interface-id vlan [vlan-list]	(Optional) Reenables individual VLANs that have been error disabled. <ul style="list-style-type: none"> For <i>interface-id</i> specify the port on which to reenables individual VLANs. (Optional) For <i>vlan-list</i> specify a list of VLANs to be re-enabled. If <i>vlan-list</i> is not specified, all VLANs are re-enabled.
Step 7	Switch(config)# interface interface-id	Enters interface configuration mode.
Step 8	Switch(config-if)# shutdown no-shutdown	(Optional) Re-enables an error-disabled VLAN, and clears all error-disable indications.
Step 9	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 10	Switch# show errdisable detect	Verifies your settings.
Step 11	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

```
Switch# configure terminal
Switch(config)# errdisable detect cause security-violation shutdown vlan
Switch(config)# errdisable recovery cause security-violation
Switch(config)# errdisable recovery interval interval
Switch(config)# end
```

```
Switch# clear errdisable interface interface-id vlan [vlan-list]
Switch(config)# interface interface-id
Switch(config-if)# shutdown
Switch(config-if)# end
Switch# show errdisable detect
Switch# copy running-config startup-config
```

This example shows how to configure the switch to shut down any VLAN on which a security violation error occurs:

```
Switch(config)# errdisable detect cause security-violation shutdown vlan
```

This example shows how to re-enable all VLANs that were error disabled on port Gi4/0/2:

```
Switch# clear errdisable interface GigabitEthernet4/0/2 vlan
```

You can verify your settings by entering the **show errdisable detect** privileged EXEC command.

Configuring 802.1X with VLAN Assignment

For enabling dynamic VLAN assignment, no additional configuration is required in the switch. For information on configuring Multiple- authentication (MDA), refer to the [“Configuring Multiple Domain Authentication and Multiple Authorization”](#) section on page 49-33. To enable VLAN assignment, you must configure the Cisco ACS server.

Note

802.1x authentication with VLAN assignment is not supported on trunk ports, dynamic ports, or with dynamic-access port assignment through a VLAN Membership Policy Server (VMPS).

To enable 802.1X with VLAN assignment, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode.
Step 3	Switch(config-if)# switchport access <i>vlan-id</i>	Sets the VLAN for a switched interface in access mode.
Step 4	Switch(config-if)# switchport mode access	Specifies a nontrunking, nontagged single VLAN Layer 2 interface.
Step 5	Switch(config-if)# switchport voice vlan <i>vlan-id</i>	Sets the voice VLAN for the interface.
Step 6	Switch(config-if)# authentication host-mode multi-domain	Enables MDA on the interface.
Step 7	Switch(config-if)# authentication port-control auto	Enables 802.1X authentication on the interface.
Step 8	Switch(config-if)# dot1x pae authenticator	Enables 802.1X authentication on the port with default parameters. Refer to the “Default 802.1X Configuration” section on page 49-27.
Step 9	Switch(config)# end	Returns to privileged EXEC mode.

	Command	Purpose
Step 10	Switch# show dot1x interface interface-id details	(Optional) Verifies your entries.
Step 11	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

The following example shows how to configure MDA on an interface and 802.1X as the authentication mechanism:

```
Switch(config)# interface FastEthernet3/3
Switch(config-if)# switchport access vlan 10
Switch(config-if)# switchport mode access
Switch(config-if)# switchport voice vlan 16
Switch(config-if)# authentication host-mode multi-domain
Switch(config-if)# authentication port-control auto
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# end
```

Note You must configure VLAN assignment in the ACS server. No configuration changes are required on the switch.

Cisco ACS Configuration for VLAN Assignment

The procedure for enabling MDA with voice VLAN assignment is the same as that for activating MDA except for one step: Configure a VLAN for dynamic VLAN assignment after selecting **User > IETF RADIUS Attributes** (Figure 49-19). This step ensures correct functioning of the ACS configuration required for dynamic VLAN assignment.

Figure 49-19 User Set Up

IETF RADIUS Attributes

☐ [011] Filter-Id

☒ [064] Tunnel-Type

Tag 1 Value VLAN
Tag 2 Value

☒ [065] Tunnel-Medium-Type

Tag 1 Value 802
Tag 2 Value

☒ [081] Tunnel-Private-Group-ID

Tag 1 Value VLAN0020
Tag 2 Value

**Note**

The procedure is the same for voice devices except that the AAA server must be configured to send a Cisco Attribute-Value (AV) pair attribute with a value of device-traffic-class=voice.

Enabling Fallback Authentication

On a port in multiauthentication mode, either or both of MAB and web-based authentication can be configured as fallback authentication methods for non-802.1X hosts (those that do not respond to EAPOL). You can configure the order and priority of the authentication methods.

For detailed configuration information for MAB, see the [“Configuring 802.1X with MAC Authentication Bypass”](#) section on page 49-62.

For detailed configuration information for web-based authentication, see [Chapter 53, “Configuring Web-Based Authentication.”](#)

**Note**

When web-based authentication and other authentication methods are configured on an MDA or multiauthentication port, downloadable ACL policies must be configured for all devices attached to that port.

To enable fallback authentication, perform this task:

	Command	Purpose
Step 1	Switch(config)# ip admission name <i>rule-name</i> proxy http	Configures an authentication rule for web-based authentication.
Step 2	Switch(config)# fallback profile <i>profile-name</i>	Creates a fallback profile for web-based authentication.
Step 3	Switch(config-fallback-profile)# ip access-group <i>rule-name</i> in	Specifies the default ACL to apply to network traffic before web-based authentication.
Step 4	Switch(config-fallback-profile)# ip admission name <i>rule-name</i>	Associates an IP admission rule with the profile and specifies that a client connecting by web-based authentication uses this rule.
Step 5	Switch(config-fallback-profile)# exit	Returns to global configuration mode.
Step 6	Switch(config)# interface <i>type slot/port</i>	Specifies the port to be configured and enters interface configuration mode. <i>type</i> = fastethernet , gigabitethernet , or tengigabitethernet
Step 7	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# authentication port-control auto Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x port-control auto	Enables authentication on the port.
Step 8	Switch(config-if)# authentication order <i>method1</i> [<i>method2</i>] [<i>method3</i>]	(Optional) Specifies the fallback order of authentication methods to be used. The three values of <i>method</i> , in the default order, are dot1x , mab , and webauth . The specified order also determines the relative priority of the methods for reauthentication (highest to lowest).

	Command	Purpose
Step 9	Switch(config-if)# authentication priority <i>method1 [method2] [method3]</i>	(Optional) Overrides the relative priority of authentication methods to be used. The three values of <i>method</i> , in the default order of priority, are dot1x , mab , and webauth .
Step 10	Switch(config-if)# authentication event fail action next-method	Specifies that the next configured authentication method be applied if authentication fails.
Step 11	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# mab [eap] Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x mac-auth-bypass [eap]	Enables MAC authentication bypass. The optional eap keyword specifies that the EAP extension be used during RADIUS authentication.
Step 12	Switch(config-if)# authentication fallback <i>profile-name</i>	Enables web-based authentication using the specified profile.
Step 13	Switch(config-if)# authentication violation [shutdown restrict]	(Optional) Configures the disposition of the port if a security violation occurs. The default action is to shut down the port. If the restrict keyword is configured, the port does not shut down, but trap entries are installed for the violating MAC address, and traffic from that MAC address is dropped.
Step 14	Switch(config-if)# authentication timer inactivity { <i>seconds</i> server }	(Optional) Configures the inactivity timeout value for MAB and 802.1X. By default, inactivity aging is disabled for a port. <ul style="list-style-type: none"> <i>seconds</i>—Specifies inactivity timeout period. The range is from 1 to 65535 seconds. server—Specifies that the inactivity timeout period value be obtained from the authentication server.
Step 15	Switch(config-if)# authentication timer restart <i>seconds</i>	(Optional) Specifies a period after which the authentication process restarts in an attempt to authenticate an unauthorized port. <ul style="list-style-type: none"> <i>seconds</i>—Specifies the restart period. The range is from 1 to 65535 seconds.
Step 16	Switch(config-if)# exit	Returns to global configuration mode.
Step 17	Switch(config)# ip device tracking	Enables the IP device tracking table, which is required for web-based authentication.
Step 18	Switch(config)# exit	Returns to privileged EXEC mode.
Step 19	Switch# show dot1x interface <i>type slot/port</i>	Verifies your entries.

This example shows how to enable 802.1X fallback to MAB, and then to enable web-based authentication, on an 802.1X-enabled port:

```
Switch(config)# ip admission name rule1 proxy http
Switch(config)# fallback profile fallback1
Switch(config-fallback-profile)# ip access-group default-policy in
Switch(config-fallback-profile)# ip admission rule1
Switch(config-fallback-profile)# exit
Switch(config)# interface gigabit5/9
```

```

Switch(config-if)# switchport mode access
Switch(config-if)# authentication port-control auto
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication order dot1x mab webauth
Switch(config-if)# mab eap
Switch(config-if)# authentication fallback fallback1
Switch(config-if)# exit
Switch(config)# ip device tracking
Switch(config)# exit

```

To determine if a host was authenticated using 802.1X when fallback authentication is configured on the port, enter the following commands:

```
Switch# show authentication sessions interface g7/2
```

```

Interface: GigabitEthernet7/2
MAC Address: 0060.b057.4687
IP Address: Unknown
User-Name: test2
Status: Authz Success
Domain: DATA
Oper host mode: multi-auth
Oper control dir: both
Authorized By: Authentication Server
Vlan Policy: N/A
Session timeout: N/A
Idle timeout: N/A
Common Session ID: C0A8013F0000000901BAB560
Acct Session ID: 0x0000000B

Port Status = AUTHORIZED

```

To determine if a host was authenticated using MAB when fallback authentication is configured on the port, enter the following commands:

```
Switch# show authentication sessions interface g7/2
```

```

      Interface: GigabitEthernet7/2
      MAC Address: 0060.b057.4687
      IP Address: 192.168.22.22
      User-Name: 0060b0574687
      Status: Authz Success
      Domain: DATA
      Oper host mode: multi-auth
      Oper control dir: both
      Authorized By: Authentication Server
      Vlan Policy: N/A
      Session timeout: N/A
      Idle timeout: N/A
      Common Session ID: C0A8013F0000000B01BBD278

Total Sessions: 1 Init Sessions: 0
Client IP 10.5.63.13 Port 4643, timeout 1000, state ESTAB
```

Cisco IOS Release 12.2(46)SG or earlier

```
Switch(config)# ip admission name rule1 proxy http
Switch(config)# fallback profile fallback1
Switch(config-fallback-profile)# ip access-group default-policy in
Switch(config-fallback-profile)# ip admission rule1
Switch(config-fallback-profile)# exit
Switch(config)# interface gigabit5/9
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x port-control auto
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication order dot1x mab webauth
Switch(config-if)# dot1x mac-auth-bypass eap
Switch(config-if)# adot1x fallback fallback1
Switch(config-if)# exit
Switch(config)# ip device tracking
Switch(config)# exit
```

Enabling Periodic Reauthentication

You can enable periodic 802.1X client reauthentication and specify how often it occurs. If you do not specify a time value before enabling reauthentication, the interval between reauthentication attempts is 3600 seconds.

Automatic 802.1X client reauthentication is a per-interface setting and can be set for clients connected to individual ports. To manually reauthenticate the client connected to a specific port, see the [“Changing the Quiet Period”](#) section on page 49-86.

To enable periodic reauthentication of the client and to configure the number of seconds between reauthentication attempts, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode and specifies the interface to be enabled for periodic reauthentication.
Step 3	Switch(config-if)# switchport mode access	Specifies a nontrunking, nontagged single VLAN Layer 2 interface.
Step 4	Switch(config-if)# dot1x pae authenticator	Enables 802.1X authentication on the port with default parameters. Refer to the “Default 802.1X Configuration” section on page 49-27.
Step 5	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# authentication periodic Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x reauthentication	Enables periodic reauthentication of the client, which is disabled by default. To disable periodic reauthentication, use the no authentication periodic interface configuration command (for earlier releases, use the no dot1x reauthentication interface configuration command).

	Command	Purpose
Step 6	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# authentication timer reauthenticate {seconds / server}	Specifies the number of seconds between reauthentication attempts or have the switch use a RADIUS-provided session timeout. The range is 1 to 65,535; the default is 3600 seconds.
	Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x timeout reauth-period {seconds / server}	To return to the default number of seconds between reauthentication attempts, use the no authentication timer reauthenticate global configuration command (for earlier releases, use the dot1x timeout reauth-attempts command). This command affects the behavior of the switch only if periodic reauthentication is enabled.
Step 7	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# authentication port-control auto Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x port-control auto	Enables 802.1X authentication on the interface.
Step 8	Switch(config-if)# end	Returns to privileged EXEC mode.

This example shows how to enable periodic reauthentication and set the number of seconds between reauthentication attempts to 4000:

Cisco IOS Release 12.2(50)SG and later

```
Switch# configure terminal
Switch(config)# interface fastethernet5/9
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication periodic
Switch(config-if)# authentication timer reauthenticate 4000
Switch(config-if)# authentication port-control auto
Switch(config-if)# end
Switch#
```

Cisco IOS Release 12.2(46)SG or earlier

```
Switch# configure terminal
Switch(config)# interface fastethernet5/9
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# dot1x reauthentication
Switch(config-if)# dot1x timeout reauth-period 4000
Switch(config-if)# dot1x port-control auto
Switch(config-if)# end
Switch#
```

Enabling Multiple Hosts

You can attach multiple hosts (clients) to a single 802.1X-enabled port as shown in [Figure 49-9 on page 49-25](#). In this mode, when the port is authorized, all other hosts that are indirectly attached to the port are granted access to the network. If the port becomes unauthorized (reauthentication fails or an EAPOL-logoff message is received), the switch denies access to the network for all wireless access point-attached clients.

To allow multiple hosts (clients) on an 802.1X-authorized port that has the **dot1x port-control** interface configuration command set to **auto**, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode and specifies the interface to which multiple hosts are indirectly attached.
Step 3	Switch(config-if)# switchport mode access	Specifies a nontrunking, nontagged single VLAN Layer 2 interface.
Step 4	Switch(config-if)# dot1x pae authenticator	Enables 802.1X authentication on the port with default parameters. Refer to the “ Default 802.1X Configuration ” section on page 49-27.
Step 5	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# authentication host-mode multi-host Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x host-mode multi-host	Allows multiple hosts (clients) on an 802.1X-authorized port. Note Ensure that the dot1x port-control interface configuration command set is set to auto for the specified interface. To disable multiple hosts on the port, use the no authentication host-mode multi-host interface configuration command (for earlier releases, use the no dot1x host-mode multi-host interface configuration command).
Step 6	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# authentication port-control auto Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x port-control auto	Enables 802.1X authentication on the interface.
Step 7	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 8	Switch# show dot1x all interface <i>interface-id</i>	Verifies your entries.
Step 9	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to enable 802.1X on Fast Ethernet interface 5/9 and to allow multiple hosts:

Cisco IOS Release 12.2(50)SG and later

```
Switch# configure terminal
Switch(config)# interface fastethernet5/9
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication host-mode multi-host
Switch(config-if)# authentication port-control auto
Switch(config-if)# end
Switch#
```

Cisco IOS Release 12.2(46)SG or earlier

```
Switch# configure terminal
Switch(config)# interface fastethernet5/9
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
```

```
Switch(config-if)# dot1x host-mode multi-host
Switch(config-if)# dot1x port-control auto
Switch(config-if)# end
Switch#
```

Changing the Quiet Period

When the switch cannot authenticate the client, the switch remains idle for a set period of time, and then tries again. The idle time is determined by the **quiet-period** value. A failed authentication of the client might occur because the client provided an invalid password. You can provide a faster response time to the user by entering a number smaller than the default.

To change the quiet period, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode and specifies the interface to be enabled for timeout quiet-period .
Step 3	Switch(config-if)# switchport mode access	Specifies a nontrunking, nontagged single VLAN Layer 2 interface.
Step 4	Switch(config-if)# dot1x pae authenticator	Enables 802.1X authentication on the port with default parameters. Refer to the “Default 802.1X Configuration” section on page 49-27.
Step 5	Switch(config-if)# dot1x timeout quiet-period <i>seconds</i>	Sets the number of seconds that the switch remains in the quiet-period following a failed authentication exchange with the client. To return to the default quiet-period, use the no dot1x timeout quiet-period configuration command. The range is 0 to 65,535 seconds; the default is 60.
Step 6	Switch(config-if)# authentication port-control auto	Enables 802.1X authentication on the interface.
Step 7	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 8	Switch# show dot1x all	Verifies your entries.
Step 9	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to set the quiet period on the switch to 30 seconds:

Cisco IOS Release 12.2(50)SG and later

```
Switch# configure terminal
Switch(config)# interface fastethernet4/1
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# dot1x timeout quiet-period 30
Switch(config-if)# authentication port-control auto
Switch(config-if)# end
Switch#
```

Cisco IOS Release 12.2(46)SG or earlier

```
Switch# configure terminal
Switch(config)# interface fastethernet4/1
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# dot1x timeout quiet-period 30
Switch(config-if)# dot1x port-control auto
Switch(config-if)# end
Switch#
```

Changing the Switch-to-Client Retransmission Time

The client responds to the EAP-request/identity frame from the switch with an EAP-response/identity frame. If the switch does not receive this response, it waits a set period of time (known as the retransmission time) and then retransmits the frame.

**Note**

You should change the default value of this command only to adjust for unusual circumstances, such as unreliable links or specific behavioral problems with certain clients and authentication servers.

To change the amount of time that the switch waits for client notification, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode and specifies the interface to be enabled for timeout tx-period.
Step 3	Switch(config-if)# switchport mode access	Specifies a nontrunking, nontagged single VLAN Layer 2 interface.
Step 4	Switch(config-if)# dot1x pae authenticator	Enables 802.1X authentication on the port with default parameters. Refer to the “Default 802.1X Configuration” section on page 49-27.
Step 5	Switch(config-if)# dot1x timeout tx-period <i>seconds</i>	Sets the number of seconds that the switch waits for a response to an EAP-request/identity frame from the client before retransmitting the request. The range is 1 to 65,535 seconds; the default is 30. To return to the default retransmission time, use the no dot1x timeout tx-period interface configuration command.
Step 6	Cisco IOS Release 12.2(50)SG and later Switch(config-if)# authentication port-control auto Cisco IOS Release 12.2(46)SG or earlier releases Switch(config-if)# dot1x port-control auto	Enables 802.1X authentication on the interface.
Step 7	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 8	Switch# show dot1x all	Verifies your entries.
Step 9	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to set the retransmission time to 60 seconds:

Cisco IOS Release 12.2(50)SG and later

```
Switch# configure terminal
Switch(config)# interface fastethernet5/9
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# dot1x timeout tx-period 60
Switch(config-if)# authentication port-control auto
Switch(config-if)# end
Switch#
```

Cisco IOS Release 12.2(46)SG or earlier

```
Switch# configure terminal
Switch(config)# interface fastethernet5/9
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# dot1x timeout tx-period 60
Switch(config-if)# dot1x port-control auto
Switch(config-if)# end
Switch#
```

Setting the Switch-to-Client Frame-Retransmission Number

In addition to changing the switch-to-client retransmission times, you can change the number of times that the switch sends EAP-Request/Identity and other EAP-Request frames to the client before restarting the authentication process. The number of EAP-Request/Identity retransmissions is controlled by the **dot1x max-reauth-req** command; the number of retransmissions for other EAP-Request frames is controlled by the **dot1x max-req** command.

Note

You should change the default values of these commands only to adjust for unusual circumstances such as unreliable links or specific behavioral problems with certain clients and authentication servers.

To set the switch-to-client frame-retransmission numbers, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode and specifies the interface to be enabled for max-reauth-req and/or max-req .
Step 3	Switch(config-if)# switchport mode access	Specifies a nontrunking, nontagged single VLAN Layer 2 interface.
Step 4	Switch(config-if)# dot1x pae authenticator	Enables 802.1X authentication on the port with default parameters. Refer to the “Default 802.1X Configuration” section on page 49-27.

	Command	Purpose
Step 5	Switch(config-if) # dot1x max-req count	Specifies the number of times EAPOL DATA packets are retransmitted (if lost or not replied to). For example, if you have a supplicant that is authenticating and it experiences a problem, the authenticator retransmits requests for data three times before abandoning the authentication request. The range for <i>count</i> is 1 to 10; the default is 2.
	or Switch(config-if) # dot1x max-reauth-req count	Specifies the timer for EAPOL-Identity-Request frames (only). If you plug in a device incapable of 802.1X, three EAPOL-Id-Req frames are sent before the state machine resets. Alternatively, if you have configured Guest-VLAN, three frames are sent before the port is enabled. This parameter has a default value of 2. To return to the default retransmission number, use the no dot1x max-req and no dot1x max-reauth-req global configuration command.
Step 6	Switch(config-if) # authentication port-control auto	Enables 802.1X authentication on the interface.
Step 7	Switch(config-if) # end	Returns to privileged EXEC mode.
Step 8	Switch# show dot1x all	Verifies your entries.
Step 9	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to set 5 as the number of times that the switch retransmits an EAP-request/identity request before restarting the authentication process:

Cisco IOS Release 12.2(50)SG and later

```
Switch# configure terminal
Switch(config)# interface fastethernet5/9
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# dot1x max-reauth-req 5
Switch(config-if)# authentication port-control auto
Switch(config-if)# end
Switch#
```

Cisco IOS Release 12.2(46)SG or earlier

```
Switch# configure terminal
Switch(config)# interface fastethernet5/9
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# dot1x max-reauth-req 5
Switch(config-if)# dot1x port-control auto
Switch(config-if)# end
Switch#
```

Configuring an Authenticator and a Supplicant Switch with NEAT

Configuring NEAT requires that one switch outside a wiring closet is configured as a supplicant and is connected to an authenticator switch.

This section includes these topics:

- [Configuring Switch as an Authenticator, page 49-90](#)
- [Configuring Switch as a Supplicant, page 49-93](#)

- [Configuring NEAT with ASP, page 49-94](#)
- [Configuration Guidelines, page 49-94](#)

Note

For overview information, see the “[802.1X Supplicant and Authenticator Switches with Network Edge Access Topology](#)” section on page 49-23.

Configuring Switch as an Authenticator

To configure a switch as an authenticator, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# cisp enable	Enables CISP.
Step 3	Switch(config)# interface <i>interface-id</i>	Specifies the port to be configured, and enter interface configuration mode.
Step 4	Switch(config-if)# switchport mode access	Sets the port mode to access.
Step 5	Switch(config-if)# authentication port-control auto	Sets the port-authentication mode to auto.
Step 6	Switch(config-if)# dot1x pae authenticator	Configures the interface as a port access entity (PAE) authenticator.
Step 7	Switch(config-if)# spanning-tree portfast	Enables Port Fast on an access port connected to a single workstation or server.
Step 8	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 9	Switch# show running-config interface interface-id	Verifies your configuration.
Step 10	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

When CISP is enabled on a trunk port, the following features are inert. When CISP is neither running nor configured, these features operate as expected:

- VLAN assignment
- Guest, Authentication Failure, voice, and critical VLANs
- Critical authentication
- Wake-on-LAN
- Web authentication
- Port security
- Violation modes (restrict, shut down, and shut down VLAN)

The following example shows how to enable CISP on a port. You must configure the following procedure in the Cisco ACS server. Configuring a user with Cisco AV Pair value, allows SSW to authenticate itself with the ASW. Because the user is attached with the AV pair value, upon successful authentication on ASW, the macro is executed on the interface on which SSW is authenticated:

```
Switch# configure terminal
Switch(config)# cisp enable
```

```
Switch(config)# interface GigabitEthernet5/23
Switch(config-if)# switchport mode access
Switch(config-if)# spanning-tree portfast
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
```

Cisco AV Pair Configuration

Next, you need to configure a Cisco AV pair value.

Log into ACS, and Select/Create a User. Go to User Setup and scroll down to the [009\001] cisco-av-pair Tab. Enter `device-traffic-class=switch` (Figure 49-20).

Figure 49-20 Specifying the Cisco AV Pair

Starting with Cisco IOS XE Release 3.2.0 SG (15.0(2)SG) the spanning-tree bpduguard feature is automatically disabled or enabled as part of a macro provided it was previously enabled in the port configuration. If the configuration did not have BPDU Guard enabled before the supplicant switch was authenticated, the spanning-tree bpduguard feature is not applied to the macro.

Note

Disabling spanning-tree bpduguard happens only if it was previously enabled through the **port level** command. Enabling it globally without a specific port level CLI prevents NEAT from disabling it on the port after the authenticator switch receives a `device-traffic-class=switch` AV Pair and applies the macro.

There are 2 scenarios:

Scenario 1: With Port Level BPDU Guard Configuration

Before Authorization

```

interface GigabitEthernet5/1
  switchport access vlan 81
  switchport mode access
  dot1x pae authenticator
  authentication port-control auto
  spanning-tree bpduguard enable
end

```

Post Authorization and Application of Internal Macro

```

interface GigabitEthernet5/1
  switchport trunk encapsulation dot1q
  switchport trunk native vlan 81
  switchport mode trunk
  dot1x pae authenticator
  authentication port-control auto
  spanning-tree portfast trunk
  no spanning-tree bpduguard
end

```

Scenario 2: Without port level BPDU Guard Configuration (with or without globally enabling BPDU Guard)

Before Authorization

```

interface GigabitEthernet5/1
  switchport access vlan 81
  switchport mode access
  dot1x pae authenticator
  authentication port-control auto
end

```

Post Authorization and Application of Internal Macro

```

interface GigabitEthernet5/1
  switchport trunk encapsulation dot1q
  switchport trunk native vlan 81
  switchport mode trunk
  dot1x pae authenticator
  authentication port-control auto
  spanning-tree portfast trunk
  no spanning-tree bpduguard
end

```

When the authenticator switch receives a device-traffic-class=switch AV pair, the following macro is applied to the authenticator switch port:

```

no switchport access vlan $AVID
no switchport nonegotiate
switchport mode trunk
switchport trunk native vlan $AVID
no spanning-tree bpduguard enable
spanning-tree portfast trunk

```

After the supplicant switch is authenticated as a switch device, the configuration will appear as follows:

```

interface GigabitEthernet5/23
  switchport mode trunk
  authentication port-control auto
  dot1x pae authenticator
  spanning-tree portfast trunk
end

```

Radius Config (Cisco AV Pair value)

```
-----
device-traffic-class=switch
```

show running-config interface is the only command that informs you that the smart macro has been applied after the supplicant switch is authenticated:

```
Switch# show authentication session
```

```
Interface  MAC Address      Method  Domain  Status      Session ID
Gi5/23     0024.9844.de23  dot1x   DATA   Authz Success  0909117A0000000000010561C
```

```
Switch# show running-configuration interface gi 5/23
```

```
Building configuration...
```

```
Current configuration : 149 bytes
```

```
!
```

```
interface GigabitEthernet5/23
 switchport mode trunk
 authentication port-control auto
 dot1x pae authenticator
 spanning-tree portfast trunk
end
```

```
Switch#
```

NEAT changes the port configuration on the authenticator switch. So, to perform ISSU from one version that supports NEAT to another that does not support NEAT, you must first deactivate NEAT on all switch ports for ISSU. Similarly, NEAT cannot activate when ISSU is in progress. If a supplicant switch tries to authenticate during ISSU, authorization would fail on the port.

Configuring Switch as a Supplicant

Note

The Catalyst 4500 series switch does not support supplicant switch functionality. The following supplicant specific commands are mentioned for a quick reference. For more details, see the *Catalyst 3750 Switch Software Configuration Guide*.

To configure a switch as a supplicant, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# cisp enable	Enables CISP.
Step 3	Switch(config)# dot1x credentials profile	Creates 802.1x credentials profile. This must be attached to the port that is configured as supplicant.
Step 4	Switch(config)# username suppswitch	Creates a username.
Step 5	Switch(config)# password password	Creates a password for the new username.
Step 6	Switch(config)# dot1x supplicant force-multicast	Forces the switch to send <i>only</i> multicast EAPOL packets when it receives either unicast or multicast packets. This also allows NEAT to work on the supplicant switch in all host modes.

	Command	Purpose
Step 7	Switch(config)# interface <i>interface-id</i>	Specifies the port to be configured, and enter interface configuration mode.
Step 8	Switch(config-if)# switchport trunk encapsulation dot1q	Sets the port to trunk mode.
Step 9	Switch(config-if)# switchport mode trunk	Configures the interface as a VLAN trunk port.
Step 10	Switch(config-if)# dot1x pae supplicant	Configures the interface as a port access entity (PAE) supplicant.
Step 11	Switch(config-if)# dot1x credentials profile-name	Attaches the 802.1x credentials profile to the interface.
Step 12	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 13	Switch# show running-config interface interface	Verifies your configuration. Note it is the only command that tells you that the smart macro has been applied after the supplicant switch has been authenticated.
Step 14	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to configure a switch as a supplicant:

```
Switch# configure terminal
Switch(config)# cisp enable
Switch(config)# dot1x credentials test
Switch(config)# username suppswitch
Switch(config)# password myswitch
Switch(config)# dot1x supplicant force-multicast
Switch(config)# interface gigabitethernet1/0/1
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# dot1x pae supplicant
Switch(config-if)# dot1x credentials test
Switch(config-if)# end
```

The following macro is applied to the authenticator switch port after the supplicant switch is deauthenticated due to a link-down or a reauthenticating event:

```
no switchport nonegotiate
switchport mode access
no switchport trunk native vlan $AVID
no spanning-tree portfast trunk
switchport access vlan $AVID
spanning-tree bpduguard enable
spanning-tree portfast
```

Configuring NEAT with ASP

You can also use an AutoSmart Ports user-defined macro rather than a switch VSA to configure the authenticator switch. For more information, see the [Chapter 22, “Configuring Cisco IOS Auto Smartport Macros.”](#)

Configuration Guidelines

- If BPDU Guard was enabled prior to supplicant switch authentication, it is re-enabled after the supplicant switch unauthenticates.

- You can configure NEAT ports and non-NEAT ports with the same configuration. When the supplicant switch authenticates, the port mode is changed from access to trunk based on the switch vendor-specific attributes (`device-traffic-class=switch`).
- To enable NEAT, you must configure the vendor-specific attributes (VSA) attribute as switch. Configuring the trunk with an 802.1X configuration and enabling CISP globally will not enable NEAT.
- VSA `device-traffic-class=switch` assists the authenticator switch in identifying the supplicant as a switch-device. This identification changes the authenticator switch port mode from access to trunk and enables 802.1X trunk encapsulation. The access VLAN, if any, is converted to a native trunk VLAN. VSA does not change any of the port configurations on the supplicant.
- Although modified trunk parameters are retained, when the trunk link is down or authentication is cleared, the interface is reconfigured to the following:
 - **spanning-tree portfast**
 - **switchport mode access**
 - **switchport access vlan** *access-vlan-id*

Note *access-vlan-id* is derived from the **switchport trunk native vlan** *x* command entered on the interface. If you have modified the trunk native VLAN, the configured native VLAN is used as the access-vlan-id when the port returns to access mode.

- We recommend using 802.1X authentication mode single-host for NEAT configuration on the interface.
- The `cisco-av-pairs` must be configured as `device-traffic-class=switch` on the ACS. This sets the interface as a trunk after the supplicant is successfully authenticated.
- You should not modify the trunk mode configurations that are based on *device-traffic-class* either manually or through features such as AutoSmart Ports. It is because 802.1X configuration is not supported for trunk ports.
- To change the host mode and apply a standard port configuration on the authenticator switch port, you can also use AutoSmart ports user-defined macros rather than the switch VSA. Doing this allows you to remove unsupported configurations on the authenticator switch port and to change the port mode from access to trunk. For details, see [Chapter 22, “Configuring Cisco IOS Auto Smartport Macros.”](#)

Note Configuring only the Auto SmartPorts macro does not identify the end host as a supplicant switch. The switch VSA is required to identify the supplicant switch. However, when Auto Smartports macro is configured, the internal macro that reconfigures the port from access to trunk is not executed and the Auto Smartports macro should ensure that the port reconfigures as a trunk port.

Manually Reauthenticating a Client Connected to a Port

You can manually reauthenticate a client connected to a specific port at any time by entering the **dot1x re-authenticate interface** privileged EXEC command. If you want to enable or disable periodic reauthentication, see the [“Enabling Periodic Reauthentication” section on page 49-83](#).

This example shows how to manually reauthenticate the client connected to Fast Ethernet port 1/1:

```
Switch# dot1x re-authenticate interface fastethernet1/1
Starting reauthentication on FastEthernet1/1
```

Initializing the 802.1X Authentication State

The **dot1x initialize** command causes the authentication process to be restarted regardless of its current state.

This example shows how to restart the authentication process on Fast Ethernet port 1/1:

```
Switch# dot1x initialize interface fastethernet1/1
```

This example shows how to restart the authentication process on all ports of the switch:

```
Switch# dot1x initialize
```

Removing 802.1X Client Information

The **clear dot1x** command causes all existing supplicants to be completely deleted from an interface or from all the interfaces on a switch.

This example shows how to remove 802.1X client information on Fast Ethernet port 1/1:

```
Switch# clear dot1x interface fastethernet1/1
```

This example shows how to remove 802.1X client information on all ports of the switch:

```
Switch# clear dot1x all
```

Resetting the 802.1X Configuration to the Default Values

To reset the 802.1X configuration to the default values, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# dot1x default	Resets the configurable 802.1X parameters to the default values.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show dot1x all	Verifies your entries.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Controlling Switch Access with RADIUS

This section describes how to enable and configure the RADIUS, which provides detailed accounting information and flexible administrative control over authentication and authorization processes. RADIUS is facilitated through AAA and can be enabled only through AAA commands.

**Note**

For complete syntax and usage information for the commands used in this section, see the *Cisco IOS Security Command Reference, Release 12.2*.

These sections contain this configuration information:

- [Understanding RADIUS, page 49-97](#)
- [RADIUS Operation, page 49-98](#)
- [RADIUS Change of Authorization, page 49-99](#)
- [Configuring RADIUS, page 49-104](#)
- [Displaying the RADIUS Configuration, page 49-117](#)

Understanding RADIUS

RADIUS is a distributed client/server system that secures networks against unauthorized access. RADIUS clients run on supported Cisco routers and switches. Clients send authentication requests to a central RADIUS server, which contains all user authentication and network service access information. The RADIUS host is normally a multiuser system running RADIUS server software from Cisco (Cisco Secure Access Control Server Version 3.0), Livingston, Merit, Microsoft, or another software provider. For more information, see the RADIUS server documentation.

Use RADIUS in these network environments that require access security:

- Networks with multiple-vendor access servers, each supporting RADIUS. For example, access servers from several vendors use a single RADIUS server-based security database. In an IP-based network with multiple vendors' access servers, dial-in users are authenticated through a RADIUS server that has been customized to work with the Kerberos security system.
- Turnkey network security environments in which applications support the RADIUS protocol, such as in an access environment that uses a *smart card* access control system. In one case, RADIUS has been used with Enigma's security cards to validate users and to grant access to network resources.
- Networks already using RADIUS. You can add a Cisco switch containing a RADIUS client to the network. This might be the first step when you make a transition to a TACACS+ server. See [Figure 49-21 on page 49-98](#).
- Network in which the user must only access a single service. Using RADIUS, you can control user access to a single host, to a single utility such as Telnet, or to the network through a protocol such as IEEE 802.1X.
- Networks that require resource accounting. You can use RADIUS accounting independently of RADIUS authentication or authorization. The RADIUS accounting functions allow data to be sent at the start and end of services, showing the amount of resources (such as time, packets, bytes, and so forth) used during the session. An Internet service provider might use a freeware-based version of RADIUS access control and accounting software to meet special security and billing needs.

RADIUS is not suitable in these network security situations:

- Multiprotocol access environments. RADIUS does not support AppleTalk Remote Access (ARA), NetBIOS Frame Control Protocol (NBFCP), NetWare Asynchronous Services Interface (NASI), or X.25 PAD connections.
- Switch-to-switch or router-to-router situations. RADIUS does not provide two-way authentication. RADIUS can be used to authenticate from one device to a non-Cisco device if the non-Cisco device requires authentication.
- Networks using a variety of services. RADIUS generally binds a user to one service model.

Figure 49-21 Transitioning from RADIUS to TACACS+ Services

RADIUS Operation

When a user attempts to log in and authenticate to a switch that is access controlled by a RADIUS server, these events occur:

1. The user is prompted to enter a username and password.
2. The username and encrypted password are sent over the network to the RADIUS server.
3. The user receives one of these responses from the RADIUS server:
 - a. ACCEPT—The user is authenticated.
 - b. REJECT—The user is either not authenticated and is prompted to re-enter the username and password, or access is denied.
 - c. CHALLENGE—A challenge requires additional data from the user.
 - d. CHALLENGE PASSWORD—A response requests the user to select a new password.

The ACCEPT or REJECT response is bundled with additional data that is used for privileged EXEC or network authorization. Users must first successfully complete RADIUS authentication before proceeding to RADIUS authorization, if it is enabled. The additional data included with the ACCEPT or REJECT packets includes these items:

- Telnet, SSH, rlogin, or privileged EXEC services
- Connection parameters, including the host or client IP address, access list, and user timeouts

RADIUS Change of Authorization

This section provides an overview of the RADIUS interface including available primitives and how they are used during a Change of Authorization (CoA).

- [Overview, page 49-99](#)
- [Change-of-Authorization Requests, page 49-99](#)
- [CoA Request Response Code, page 49-100](#)
- [CoA Request Commands, page 49-101](#)
- [Session Reauthentication, page 49-102](#)
- [Displaying 802.1X Statistics and Status, page 49-126](#)

Overview

A standard RADIUS interface is typically used in a pulled model where the request originates from a network attached device and the response come from the queried servers. Catalyst switches support the RADIUS Change of Authorization (CoA) extensions defined in RFC 5176 that are typically used in a pushed model and allow for the dynamic reconfiguring of sessions from external authentication, authorization, and accounting (AAA) or policy servers.

The switch supports these per-session CoA requests:

- Session reauthentication
- Session termination
- Session termination with port shut down
- Session termination with port bounce

The RADIUS interface is enabled by default on Catalyst switches.

Change-of-Authorization Requests

Change of Authorization (CoA) requests, as described in RFC 5176, are used in a push model to allow for session identification, host reauthentication, and session termination. The model is comprised of one request (CoA-Request) and two possible response codes:

- CoA acknowledgement (ACK) [CoA-ACK]
- CoA non-acknowledgement (NAK) [CoA-NAK]

The request is initiated from a CoA client (typically a RADIUS or policy server) and directed to the switch that acts as a listener.

This section includes these topics:

- [CoA Request Response Code](#)
- [CoA Request Commands](#)
- [Session Reauthentication](#)

RFC 5176 Compliance

The Disconnect Request message, which is also referred to as Packet of Disconnect (POD), is supported by the switch for session termination.

Table 49-2 shows the IETF attributes are supported for this feature.

Table 49-2 Supported IETF Attributes

Attribute Number	Attribute Name
24	State
31	Calling-Station-ID
44	Acct-Session-ID
80	Message-Authenticator
101	Error-Cause

Table 49-3 shows the possible values for the Error-Cause attribute.

Table 49-3 Error-Cause Values

Value	Explanation
201	Residual Session Context Removed
202	Invalid EAP Packet (Ignored)
401	Unsupported Attribute
402	Missing Attribute
403	NAS Identification Mismatch
404	Invalid Request
405	Unsupported Service
406	Unsupported Extension
407	Invalid Attribute Value
501	Administratively Prohibited
502	Request Not Routable (Proxy)
503	Session Context Not Found
504	Session Context Not Removable
505	Other Proxy Processing Error
506	Resources Unavailable
507	Request Initiated
508	Multiple Session Selection Unsupported

Preconditions

To use the CoA interface, a session must already exist on the switch. CoA can be used to identify a session and enforce a disconnect request. The update affects only the specified session.

CoA Request Response Code

The CoA Request response code can be used to convey a command to the switch. The supported commands are listed in Table 49-4 on page 49-102.

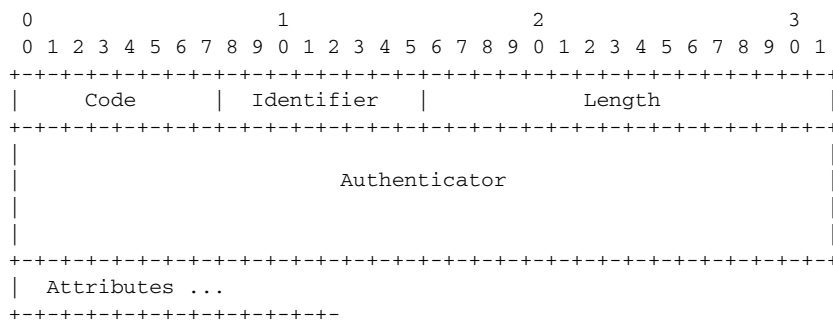

Session Identification

For disconnect and CoA requests targeted at a particular session, the switch locates the session based on one or more of the following attributes:

- Calling-Station-Id (IETF attribute #31 which contains the host MAC address)
- Audit-Session-Id (Cisco VSA)
- Acct-Session-Id (IETF attribute #44)

Unless all session identification attributes included in the CoA message match the session, the switch returns a Disconnect-NAK or CoA-NAK with the “Invalid Attribute Value” error-code attribute.

The packet format for a CoA Request code as defined in RFC 5176 consists of the fields: Code, Identifier, Length, Authenticator, and Attributes in Type:Length:Value (TLV) format.

The attributes field is used to carry Cisco VSAs.

CoA ACK Response Code

If the authorization state is changed successfully, a positive acknowledgement (ACK) is sent. The attributes returned within CoA ACK will vary based on the CoA Request and are discussed in individual CoA Commands.

CoA NAK Response Code

A negative acknowledgement (NAK) indicates a failure to change the authorization state and can include attributes that indicate the reason for the failure. Use **show** commands to verify a successful CoA.

CoA Request Commands

This section includes:

- [Session Reauthentication](#)
- [Session Termination](#)
- [CoA Disconnect-Request](#)
- [CoA Request: Disable Host Port](#)
- [CoA Request: Bounce-Port](#)

The switch supports the commands shown in [Table 49-4](#).

Table 49-4 CoA Commands Supported on the Switch

Command ¹	Cisco VSA
Reauthenticate host	Cisco:Avpair="subscriber:command=reauthenticate"
Terminate session	it is a standard disconnect request that does not require a VSA.
Bounce host port	Cisco:Avpair="subscriber:command=bounce-host-port"
Disable host port	Cisco:Avpair="subscriber:command=disable-host-port"

1. All CoA commands must include the session identifier between the switch and the CoA client.

Session Reauthentication

The AAA server typically generates a session reauthentication request when a host with an unknown identity or posture joins the network and is associated with a restricted access authorization profile (such as a guest VLAN). A reauthentication request allows the host to be placed in the appropriate authorization group when its credentials are known.

To initiate session authentication, the AAA server sends a standard CoA-Request message which contains a Cisco vendor-specific attribute (VSA) in this form:

Cisco:Avpair="subscriber:command=reauthenticate" and one or more session identification attributes.

The current session state determines the switch response to the message. If the session is currently authenticated by IEEE 802.1x, the switch responds by sending an EAPoL¹-RequestId message (see footnote 1 below) to the server.

If the session is currently authenticated by MAC authentication bypass (MAB), the switch sends an access-request to the server, passing the same identity attributes used for the initial successful authentication.

If session authentication is in progress when the switch receives the command, the switch terminates the process, and restarts the authentication sequence, starting with the method configured to be attempted first.

If the session is not yet authorized, or is authorized by using guest VLAN, or critical VLAN, or similar policies, the reauthentication message restarts the access control methods, beginning with the method configured to be attempted first. The current authorization of the session is maintained until the reauthentication leads to a different authorization result.

Session Termination

Three types of CoA requests can trigger session termination. A CoA Disconnect-Request terminates the session, without disabling the host port. This command causes re-initialization of the authenticator state machine for the specified host, but does not restrict that hosts' access to the network.

To restrict a hosts' access to the network, use a CoA Request with the *Cisco:Avpair="subscriber:command=disable-host-port"* VSA. This command is useful when a host is known to be causing problems on the network, and you need to immediately block network access for the host. When you want to restore network access on the port, reenale it using a non-RADIUS mechanism.

When a device with no supplicant, such as a printer, needs to acquire a new IP address (for example, after a VLAN change), terminate the session on the host port with port-bounce (temporarily disable and then re-enable the port).

1. Extensible Authentication Protocol over Lan

CoA Disconnect-Request

This command is a standard Disconnect-Request. Because this command is session-oriented, it must be accompanied by one or more of the session identification attributes described in the [“Session Identification” section on page 49-101](#). If the session cannot be located, the switch returns a Disconnect-NAK message with the “Session Context Not Found” error-code attribute. If the session *is* located, the switch terminates the session. After the session has been completely removed, the switch returns a Disconnect-ACK.

If the switch fails-over to a standby switch before returning a Disconnect-ACK to the client, the process is repeated on the new active switch when the request is re-sent from the client. If the session is not found following re-sending, a Disconnect-ACK is sent with the “Session Context Not Found” error-code attribute.

CoA Request: Disable Host Port

This command is carried in a standard CoA-Request message that has this new VSA:

```
Cisco:Avpair="subscriber:command=disable-host-port"
```

Because this command is session-oriented, it must be accompanied by one or more of the session identification attributes described in the [“Session Identification” section on page 49-101](#). If the session cannot be located, the switch returns a CoA-NAK message with the “Session Context Not Found” error-code attribute. If the session is located, the switch disables the hosting port and returns a CoA-ACK message.

If the switch fails before returning a CoA-ACK to the client, the process is repeated on the new active switch when the request is re-sent from the client. If the switch fails after returning a CoA-ACK message to the client but before the operation has completed, the operation is restarted on the new active switch.

Note

A Disconnect-Request failure following command re-sending could be the result of either a successful session termination before change-over (if the Disconnect-ACK was not sent) or a session termination by other means (for example, a link failure) that occurred after the original command was issued and before the standby switch became active.

CoA Request: Bounce-Port

This command is carried in a standard CoA-Request message that contains the following new VSA:

```
Cisco:Avpair="subscriber:command=bounce-host-port"
```

Because this command is session-oriented, it must be accompanied by one or more of the session identification attributes described in the [“Session Identification” section on page 49-101](#). If the session cannot be located, the switch returns a CoA-NAK message with the “Session Context Not Found” error-code attribute. If the session is located, the switch disables the hosting port for a period of 10 seconds, re-enables it (port-bounce), and returns a CoA-ACK.

If the switch fails before returning a CoA-ACK to the client, the process is repeated on the new active switch when the request is re-sent from the client. If the switch fails after returning a CoA-ACK message to the client but before the operation has completed, the operation is re-started on the new active switch.

Configuring RADIUS

This section describes how to configure your switch to support RADIUS. At a minimum, you must identify the host or hosts that run the RADIUS server software and define the method lists for RADIUS authentication. You can optionally define method lists for RADIUS authorization and accounting.

A method list defines the sequence and methods to be used to authenticate, to authorize, or to keep accounts on a user. You can use method lists to designate one or more security protocols to be used (such as TACACS+ or local username lookup), thus ensuring a backup system if the initial method fails. The software uses the first method listed to authenticate, to authorize, or to keep accounts on users. If that method does not respond, the software selects the next method in the list. This process continues until there is successful communication with a listed method or the method list is exhausted.

You should have access to and should configure a RADIUS server before configuring RADIUS features on your switch.

- [Configuring RADIUS Server Load Balancing, page 49-117](#) (optional)

Default RADIUS Configuration

RADIUS and AAA are disabled by default.

To prevent a lapse in security, you cannot configure RADIUS through a network management application. When enabled, RADIUS can authenticate users accessing the switch using the CLI.

Identifying the RADIUS Server Host

Switch-to-RADIUS-server communication involves several components:

- Hostname or IP address
- Authentication destination port
- Accounting destination port
- Key string
- Timeout period
- Retransmission value

You identify RADIUS security servers by their hostname or IP address, hostname and specific UDP port numbers, or their IP address and specific UDP port numbers. The combination of the IP address and the UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. This unique identifier enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address.

If two different host entries on the same RADIUS server are configured for the same service—for example, accounting—the second host entry configured acts as a failover backup to the first one. Using this example, if the first host entry fails to provide accounting services, the `%RADIUS-4-RADIUS_DEAD` message appears, and then the switch tries the second host entry configured on the same device for accounting services. (The RADIUS host entries are tried in the order that they are configured.)

A RADIUS server and the switch use a shared secret text string to encrypt passwords and exchange responses. To configure RADIUS to use the AAA security commands, you must specify the host running the RADIUS server daemon and a secret text (key) string that it shares with the switch.

The timeout, retransmission, and encryption key values can be configured globally for all RADIUS servers, on a per-server basis, or in some combination of global and per-server settings. To apply these settings globally to all RADIUS servers communicating with the switch, use the three unique global configuration commands: **radius-server timeout**, **radius-server retransmit**, and **radius-server key**. To apply these values on a specific RADIUS server, use the **radius server host** global configuration command.

**Note**

- If you configure both global and per-server functions (timeout, retransmission, and key commands) on the switch, the per-server timer, retransmission, and key value commands override global timer, retransmission, and key value commands. For information on configuring these settings on all RADIUS servers, see the [“Configuring Settings for All RADIUS Servers” section on page 49-113](#).
- In Cisco IOS XE Release 3.8.7E, the legacy command **radius-server host** is deprecated. Use the **radius server host** command if the software running on your device is Cisco IOS XE Release 3.8.7E or later.

You can configure the switch to use AAA server groups to group existing server hosts for authentication. For more information, see the [“Defining AAA Server Groups” section on page 49-109](#).

To configure per-server RADIUS server communication, perform this task. This procedure is required.

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# radius server host {hostname ip-address} [auth-port port-number] [acct-port port-number] [timeout seconds] [retransmit retries] [key string]	<p>Specifies the IP address or hostname of the remote RADIUS server host.</p> <ul style="list-style-type: none"> • (Optional) For auth-port port-number, specify the UDP destination port for authentication requests. • (Optional) For acct-port port-number, specify the UDP destination port for accounting requests. • (Optional) For timeout seconds, specify the time interval that the switch waits for the RADIUS server to reply before resending. The range is 1 to 1000. This setting overrides the radius-server timeout global configuration command setting. If no timeout is set with the radius server host command, the setting of the radius-server timeout command is used. • (Optional) For retransmit retries, specify the number of times a RADIUS request is resent to a server if that server is not responding or responding slowly. The range is 1 to 1000. If no retransmit value is set with the radius server host command, the setting of the radius-server retransmit global configuration command is used. • (Optional) For key string, specify the authentication and encryption key used between the switch and the RADIUS daemon running on the RADIUS server. <p>Note The key is a text string that must match the encryption key used on the RADIUS server. Always configure the key as the last item in the radius server host command. Leading spaces are ignored, but spaces within and at the end of the key are used. If you use spaces in your key, do not enclose the key in quotation marks unless the quotation marks are part of the key.</p> <p>To configure the switch to recognize more than one host entry associated with a single IP address, enter this command as many times as necessary, making sure that each UDP port number is different. The switch software searches for hosts in the order in which you specify them. Set the timeout, retransmit, and encryption key values to use with the specific RADIUS host.</p>
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show running-config	Verifies your entries.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To remove the specified RADIUS server, use the **no radius server host** hostname | ip-address global configuration command.

This example shows how to configure one RADIUS server to be used for authentication and another to be used for accounting:

```
Switch(config)# radius server host 172.29.36.49 auth-port 1612 key rad1
Switch(config)# radius server host 172.20.36.50 acct-port 1618 key rad2
```

This example shows how to configure *host1* as the RADIUS server and to use the default ports for both authentication and accounting:

```
Switch(config)# radius server host host1
```

**Note**

You also need to configure some settings on the RADIUS server. These settings include the IP address of the switch and the key string to be shared by both the server and the switch. For more information, see the RADIUS server documentation.

Configuring RADIUS Login Authentication

To configure AAA authentication, you define a named list of authentication methods and then apply that list to various ports. The method list defines the types of authentication to be performed and the sequence in which they are performed; it must be applied to a specific port before any of the defined authentication methods are performed. The only exception is the default method list (which, by coincidence, is named *default*). The default method list is automatically applied to all ports except those that have a named method list explicitly defined.

A method list describes the sequence and authentication methods to be queried to authenticate a user. You can designate one or more security protocols to be used for authentication, thus ensuring a backup system for authentication in case the initial method fails. The software uses the first method listed to authenticate users; if that method fails to respond, the software selects the next authentication method in the method list. This process continues until there is successful communication with a listed authentication method or until all defined methods are exhausted. If authentication fails at any point in this cycle—meaning that the security server or local username database responds by denying the user access—the authentication process stops, and no other authentication methods are attempted.

To configure login authentication, perform this task. This procedure is required.

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# aaa new-model	Enables AAA.

	Command	Purpose
Step 3	Switch(config)# aaa authentication login { default <i>list-name</i> } <i>method1</i> [<i>method2...</i>]	<p>Creates a login authentication method list.</p> <ul style="list-style-type: none"> To create a default list that is used when a named list is <i>not</i> specified in the login authentication command, use the default keyword followed by the methods that are to be used in default situations. The default method list is automatically applied to all ports. For <i>list-name</i>, specify a character string to name the list you are creating. For <i>method1...</i>, specify the actual method the authentication algorithm tries. The additional methods of authentication are used only if the previous method returns an error, not if it fails. <p>Select one of these methods:</p> <ul style="list-style-type: none"> enable—Use the enable password for authentication. Before you can use this authentication method, you must define an enable password by using the enable password global configuration command. group radius—Use RADIUS authentication. Before you can use this authentication method, you must configure the RADIUS server. For more information, see the “Identifying the RADIUS Server Host” section on page 49-104. line—Use the line password for authentication. Before you can use this authentication method, you must define a line password. Use the password password line configuration command. local—Use the local username database for authentication. You must enter username information in the database. Use the username name password global configuration command. local-case—Use a case-sensitive local username database for authentication. You must enter username information in the database by using the username password global configuration command. none—Do not use any authentication for login.
Step 4	Switch(config)# line [console tty vty] <i>line-number</i> [<i>ending-line-number</i>]	Enters line configuration mode, and configure the lines to which you want to apply the authentication list.
Step 5	Switch(config)# login authentication { default <i>list-name</i> }	<p>Applies the authentication list to a line or set of lines.</p> <ul style="list-style-type: none"> If you specify default, use the default list created with the aaa authentication login command. For <i>list-name</i>, specify the list created with the aaa authentication login command.
Step 6	Switch(config)# end	Returns to privileged EXEC mode.
Step 7	Switch# show running-config	Verifies your entries.
Step 8	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To disable AAA, use the **no aaa new-model** global configuration command. To disable AAA authentication, use the **no aaa authentication login {default | list-name} method1 [method2...]** global configuration command. To either disable RADIUS authentication for logins or to return to the default value, use the **no login authentication {default | list-name}** line configuration command.

**Note**

To secure the switch for HTTP access by using AAA methods, you must configure the switch with the **ip http authentication aaa** global configuration command. Configuring AAA authentication does not secure the switch for HTTP access by using AAA methods.

For more information about the **ip http authentication** command, see the *Cisco IOS Security Command Reference, Release 12.2* from the Cisco.com page under **Documentation > Cisco IOS Software > 12.2 Mainline > Command References**.

Defining AAA Server Groups

You can configure the switch to use AAA server groups to group existing server hosts for authentication. You select a subset of the configured server hosts and use them for a particular service. The server group is used with a global server-host list, which lists the IP addresses of the selected server hosts.

Server groups also can include multiple host entries for the same server if each entry has a unique identifier (the combination of the IP address and UDP port number), allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. If you configure two different host entries on the same RADIUS server for the same service, (for example, accounting), the second configured host entry acts as a failover backup to the first one.

You use the **server** group server configuration command to associate a particular server with a defined group server. You can either identify the server by its IP address or identify multiple host instances or entries by using the optional **auth-port** and **acct-port** keywords.

To define the AAA server group and associate a particular RADIUS server with it, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# radius server host {hostname ip-address} [auth-port port-number] [acct-port port-number] [timeout seconds] [retransmit retries] [key string]	<p>Specifies the IP address or hostname of the remote RADIUS server host.</p> <ul style="list-style-type: none"> • (Optional) For auth-port port-number, specify the UDP destination port for authentication requests. • (Optional) For acct-port port-number, specify the UDP destination port for accounting requests. • (Optional) For timeout seconds, specify the time interval that the switch waits for the RADIUS server to reply before resending. The range is 1 to 1000. This setting overrides the radius-server timeout global configuration command setting. If no timeout is set with the radius server host command, the setting of the radius-server timeout command is used. • (Optional) For retransmit retries, specify the number of times a RADIUS request is resent to a server if that server is not responding or responding slowly. The range is 1 to 1000. If no retransmit value is set with the radius server host command, the setting of the radius-server retransmit global configuration command is used. • (Optional) For key string, specify the authentication and encryption key used between the switch and the RADIUS daemon running on the RADIUS server. <p>Note The key is a text string that must match the encryption key used on the RADIUS server. Always configure the key as the last item in the radius server host command. Leading spaces are ignored, but spaces within and at the end of the key are used. If you use spaces in your key, do not enclose the key in quotation marks unless the quotation marks are part of the key.</p> <p>To configure the switch to recognize more than one host entry associated with a single IP address, enter this command as many times as necessary, making sure that each UDP port number is different. The switch software searches for hosts in the order in which you specify them. Set the timeout, retransmit, and encryption key values to use with the specific RADIUS host.</p>
Step 3	Switch(config)# aaa new-model	Enables AAA.
Step 4	Switch(config)# aaa group server radius group-name	<p>Defines the AAA server-group with a group name.</p> <p>This command puts the switch in a server group configuration mode.</p>
Step 5	Switch(config)# server ip-address	<p>Associates a particular RADIUS server with the defined server group. Repeat this step for each RADIUS server in the AAA server group.</p> <p>Each server in the group must be previously defined in Step 2.</p>
Step 6	Switch(config)# end	Returns to privileged EXEC mode.
Step 7	Switch# show running-config	Verifies your entries.

	Command	Purpose
Step 8	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.
Step 9		Enables RADIUS login authentication. See the “Configuring RADIUS Login Authentication” section on page 49-107.

To remove the specified RADIUS server, use the **no radius server host** *hostname | ip-address* global configuration command. To remove a server group from the configuration list, use the **no aaa group server radius** *group-name* global configuration command. To remove the IP address of a RADIUS server, use the **no server ip-address** server group configuration command.

In this example, the switch is configured to recognize two different RADIUS group servers (*group1* and *group2*). Group1 has two different host entries on the same RADIUS server configured for the same services. The second host entry acts as a failover backup to the first entry.

```
Switch(config)# radius server host 172.20.0.1 auth-port 1000 acct-port 1001
Switch(config)# radius server host 172.10.0.1 auth-port 1645 acct-port 1646
Switch(config)# aaa new-model
Switch(config)# aaa group server radius group1
Switch(config-sg-radius)# server 172.20.0.1 auth-port 1000 acct-port 1001
Switch(config-sg-radius)# exit
Switch(config)# aaa group server radius group2
Switch(config-sg-radius)# server 172.20.0.1 auth-port 2000 acct-port 2001
Switch(config-sg-radius)# exit
```

Configuring RADIUS Authorization for User Privileged Access and Network Services

AAA authorization limits the services available to a user. When AAA authorization is enabled, the switch uses information retrieved from the user's profile, which is in the local user database or on the security server, to configure the user's session. The user is granted access to a requested service only if the information in the user profile allows it.

You can use the **aaa authorization** global configuration command with the **radius** keyword to set parameters that restrict a user's network access to privileged EXEC mode.

The **aaa authorization exec radius local** command sets these authorization parameters:

- Use RADIUS for privileged EXEC access authorization if authentication was performed by using RADIUS.
- Use the local database if authentication was not performed by using RADIUS.

Note

Authorization is bypassed for authenticated users who log in using the CLI even if authorization has been configured.

We recommend that you use the **aaa authorization network default group radius local** command to configure RADIUS authentications. Custom authorization method of RADIUS authentication is not supported.

To specify RADIUS authorization for privileged EXEC access and network services, perform this task:

■ Controlling Switch Access with RADIUS

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# aaa authorization network radius	Configures the switch for user RADIUS authorization for all network-related service requests.
Step 3	Switch(config)# aaa authorization exec radius	Configures the switch for user RADIUS authorization if the user has privileged EXEC access. The exec keyword might return user profile information (such as autocommand information).
Step 4	Switch(config)# end	Returns to privileged EXEC mode.
Step 5	Switch# show running-config	Verifies your entries.
Step 6	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To disable authorization, use the **no aaa authorization {network | exec} method1** global configuration command.

Starting RADIUS Accounting

The AAA accounting feature tracks the services that users are accessing and the amount of network resources that they are consuming. When AAA accounting is enabled, the switch reports user activity to the RADIUS security server in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server. This data can then be analyzed for network management, client billing, or auditing.

To enable RADIUS accounting for each Cisco IOS privilege level and for network services, perform these steps:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# aaa accounting network start-stop radius	Enables RADIUS accounting for all network-related service requests.
Step 3	Switch(config)# aaa accounting exec start-stop radius	Enables RADIUS accounting to send a start-record accounting notice at the beginning of a privileged EXEC process and a stop-record at the end.
Step 4	Switch(config)# end	Returns to privileged EXEC mode.
Step 5	Switch# show running-config	Verifies your entries.
Step 6	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To disable accounting, use the **no aaa accounting {network | exec} {start-stop} method1...** global configuration command.

Configuring Settings for All RADIUS Servers

To configure global communication settings between the switch and all RADIUS servers, perform these steps:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# radius-server key <i>string</i>	Specifies the shared secret text string used between the switch and all RADIUS servers. Note The key is a text string that must match the encryption key used on the RADIUS server. Leading spaces are ignored, but spaces within and at the end of the key are used. If you use spaces in your key, do not enclose the key in quotation marks unless the quotation marks are part of the key.
Step 3	Switch(config)# radius-server retransmit <i>retries</i>	Specifies the number of times the switch sends each RADIUS request to the server before giving up. The default is 3; the range 1 to 1000.
Step 4	Switch(config)# radius-server timeout <i>seconds</i>	Specifies the number of seconds a switch waits for a reply to a RADIUS request before resending the request. The default is 5 seconds; the range is 1 to 1000.
Step 5	Switch(config)# radius-server deadtime <i>minutes</i>	Specifies the number of minutes a RADIUS server, which is not responding to authentication requests, to be skipped, thus avoiding the wait for the request to timeout before trying the next configured server. The default is 0; the range is 1 to 1440 minutes.
Step 6	Switch(config)# end	Returns to privileged EXEC mode.
Step 7	Switch# show running-config	Verifies your settings.
Step 8	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To return to the default setting for the retransmit, timeout, and deadtime, use the **no** forms of these commands.

Configuring the Switch to Use Vendor-Specific RADIUS Attributes

The Internet Engineering Task Force (IETF) draft standard specifies a method for communicating vendor-specific information between the switch and the RADIUS server by using the vendor-specific attribute (attribute 26). Vendor-specific attributes (VSAs) allow vendors to support their own extended attributes not suitable for general use. The Cisco RADIUS implementation supports one vendor-specific option by using the format recommended in the specification. Cisco's vendor-ID is 9, and the supported option has vendor-type 1, which is named *cisco-avpair*. The value is a string with this format:

```
protocol : attribute sep value *
```

Protocol is a value of the Cisco protocol attribute for a particular type of authorization. *Attribute* and *value* are an appropriate attribute-value (AV) pair defined in the Cisco TACACS+ specification, and *sep* is = for mandatory attributes and is * for optional attributes. The full set of features available for TACACS+ authorization can then be used for RADIUS.

For example, this AV pair activates Cisco’s *multiple named ip address pools* feature during IP authorization (during PPP IPCP address assignment):

```
cisco-avpair= "ip:addr-pool=first"
```

This example shows how to provide a user logging in from a switch with immediate access to privileged EXEC commands:

```
cisco-avpair= "shell:priv-lvl=15"
```

This example shows how to specify an authorized VLAN in the RADIUS server database:

```
cisco-avpair= "tunnel-type(#64)=VLAN(13)"
cisco-avpair= "tunnel-medium-type(#65)=802 media(6)"
cisco-avpair= "tunnel-private-group-ID(#81)=vlanid"
```

This example shows how to apply an input ACL in ASCII format to an interface for the duration of this connection:

```
cisco-avpair= "ip:inacl#1=deny ip 10.10.10.10 0.0.255.255 20.20.20.20 255.255.0.0"
cisco-avpair= "ip:inacl#2=deny ip 10.10.10.10 0.0.255.255 any"
cisco-avpair= "mac:inacl#3=deny any any decnet-iv"
```

This example shows how to apply an output ACL in ASCII format to an interface for the duration of this connection:

```
cisco-avpair= "ip:outacl#2=deny ip 10.10.10.10 0.0.255.255 any"
```

Other vendors have their own unique vendor-IDs, options, and associated VSAs. For more information about vendor-IDs and VSAs, see RFC 2138, “Remote Authentication Dial-In User Service (RADIUS).”

To configure the switch to recognize and use VSAs, perform these steps:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# radius-server vsa send [accounting authentication]	Enables the switch to recognize and use VSAs as defined by RADIUS IETF attribute 26. <ul style="list-style-type: none"> • (Optional) Use the accounting keyword to limit the set of recognized vendor-specific attributes to only accounting attributes. • (Optional) Use the authentication keyword to limit the set of recognized vendor-specific attributes to only authentication attributes. If you enter this command without keywords, both accounting and authentication vendor-specific attributes are used.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show running-config	Verifies your settings.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Note

For a complete list of RADIUS attributes or more information about vendor-specific attribute 26, see the “RADIUS Attributes” appendix in the *Cisco IOS Security Configuration Guide, Release 12.2* from the Cisco.com page under **Documentation > Cisco IOS Software > 12.2 Mainline > Command References**.

Configuring the Switch for Vendor-Proprietary RADIUS Server Communication

Although an IETF draft standard for RADIUS specifies a method for communicating vendor-proprietary information between the switch and the RADIUS server, some vendors have extended the RADIUS attribute set in a unique way. Cisco IOS software supports a subset of vendor-proprietary RADIUS attributes.

As mentioned earlier, to configure RADIUS (whether vendor-proprietary or IETF draft-compliant), you must specify the host running the RADIUS server daemon and the secret text string it shares with the switch. You specify the RADIUS host and secret text string by using the **radius-server** global configuration commands.

To specify a vendor-proprietary RADIUS server host and a shared secret text string, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# radius server host {hostname ip-address} non-standard	Specifies the IP address or hostname of the remote RADIUS server host and identify that it is using a vendor-proprietary implementation of RADIUS.
Step 3	Switch(config)# radius-server key string	Specifies the shared secret text string used between the switch and the vendor-proprietary RADIUS server. The switch and the RADIUS server use this text string to encrypt passwords and exchange responses. Note The key is a text string that must match the encryption key used on the RADIUS server. Leading spaces are ignored, but spaces within and at the end of the key are used. If you use spaces in your key, do not enclose the key in quotation marks unless the quotation marks are part of the key.
Step 4	Switch(config)# end	Returns to privileged EXEC mode.
Step 5	Switch# show running-config	Verifies your settings.
Step 6	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To delete the vendor-proprietary RADIUS host, use the **no radius server host {hostname | ip-address} non-standard** global configuration command. To disable the key, use the **no radius-server key** global configuration command.

This example shows how to specify a vendor-proprietary RADIUS host and to use a secret key of *rad124* between the switch and the server:

```
Switch(config)# radius server host 172.20.30.15 nonstandard
Switch(config)# radius-server key rad124
```

Configuring CoA on the Switch

To configure CoA on a switch, perform these steps. This procedure is required.

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# aaa new-model	Enables AAA.
Step 3	Switch(config)# aaa server radius dynamic-author	Configures the switch as an authentication, authorization, and accounting (AAA) server to facilitate interaction with an external policy server.
Step 4	Switch(config-locsvr-da-radius)# client { <i>ip-address</i> <i>name</i> } [vrf <i>vrfname</i>] [server-key <i>string</i>]	Enters dynamic authorization local server configuration mode and specify a RADIUS client from which a device will accept CoA and disconnect requests.
Step 5	Switch(config-locsvr-da-radius)# server-key [0 7] <i>string</i>	Configures the RADIUS key to be shared between a device and RADIUS clients.
Step 6	Switch(config-locsvr-da-radius)# port <i>port-number</i>	Specifies the port on which a device listens for RADIUS requests from configured RADIUS clients.
Step 7	Switch(config-locsvr-da-radius)# auth-type { <i>any</i> <i>all</i> <i>session-key</i> }	Specifies the type of authorization the switch uses for RADIUS clients. The client must match all the configured attributes for authorization.
Step 8	Switch(config-locsvr-da-radius)# ignore session-key	(Optional) Configures the switch to ignore the session-key. For more information about the ignore command, see the Cisco IOS Intelligent Services Gateway Command Reference on Cisco.com.
Step 9	Switch(config-locsvr-da-radius)# ignore server-key	(Optional) Configures the switch to ignore the server-key. For more information about the ignore command, see the Cisco IOS Intelligent Services Gateway Command Reference on Cisco.com.
Step 10	Switch(config-locsvr-da-radius)# exit	Switches to global configuration mode.
Step 11	Switch(config)# authentication command bounce-port ignore	(Optional) Configures the switch to ignore a CoA request to temporarily disable the port hosting a session. The purpose of temporarily disabling the port is to trigger a DHCP renegotiation from the host when a VLAN change occurs and there is no supplicant on the endpoint to detect the change.
Step 12	Switch(config)# authentication command disable-port ignore	(Optional) Configures the switch to ignore a nonstandard command requesting that the port hosting a session be administratively shut down. Shutting down the port results in termination of the session. Use standard CLI or SNMP commands to re-enable the port.
Step 13	Switch# end	Returns to privileged EXEC mode.
Step 14	Switch# show running-config	Verifies your entries.
Step 15	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To disable AAA, use the **no aaa new-model** global configuration command. To disable the AAA server functionality on the switch, use the **no aaa server radius dynamic authorization** global configuration command:

```
Switch(config)# aaa server radius dynamic-author
Switch(config-locsvr-da-radius)# client ip addr vrf vrfname
Switch(config-locsvr-da-radius)# server-key cisco123
Switch(config-locsvr-da-radius)# port 3799
```

**Note**

Default port for packet of disconnect is 1700. Port 3799 is required to interoperate with ACS 5.1.

```
Switch(config)# authentication command bounce-port ignore
```

Monitoring and Troubleshooting CoA Functionality

The following Cisco IOS commands can be used to monitor and troubleshoot CoA functionality on the switch:

- **debug radius**
- **debug aaa coa**
- **debug aaa pod**
- **debug aaa subsys**
- **debug cmdhd [detail | error | events]**
- **show aaa attributes protocol radius**

Configuring RADIUS Server Load Balancing

This feature allows access and authentication requests to be evenly across all RADIUS servers in a server group. For more information, see the *RADIUS Server Load Balancing* chapter of the *Cisco IOS Security Configuration Guide*, Release 12.2:

http://www.ciscosystems.com/en/US/docs/ios/12_2sb/feature/guide/sbrldbl.html

Displaying the RADIUS Configuration

To display the RADIUS configuration, use the **show running-config** privileged EXEC command.

Configuring Device Sensor

This section includes the following:

- [About Device Sensor, page 49-118](#)
- [MSP-IOS Sensor Device Classifier Interaction, page 49-119](#)
- [Configuring Device Sensor, page 49-119](#)
- [Configuration Examples for the Device Sensor Feature, page 49-125](#)

About Device Sensor

Device Sensor uses protocols such as Cisco Discovery Protocol (CDP), Link Layer Discovery Protocol (LLDP), and DHCP to obtain endpoint information from network devices and make this information available to its clients. Device Sensor has internal clients, such as the embedded Device Classifier (local analyzer), Auto Smartports (ASP), MediaNet Service Interface Media Services Proxy, and EnergyWise. Device Sensor also has an external client, Identity Services Engine (ISE), which uses RADIUS accounting to receive and analyze endpoint data. When integrated with ISE, Device Sensor provides central policy management and device-profiling capabilities.

Note

Cisco Identity Services Engine (ISE) based profiling is not supported on the LAN Base image.

Device profiling capability consists of two parts:

- Collector--Gathers endpoint data from network devices.
- Analyzer--Processes the data and determines the type of device.

For more information on device profiling, see the “Configuring Endpoint Profiling Policies” chapter in the *Cisco Identity Services Engine User Guide* at this URL:

http://www.cisco.com/en/US/docs/security/ise/1.1/user_guide/ise_prof_pol.html

Device Sensor represents the embedded collector functionality. Figure 22 shows a Device Sensor in the context of its internal clients and the ISE.

Figure 22 **Device Sensor and Clients**

Client notifications and accounting messages that contain profiling data and other session-related data are generated and sent to the internal clients and the ISE. By default, client notifications and accounting events are generated only when an incoming packet includes a Type-Length-Value (TLV) that has not previously been received within a given access session. You can enable client notifications and accounting events for TLV changes; that is, when a previously received TLV is received with a different value.

Device Sensor port security protects a switch from consuming memory and crashing during deliberate or unintentional denial-of-service (DoS)-type attacks. Device Sensor limits the maximum number of device monitoring sessions to 32 per port. While hosts are inactive, the age session limit is 12 hours.

MSP-IOS Sensor Device Classifier Interaction

Note

To enable MSP, you must configure the **profile flow** command. Once done, when SIP, H323, or mDNS traffic are present, appropriate (SIP, H323, or mDNS) TLV notifications are sent to the IOS sensor.

MSP (Media Service Proxy) offers bandwidth reservation for audio or video flows and Metadata services to 3rd-party endpoints. To offer and install Media services, MSP must identify flow attributes and device details. MSP device identification requires automatic identification of various media end points in the network, thereby avoiding any change to the installed end point base. To offer MSP device discovery services, MSP leverages current IOS sensor capability for device classification. (Starting with Release IOS XE 3.3.0SG and IOS 15.1(1)SG, IOS sensor can be used to perform device identification. MSP uses the same functionality with the addition of SIP, H323, and Multicast DNS (mDNS) protocols.) Starting with Release IOS XE 3.4.0SG and IOS 15.1(2)SG, MSP offers Media services to two kinds of media endpoints: IP Surveillance Cameras and Video-Conferencing Endpoints. Surveillance cameras are identified using mDNS protocol whereas Video-conference-Endpoints are identified using SIP and H.323 protocols.

mDNS compatible devices (Axis, Pelco cameras etc) send mDNS messages for DNS service discovery to a multicast IP address (224.0.0.251) on a standard mDNS port 5353. The mDNS client module listens to this UDP port, receives the mDNS message, and sends it in TLV format to the mDNS IOS sensor shim for further device classification. The module parses the mDNS query and Answer messages fields to create these TLVs.

A Session Initiation Protocol (SIP) registration message is used for SIP based device-discovery and is sent to Cisco Call manager by the SIP Client. A H.225 RAS client registration message is used for H323-based device discovery.

If no Cisco Unified Communicator Manager or GateKeeper exists in the topology, the Endpoint will not generate device Register messages. To handle device discovery in these scenarios, MSP expects the endpoint to make a SIP or H323 call so that MSP snoops the SIP invite or the H323 setup message to identify endpoint details and notify the IOS sensor.

After the IOS sensor receives these protocol details from MSP, the IOS sensor prepares Normalized TLVs, with the new protocols. These protocol details are sent to session manager for further classification.

Configuring Device Sensor

Device Sensor is enabled by default. Complete the following tasks when you want Device Sensor to include or exclude a list of TLVs (termed filter lists) for a particular protocol.

Note

If you do not perform any Device Sensor configuration tasks, the following TLVs are included by default:

- CDP filter--secondport-status-type and powernet-event-type (types 28 and 29)
- LLDP filter--organizationally-specific (type 127)
- DHCP filter--message-type (type 53)

- [Troubleshooting Commands, page 49-125](#)
- [Restrictions for Device Sensor, page 49-125](#)

Enabling MSP

You must configure the MSP **profile flow** command to activate the MSP platform Packet parser. This is because the MSP device handler is tightly coupled with MSP flow parser. Not enabling this command means that MSP will not send SIP, H323 notifications to the IOS sensor.

To enable MSP, follow these steps, beginning in privileged EXEC mode:

	Command	Purpose
Step 1	configure terminal Switch# configure terminal	Enters global configuration mode.
Step 2	profile flow Switch(config)# profile flow	Enables MSP.
Step 3	end Switch(config)# end	Returns to privileged EXEC mode.

Use the **no** form of the profile flow command to disable MSP.

Enabling Accounting Augmentation

For the Device Sensor protocol data to be added to accounting messages, you must first enable session accounting by using the following standard Authentication, Authorization, and Accounting (AAA) and RADIUS configuration commands:

```
Switch(config)# aaa new-model
Switch(config)# aaa accounting dot1x default start-stop group radius
```

```
Switch(config)# radius server host{hostname|ip-address}[auth-port
port-number][acct-port port-number] [timeout seconds][retransmit retries][key string]
Switch(config)# radius-server vsa send accounting
```

To add Device Sensor protocol data to accounting records, follow these steps, beginning in privileged EXEC mode:

	Command	Purpose
Step 1	configure terminal Switch# configure terminal	Enters global configuration mode.
Step 2	device-sensor accounting Switch(config)# device-sensor accounting	Enables the addition of sensor protocol data to accounting records and also enables the generation of additional accounting events when new sensor data is detected.
Step 3	end Switch(config)# end	Returns to privileged EXEC mode.

Creating a Cisco Discovery Protocol Filter

To create a CDP filter containing a list of TLVs that can be included or excluded in the Device Sensor output, follow these steps, beginning in privileged EXEC mode:

	Command	Purpose
Step 1	configure terminal Switch# configure terminal	Enters global configuration mode.
Step 2	device-sensor filter-list cdp list tlv-list-name Switch(config)# device-sensor filter-list cdp list cdp-list	Creates a TLV list and enters CDP sensor configuration mode, where you can configure individual TLVs.
Step 3	tlv {name tlv-name number tlv-number} Switch(config-sensor-cdplist)# tlv number 10	Adds individual CDP TLVs to the TLV list. You can delete the TLV list without individually removing TLVs from the list by using the no device-sensor filter-list cdp list tlv-list-name command.
Step 4	end Switch(config-sensor-cdplist)# end	Returns to privileged EXEC mode.

Creating an LLDP Filter

To create an LLDP filter containing a list of TLVs that can be included or excluded in the Device Sensor output, follow these steps, beginning in privileged EXEC mode:

	Command	Purpose
Step 1	configure terminal Switch# configure terminal	Enters global configuration mode.
Step 2	device-sensor filter-list lldp list tlv-list-name Switch(config)# device-sensor filter-list lldp list lldp-list	Creates a TLV list and enters LLDP sensor configuration mode, where you can configure individual TLVs.
Step 3	tlv {name tlv-name number tlv-number} Switch(config-sensor-cdplist)# tlv number 10	Adds individual LLDP TLVs to the TLV list. You can delete the TLV list without individually removing TLVs from the list by using the no device-sensor filter-list lldp list tlv-list-name command.
Step 4	end Switch(config-sensor-llldplist)# end	Returns to privileged EXEC mode.

Creating a DHCP Filter

To create a DHCP filter containing a list of DHCP options that can be included or excluded in the Device Sensor output, follow these steps, beginning in privileged EXEC mode:

	Command	Purpose
Step 1	configure terminal Switch# configure terminal	Enters global configuration mode.
Step 2	device-sensor filter-list dhcp list option-list-name Switch(config)# device-sensor filter-list dhcp list dhcp-list	Creates an options list and enters DHCP sensor configuration mode, where you can specify individual DHCP options.
Step 3	option {name option-name number option-number} Switch(config-sensor-dhcplist)# option number 50	Adds individual DHCP options to the option list. You can delete the entire option list without removing options individually from the list by using the no device-sensor filter-list dhcp list option-list-name command.
Step 4	end Switch(config)# end	Returns to privileged EXEC mode.

Applying a Protocol Filter to the Device Sensor Output

Beginning in privileged EXEC mode, follow these steps to apply a CDP, LLDP, or DHCP filter to the sensor output. The output is session notifications to internal sensor clients and accounting requests to the RADIUS server.

Note

Only one filter list can be included or excluded at a time.

	Command	Purpose
Step 1	configure terminal Switch# configure terminal	Enters global configuration mode.
Step 2	device-sensor filter-spec {cdp dhcp lldp} {exclude {all list list-name} include list list-name} Switch(config)# device-sensor filter-spec cdp include list list1	Applies a specific protocol filter containing a list of protocol TLV fields or DHCP options to the Device Sensor output. <ul style="list-style-type: none"> • cdp--Applies a CDP TLV filter list to the device sensor output. • lldp--Applies an LLDP TLV filter list to the device sensor output. • dhcp--Applies a DHCP option filter list to the device sensor output. • exclude--Specifies the TLVs that must be excluded from the device sensor output. • include--Specifies the TLVs that must be included from the device sensor output. • all--Disables all notifications for the associated protocol. • list list-name--Specifies the protocol TLV filter list name.
Step 3	end Switch(config)# end	Returns to privileged EXEC mode.

Tracking TLV Changes

By default, client notifications and accounting events are generated only when an incoming packet includes a TLV that has not previously been received within a given session.

To enable client notifications and accounting events for TLV changes, follow these steps, beginning in privileged EXEC mode:

	Command	Purpose
Step 1	configure terminal Switch# configure terminal	Enters global configuration mode.
Step 2	device-sensor notify all-changes Switch(config)# device-sensor notify all-changes	Enables client notifications and accounting events for all TLV changes, that is, where either a new TLV is received or a previously received TLV is received with a new value in the context of a given session. Note Use the default device-sensor notify or the device-sensor notify new-tlvs command to return to the default TLV.
Step 3	end Switch(config)# end	Returns to privileged EXEC mode.

Verifying the Device Sensor Configuration

To verify the sensor cache entries for all devices, follow these steps, beginning in privileged EXEC mode:

	Command	Purpose
Step 1	show device-sensor cache mac <i>mac-address</i>	Displays sensor cache entries (the list of protocol TLVs or options received from a device) for a specific device. <ul style="list-style-type: none"> mac-address is the MAC address of the endpoint
Step 2	show device-sensor cache all Switch(config)# device-sensor notify all-changes	Displays sensor cache entries for all devices.

This is an example of the **show device-sensor cache mac mac-address** privileged EXEC command output:

```
Switch# show device-sensor cache mac 0024.14dc.df4d

Device: 0024.14dc.df4d on port GigabitEthernet1/0/24
-----
Proto Type:Name                               Len Value
cdp    26:power-available-type                 16 00 1A 00 10 00 00 00 01 00 00 00 00 FF FF FF FF

```

Troubleshooting Commands

The following commands can help troubleshoot Device Sensor.

- **debug device-sensor {errors | events}**
- **debug authentication all**

Restrictions for Device Sensor

- Only CDP, LLDP, and DHCP protocols are supported.
- The session limit for profiling ports is 32.
- The length of one TLV must not be more than 1024 and the total length of TLVs (combined length of TLVs) of all protocols must not be more than 4096.
- Device Sensor profiles devices that are only one hop away.

Configuration Examples for the Device Sensor Feature

The following example shows how to create a CDP filter containing a list of TLVs:

```
Switch> enable
Switch# configure terminal
Switch(config)# device-sensor filter-list cdp list cdp-list
Switch(config-sensor-cdplist)# tlv name address-type
Switch(config-sensor-cdplist)# tlv name device-name
Switch(config-sensor-cdplist)# tlv number 34
Switch(config-sensor-cdplist)# end
```

The following example shows how to create an LLDP filter containing a list of TLVs:

```
Switch> enable
Switch# configure terminal
Switch(config)# device-sensor filter-list lldp list lldp-list
Switch(config-sensor-llldplist)# tlv name chassis-id
Switch(config-sensor-llldplist)# tlv name management-address
Switch(config-sensor-llldplist)# tlv number 28
Switch(config-sensor-llldplist)# end
```

The following example shows how to create a DHCP filter containing a list of options:

```
Switch> enable
Switch# configure terminal
Switch(config)# device-sensor filter-list dhcp list dhcp-list
Switch(config)# device-sensor filter-list dhcp list dhcp-list
Switch(config-sensor-dhcplist)# option name domain-name
Switch(config-sensor-dhcplist)# option name host-name
Switch(config-sensor-dhcplist)# option number 50
Switch(config-sensor-dhcplist)# end
```

The following example shows how to apply a CDP TLV filter list to the Device Sensor output:

```
Switch> enable
Switch# configure terminal
Switch(config)# device-sensor filter-spec cdp include cdp-list1
```

The following example shows how to enable client notifications and accounting events for all TLV changes:

```
Switch> enable
Switch# configure terminal
Switch(config)# device-sensor notify all-changes
```

Displaying 802.1X Statistics and Status

To display 802.1X statistics for all interfaces, use the **show dot1x all statistics** privileged EXEC command.

To display the 802.1X administrative and operational status for the switch, use the **show dot1x all details** privileged EXEC command. To display the 802.1X administrative and operational status for a specific interface, use the **show dot1x interface details** privileged EXEC command.

Displaying Authentication Details

This section includes these topics:

- [Determining the Authentication Methods Registered with the Auth Manager, page 49-126](#)
- [Displaying the Auth Manager Summary for an Interface, page 49-127](#)
- [Displaying the Summary of All Auth Manager Sessions on the Switch, page 49-127](#)
- [Displaying a Summary of All Auth Manager Sessions on the Switch Authorized for a Specified Authentication Method, page 49-127](#)
- [Verifying the Auth Manager Session for an Interface, page 49-127](#)
- [Displaying MAB Details, page 49-129](#)
- [EPM Logging, page 49-130](#)

Determining the Authentication Methods Registered with the Auth Manager

This example show how to display the registered authentication methods:

Enter the following:

```
Switch# show authentication registrations
Handle Priority Name
      3         0 dot1x
      2         1 mab
      1         2 webauth
```

Displaying the Auth Manager Summary for an Interface

In the following example, MAB was configured for a higher priority (lower value) than 802.1X:

```
Switch# show authentication int gi1/5
Client list:
Interface  MAC Address      Method  Domain  Status      Session ID
Gi1/5      000f.23c4.a401    mab     DATA   Authz Success 0A3462B10000000D24F80B58
Gi1/5      0014.bf5d.d26d    dot1x   DATA   Authz Success 0A3462B10000000E29811B94

Available methods list:
Handle  Priority  Name
3       0        dot1x
2       1        mab

Runnable methods list:
Handle  Priority  Name
2       0        mab
3       1        dot1x
```

Displaying the Summary of All Auth Manager Sessions on the Switch

This example shows how to display the summary of all sessions:

```
Switch# show authentication sessions
Interface  MAC Address      Method  Domain  Status      Session ID
Gi1/48     0015.63b0.f676   dot1x   DATA   Authz Success 0A3462B1000000102983C05C
Gi1/5      000f.23c4.a401   mab     DATA   Authz Success 0A3462B10000000D24F80B58
Gi1/5      0014.bf5d.d26d   dot1x   DATA   Authz Success 0A3462B10000000E29811B94
```

Displaying a Summary of All Auth Manager Sessions on the Switch Authorized for a Specified Authentication Method

This example shows how to display a summary of all sessions for a specific authentication method:

```
Switch# show authentication method dot1x
Interface  MAC Address      Method  Domain  Status      Session ID
Gi1/48     0015.63b0.f676   dot1x   DATA   Authz Success 0A3462B1000000102983C05C
Gi1/5      0014.bf5d.d26d   dot1x   DATA   Authz Success 0A3462B10000000E29811B94
```

Verifying the Auth Manager Session for an Interface

The Auth manage session can be verified by using the **show authentication sessions** command:

```
Switch# show authentication sessions int gi1/5
Interface: GigabitEthernet1/5
MAC Address: 000f.23c4.a401
IP Address: Unknown
User-Name: 000f23c4a401
Status: Authz Success
Domain: DATA
Oper host mode: multi-auth
Oper control dir: both
Authorized By: Authentication Server
```

```

Vlan Policy: N/A
Session timeout: N/A
Idle timeout: N/A
Common Session ID: 0A3462B10000000D24F80B58
Acct Session ID: 0x0000000F
Handle: 0x2400000D
Runnable methods list:
Method State
dot1x Failed over
mab Authc Success
-----
Interface: GigabitEthernet1/5
MAC Address: 0014.bf5d.d26d
IP Address: 20.0.0.7
User-Name: johndoe
Status: Authz Success
Domain: DATA
Oper host mode: multi-auth
Oper control dir: both
Authorized By: Authentication Server
Vlan Policy: N/A
Session timeout: N/A
Idle timeout: N/A
Common Session ID: 0A3462B10000000E29811B94
Acct Session ID: 0x00000010
Handle: 0x1100000E
Runnable methods list:
Method State
dot1x Authc Success
mab Not run

```

The individual output can be further refined by using the **handle**, **interface**, **MAC**, **session-id**, or **method** keywords:

```

Switch# show authentication sessions mac 000f.23c4.a401
Interface: GigabitEthernet1/5
MAC Address: 000f.23c4.a401
IP Address: Unknown
User-Name: 000f23c4a401
Status: Authz Success
Domain: DATA
Oper host mode: multi-auth
Oper control dir: both
Authorized By: Authentication Server
Vlan Policy: N/A
Session timeout: N/A
Idle timeout: N/A
Common Session ID: 0A3462B10000000D24F80B58
Acct Session ID: 0x0000000F
Handle: 0x2400000D
Runnable methods list:
Method State
dot1x Failed over
mab Authc Success

Switch# show authentication sessions session-id 0A3462B10000000D24F80B58
Interface: GigabitEthernet1/5
MAC Address: 000f.23c4.a401
IP Address: Unknown
User-Name: 000f23c4a401

```

```

Status: Authz Success
Domain: DATA
Oper host mode: multi-auth
Oper control dir: both
Authorized By: Authentication Server
Vlan Policy: N/A
Session timeout: N/A
Idle timeout: N/A
Common Session ID: 0A3462B10000000D24F80B58
Acct Session ID: 0x0000000F
Handle: 0x2400000D
Runnable methods list:
Method State
dot1x Failed over
mab uthc Success

Switch# show authentication session method dot1x int gi1/5
Interface: GigabitEthernet1/5
MAC Address: 0014.bf5d.d26d
IP Address: 20.0.0.7
User-Name: johndoe
Status: Authz Success
Domain: DATA
Oper host mode: multi-auth
Oper control dir: both
Authorized By: Authentication Server
Vlan Policy: N/A
Session timeout: N/A

mab Not run

```

Displaying MAB Details

The following commands display these details:

```

Switch# show mab all
MAB details for FastEthernet5/9
-----
Mac-Auth-Bypass           = Enabled
Inactivity Timeout        = None

Switch# show mab all detail
MAB details for FastEthernet5/9
-----
Mac-Auth-Bypass           = Enabled
Inactivity Timeout        = None
MAB Client List
-----
Client MAC                 = 000f.23c4.a401
MAB SM state               = TERMINATE
Auth Status                = AUTHORIZED

```

```

Switch# show mab int fa5/9
MAB details for FastEthernet5/9
-----
Mac-Auth-Bypass           = Enabled
Inactivity Timeout        = None

Switch# show mab int fa5/9 detail
MAB details for FastEthernet5/9
-----
Mac-Auth-Bypass           = Enabled
Inactivity Timeout        = None
MAB Client List
-----
Client MAC                 = 000f.23c4.a401
MAB SM state               = TERMINATE
Auth Status                = AUTHORIZED

```

EPM Logging

EPM logging enables you to display EPM logging messages by using the **epm logging** command in global configuration mode. To disable EPM logging, enter **no epm logging**.

Logging messages are displayed during the following events:

- **POLICY_APP_SUCCESS**—Policy application success events on Named ACLs, Proxy ACLs, and service policies, URL redirect policies.
- **POLICY_APP_FAILURE**—Policy application failure conditions similar to unconfigured policies, wrong policies, download request failures and download failures from AAA.
- **IPEVENT**—IP assignment, IP release and IP wait events for clients.
- **AAA**—AAA events (similar to download requests, or download successes from AAA)

Example 1

```

Switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# epm logging
Switch# clear dot1x all
Switch#
*May 15 08:31:26.561: %EPM-6-POLICY_REQ: IP=100.0.0.222| MAC=0000.0000.0001|
AUDITSEID=0A050B2C000000030004956C| AUTHTYPE=DOT1X|
EVENT=REMOVE
*May 15 08:31:26.581: %AUTHMGR-5-START: Starting 'dot1x' for client (0000.0000.0001) on
Interface Fa9/25
*May 15 08:31:26.681: %DOT1X-5-SUCCESS: Authentication successful for client
(0000.0000.0001) on Interface Fa9/25
*May 15 08:31:26.681: %AUTHMGR-7-RESULT: Authentication result 'success' from 'dot1x' for
client (0000.0000.0001) on Interface Fa9/25

```

Example 2

```
Switch# conf terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# epm logging
Switch(config)# int f9/25
Switch(config-if)# shut
Switch(config-if)# no shut
*May 15 08:41:56.329: %EPM-6-IPEVENT: IP=100.0.0.222| MAC=0000.0000.0001|

EVENT=IP-RELEASE
*May 15 08:41:56.333: %EPM-6-IPEVENT: IP=100.0.0.222| MAC=0000.0000.0001|
AUDITSESID=0A050B2C0000026108FB7924| AUTHTYPE=DOT1X|
EVENT=IP-WAIT
```

Cisco IOS Security Features

This document provides a list of security software features that are supported in Cisco IOS XE 3.1.0SG. Links to the feature documentation are included.

Feature guides may contain information about more than one feature. To find information about a specific feature within a feature guide, see the Feature Information table at the end of the guide.

Feature guides document features that are supported on many different software releases and platforms. Your Cisco software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release. Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

X.509v3 Certificates for SSH Authentication

The X.509v3 Certificates for SSH Authentication feature uses public key algorithm (PKI) for server and user authentication, and allows the Secure Shell (SSH) protocol to verify the identity of the owner of a key pair via digital certificates, signed and issued by a Certificate Authority (CA).

This module describes how to configure server and user certificate profiles for a digital certificate.

This module describes the feature and consists of these sections:

- [Prerequisites for X.509v3 Certificates for SSH Authentication, page 50-1](#)
- [Restrictions for X.509v3 Certificates for SSH Authentication, page 50-2](#)
- [Information About X.509v3 Certificates for SSH Authentication, page 50-2](#)
- [How to Configure X.509v3 Certificates for SSH Authentication, page 50-3](#)
- [Configuration Examples for X.509v3 Certificates for SSH Authentication, page 50-5](#)
- [Verifying Server and User Authentication Using Digital Certificates, page 50-6](#)
- [Additional References for X.509v3 Certificates for SSH Authentication, page 50-9](#)
- [Feature Information for X.509v3 Certificates for SSH Authentication, page 50-11](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Prerequisites for X.509v3 Certificates for SSH Authentication

The X.509v3 Certificates for SSH Authentication feature replaces the **ip ssh server authenticate user** command with the **ip ssh server algorithm authentication** command. Configure the **default ip ssh server authenticate user** command to remove the **ip ssh server authenticate user** command from the configuration. The IOS secure shell (SSH) server will start using the **ip ssh server algorithm authentication** command.

When you configure the **ip ssh server authenticate user** command, the following message is displayed: “SSH command accepted; but this CLI will be deprecated soon. Please move to new CLI **ip ssh server algorithm authentication**. Please configure the “**default ip ssh server authenticate user**” to make the CLI ineffective.”

Restrictions for X.509v3 Certificates for SSH Authentication

- The X.509v3 Certificates for SSH Authentication feature implementation is applicable only on the Cisco IOS Secure Shell (SSH) server side.
- The Cisco IOS SSH server supports only the x509v3-ssh-rsa algorithm-based certificate for server and user authentication.
- The Rivest, Shamir, and Adelman (RSA) 2-factor authentication on Catalyst 4506 SUP7L-E switches and Cisco Identity Services Engine (ISE) does not work correctly, when a user enters the incorrect password. Normal authentication and interworking with Cisco Adaptive Security Appliance (ASA) works fine. Configure the **ip ssh server algorithm authentication keyboard** command for the authentication to work.

Information About X.509v3 Certificates for SSH Authentication

- [X.509v3 Certificates for SSH Authentication Overview, page 50-2](#)
- [Server and User Authentication Using X.509v3, page 50-2](#)
- [OCSP Response Stapling, page 50-3](#)

X.509v3 Certificates for SSH Authentication Overview

The Secure Shell (SSH) protocol provides a secure remote access connection to network devices. The communication between the client and server is encrypted.

There are two SSH protocols that use public key cryptography for authentication. The Transport Layer Protocol, uses a digital signature algorithm (called the public key algorithm) to authenticate the server to the client. And the User Authentication Protocol uses a digital signature to authenticate (public key authentication) the client to the server.

The validity of the authentication depends upon the strength of the linkage between the public signing key and the identity of the signer. Digital certificates, such as those in X.509 Version 3 (X.509v3), are used to provide identity management. X.509v3 uses a chain of signatures by a trusted root certification authority and intermediate certificate authorities to bind a public signing key to a specific digital identity. This implementation allows the use of a public key algorithm for server and user authentication, and allows SSH to verify the identity of the owner of a key pair via digital certificates, signed and issued by a Certificate Authority (CA).

Server and User Authentication Using X.509v3

For server authentication, the Secure shell (SSH) server sends its own certificate to the SSH client for verification. This server certificate is associated with the trustpoint configured in the server certificate profile (ssh-server-cert-profile-server configuration mode).

For user authentication, the SSH client sends the user's certificate to the IOS SSH server for verification. The SSH server validates the incoming user certificate using public key infrastructure (PKI) trustpoints configured in the server certificate profile (ssh-server-cert-profile-user configuration mode).

By default, certificate-based authentication is enabled for server and user at the IOS SSH server end.

OCSP Response Stapling

The Online Certificate Status Protocol (OCSP) enables applications to determine the (revocation) state of an identified certificate. This protocol specifies the data that needs to be exchanged between an application checking the status of a certificate and the server providing that status. An OCSP client issues a status request to an OCSP responder and suspends acceptance of the certificate until a response is received. An OCSP response at a minimum consists of a responseStatus field that indicates the processing status of the a request.

For the public key algorithms, the key format consists of a sequence of one or more X.509v3 certificates followed by a sequence of zero or more OCSP responses.

The X.509v3 Certificate for SSH Authentication feature uses OCSP Response Stapling. By using OCSP response stapling, a device obtains the revocation information of its own certificate by contacting the OCSP server and then stapling the result along with its certificates and sending the information to the peer rather than having the peer contact the OCSP responder.

How to Configure X.509v3 Certificates for SSH Authentication

- [Configuring Digital Certificates for Server Authentication, page 50-3](#)
- [Configuring Digital Certificates for User Authentication, page 50-4](#)

Configuring Digital Certificates for Server Authentication

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# ip ssh server algorithm hostkey {x509v3-ssh-rsa [ssh-rsa] ssh-rsa [x509v3-ssh-rsa]}	Defines the order of host key algorithms. Only the configured algorithm is negotiated with the Secure Shell (SSH) client. <div>  <p>Note The IOS SSH server must have at least one configured host key algorithm.</p> </div> <ul style="list-style-type: none"> • x509v3-ssh-rsa—certificate-based authentication • ssh-rsa—public key-based authentication
Step 4	Switch(config)# ip ssh server certificate profile	Configures server and user certificate profiles and enters SSH certificate profile configuration mode.
Step 5	Switch(ssh-server-cert-profile)# server	Configures server certificate profile and enters SSH server certificate profile server configuration mode. <ul style="list-style-type: none"> • The server profile is used to send out the certificate of the server to the SSH client during server authentication.

	Command or Action	Purpose
Step 6	Switch(ssh-server-cert-profile-server)# trustpoint sign <i>PKI-trustpoint-name</i>	Attaches the public key infrastructure (PKI) trustpoint to the server certificate profile. <ul style="list-style-type: none"> The SSH server uses the certificate associated with this PKI trustpoint for server authentication.
Step 7	Switch(ssh-server-cert-profile-server)# ocsp-response include	(Optional) Sends the Online Certificate Status Protocol (OCSP) response or OCSP stapling along with the server certificate. <div>  <p>Note By default, no OCSP response is sent along with the server certificate.</p> </div>
Step 8	Switch(ssh-server-cert-profile-server)# end	Exits SSH server certificate profile server configuration mode and returns to privileged EXEC mode.
Step 9	Switch(config)# line vty <i>line_number</i> <i>[ending_line_number]</i>	Enters line configuration mode to configure the virtual terminal line settings. For <i>line_number</i> and <i>ending_line_number</i> , specify a pair of lines. The range is 0 to 15.
Step 10	Switch(config-line)# transport input ssh	Specifies that the Switch prevent non-SSH Telnet connections. This limits the router to only SSH connections.

Configuring Digital Certificates for User Authentication

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# ip ssh server algorithm authentication { publickey keyboard password }	Defines the order of host key algorithms. Only the configured algorithm is negotiated with the Secure Shell (SSH) client. <div>  <p>Note The IOS SSH server must have at least one configured host key algorithm.</p> </div> <ul style="list-style-type: none"> To use the certificate method for user authentication, the publickey keyword must be configured.
Step 4	Switch(config)# ip ssh server algorithm publickey { x509v3-ssh-rsa [ssh-rsa] ssh-rsa [x509v3-ssh-rsa]}	Defines the order of public key algorithms. Only the configured algorithm is accepted by the SSH client for user authentication. <div>  <p>Note The IOS SSH client must have at least one configured public key algorithm.</p> </div> <ul style="list-style-type: none"> x509v3-ssh-rsa—Certificate-based authentication ssh-rsa—Public-key-based authentication

	Command or Action	Purpose
Step 5	Switch(config)# ip ssh server certificate profile	Configures server certificate profile and user certificate profile and enters SSH certificate profile configuration mode.
Step 6	Switch(ssh-server-cert-profile)# user	Configures user certificate profile and enters SSH server certificate profile user configuration mode.
Step 7	Switch(ssh-server-cert-profile-user)# trustpoint sign <i>PKI-trustpoint-name</i>	Configures the public key infrastructure (PKI) trustpoint that is used to verify the incoming user certificate. <div>  Note </div> Configure multiple trustpoints by executing the same command multiple times. A maximum of 10 trustpoints can be configured.
Step 8	Switch(ssh-server-cert-profile-user)# ocsp-response include	(Optional) Sends the Online Certificate Status Protocol (OCSP) response or OCSP stapling along with the server certificate. <div>  Note </div> By default, no OCSP response is sent along with the server certificate.
Step 9	Switch(ssh-server-cert-profile-user)# end	Exits SSH server certificate profile user configuration mode and returns to privileged EXEC mode.
Step 10	Switch(config)# line vty <i>line_number</i> [<i>ending_line_number</i>]	Enters line configuration mode to configure the virtual terminal line settings. For line_number and ending_line_number, specify a pair of lines. The range is 0 to 15.
Step 11	Switch(config-line)# transport input ssh	Specifies that the Switch prevent non-SSH Telnet connections. This limits the router to only SSH connections.

Configuration Examples for X.509v3 Certificates for SSH Authentication

- [Example: Configuring Digital Certificates for Server Authentication, page 50-5](#)
- [Example: Configuring Digital Certificate for User Authentication, page 50-5](#)

Example: Configuring Digital Certificates for Server Authentication

```
Switch> enable
Switch# configure terminal
Switch(config)# ip ssh server algorithm hostkey x509v3-ssh-rsa
Switch(config)# ip ssh server certificate profile
Switch(ssh-server-cert-profile)# server
Switch(ssh-server-cert-profile-server)# trustpoint sign trust1
Switch(ssh-server-cert-profile-server)# exit
```

Example: Configuring Digital Certificate for User Authentication

```
Switch> enable
```

```
Switch# configure terminal
Switch(config)# ip ssh server algorithm authentication publickey
Switch(config)# ip ssh server algorithm publickey x509v3-ssh-rsa
Switch(config)# ip ssh server certificate profile
Switch(ssh-server-cert-profile)# user
Switch(ssh-server-cert-profile-user)# trustpoint verify trust2
Switch(ssh-server-cert-profile-user)# end
```

Verifying Server and User Authentication Using Digital Certificates

Displays the currently configured authentication methods. To confirm the use of certificate-based authentication, ensure that the x509v3-ssh-rsa algorithm is the configured host key algorithm.

```
Switch# show ip ssh
```

```
SSH Enabled - version 1.99
Authentication methods:publickey,keyboard-interactive,password
Authentication Publickey Algorithms:x509v3-ssh-rsa,ssh-rsa
Hostkey Algorithms:x509v3-ssh-rsa,ssh-rsa
Authentication timeout: 120 secs; Authentication retries: 3
Minimum expected Diffie Hellman key size : 1024 bits
```

Use the **debug ip ssh detail** and **debug ip packet** debug commands to debug the SSH authentication using x.509v3 Certificates.

The following example shows the sample output for the **debug ip ssh detail** command:

```
Switch#debug ip ssh detail
ssh detail messages debugging is on
Switch#sh log
Syslog logging: enabled (0 messages dropped, 9 messages rate-limited, 0 flushes, 0
overruns, xml disabled, filtering disabled)
```

```
No Active Message Discriminator.
```

```
No Inactive Message Discriminator.
```

```
Console logging: disabled
Monitor logging: level debugging, 0 messages logged, xml disabled,
                  filtering disabled
Buffer logging:  level debugging, 233 messages logged, xml disabled,
                  filtering disabled
Exception Logging: size (4096 bytes)
Count and timestamp logging messages: disabled
File logging: disabled
Persistent logging: disabled
```

```
No active filter modules.
```

```
Trap logging: level informational, 174 message lines logged
Logging Source-Interface:      VRF Name:
```

```

Log Buffer (4096 bytes):

Description	Link
The Cisco Support and Documentation website provides online resources to download documentation, software, and tools. Use these resources to install and configure the software and to troubleshoot and resolve technical issues with Cisco products and technologies. Access to most tools on the Cisco Support and Documentation website requires a Cisco.com user ID and password.	http://www.cisco.com/cisco/web/support/index.html

Feature Information for X.509v3 Certificates for SSH Authentication

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

**Note**

Table 1 lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 1 Feature Information for X509v3 Certificates for SSH Authentication

Feature Name	Releases	Feature Information
X509v3 Certificates for SSH Authentication	Cisco IOS Release 15.2(4)E1 Cisco IOS XE Release 3.8.1E	The X.509v3 Certificates for SSH Authentication feature uses the X5.09v3 digital certificates in server and user authentication at the SSH server side. The following commands were introduced or modified: ip ssh server algorithm hostkey , ip ssh server algorithm authentication , and ip ssh server certificate profile .

Configuring SSH File Transfer Protocol

Secure Shell (SSH) includes support for SSH File Transfer Protocol (SFTP), which is a new standard file transfer protocol introduced in SSHv2. This feature provides a secure and authenticated method for copying device configuration or device image files.

This module describes the feature and consists of these sections:

- [Prerequisites for SSH File Transfer Protocol, page 51-1](#)
- [Restrictions for SSH File Transfer Protocol, page 51-1](#)
- [Information About SSH File Transfer Protocol, page 51-2](#)
- [How to Configure SSH File Transfer Protocol, page 51-2](#)
- [Example: Configuring SSH File Transfer Protocol, page 51-3](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see publications at this location:

[Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#)

If a command is not in the *Catalyst 4500 Series Switch Command Reference*, you can locate it in the Cisco IOS library, at this location:

[Cisco IOS Master Command List, All Releases](#)

Prerequisites for SSH File Transfer Protocol

- SSH must be enabled.
- The **ip ssh source-interface** *interface-type interface-number* command must be configured.

Restrictions for SSH File Transfer Protocol

- The SFTP server is not supported.
- SFTP boot is not supported.
- The **sftp** option in the **install add** command is not supported.

Information About SSH File Transfer Protocol

The SFTP client functionality is provided as part of the SSH component and is always enabled on the corresponding device. Therefore, any SFTP server user with the appropriate permission can copy files to and from the device.

An SFTP client is VRF-aware; you can configure the secure FTP client to use the virtual routing and forwarding (VRF) associated with a particular source interface during connection attempts.

How to Configure SSH File Transfer Protocol

The following sections provide information about the various tasks that comprise an SFTP configuration.

- [Configuring SFTP, page 51-2](#)
- [Perform an SFTP Copy Operation, page 51-2](#)

Configuring SFTP

Before you begin

To configure a Cisco device for SFTP client-side functionality, the **ip ssh source-interface interface-type interface-number** command must be configured first.

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# ip ssh source-interface interface-type interface-number	Defines the source IP for the SSH session.
Step 4	Switch(config)# exit	Exits global configuration mode and returns to privileged EXEC mode.
Step 5	Switch# show running-config	(Optional) Displays the SFTP client-side functionality.
Step 6	Switch# debug ip sftp	(Optional) Enables SFTP debugging.

Perform an SFTP Copy Operation

SFTP copy takes the IP or hostname of the corresponding server if Domain Name System (DNS) is configured. To perform SFTP copy operations, use the following commands in privileged EXEC mode.

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# copy ios-file-system:file sftp://user:pwd@server-ip//filepath Or Switch# copy ios-file-system: sftp:	Copies a file from the local Cisco IOS file system to the server. Specify the username, password, IP address, and filepath of the server.
Step 3	Switch# copy sftp://user:pwd@server-ip //filepath ios-file-system:file Or Switch# copy sftp: ios-file-system:	Copies the file from the server to the local Cisco IOS file system. Specify the username, password, IP address, and filepath of the server.

Example: Configuring SSH File Transfer Protocol

The following example shows how to configure the client-side functionality of SFTP:

```
Switch> enable
Switch# configure terminal
Switch(config)# ip ssh source-interface gigabitethernet 1/0/1
Switch(config)# end
```

■ Example: Configuring SSH File Transfer Protocol

Configuring the PPPoE Intermediate Agent

DSL Forum TR-101 [1] offers a means by which the PPPoE Discovery packets are tagged at the service provider's access switch with subscriber line specific information. The mechanism specifies using VSA of the PPPoE Discovery packets to add the line specific information at the switch. Even though you can perform Subscriber Line Identification (SLI) in another way (recreating virtual paths and circuits using stacked VLAN tags), DSL Forum 2004-071 [4] recommends the PPPoE Intermediate Agent mechanism. It cites lower provisioning costs and simpler co-ordination between OSS systems in charge of access switch and BRAS. PPPoE Intermediate Agent helps the service provider, BRAS, distinguish between end hosts connected over Ethernet to an access switch.

This chapter describes PPPoE Intermediate Agent on Catalyst 4500 series switches. It includes the following sections:

- [About PPPoE Intermediate Agent, page 52-2](#)
- [Enabling PPPoE IA on a Switch, page 52-2](#)
- [Configuring the Access Node Identifier for PPPoE IA on a Switch, page 52-2](#)
- [Configuring the Identifier String, Option, and Delimiter for PPPoE IA on a Switch, page 52-3](#)
- [Configuring the Generic Error Message for PPPoE IA on a Switch, page 52-3](#)
- [Enabling PPPoE IA on an Interface, page 52-4](#)
- [Configuring the PPPoE IA Trust Setting on an Interface, page 52-4](#)
- [Configuring PPPoE IA Rate Limiting Setting on an Interface, page 52-4](#)
- [Configuring PPPoE IA Vendor-tag Stripping on an Interface, page 52-5](#)
- [Configuring PPPoE IA Circuit-ID and Remote-ID on an Interface, page 52-5](#)
- [Enabling PPPoE IA for a Specific VLAN on an Interface, page 52-5](#)
- [Configuring PPPoE IA Circuit-ID and Remote-ID for a VLAN on an Interface, page 52-6](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

RFCs

RFC	Title
RFC 2516	A Method for Transmitting PPP over Ethernet (PPPoE)

About PPPoE Intermediate Agent

PPPoE Intermediate Agent (PPPoE IA) is placed between a subscriber and BRAS to help the service provider BRAS distinguish between end hosts connected over Ethernet to an access switch. On the access switch, PPPoE IA enables Subscriber Line Identification by appropriately tagging Ethernet frames of different users. (The tag contains specific information such as which subscriber is connected to the switch and VLAN.) PPPoE IA acts as mini security firewall between host and BRAS by intercepting all PPPoE Active Discovery (PAD) messages on a per-port per-VLAN basis. It provides specific security feature such as verifying the intercepted PAD message from untrusted port, performing per-port PAD message rate limiting, inserting and removing VSA Tags into and from PAD messages, respectively.

Enabling PPPoE IA on a Switch

This functionality allows you to enable or disable PPPoE IA globally on the switch:

```
Switch> enable
Switch# configure terminal
Switch(config)# pppoe intermediate-agent
```

By default, PPPoE IA is disabled globally.

Configuring the Access Node Identifier for PPPoE IA on a Switch

This functionality allows you to set the Access Node Identifier of the switch. If unspecified, this parameter is derived automatically with the IP address of the management interface.

The following example shows how to set an access node identifier of **abcd**:

```
Switch> enable
Switch# configure terminal
Switch(config)# pppoe intermediate-agent format-type access-node-id string abcd
```

By default, *access-node-id* is not set.

Configuring the Identifier String, Option, and Delimiter for PPPoE IA on an Switch

This functionality overrides the default automatic generation of circuit-id by the system.

The options available are sp, sv, pv and spv denoting slot:port, slot-vlan, port-vlan, and slot-port-vlan combinations, respectively. Valid delimiters are # . , ; / space.

The **no** form of this command without *WORD*, *options*, and *delimiters*, reverts to the default automatic generation of circuit-id.

The following example shows how to set an identifier string **word** with option **spv** delimited by “:”:

```
Switch> enable
Switch# configure terminal
Switch(config)# pppoe intermediate-agent format-type
                identifier-string string word
                option spv delimiter :
```

This command does not affect the circuit ID configured explicitly per-interface or per-interface per-VLAN with the **pppoe intermediate-agent format-type circuit-id** or **pppoe intermediate-agent vlan num format-type circuit-id** commands.

Configuring the Generic Error Message for PPPoE IA on an Switch

This functionality sets the Generic-Error message of the switch. PPPoE IA sends this message only on a specific error condition. If you do not specify **string {WORD}**, the error message is not added.

The following example shows how to configure a generic message of **packet_length>1484**:

```
Switch> enable
Switch# configure terminal
Switch(config)# pppoe intermediate-agent format-type
                generic-error-message string packet_length>1484
PPPoE Discover packet too large to process. Try reducing the number of tags added.
```

By default the **generic-error-message** is not set. The **string** value is converted to UTF-8 before it is added to the response. The message similar to the following will appear:

PPPoE Discover packet too large to process. Try reducing the number of tags added.

Note

This TAG (0x0203 Generic-Error) indicates an error. It can be added to PADO or PADS packets generated by PPPoE IA and then sent back to user in reply of PADI or PADR, when a PPPoE discovery packet received by PPPoE IA with PPPoE payload greater than 1484 bytes. Error data must be a UTF-8 string.

Enabling PPPoE IA on an Interface

This functionality enables the PPPoE IA feature on an interface. The **pppoe intermediate-agent** command has an effect only if the PPPoE IA feature was enabled globally with this command. (You need to enable *globally* to activate PPPoE IA static ACL and on an interface for PPPoE IA processing of PPPoE discovery packets received on that interface.)

This setting applies to all frames passing through this interface, regardless of the VLAN they belong to. By default the PPPoE IA feature is disabled on all interfaces. You need to run this command on every interface that requires this feature.

The following example shows how to enable PPPoE IA on FastEthernet 3/1:

```
Switch> enable
Switch# configure terminal
Switch(config) interface FastEthernet 3/1
Switch(config-if) pppoe intermediate-agent
```

**Note**

Enabling PPPoE IA on an interface does not ensure that incoming packets are tagged. For this to happen PPPoE IA must be enabled globally, and at least one interface that connects the switch to PPPoE server has a trusted PPPoE IA setting. Refer to the following section for details.

Configuring the PPPoE IA Trust Setting on an Interface

This functionality sets a physical interface as trusted. The following example shows how to set FastEthernet interface 3/2 as trusted:

```
Switch> enable
Switch# configure terminal
Switch(config) interface FastEthernet 3/2
Switch(config-if) pppoe intermediate-agent trust
```

This setting is disabled by default.

**Note**

Interfaces that connect the switch to PPPoE server are configured as trusted. Interfaces that connect the switch to users (PPPoE clients) are untrusted.

Configuring PPPoE IA Rate Limiting Setting on an Interface

This functionality limits the rate (per second) at which PPPoE Discovery packets (PADI, PADO, PADR, PADS, or PADT) are received on an interface. When the incoming packet rate achieves or exceeds the configured limit, a port enters an err-disabled state.

The following example shows how to set a rate limit of 30 at FastEthernet 3/1:

```
Switch> enable
Switch# configure terminal
Switch(config) interface FastEthernet 3/1
Switch(config-if) pppoe intermediate-agent limit rate 30
```

**Note**

The parameter for rate limiting is the number of packets per second. If the incoming packet rate exceeds this value, the port shuts down.

Configuring PPPoE IA Vendor-tag Stripping on an Interface

This functionality enables an administrator to strip the vendor-specific tag (VSA) from PADO, PADS, and PADT packets received on an interface before forwarding them to the user.

The following example shows how to enable stripping on FastEthernet 3/2:

```
Switch> enable
Switch# configure terminal
Switch(config) interface FastEthernet 3/2
Switch(config-if) pppoe intermediate-agent vendor-tag strip
```

This setting is disabled by default.

Note

Generally, you would configure vendor-tag stripping on an interfaces connected to the PPPoE server. If you configure stripping, incoming packets are stripped of their VSAs (which carry subscriber and line identification information). For this to happen, the PPPoE Intermediate agent must be enabled to make the **pppoe intermediate-agent vendor-tag strip** command effective, and the interface must be set to trust. In isolation, the command has no effect.

Configuring PPPoE IA Circuit-ID and Remote-ID on an Interface

The **[no] pppoe intermediate-agent format-type circuit-id** command sets the circuit ID on an interface and overrides the automatic generation of circuit ID by the switch. Without this command, one default tag (for example, Ethernet x/y:z on the PPPoE to which the user is connected) inserted by an intermediate-agent.

The **[no] pppoe intermediate-agent format-type remote-id** command sets the remote ID on an interface.

This functionality causes tagging of PADI, PADR, and PADT packets (belonging to PPPoE Discovery stage) received on this physical interface with circuit ID or remote ID. This happens regardless s of their VLAN if PPPoE IA is not enabled for that VLAN.

You should use remote ID instead of circuit ID for subscriber line identification. You should configure this setting on every interface where you enabled PPPoE IA because it is not set by default. The default value for remote-id is the switch MAC address (for all physical interfaces).

The following example shows how to configure the circuit ID as root and the remote ID as granite:

```
Switch> enable
Switch# configure terminal
Switch(config) interface FastEthernet 3/1
Switch(config-if) pppoe intermediate-agent format-type circuit-id string root
Switch(config-if) pppoe intermediate-agent format-type remote-id string granite
```

Enabling PPPoE IA for a Specific VLAN on an Interface

This functionality allows you to enable PPPoE IA on either a specific VLAN, a comma-separated list such as “x,y,” or a range such as “x-y.”

Specific VLAN:

```
Switch# configure terminal
Switch(config)# interface FastEthernet 3/1
Switch(config-if)# vlan-range 5
Switch(config-if-vlan-range)# pppoe intermediate-agent
```

Comma-separated VLAN list:

```
Switch# configure terminal
Switch(config)# interface FastEthernet 3/1
Switch(config-if)# vlan-range 5,6
Switch(config-if-vlan-range)# pppoe intermediate-agent
```

VLAN range:

```
Switch# configure terminal
Switch(config)# interface FastEthernet 3/1
Switch(config-if)# vlan-range 5-9
Switch(config-if-vlan-range)# pppoe intermediate-agent
```

Note

The **pppoe intermediate-agent** command in the vlan-range mode is not dependent on the same command in interface mode. The **pppoe intermediate-agent** command will take effect independently of the command in the interface mode. To make this happen, PPPoE IA must be enabled globally and at least one interface is connected to the PPPoE server.

Configuring PPPoE IA Circuit-ID and Remote-ID for a VLAN on an Interface

In this section you set the circuit ID and remote ID for a specific VLAN on an interface. The command overrides the circuit ID and remote ID specified for this physical interface and the switch uses the *WORD* value to tag packets received on this VLAN. This parameter is unset by default.

The default value of **remote-id** is the switch MAC address (for all VLANs). You would set this parameter to encode subscriber-specific information.

Note

The **circuit-id** and **remote-id** configurations in vlan-range mode are affected only if PPPoE IA is enabled globally and in vlan-range mode.

This example shows how to set the circuit-id to aaa and the remote-id as ccc on interface g3/7:

```
Switch(config)# int g3/7
Switch(config-if)# vlan-range 5
Switch(config-if)# pppoe intermediate-agent
Switch(config-if-vlan-range)# pppoe intermediate-agent format-type circuit-id string aaa
Switch(config-if-vlan-range)# pppoe intermediate-agent format-type remote-id string ccc
```

Note

The **vlan-range** mode commands configure PPPoE IA for either a specific VLAN, multiple VLANs, or VLAN range, depending on what you specify in the syntax.

Displaying Configuration Parameters

The **show pppoe intermediate-agent [info|statistics] [interface {interface}]** command displays the various configuration parameters, statistics, and counters stored for PPPoE.

The **info** keyword appears if the PPPoE Intermediate Agent is enabled globally on an interface or on a VLAN (in an interface). It also informs you about the access node ID and generic error message of the switch, as well as the identifier string options and delimiter values configured globally by the following command:

```
Switch(config)# pppoe intermediate-agent format-type ?
  access-node-id      Access Node Identifier
  generic-error-message  Generic Error Message
  identifier-string    Identifier String
```

The **info** keyword also displays the circuit ID, remote ID, trust and rate limit configurations, and vendor tag strip setting for all interfaces and for all VLANs pertaining to those interfaces. If any of these parameters are not set, they are not displayed.

The **statistics** option displays the number of PADI/PADR/PADT packets received, and the time the last packet was received on all interfaces and on all VLANs pertaining to those interfaces.

If **interface** is specified, information or statistics applicable only to that physical interface and pertaining VLANs is displayed.

Although PPoE IA is supported on PVLANS, be aware that no PVLAN association (primary and secondary VLAN mapping) information is displayed.

The PPPoE IA show commands such as **show pppoe intermediate-agent info**, **show pppoe intermediate-agent info interface g3/7**, or **show pppoe intermediate-agent statistics** do not provide information about private VLAN association (primary and secondary VLAN mapping). However, they do provide information about VLANs regardless of private or normal VLANs, as the following example illustrate:

```
Switch# show pppoe intermediate-agent info
Switch PPPOE Intermediate-Agent is enabled
```

PPPOE Intermediate-Agent trust/rate is configured on the following Interfaces:

Interface	IA	Trusted	Vsa Strip	Rate limit (pps)
GigabitEthernet3/4	no	yes	yes	unlimited

PPPOE Intermediate-Agent is configured on following VLANs:
2-3

Interface	IA	Trusted	Vsa Strip	Rate limit (pps)
GigabitEthernet3/7	no	no	no	unlimited

PPPOE Intermediate-Agent is configured on following VLANs:
2-3

```
Switch# show pppoe intermediate-agent info interface g3/7
Interface      IA      Trusted  Vsa Strip  Rate limit (pps)
-----
GigabitEthernet3/7  yes    no       no         unlimited
PPPoE Intermediate-Agent is configured on following VLANs:
2-3
```

```
Switch# show pppoe intermediate-agent statistics
```

```
PPPOE IA Per-Port Statistics
-----
```

```
Interface : GigabitEthernet3/7
Packets received
All = 0
PADI = 0 PADO = 0
PADR = 0 PADS = 0
PADT = 0
Packets dropped:
Rate-limit exceeded = 0
```

```

Server responses from untrusted ports = 0
Client requests towards untrusted ports = 0
Malformed PPPoE Discovery packets = 0
Vlan 2: Packets received PADI = 0 PADO = 0 PADR = 0 PADS = 0 PADT = 0
Vlan 3: Packets received PADI = 0 PADO = 0 PADR = 0 PADS = 0 PADT = 0

Switch# show pppoe intermediate-agent statistics interface g3/7
Interface : GigabitEthernet3/7
Packets received
  All = 3
  PADI = 0 PADO = 0
  PADR = 0 PADS = 0
  PADT = 3
Packets dropped:
  Rate-limit exceeded = 0
  Server responses from untrusted ports = 0
  Client requests towards untrusted ports = 0
  Malformed PPPoE Discovery packets = 0
Vlan 2: Packets received PADI = 6 PADO = 0 PADR = 6 PADS = 0 PADT = 6
Vlan 3: Packets received PADI = 4 PADO = 0 PADR = 4 PADS = 0 PADT = 4

```

Clearing Packet Counters

This section illustrates how to clear packet counters on all interfaces (per-port and per-port-per-VLAN).

The following example illustrates how to do this:

```
Switch# clear pppoe intermediate-agent statistics
```

Issuing of the above command clears the counters for all PPPoE discovery packets (PADI,PADO,PADR,PADS,PADT) received on DUT.

```

Switch# show pppoe intermediate-agent statistics interface g3/7
Interface : GigabitEthernet3/7
Packets received
  All = 0
  PADI = 0 PADO = 0
  PADR = 0 PADS = 0
  PADT = 0
Packets dropped:
  Rate-limit exceeded = 0
  Server responses from untrusted ports = 0
  Client requests towards untrusted ports = 0
  Malformed PPPoE Discovery packets = 0
Vlan 2: Packets received PADI = 0 PADO = 0 PADR = 0 PADS = 0 PADT = 0
Vlan 3: Packets received PADI = 0 PADO = 0 PADR = 0 PADS = 0 PADT = 0

```

Debugging PPPoE Intermediate Agent

The **debug pppoe intermediate-agent [packet | event | all]** command enables you to display useful PPPoE information that assists in debugging. This command is disabled by default.

The **packet** option of the command displays the contents of a packet received in the software: source and destination MAC address of Ethernet frame, code, version and type of PPPoE Discovery packet and a list of TAGs present.

The **event** option of the command echoes important messages (interface state change to errdisabled due to PPPoE discovery packets entering at a rate exceeding the configured limit). It is the only event shown by the **debug pppoe intermediate-agent event** command.

The **all** option enables both package and event options.

The following example illustrates how to enter the debug command with the **packet** option:

```
Switch# debug pppoe intermediate-agent packet
PPPOE IA Packet debugging is on

*Sep  2 06:12:56.133: PPPOE_IA: Process new PPPoE packet, Message type: PADI, input
interface: Gi3/7, vlan : 2 MAC da: ffff.ffff.ffff, MAC sa: aabb.cc00.0000
*Sep  2 06:12:56.137: PPPOE_IA: received new PPPOE packet from inputinterface
(GigabitEthernet3/4)
*Sep  2 06:12:56.137: PPPOE_IA: received new PPPOE packet from inputinterface
(GigabitEthernet3/8)
*Sep  2 06:12:56.137: PPPOE_IA: Process new PPPoE packet, Message type: PADO, input
interface: Gi3/4, vlan : 2 MAC da: aabb.cc00.0000, MAC sa: 001d.e64c.6512
*Sep  2 06:12:56.137: PPPOE_IA: Process new PPPoE packet, Message type: PADO, input
interface: Gi3/8, vlan : 2 MAC da: aabb.cc00.0000, MAC sa: aabb.cc80.0000
*Sep  2 06:12:56.137: PPPOE_IA: received new PPPOE packet from inputinterface
(GigabitEthernet3/7)
*Sep  2 06:12:56.137: PPPOE_IA: Process new PPPoE packet, Message type: PADR, input
interface: Gi3/7, vlan : 2 MAC da: 001d.e64c.6512, MAC sa: aabb.cc00.0000
*Sep  2 06:12:56.145: PPPOE_IA: received new PPPOE packet from inputinterface
(GigabitEthernet3/4)
*Sep  2 06:12:56.145: PPPOE_IA: Process new PPPoE packet, Message type: PADS, input
interface: Gi3/4, vlan : 2 MAC da: aabb.cc00.0000, MAC sa: 001d.e64c.6512
```

The following example illustrates how to enter the debug command with the **event** option:

```
Switch# debug pppoe intermediate-agent event
PPPOE IA Event debugging is on

*Jul 30 19:00:10.254: %PPPOE_IA-4-PPPOE_IA_ERRDISABLE_WARNING: PPPOE IA received 5 PPPOE
packets on interface Gi3/7
*Jul 30 19:00:10.254: %PPPOE_IA-4-PPPOE_IA_RATE_LIMIT_EXCEEDED: The interface Gi3/7 is
receiving more than the threshold set
*Jul 30 19:00:10.394: %PM-4-ERR_DISABLE: STANDBY:pppoe-ia-rate-limit error detected on
Gi3/7, putting Gi3/7 in err-disable stat
```

Troubleshooting Tips

When the **radius-server attribute 31 remote-id** global configuration command is entered in the PPPoE Agent Remote-ID Tag and DSL Line Characteristics feature configuration on the BRAS, the **debug radius** privileged EXEC command can be used to generate a report that includes information about the incoming access interface, where discovery frames are received, and about the session being established in PPPoE extended NAS-Port format (format d).

Configuring Web-Based Authentication

This chapter describes how to configure web-based authentication. It consists of these sections:

- [About Web-Based Authentication, page 53-1](#)
- [Configuring Web-Based Authentication, page 53-6](#)
- [Displaying Web-Based Authentication Status, page 53-14](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Web-Based Authentication

The web-based authentication feature, known as Web Authentication Proxy, enables you to authenticate end users on host systems that do not run the IEEE 802.1X supplicant.

Note

You can configure web-based authentication on Layer 2 and Layer 3 interfaces.

When you initiate an HTTP session, web-based authentication intercepts ingress HTTP packets from the host and sends an HTML login page to the user. The user keys in their credentials, which the web-based authentication feature sends to the AAA server for authentication:

- If authentication succeeds, web-based authentication sends a Login-Successful HTML page to the host and applies the access policies returned by the AAA server.
- If authentication fails, web-based authentication forwards a Login-Fail HTML page to the user, prompting the user to retry the login. If the user exceeds the maximum number of attempts, web-based authentication forwards a Login-Expired HTML page to the host and the user is placed on a watch-list for a waiting period.

These sections describe the role of web-based authentication as part of the authentication, authorization, and accounting (AAA) system:

- [Device Roles, page 53-2](#)
- [Host Detection, page 53-2](#)
- [Session Creation, page 53-3](#)

- [Authentication Process, page 53-3](#)
- [Customization of the Authentication Proxy Web Pages, page 53-4](#)
- [Web-Based Authentication Interactions with Other Features, page 53-4](#)

Device Roles

With web-based authentication, the devices in the network have specific roles ([Figure 53-1](#)).

Figure 53-1 Web-Based Authentication Device Roles

The roles are as follows:

- *Client*—The device (workstation) that requests access to the LAN and switch services and responds to requests from the switch. The workstation must be running an HTML browser with Java Script enabled.
- *Authentication server*—Performs the actual authentication of the client. The authentication server validates the identity of the client and notifies the switch that the client is authorized to access the LAN and switch services or that the client is denied.
- *Switch*—Controls the physical access to the network based on the authentication status of the client. The switch acts as an intermediary (proxy) between the client and the authentication server, requesting identity information from the client, verifying that information with the authentication server, and relaying a response to the client.

Host Detection

The switch maintains an IP device tracking table to store information about detected hosts.

Note

By default, the IP device tracking feature is disabled on a switch. You must enable the IP device tracking feature to use web-based authentication.

For Layer 3 interfaces, web-based authentication sets an HTTP intercept ACL when the feature is configured on the interface (or when the interface is put in service).

For Layer 2 interfaces, web-based authentication detects IP hosts using the following mechanisms:

- ARP-based trigger—ARP redirect ACL allows web-based authentication to detect hosts with static IP address or dynamically acquired IP address.
- Dynamic ARP inspection (DAI)

- DHCP snooping—Web-based authentication is notified when the switch creates a DHCP binding entry for the host.

Session Creation

When web-based authentication detects a new host, it creates a session as follows:

- Checks for Auth bypass

If the host IP is not on the exception list, web-based authentication sends a nonresponsive host (NRH) request to the server.

If the server response is Access Accepted, authorization is bypassed for this host. The session is established.
- Sets up the HTTP Intercept ACL

If the server response to the NRH request is Access Rejected, the HTTP intercept ACL is activated and the session waits for HTTP traffic from the host.

Authentication Process

When you enable web-based authentication, the following events occur:

- The user initiates an HTTP session.
- The HTTP traffic is intercepted, and authorization is initiated. The switch sends the login page to the user. The user enters a username and password on the login page, and the switch sends the entries to the authentication server.
- If the client identity is valid and the authentication succeeds, the switch downloads and activates the user's access policy from the authentication server. The login success page is sent to the user.
- If the authentication fails, the switch sends the login fail page. The user retries the login. If the maximum number of attempts fails, the switch sends the login expired page and the host is placed in a watch list, using the following commands:

ip admission watch-list enable

ip admission watch-list expiry-time <milliseconds>

- After the watch list times out, the user can retry the authentication process.
- If the authentication server does not respond to the switch, and if an AAA fail policy is configured, the switch applies the failure access policy to the host. The login success page is sent to the user. See the [“Customization of the Authentication Proxy Web Pages”](#) section on page 53-4.
- The switch reauthenticates a client when the host does not respond to an ARP probe on a Layer 2 interface, or the host does not send any traffic within the idle timeout on a Layer 3 interface.
- The feature applies the downloaded timeout or the locally configured session timeout.
- If the terminate action is RADIUS, the feature sends a nonresponsive host (NRH) request to the server. The terminate action is included in the response from the server.
- If the terminate action is default, the session is dismantled and the applied policy is removed.

Customization of the Authentication Proxy Web Pages

During the web-based authentication process, the internal HTTP server of the switch hosts four HTML pages for delivery to an authenticating client. The four pages allow the server to notify you of the following four states of the authentication process:

- Login—Your credentials are requested.
- Success—The login was successful.
- Fail—The login failed.
- Expire—The login session has expired because of excessive login failures.

**Note**

When your customized web-based authentication page is replaced with a new page (file) of the same name in the switch system directory (i.e. flash), the new page will not be seen; you will see the older page. Beginning with Release 15.0(2)SG, the new page will not display until you enter the **ip admission proxy http refresh-all** command.

In Cisco IOS Release 12.2(50)SG, you can substitute your custom HTML pages for the four default internal HTML pages, or you can specify a URL to which you are redirected upon successful authentication, effectively replacing the internal Success page.

Web-Based Authentication Interactions with Other Features

These sections describe web-based authentication interactions with these features:

- [Port Security, page 53-4](#)
- [LAN Port IP, page 53-5](#)
- [Gateway IP, page 53-5](#)
- [ACLs, page 53-5](#)
- [Context-Based Access Control, page 53-5](#)
- [802.1X Authentication, page 53-5](#)
- [EtherChannel, page 53-5](#)
- [Switchover, page 53-5](#)

Port Security

You can configure web-based authentication and port security on the same port. (You configure port security on the port with the **switchport port-security** interface configuration command.) When you enable port security and web-based authentication on a port, web-based authentication authenticates the port, and port security manages network access for all MAC addresses, including that of the client. You can then limit the number or group of clients that can access the network using the port.

For more information about enabling port security, see [Chapter 55, “Configuring Port Security.”](#)

LAN Port IP

You can configure LAN port IP (LPIP) and Layer 2 web-based authentication on the same port. The host is authenticated using web-based authentication first, followed by LPIP posture validation. The LPIP host policy overrides the web-based authentication host policy.

If the web-based authentication idle timer expires, the NAC policy is removed. The host is authenticated and posture is validated again.

Gateway IP

You cannot configure Gateway IP on a Layer 3 VLAN interface if web-based authentication is configured on any of the switch ports in the VLAN.

You can configure web-based authentication on the same Layer 3 interface as Gateway IP. The host policies for both features are applied in software. The GWIP policy overrides the web-based authentication host policy.

ACLs

If you configure a VLAN ACL or Cisco IOS ACL on an interface, the ACL is applied to the host traffic only after the web-based authentication host policy is applied.

For Layer 2 web-based authentication, you must configure a port ACL (PACL) as the default access policy for ingress traffic from hosts connected to the port. After authentication, the web-based authentication host policy overrides the PACL.

You cannot configure a MAC ACL and web-based authentication on the same interface.

You cannot configure web-based authentication on a port whose access VLAN is configured for VACL capture.

Context-Based Access Control

Web-based authentication cannot be configured on a Layer 2 port if context-based access control (CBAC) is configured on the Layer 3 VLAN interface of the port's VLAN.

802.1X Authentication

You cannot configure web-based authentication on the same port as 802.1X authentication except as a fallback authentication method.

EtherChannel

You can configure web-based authentication on a Layer 2 EtherChannel interface. The web-based authentication configuration applies to all member channels.

Switchover

On Catalyst 4500 series switches with redundant supervisor engines in RPR mode, information about currently authenticated hosts is maintained during a switchover. You do not need to reauthenticate.

Configuring Web-Based Authentication

These sections describe how to configure web-based authentication:

- [Default Web-Based Authentication Configuration, page 53-6](#)
- [Web-Based Authentication Configuration Guidelines and Restrictions, page 53-6](#)
- [Web-Based Authentication Configuration Task List, page 53-7](#)
- [Configuring the Authentication Rule and Interfaces, page 53-7](#)
- [Configuring AAA Authentication, page 53-9](#)
- [Configuring Switch-to-RADIUS-Server Communication, page 53-9](#)
- [Configuring the HTTP Server, page 53-11](#)
- [Configuring the Web-Based Authentication Parameters, page 53-13](#)
- [Removing Web-Based Authentication Cache Entries, page 53-14](#)

Default Web-Based Authentication Configuration

Table 53-1 shows the default web-based authentication configuration.

Table 53-1 **Default Web-based Authentication Configuration**

Feature	Default Setting
AAA	Disabled
RADIUS server	
• IP address	• None specified
• UDP authentication port	• 1812
• Key	• None specified
Default value of inactivity timeout	3600 seconds
Inactivity timeout	Enabled

Web-Based Authentication Configuration Guidelines and Restrictions

When configuring web-based authentication, consider these guidelines and restrictions:

- Web authentication requires two Cisco Attribute-Value (AV) pair attributes:

The first attribute, `priv-lvl=15`, must always be set to 15. This sets the privilege level of the user who is logging into the switch.

The second attribute is an access list to be applied for web-authenticated hosts. The syntax is similar to 802.1x per-user access control lists (ACLs). However, instead of `ip:inacl`, this attribute must begin with `proxyacl`, and the source field in each entry must be any. (After authentication, the client IP address replaces the any field when the ACL is applied.)

For example:

```
proxyacl# 10=permit ip any 10.0.0.0 255.0.0.0
proxyacl# 20=permit ip any 11.1.0.0 255.255.0.0
proxyacl# 30=permit udp any any eq syslog
```

```
proxyacl# 40=permit udp any any eq tftp
```

Note The proxyacl entry determines the type of allowed network access.

- Web-based authentication is an ingress-only feature.
- You can configure web-based authentication only on access ports. Web-based authentication is not supported on trunk ports, EtherChannel member ports, or dynamic trunk ports.
- You must configure the default ACL on the interface before configuring web-based authentication. Configure a port ACL for a Layer 2 interface, or a Cisco IOS ACL for a Layer 3 interface.
- On Layer 2 interfaces, you cannot authenticate hosts with static ARP cache assignment. These hosts are not detected by the web-based authentication feature, because they do not send ARP messages.
- By default, the IP device tracking feature is disabled on a switch. You must enable the IP device tracking feature to use web-based authentication.
- You must configure at least one IP address to run the HTTP server on the switch. You must also configure routes to reach each host IP address. The HTTP server sends the HTTP login page to the host.
- Hosts that are more than one hop away may experience traffic disruption if an STP topology change results in the host traffic arriving on a different port. It is because ARP and DHCP updates may not be sent after a Layer 2 (STP) topology change.
- Web-based authentication does not support VLAN assignment as a downloadable host policy.
- Cisco IOS Release 12.2(50)SG supports downloadable ACLs (DACLS) from the RADIUS server.
- Web-based authentication is not supported for IPv6 traffic.

Web-Based Authentication Configuration Task List

To configure the web-based authentication feature, perform the following tasks:

- [Configuring the Authentication Rule and Interfaces, page 53-7](#)
- [Configuring AAA Authentication, page 53-9](#)
- [Configuring Switch-to-RADIUS-Server Communication, page 53-9](#)
- [Configuring the HTTP Server, page 53-11](#)
- [Configuring the Web-Based Authentication Parameters, page 53-13](#)
- [Removing Web-Based Authentication Cache Entries, page 53-14](#)

Configuring the Authentication Rule and Interfaces

To configure web-based authentication, perform this task:

	Command	Purpose
Step 1	Switch(config)# ip admission name name proxy http	Configures an authentication rule for web-based authorization.
	Switch(config)# no ip admission name name	Removes the authentication rule.

	Command	Purpose
Step 2	Switch(config)# interface <i>type slot/port</i>	Enters interface configuration mode and specifies the ingress Layer 2 or Layer 3 interface to be enabled for web-based authentication. <i>type</i> can be fastethernet, gigabit ethernet, or tengigabitethernet
Step 3	Switch(config-if)# ip access-group <i>name</i>	Applies the default ACL.
Step 4	Switch(config-if)# ip admission <i>name</i>	Configures web-based authentication on the specified interface.
Step 5	Switch(config-if)# exit	Returns to configuration mode.
Step 6	Switch(config)# ip device tracking	Enables the IP device tracking table. Note Starting from Cisco IOS XE Release 3.10.1E, the following IPDT commands are deprecated; there are no replacement commands: [no] ip device tracking probe count [no] ip device tracking probe delay . For more related information, see the <i>Configuring SISF-Based Device Tracking</i> chapter in this guide.
Step 7	Switch(config)# end	Returns to privileged EXEC mode.
Step 8	Switch# show ip admission configuration	Displays the configuration.

This example shows how to enable web-based authentication on Fast Ethernet port 5/1:

```
Switch(config)# ip admission name webauth1 proxy http
Switch(config)# interface fastethernet 5/1
Switch(config-if)# ip admission webauth1
Switch(config-if)# exit
Switch(config)# ip device tracking
```

This example shows how to verify the configuration:

```
Switch# show ip admission configuration
Authentication Proxy Banner not configured
Authentication global cache time is 60 minutes
Authentication global absolute time is 0 minutes
Authentication global init state time is 2 minutes
Authentication Proxy Watch-list is disabled

Authentication Proxy Rule Configuration
Auth-proxy name webauth1
http list not specified inactivity-time 60 minutes

Authentication Proxy Auditing is disabled
Max Login attempts per user is 5
```

Configuring AAA Authentication

To enable web-based authentication, perform this task:

Note

Beginning with Cisco IOS XE Release 3.11.3aE, the legacy command **tacacs-server** is deprecated. Use the **tacacs server** command if the software running on your device is Cisco IOS XE Release 3.11.3aE or later releases.

	Command	Purpose
Step 1	Switch(config)# aaa new-model	Enables AAA functionality.
	Switch(config)# no aaa new-model	Disables AAA functionality.
Step 2	Switch(config)# aaa authentication login default group {tacacs+ radius}	Defines the list of authentication methods at login.
Step 3	Switch(config)# aaa authorization auth-proxy default group {tacacs+ radius}	Creates an authorization method list for web-based authorization.
	Switch(config)# no aaa authorization auth-proxy default group {tacacs+ radius}	Clears the configured method list.
Step 4	Switch(config)# tacacs server servername	Specifies an AAA server. For RADIUS servers, see the section “ Configuring Switch-to-RADIUS-Server Communication ” section on page 53-9.
Step 5	Switch(config-server-tacacs)# address {ipv4 ipv6} ip-address	Configures the IP address for the TACACS server.
Step 6	Switch(config-server-tacacs)# key key-data	Configures the authorization and encryption key used between the switch and the TACACS server.

This example shows how to enable AAA:

```
Switch(config)# aaa new-model
Switch(config)# aaa authentication login default group tacacs+
Switch(config)# aaa authorization auth-proxy default group tacacs+
```

Configuring Switch-to-RADIUS-Server Communication

RADIUS security servers are identified by one of the following:

- Host name
- Host IP address
- Host name and specific UDP port numbers
- IP address and specific UDP port numbers

The combination of the IP address and UDP port number creates a unique identifier, which enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service (for example, authentication) the second host entry that is configured functions as the failover backup to the first one. The RADIUS host entries are chosen in the order that they were configured.

To configure the RADIUS server parameters, perform this task:

	Command	Purpose
Step 1	Switch(config)# ip radius source-interface <i>interface_name</i>	Specifies that the RADIUS packets have the IP address of the indicated interface.
	Switch(config)# no ip radius source-interface	Prevents the RADIUS packets from having the IP address of the previously indicated interface.
Step 2	Switch(config)# radius server host { <i>hostname</i> <i>ip-address</i> } test username <i>username</i>	Specifies the host name or IP address of the remote RADIUS server. The test username <i>username</i> option enables automated testing of the RADIUS server connection. The specified <i>username</i> does not need to be a valid user name. The key option specifies an authentication and encryption key to be used between the switch and the RADIUS server. To use multiple RADIUS servers, reenter this command.
	Switch(config)# no radius server host { <i>hostname</i> <i>ip-address</i> }	Deletes the specified RADIUS server.
	Switch(config)# radius-server key <i>string</i>	Configures the authorization and encryption key used between the switch and the RADIUS daemon running on the RADIUS server.
Step 4	Switch(config)# radius-server vsa send authentication	Enables downloading of an ACL from the RADIUS server. This feature is supported in Cisco IOS Release 12.2(50)SG.
Step 5	Switch(config)# radius-server dead-criteria tries <i>num-tries</i>	Specifies the number of unanswered transmits to a RADIUS server before considering the server to be inactive. The range of <i>num-tries</i> is 1 to 100.

When you configure the RADIUS server parameters, follow these steps:

- Specify the **key string** on a separate command line.
- For **key string**, specify the authentication and encryption key used between the switch and the RADIUS daemon running on the RADIUS server. The key is a text string that must match the encryption key used on the RADIUS server.
- When you specify the **key string**, use spaces within and at the end of the key. If you use spaces in the key, do not enclose the key in quotation marks unless the quotation marks are part of the key. This key must match the encryption used on the RADIUS daemon.
- You can globally configure the timeout, retransmission, and encryption key values for all RADIUS servers with the **radius server host** global configuration command. If you want to configure these options on a per-server basis, use the **radius-server timeout**, **radius-server retransmit**, and the **radius-server key** global configuration commands. For more information, see the URL:

http://www.cisco.com/en/US/products/ps6586/products_ios_technology_home.html

**Note**

You need to configure some settings on the RADIUS server, including: the IP address of the switch, the key string to be shared by both the server and the switch, and the downloadable ACL (DACL). (Cisco IOS Release 12.2(50)SG supports DACLs.) For more information, see the RADIUS server documentation.

This example shows how to configure the RADIUS server parameters on a switch:

```
Switch(config)# ip radius source-interface Vlan80
Switch(config)# radius server host 172.120.39.46 test username user1
Switch(config)# radius-server key rad123
Switch(config)# radius-server dead-criteria tries 2
```

Configuring the HTTP Server

To use web-based authentication, you must enable the HTTP server within the switch. You can enable the server for either HTTP or HTTPS.

To enable the server, perform one of these tasks:

Command	Purpose
Switch(config)# ip http server	Enables the HTTP server. The web-based authentication feature uses the HTTP server to communicate with the hosts for user authentication.
Switch(config)# ip http secure-server	Enables HTTPS.

Starting with Cisco IOS Release 12.2(50)SG, you can optionally configure custom authentication proxy web pages or specify a redirection URL for successful login, as described in the following sections:

- [Customizing the Authentication Proxy Web Pages, page 53-11](#)
- [Specifying a Redirection URL for Successful Login, page 53-13](#)

Customizing the Authentication Proxy Web Pages

With Cisco IOS Release 12.2(50)SG, you have the option to display four substitute HTML pages to the user in place of the switch's internal default HTML pages during web-based authentication.

To specify the use of your custom authentication proxy web pages, first store your custom HTML files on the switch's internal disk or flash memory, then perform this task in global configuration mode:

	Command	Purpose
Step 1	Switch(config)# ip admission proxy http login page file <i>device:login-filename</i>	Specifies the location in the switch memory file system of the custom HTML file to use in place of the default login page. The <i>device:</i> is either disk or flash memory, such as <i>disk0:</i> .
Step 2	Switch(config)# ip admission proxy http success page file <i>device:success-filename</i>	Specifies the location of the custom HTML file to use in place of the default login success page.

	Command	Purpose
Step 3	Switch(config)# ip admission proxy http failure page file <i>device:fail-filename</i>	Specifies the location of the custom HTML file to use in place of the default login failure page.
Step 4	Switch(config)# ip admission proxy http login expired page file <i>device:expired-filename</i>	Specifies the location of the custom HTML file to use in place of the default login expired page.

When configuring customized authentication proxy web pages, observe the following guidelines:

- To enable the custom web pages feature, specify all four custom HTML files. If you specify fewer than four files, the internal default HTML pages are used.
- The four custom HTML files must be present on the disk or flash of the switch. The maximum size of each HTML file is 8 KB.
- Any images on the custom pages must be located on an accessible HTTP server. An intercept ACL must be configured within the admission rule to allow access to the HTTP server.
- Any external link from a custom page requires configuration of an intercept ACL within the admission rule.
- Any name resolution required for external links or images requires configuration of an intercept ACL within the admission rule to access a valid DNS server.
- If the custom web pages feature is enabled, a configured auth-proxy-banner is not used.
- If the custom web pages feature is enabled, the redirection URL for successful login feature is not available.
- To remove the specification of a custom file, use the **no** form of the command.

Because the custom login page is a public web form, consider the following guidelines for this page:

- The login form must accept user input for the username and password and must POST the data as **uname** and **pwd**.
- The custom login page should follow best practices for a web form, such as page timeout, hidden password, and prevention of redundant submissions.

The following example shows how to configure custom authentication proxy web pages:

```
Switch(config)# ip admission proxy http login page file disk1:login.htm
Switch(config)# ip admission proxy http success page file disk1:success.htm
Switch(config)# ip admission proxy http fail page file disk1:fail.htm
Switch(config)# ip admission proxy http login expired page file disk1:expired.htm
```

The following example shows how to verify the configuration of custom authentication proxy web pages:

```
Switch# show ip admission configuration

Authentication proxy webpage
Login page           : disk1:login.htm
Success page         : disk1:success.htm
Fail Page            : disk1:fail.htm
Login expired Page   : disk1:expired.htm

Authentication global cache time is 60 minutes
Authentication global absolute time is 0 minutes
Authentication global init state time is 2 minutes
Authentication Proxy Session ratelimit is 100
Authentication Proxy Watch-list is disabled
Authentication Proxy Auditing is disabled
Max Login attempts per user is 5
```

Specifying a Redirection URL for Successful Login

With Cisco IOS Release 12.2(50)SG, you have the option to specify a URL to which the user is redirected upon successful authentication, effectively replacing the internal Success HTML page.

To specify a redirection URL for successful login, perform this task:

Command	Purpose
Switch(config)# ip admission proxy http success redirect <i>url-string</i>	Specifies a URL for redirection of the user in place of the default login success page.

When configuring a redirection URL for successful login, consider the following guidelines:

- If the custom authentication proxy web pages feature is enabled, the redirection URL feature is disabled and is not available in the CLI. You can perform redirection in the custom login success page.
- If the redirection URL feature is enabled, a configured auth-proxy-banner is not used.
- To remove the specification of a redirection URL, use the **no** form of the command.

The following example shows how to configure a redirection URL for successful login:

```
Switch(config)# ip admission proxy http success redirect www.cisco.com
```

The following example shows how to verify the redirection URL for successful login:

```
Switch# show ip admission configuration
```

```
Authentication Proxy Banner not configured
Customizable Authentication Proxy webpage not configured
HTTP Authentication success redirect to URL: http://www.cisco.com
Authentication global cache time is 60 minutes
Authentication global absolute time is 0 minutes
Authentication global init state time is 2 minutes
Authentication Proxy Watch-list is disabled
Authentication Proxy Max HTTP process is 7
Authentication Proxy Auditing is disabled
Max Login attempts per user is 5
```

Configuring the Web-Based Authentication Parameters

You can configure the maximum number of failed login attempts allowed before the client is placed in a watch-list for a waiting period.

To configure the web-based authentication parameters, perform this task:

	Command	Purpose
Step 1	Switch(config)# ip admission max-login-attempts <i>number</i>	Sets the maximum number of failed login attempts. The default is 5. Note A typical custom setting for this value should not exceed 50.
Step 2	Switch(config)# end	Returns to privileged EXEC mode.

	Command	Purpose
Step 3	Switch# show ip admission configuration	Displays the authentication proxy configuration.
Step 4	Switch# show ip admission cache	Displays the list of authentication entries.

This example shows how to set the maximum number of failed login attempts to 10:

```
Switch(config)# ip admission max-login-attempts 10
```

Removing Web-Based Authentication Cache Entries

To delete existing session entries, perform either of these tasks:

Command	Purpose
Switch# clear ip auth-proxy cache [* <i>host ip address</i>]	Deletes authentication proxy entries. Use an asterisk to delete all cache entries. Enter a specific IP address to delete the entry for a single host.
Switch# clear ip admission cache [* <i>host ip address</i>]	Deletes authentication proxy entries. Use an asterisk to delete all cache entries. Enter a specific IP address to delete the entry for a single host.

This example shows how to remove the web-based authentication session for the client at IP address 209.165.201.1:

```
Switch# clear ip auth-proxy cache 209.165.201.1
```

Displaying Web-Based Authentication Status

To display the web-based authentication settings for all interfaces or for specific ports, perform this task:

Command	Purpose
Switch# show authentication sessions [interface <i>type slot/port</i>]	Displays the web-based authentication settings. type = fastethernet, gigabitethernet, or tengigabitethernet (Optional) Use the interface keyword to display the web-based authentication settings for a specific interface.

This example shows how to view only the global web-based authentication status:

```
Switch# show authentication sessions
```

This example shows how to view the web-based authentication settings for interface Gi 3/27:

```
Switch# show authentication sessions interface gigabitethernet 3/27
```

Auto Identity

The Auto Identity feature provides a set of built-in policies at global configuration and interface configuration modes. This feature is available only in Class-Based Policy Language (CPL) control policy-equivalent new-style mode. To convert all the relevant authentication commands to their CPL control policy-equivalents, use the authentication convert-to new-style command.

This module describes the feature and consists of these sections:

- [Information About Auto Identity, page 54-1](#)
- [How to Configure Auto Identity, page 54-5](#)
- [Configuration Examples for Auto Identity, page 54-6](#)
- [Verifying Auto Identity, page 54-7](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Information About Auto Identity

- [Auto Identity Overview, page 54-2](#)
- [Auto Identity Global Template, page 54-2](#)
- [Auto Identity Interface Templates, page 54-3](#)
- [Auto Identity Built-in Policies, page 54-4](#)
- [Auto Identity Class Map Templates, page 54-4](#)
- [Auto Identity Parameter Maps, page 54-5](#)
- [Auto Identity Service Templates, page 54-5](#)

Auto Identity Overview

The Cisco Identity-Based Networking Services (IBNS) solution provides a policy and identity-based framework in which edge devices can deliver flexible and scalable services to subscribers. IBNS allows the concurrent operation of IEEE 802.1x (dot1x), MAC authentication bypass (MAB), and web authentication methods, making it possible to invoke multiple authentication methods in parallel, on a single subscriber session. These authentication methods, dot1x, authentication, authorization, and accounting (AAA), and RADIUS are available in global configuration and interface configuration modes.

The Auto Identity feature uses the Cisco Common Classification Policy Language-based configuration that significantly reduces the number of commands used to configure both authentication methods and interface-level commands. The Auto Identity feature provides a set of built-in policies that are based on policy maps, class maps, parameter maps, and interface templates.

In global configuration mode, the **source template AI_GLOBAL_CONFIG_TEMPLATE** command enables the Auto Identity feature. In interface configuration mode, configure the **AI_MONITOR_MODE**, **AI_LOW_IMPACT_MODE**, or **AI_CLOSED_MODE** interface templates to enable the feature on interfaces.

You can configure multiple templates; however, you must bind multiple templates together using the **merge** command. If you do not bind the templates, the last configured template is used. While binding templates, if the same command is repeated in two templates with different arguments, the last configured command is used.

**Note**

You can also enable user-defined templates that are configured using the **template name** command in global configuration mode.

Use the **show template interface** or **show template global** commands to display information about built-in templates.

Built-in templates can be edited. Built-in template information is displayed in the output of the **show running-config** command, if the template is edited. If you delete an edited built-in template, the built-in template reverts to the default and is not deleted from the configuration. However, if you delete a user-defined template, it is deleted from the configuration.

**Note**

Before you delete a template, ensure that it is not attached to a device.

Auto Identity Global Template

To enable the global template, configure the **source template template-name** command in global configuration mode.

**Note**

You must configure the RADIUS server commands, because these are not automatically configured when the global template is enabled.

The following example shows how to enable the global template:

```
Switch(config)# source template AI_GLOBAL_CONFIG_TEMPLATE
Switch(config)# radius server ISE
Switch(config-radius-server)# address ipv4 172.20.254.4 auth-port 1645 acct-port 1646
Switch(config-radius-server)# key cisco
```

```
Switch(config-radius-server)# end
```

The AI_GLOBAL_CONFIG_TEMPLATE automatically configures the following commands:

```
dot1x system-auth-control
aaa new-model
aaa authentication dot1x default group radius
aaa authorization network default group radius
aaa authorization auth-proxy default group radius
aaa accounting identity default start-stop group radius
aaa accounting system default start-stop group radius
radius-server attribute 6 on-for-login-auth
radius-server attribute 6 support-multiple
radius-server attribute 6 voice 1
radius-server attribute 8 include-in-access-req
radius-server attribute 25 access-request include
```

Auto Identity Interface Templates

The following interface templates are available in the Auto Identity feature:

- AI_MONITOR_MODE—Passively monitors sessions that have authentication in open mode.
- AI_LOW_IMPACT_MODE—Similar to monitor mode, but with a configured static policy such as a port access control list (PACL).
- AI_CLOSED_MODE—Secure mode in which data traffic is not allowed into the network, until authentication is complete. This mode is the default.

The following commands are inbuilt in the AI_MONITOR_MODE:

```
switchport mode access
access-session port-control auto
access-session host-mode multi-auth
dot1x pae authenticator
mab
service-policy type control subscriber AI_DOT1X_MAB_POLICIES
```

The following commands are inbuilt in the AI_LOW_IMPACT_MODE:

```
switchport mode access
access-session port-control auto
access-session host-mode multi-auth
dot1x pae authenticator
mab
ip access-group AI_PORT_ACL in
service-policy type control subscriber AI_DOT1X_MAB_POLICIES
```

The following commands are inbuilt in the AI_CLOSED_MODE:

```
switchport mode access
access-session closed
access-session port-control auto
access-session host-mode multi-auth
dot1x pae authenticator
mab
service-policy type control subscriber AI_DOT1X_MAB_POLICIES
```

Auto Identity Built-in Policies

The following five built-in policies are available in the Auto Identity feature:

- **AI_DOT1X_MAB_AUTH**—Enables flexible authentication with dot1x, and then MAC Address Bypass (MAB).
- **AI_DOT1X_MAB_POLICIES**—Enables flexible authentication with dot1x, and then MAB. Applies critical VLAN in case the Authentication, Authorization, and Accounting (AAA) server is not reachable.
- **AI_DOT1X_MAB_WEBAUTH**—Enables flexible authentication with dot1x, MAB, and then web authentication.
- **AI_NEXTGEN_AUTHBYBASS**—Skips authentication if an IP phone device is detected. Enables the **device classifier** command in global configuration mode and the **voice-vlan** command in interface configuration mode to detect the device. This is a reference policy map, and users can copy the contents of this policy map to other policy maps.
- **AI_STANDALONE_WEBAUTH**—Defines standalone web authentication.

Auto Identity Class Map Templates

The following built-in class maps are supported by the Auto Identity feature:

- **AI_NRH**—Specifies that the nonresponsive host (NRH) authentication method is enabled.
- **AI_WEBAUTH_METHOD**—Specifies that the web authentication method is enabled.
- **AI_WEBAUTH_FAILED**—Specifies that the web authentication method failed to authenticate.
- **AI_WEBAUTH_NO_RESP**—Specifies that the web authentication client failed to respond.
- **AI_DOT1X_METHOD**—Specifies that the dot1x method is enabled.
- **AI_DOT1X_FAILED**—Specifies that the dot1x method failed to authenticate.
- **AI_DOT1X_NO_RESP**—Specifies that the dot1x client failed to respond.
- **AI_DOT1X_TIMEOUT**—Specifies that the dot1x client stopped responding after the initial acknowledge (ACK) request.
- **AI_MAB_METHOD**—Specifies that the MAC Authentication Bypass (MAB) method is enabled.
- **AI_MAB_FAILED**—Specifies that the MAB method failed to authenticate.
- **AI_AAA_SVR_DOWN_AUTHD_HOST**—Specifies that the Authentication, Authorization, and Accounting (AAA) server is down, and the client is in authorized state.
- **AI_AAA_SVR_DOWN_UNAUTHD_HOST**—Specifies that the AAA server is down, and the client is in unauthorized state.
- **AI_IN_CRITICAL_AUTH**—Specifies that the critical authentication service template is applied.
- **AI_NOT_IN_CRITICAL_AUTH**—Specifies that the critical authentication service template is not applied.
- **AI_METHOD_DOT1X_DEVICE_PHONE**—Specifies that the method is dot1x and the device type is IP phone.
- **AI_DEVICE_PHONE**—Specifies that the device type is IP phone.

Auto Identity Parameter Maps

The following built-in parameter map templates are supported by the Auto Identity feature:

- **AI_NRH_PMAP**—Starts nonresponsive host (NRH) authentication.
- **AI_WEBAUTH_PMAP**—Starts web authentication.

Auto Identity Service Templates

Service templates are available inside built-in policy maps. The following built-in service templates are supported by the Auto Identity feature:

- **AI_INACTIVE_TIMER**—Template to start the inactivity timer.
- **AI_CRITICAL_ACL**—Dummy template; users can configure this template as per their requirements.

How to Configure Auto Identity

- [Configuring Auto Identity Globally, page 54-5](#)
- [Configuring Auto Identity at an Interface Level, page 54-6](#)

Configuring Auto Identity Globally

To configure Auto Identity globally, perform this task:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# source template { AI_GLOBAL_CONFIG_TEMPLATE <i>template-name</i> }	Configures an auto identity template. <ul style="list-style-type: none"> • AI_GLOBAL_CONFIG_TEMPLATE is a built-in template. • The <i>template-name</i> argument is a user-defined template.
Step 4	Switch(config)# aaa new-model	Enables the authentication, authorization, and accounting (AAA) access control mode.
Step 5	Switch(config)# radius server name	Specifies the name for the RADIUS server configuration for Protected Access Credential (PAC) provisioning and enters RADIUS server configuration mode.
Step 6	Switch(config-radius-server)# address ipv4 { <i>hostname</i> <i>ipv4-address</i> }	Configures the IPv4 address for the RADIUS server accounting and authentication parameters. <div>  <p>Note This command is not a part of the global template, and you must configure it.</p> </div>

	Command or Action	Purpose
Step 7	Switch(config-radius-server)# key ipv4 {0 string 7 string} string	Specifies the authentication and encryption key for all RADIUS communications between the device and the RADIUS server.
		 Note This command is not a part of the global template, and you must configure it.
Step 8	Switch(config-radius-server)# end	Exits RADIUS server configuration mode and returns to privileged EXEC mode.

Configuring Auto Identity at an Interface Level

When you configure two interface templates, you must configure the **merge** keyword. If you do not, the last configured template is used.

	Command or Action	Purpose
Step 1	Switch# enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# interface type number	Configures an interface and enters interface configuration mode.
Step 4	Switch(config-if)# source template {AI_CLOSED_MODE AI_LOW_IMPACT_MODE AI_MONITOR_MODE template-name} [merge]	Configures a source template for the interface.
Step 5	Switch(config-if)# source template {AI_CLOSED_MODE AI_LOW_IMPACT_MODE AI_MONITOR_MODE template-name} [merge]	(Optional) Configures a source template for the interface and merges this template with the previously configured template. <ul style="list-style-type: none"> When you configure two templates, if you do not configure the merge keyword, the last configured template is used.
Step 6	Switch(config-if)# switchport access vlan vlan-id	Sets the VLAN when the interface is in access mode.
Step 7	Switch(config-if)# switchport voice vlan vlan-id	Configures a voice VLAN on a multiple VLAN access port.
Step 8	Repeat Steps 4, 6, and 7 on all interfaces that must have the Auto Identity feature configured.	—
Step 9	Switch(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.

Configuration Examples for Auto Identity

- [Example: Configuring Auto Identity Globally, page 54-7](#)
- [Example: Configuring Auto Identity at an Interface Level, page 54-7](#)

Example: Configuring Auto Identity Globally

```
Switch> enable
Switch# configure terminal
Switch(config)# source template AI_GLOBAL_CONFIG_TEMPLATE
Switch(config)# aaa new-model
Switch(config)# radius server ISE
Switch(config-radius-server)# address ipv4 10.1.1.1
Switch(config-radius-server)# key ipv4 cisco
Switch(config-radius-server)# end
```

Example: Configuring Auto Identity at an Interface Level

```
Switch> enable
Switch# configure terminal
Switch(config)# interface gigabitethernet 1/0/1
Switch(config-if)# source template AI_CLOSED_MODE
Switch(config-if)# source template AI_MONITOR_MODE merge
Switch(config-if)# switchport access vlan 100
Switch(config-if)# switchport voice vlan 101
Switch(config-if)# end
```

Verifying Auto Identity

To verify the Auto Identity configuration, use the following commands:

The following output from the **show template interface source built-in all** command displays all the configured built-in interface templates:

```
Switch# show template interface source built-in all
```

```
Template Name      : AI_CLOSED_MODE
Modified           : No
Template Definition :
  dot1x pae authenticator
  switchport mode access
  mab
  access-session closed
  access-session port-control auto
  service-policy type control subscriber AI_DOT1X_MAB_POLICIES
!
```

```
Template Name      : AI_LOW_IMPACT_MODE
Modified           : No
Template Definition :
  dot1x pae authenticator
  switchport mode access
  mab
  access-session port-control auto
  service-policy type control subscriber AI_DOT1X_MAB_POLICIES
  ip access-group AI_PORT_ACL in
!
```

```
Template Name      : AI_MONITOR_MODE
Modified           : No
Template Definition :
  dot1x pae authenticator
  switchport mode access
  mab
```

```

access-session port-control auto
service-policy type control subscriber AI_DOT1X_MAB_POLICIES
!

```

The following output from the **show template global source built-in all** command displays all the configured global built-in templates:

```

Switch# show template global source built-in all

Global Template Name      : AI_GLOBAL_CONFIG_TEMPLATE
Modified                  : No
Global Template Definition : global
dot1x system-auth-control
aaa new-model
aaa authentication dot1x default group radius
aaa authorization network default group radius
aaa authorization auth-proxy default group radius
aaa accounting identity default start-stop group radius
aaa accounting system default start-stop group radius
radius-server attribute 6 on-for-login-auth
radius-server attribute 6 support-multiple
radius-server attribute 6 voice 1
radius-server attribute 8 include-in-access-req
radius-server attribute 25 access-request include
!

```

The following output from the **show derived-config | include aaa | radius-server** command displays the composite results of all the configuration commands that apply to an interface, including commands that come from sources such as static templates, dynamic templates, dialer interfaces, and authentication, authorization, and accounting (AAA) per-user attributes:

```

Switch# show derived-config | include aaa | radius-server

aaa new-model
aaa authentication dot1x default group radius
aaa authorization network default group radius
aaa authorization auth-proxy default group radius
aaa accounting identity default start-stop group radius
aaa accounting system default start-stop group radius
aaa session-id common
radius-server attribute 6 on-for-login-auth
radius-server attribute 6 support-multiple
radius-server attribute 6 voice 1
radius-server attribute 8 include-in-access-req
radius-server attribute 25 access-request include
radius server host 10.25.18.42 key cisco

```

The following output from the **show derived-config | interface type-number** command displays the composite results of all configuration for an interface:

```

Switch# show derived-config | interface gigabitethernet2/0/6

Building configuration...
Derived configuration : 267 bytes
!
interface GigabitEthernet2/0/6
 switchport mode access
 switchport voice vlan 100
 access-session closed
 access-session port-control auto
 mab

```

```
dot1x pae authenticator
spanning-tree portfast edge
service-policy type control subscriber AI_DOT1X_MAB_POLICIES
end
```

The following output from the **show access-session | interface *interface-type-number*** details command displays the policies applied to an interface:

```
Switch# show access-session interface gigabitethernet2/0/6 details
```

```
Interface          : GigabitEthernet2/0/6
                   MAC Address: c025.5c43.be00
                   IPv6 Address: Unknown
                   IPv4 Address: Unknown
                   User-Name: CP-9971-SEPC0255C43BE00
                   Device-type: Cisco-IP-Phone-9971
                   Status: Authorized
                   Domain: VOICE
                   Oper host mode: multi-auth
                   Oper control dir: both
                   Session timeout: N/A
                   Common Session ID: 091A1C5B00000017002003EE

Configuring Port Security

This chapter describes how to configure port security on the Catalyst 4500 series switch. It provides an overview of port security on the Catalyst 4500 series switch and details the configuration on various types of ports such as access, voice, trunk, and private VLAN (PVLAN).

This chapter consists of these sections:

- [Port Security Commands, page 55-1](#)
- [About Port Security, page 55-3](#)
- [Configuring Port Security on Access Ports, page 55-7](#)
- [Configuring Port Security on PVLAN Ports, page 55-14](#)
- [Configuring Port Security on Trunk Ports, page 55-17](#)
- [Configuring Port Security on Voice Ports, page 55-22](#)
- [Displaying Port Security Settings, page 55-27](#)
- [Configuring Port Security with Other Features/Environments, page 55-31](#)
- [Port Security Configuration Guidelines and Restrictions, page 55-33](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Port Security Commands

This table lists the commands most commonly used with port security.

Command	Purpose	Navigation
errdisable recovery cause psecure-violation	Brings a secure port out of error-disabled state.	Violation Actions, page 55-6
errdisable recovery interval	Customizes the time to recover from a specified error disable cause.	Violation Actions, page 55-6

Command	Purpose	Navigation
port-security mac-address	Configures all secure MAC addresses on each VLAN.	Secure MAC Addresses, page 55-3
port-security maximum	Configures a maximum number of MAC addresses on an interface.	Configuring Port Security on Access Ports, page 55-7
private-vlan association add	Creates an association between a secondary VLAN and a primary VLAN.	Example of Port Security on an Isolated Private VLAN Host Port, page 55-16
private-vlan isolated	Designates the VLAN as a private VLAN.	Configuring Port Security on an Isolated Private VLAN Host Port, page 55-14
private-vlan primary	Specifies the VLAN as the primary private VLAN.	Configuring Port Security on an Isolated Private VLAN Host Port, page 55-14
switchport mode private-vlan host	Specifies that ports with valid private VLAN trunk association become active host private VLAN trunk ports.	Configuring Port Security on an Isolated Private VLAN Host Port, page 55-14
switchport private-vlan host-association	Defines a host association on an isolated host port.	Configuring Port Security on an Isolated Private VLAN Host Port, page 55-14
switchport private-vlan mapping	Defines a private VLAN for the promiscuous ports.	Configuring Port Security on an Isolated Private VLAN Host Port, page 55-14
switchport port-security	Enables port security.	Configuring Port Security on Access Ports, page 55-7
switchport port-security aging static	Configures static aging of MAC address.	Aging Secure MAC Addresses, page 55-5
switchport port-security aging time	Specifies an aging time for a port.	Example 3: Setting the Aging Timer, page 55-11
switchport port-security limit rate invalid-source-mac	Sets the rate limit for bad packets.	Example 7: Setting a Rate Limit for Bad Packets, page 55-13
switchport port-security mac-address	Configures a secure MAC address for an interface.	Example 5: Configuring a Secure MAC Address, page 55-12
switchport port-security mac-address <i>mac_address</i> sticky	Specifies the sticky MAC address for an interface.	Configuring Port Security on Access Ports, page 55-7
switchport port-security mac-address sticky	Enables sticky Port Security.	Sticky Addresses on a Port, page 55-5
no switchport port-security mac-address sticky	Converts a sticky secure MAC address to a dynamic MAC secure address.	Configuring Port Security on Access Ports, page 55-7
switchport port-security maximum	Sets the maximum number of secure MAC addresses for an interface.	Example 1: Setting Maximum Number of Secure Addresses, page 55-11
switchport port-security violation	Sets the violation mode.	Example 2: Setting a Violation Mode, page 55-11

Command	Purpose	Navigation
no switchport port-security violation	Sets the violation mode.	Configuring Port Security on Access Ports, page 55-7
switchport trunk encapsulation dot1q	Sets the encapsulation mode to dot1q.	Example 1: Configuring a Maximum Limit of Secure MAC Addresses for All VLANs, page 55-19

About Port Security

Port security enables you to restrict the number of MAC addresses (termed *secure MAC addresses*) on a port, allowing you to prevent access by unauthorized MAC addresses. It also allows you to configure a maximum number of secure MAC addresses on a given port (and optionally for a VLAN for trunk ports). When a secure port exceeds the maximum, a security violation is triggered, and a violation action is performed based on the violation action mode configured on the port.

If you configure the maximum number of secure MAC addresses as 1 on the port, the device attached to the secure port is assured sole access to the port.

If a secure MAC address is secured on a port, that MAC address is not allowed to enter on any other port off that VLAN. If it does, the packet is dropped unnoticed in the hardware. Other than using the interface or port counters, you do not receive a log message reflecting this fact. Be aware that this condition does not trigger a violation. Dropping these packets in the hardware is more efficient and can be done without putting additional load on the CPU.

Port security has the following characteristics:

- It allows you to age out secure MAC addresses. Two types of aging are supported: inactivity and absolute.
- It supports a sticky feature whereby the secure MAC addresses on a port are retained through switch reboots and link flaps.
- It can be configured on various types of ports such as access, voice, trunk, EtherChannel, and private VLAN ports.

This overview contains the following topics:

- [Secure MAC Addresses, page 55-3](#)
- [Maximum Number of Secure MAC Addresses, page 55-4](#)
- [Aging Secure MAC Addresses, page 55-5](#)
- [Sticky Addresses on a Port, page 55-5](#)
- [Violation Actions, page 55-6](#)

Secure MAC Addresses

Port security supports the following types of secure MAC addresses:

- **Dynamic or Learned**—Dynamic secure MAC addresses are learned when packets are received from the host on the secure port. You might want to use this type if the user's MAC address is not fixed (laptop).
- **Static or configured**—Static secure MAC addresses are configured by the user through CLI or SNMP. You might want to use this type if your MAC address remains fixed (PC).

- **Sticky**—Sticky addresses are learned such as dynamic secure MAC addresses, but persist through switch reboots and link flaps such as static secure MAC addresses. You might want to use this type if a large number of fixed MAC addresses exist and you do not want to configure MAC addresses manually (100 PCs secured on their own ports).

If a port has reached its maximum number of secure MAC addresses and you try to configure a static secure MAC address, your configuration is rejected and an error message displays. If a port has reached its maximum number of secure MAC addresses and a new dynamic secure MAC address is added, a violation action is triggered.

You can clear dynamic secure MAC addresses with the **clear port-security** command. You can clear sticky and static secure MAC addresses one at a time with the **no** form of the **switchport port-security mac-address** command.

Maximum Number of Secure MAC Addresses

A secure port has a default of one MAC address. You can change the default to any value between 1 and 3,000. The upper limit of 3,000 guarantees one MAC address per-port and an additional 3,000 across all ports in the system.

After you have set the maximum number of secure MAC addresses on a port, you can include the secure addresses in an address table in one of the following ways:

- You can configure the secure MAC addresses with the **switchport port-security mac-address mac_address** interface configuration command.
- You can configure all secure MAC addresses on a range of VLANs with the **port-security mac-address** VLAN range configuration command for trunk ports.
- You can allow the port to dynamically configure secure MAC addresses with the MAC addresses of connected devices.
- You can configure some of the addresses and allow the rest to be dynamically configured.

Note

If a port's link goes down, all dynamically secured addresses on that port are no longer secure.

- You can configure MAC addresses to be sticky. These can be dynamically learned or manually configured, stored in the address table, and added to the running configuration. After these addresses are saved in the configuration file, the interface does not need to dynamically relearn them when the switch restarts. Although you can manually configure sticky secure addresses, this action is not recommended.

Note

On a trunk port, a maximum number of secure MAC addresses can be configured on both the port and port VLAN. The port's maximum value can be greater than or equal to the port VLAN maximum(s) but not less than the port VLAN maximum(s). If the port's maximum value is less than at least one of the port VLAN's maximum (for example, if we have max set to 3 on VLAN 10 while no "sw port max" is set (defaults to 1)), the port shuts down when dynamic adds reaches 2 on VLAN 10 (see "Port Security Configuration Guidelines and Restrictions" on page 33). The port VLAN maximum enforces the maximum allowed on a given port on a given VLAN. If the maximum is exceeded on a given VLAN but the port's maximum is not exceeded, the port still shuts down. The entire port is shut down even if one of the VLANs on the port has actually caused the violation.

Aging Secure MAC Addresses

You might want to age secure MAC addresses when the switch may be receiving more than 3,000 MAC addresses ingress.

**Note**

Aging of sticky addresses is not supported.

By default, port security does not age out the secure MAC addresses. After learned, the MAC addresses remain on the port until either the switch reboots or the link goes down (unless the sticky feature is enabled). However, port security does allow you to configure aging based on the absolute or inactivity mode and aging interval (in minutes, from 1 to n).

- Absolute mode—Ages between n and n+1
- Inactivity mode—Ages between n+1 and n+2

Use this feature to remove and add PCs on a secure port without manually deleting the existing secure MAC addresses, while still limiting the number of secure addresses on a port.

Unless static aging is explicitly configured with the **switchport port-security aging static** command, static addresses are not aged even if aging is configured on the port.

**Note**

The aging increment is one minute.

Sticky Addresses on a Port

By enabling sticky port security, you can configure an interface to convert the dynamic MAC addresses to sticky secure MAC addresses and to add them to the running configuration. You might want to do this if you do not expect the user to move to another port, and you want to avoid statically configuring a MAC address on every port.

**Note**

If you use a different chassis, you might need another MAC address.

To enable sticky port security, enter the **switchport port-security mac-address sticky** command. When you enter this command, the interface converts all the dynamic secure MAC addresses, including those that were dynamically learned before sticky learning was enabled, to sticky secure MAC addresses.

The sticky secure MAC addresses do not automatically become part of the configuration file, which is the startup configuration used each time the switch restarts. If you save the running config file to the configuration file, the interface does not need to relearn these addresses when the switch restarts. If you do not save the configuration, they are lost.

If sticky port security is disabled, the sticky secure MAC addresses are converted to dynamic secure addresses and are removed from the running configuration.

After the maximum number of secure MAC addresses is configured, they are stored in an address table. To ensure that an attached device has sole access of the port, configure the MAC address of the attached device and set the maximum number of addresses to one, which is the default.

A security violation occurs if the maximum number of secure MAC addresses to a port has been added to the address table and a workstation whose MAC address is not in the address table attempts to access the interface.

Forbidden MAC Addresses

You can prevent the switch from learning specific MAC addresses, by forbidding the MAC addresses on all interfaces, globally, or on a specific port-security enabled interface.

Violation Actions

A security violation is triggered in these situations:

- When the number of secure MAC addresses on the port exceeds the maximum number of secure MAC addresses allowed on the port.

**Note**

A secure violation is not triggered if the host secured on one port shows up on another port. The Catalyst 4500 series switch drops such packets on the new port silently in the hardware and does not overload the CPU.

- Running diagnostic tests with port security enabled.

You can configure the interface for one of following violation modes, which are based on the response to the violation:

- Restrict—A port security violation restricts data (that is, packets are dropped in software), causes the SecurityViolation counter to increment, and causes an SNMP Notification to be generated. You might want to configure this mode in order to provide uninterrupted service/access on a secure port.

The rate at which SNMP traps are generated can be controlled by the **snmp-server enable traps port-security trap-rate** command. The default value (“0”) causes an SNMP trap to be generated for every security violation.

- Shutdown—A port security violation causes the interface to shut down immediately. You might want to configure this mode in a highly secure environment, where you do not want unsecured MAC addresses to be denied in software and service interruption is not an issue.
- Shutdown VLAN—Use to set the security violation mode for each VLAN. In this mode, the offending VLAN is error disabled instead of the entire port when a violation occurs.

When a secure port is in the error-disabled state, you can bring it out of this state automatically by configuring the **errdisable recovery cause psecure-violation** global configuration command or you can manually reen able it by entering the **shutdown** and **no shut down** interface configuration commands. it is the default mode. If a port is in per-VLAN errdisable mode, you can also use **clear errdisable interface name vlan range** command to reen able the VLAN on the port.

You can also customize the time to recover from the specified error disable cause (default is 300 seconds) by entering the **errdisable recovery interval interval** command.

Invalid Packet Handling

You might want to rate limit invalid source MAC address packets on a secure port if you anticipate that a device will send invalid packets (such as traffic generator, sniffer, and bad NICs).

The port security feature considers the following as “invalid frames”:

- Packets with a source or destination MAC address that is all zero
- Packets with a multicast or broadcast source MAC address
- Packets from an address either learned or configured on a secure interface that are observed on another secure interface in the same VLAN

You can chose to rate limit these packets. If the rate is exceeded, you can trigger a violation action for the port.

Configuring Port Security on Access Ports

These sections describe how to configure port security:

- [Configuring Port Security on Access Ports, page 55-7](#)
- [Examples of Port Security on Access Ports, page 55-10](#)

Note

Port security can be enabled on a Layer 2 port channel interface configured in access mode. The port security configuration on an EtherChannel is independent of the configuration of any member ports.

Configuring Port Security on Access Ports

To restrict traffic through a port by limiting and identifying MAC addresses of the stations allowed to the port, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface <i>interface_id</i> interface <i>port-channel port_channel_number</i>	Enters interface configuration mode and specifies the interface to configure. Note The interface can be a Layer 2 port channel logical interface.
Step 2	Switch(config-if)# switchport mode access	Sets the interface mode. Note An interface in the default mode (dynamic auto) cannot be configured as a secure port.
Step 3	Switch(config-if)# [no] switchport port-security	Enables port security on the interface. To return the interface to the default condition as a not secured, use the no switchport port-security command.
Step 4	Switch(config-if)# [no] switchport port-security maximum <i>value</i>	(Optional) Sets the maximum number of secure MAC addresses for the interface. The range is 1 to 3072; the default is 1. To return the interface to the default number of secure MAC addresses, use the no switchport port-security maximum <i>value</i> .

Command	Purpose
Step 5 Switch(config-if)# switchport port-security mac-address forbidden OR Switch(config)# port-security mac-address forbidden	(Optional) Sets the MAC address forbidden on the interface. OR Optional) Sets the MAC address forbidden on all interfaces, globally. To verify the MAC addresses forbidden on the interface, use the show port-security address forbidden command, in privileged EXEC mode.
Step 6 Switch(config-if)# switchport port-security [aging {static time aging_time type {absolute inactivity}}]	Sets the aging time and aging type for all secure addresses on a port. Use this feature to remove and add PCs on a secure port without manually deleting the existing secure MAC addresses while still limiting the number of secure addresses on a port. The static keyword enables aging for statically configured secure addresses on this port. The time aging_time value specifies the aging time for this port. Valid range for <i>aging_time</i> is from 0 to 1440 minutes. If the time is equal to 0, aging is disabled for this port. The type keyword sets the aging type as absolute or inactive . <ul style="list-style-type: none"> • absolute—All the secure addresses on this port age out exactly after the time (minutes) specified and are removed from the secure address list. • inactive—The secure addresses on this port age out only if there is no data traffic from the secure source address for the specified time period. To disable port security aging for all secure addresses on a port, use the no switchport port-security aging time interface configuration command.

	Command	Purpose
Step 7	Switch(config-if)# [no] switchport port-security violation {restrict shutdown shutdown vlan}	<p>(Optional) Sets the violation mode, the action to be taken when a security violation is detected, as one of these:</p> <ul style="list-style-type: none"> • restrict—A port security violation restricts data and causes the SecurityViolation counter to increment and send an SNMP trap notification. • shutdown—The interface is error-disabled when a security violation occurs. • shutdown vlan—Use to set the security violation mode for each VLAN. In this mode, the VLAN is error-disabled instead of the entire port when a violation occurs. <p>Note When a secure port is in the error-disabled state, you can bring it out of this state by entering the errdisable recovery cause psecure-violation global configuration command or you can manually reenable it by entering the shutdown and no shut down interface configuration commands.</p> <p>To return the violation mode to the default condition (shutdown mode), use the no switchport port-security violation shutdown command.</p>
Step 8	Switch(config-if)# switchport port-security limit rate invalid-source-mac <i>packets_per_sec</i>	<p>Sets the rate limit for bad packets.</p> <p>Default is 10 pps.</p>
Step 9	Switch(config-if)# [no] switchport port-security mac-address <i>mac_address</i>	<p>(Optional) Enters a secure MAC address for the interface. You can use this command to configure a secure MAC addresses. If you configure fewer secure MAC addresses than the maximum, the remaining MAC addresses are dynamically learned.</p> <p>To delete a MAC address from the address table, use the no switchport port-security mac-address <i>mac_address</i> command.</p> <p>Note This command only applies to access, PVLAN host, and PVLAN promiscuous mode. For more details on PVLAN, trunk, or regular trunk mode, refer to the “Configuring Port Security on Trunk Ports” section on page 55-17.</p>
Step 10	Switch(config-if)# [no] switchport port-security mac-address sticky	<p>(Optional) Enables sticky learning on the interface.</p> <p>To disable sticky learning on an interface, use the no switchport port-security mac-address sticky command. The interface converts the sticky secure MAC addresses to dynamic secure addresses.</p>

Command	Purpose
Step 11 Switch(config-if)# [no] switchport port-security mac-address <i>mac_address</i> sticky [vlan [voice access]]	<p>Specifies the sticky mac-address for the interface.</p> <p>When you specify the vlan keyword, the mac-address becomes sticky in the specified VLAN.</p> <p>To delete a sticky secure MAC addresses from the address table, use the no switchport port-security mac-address <i>mac_address</i> sticky command. To convert sticky to dynamic addresses, use the no switchport port-security mac-address sticky command.</p> <p>Note This command only applies to access, PVLAN host, and PVLAN promiscuous mode. For more details on PVLAN or trunk or regular trunk mode, refer to the “Configuring Port Security on Trunk Ports” section on page 55-17.</p>
Step 12 Switch(config-if)# end	Returns to privileged EXEC mode.
Step 13 Switch# show port-security address Switch# show port-security address	Verifies your entries.

**Note**

To clear dynamically learned port security MAC addresses in the CAM table, use the clear port-security dynamic command. The address keyword enables you to clear a secure MAC addresses. The interface keyword enables you to clear all secure addresses on any interface (including any port channel interface). The VLAN keyword allows you to clear port security MACs on a per-VLAN per-port basis.

Examples of Port Security on Access Ports

The following examples are provided:

- [Example 1: Setting Maximum Number of Secure Addresses, page 55-11](#)
- [Example 2: Setting a Violation Mode, page 55-11](#)
- [Example 3: Setting the Aging Timer, page 55-11](#)
- [Example 4: Setting the Aging Timer Type, page 55-12](#)
- [Example 5: Configuring a Secure MAC Address, page 55-12](#)
- [Example 6: Configuring Sticky Port Security, page 55-13](#)
- [Example 7: Setting a Rate Limit for Bad Packets, page 55-13](#)
- [Example 8: Clearing Dynamic Secure MAC Addresses, page 55-14](#)

Example 1: Setting Maximum Number of Secure Addresses

This example shows how to enable port security on the Fast Ethernet interface 3/12 and how to set the maximum number of secure addresses to 5. The violation mode is the default, and no secure MAC addresses are configured.

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 3/12
Switch(config-if)# switchport mode access
Switch(config-if)# switchport port-security
Switch(config-if)# switchport port-security maximum 5
Switch(config-if)# switchport port-security mac-address sticky
Switch(config-if)# end
Switch# show port-security interface fastethernet 3/12
Port Security                : Enabled
Port Status                  : Secure-up
Violation Mode                : Shutdown
Aging Time                   : 0 mins
Aging Type                    : Absolute
SecureStatic Address Aging   : Enabled
Maximum MAC Addresses        : 5
Total MAC Addresses          : 0
Configured MAC Addresses     : 0
Sticky MAC Addresses         : 0
Last Source Address:Vlan    : 0000.0000.0000:0
Security Violation Count     : 0
```

Example 2: Setting a Violation Mode

This example shows how to set the violation mode on the Fast Ethernet interface 3/12 to restrict.

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 3/12
Switch(config-if)# switchport port-security violation restrict
Switch(config-if)# end
Switch#
```

SNMP traps can be enabled with a rate-limit to detect port-security violations due to restrict mode. The following example shows how to enable traps for port-security with a rate of 5 traps per second:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# snmp-server enable traps port-security trap-rate 5
Switch(config)# end
Switch#
```

Example 3: Setting the Aging Timer

This example shows how to set the aging time to 2 hours (120 minutes) for the secure addresses on the Fast Ethernet interface 5/1:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 5/1
Switch(config-if)# switchport port-security aging time 120
Switch(config-if)# end
Switch#
```

This example shows how to set the aging time to 2 minutes:

```
Switch(config-if)# switchport port-security aging time 2
```

You can verify the previous commands with the **show port-security interface** command.

Example 4: Setting the Aging Timer Type

This example shows how to set the aging timer type to Inactivity for the secure addresses on the Fast Ethernet interface 3/5:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 3/5
Switch(config-if)# switchport port-security aging type inactivity
Switch(config-if)# end
Switch# show port-security interface fastethernet 3/5
Port Security           : Enabled
Port Status             : Secure-up
Violation Mode          : Shutdown
Aging Time              : 0 mins
Aging Type              : Inactivity
SecureStatic Address Aging : Disabled
Maximum MAC Addresses   : 1
Total MAC Addresses     : 0
Configured MAC Addresses : 0
Sticky MAC Addresses    : 0
Last Source Address:Vlan : 0000.0000.0000:0
Security Violation Count : 0
```

Example 5: Configuring a Secure MAC Address

This example shows how to configure a secure MAC address on Fast Ethernet interface 5/1 and to verify the configuration:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 5/1
Switch(config-if)# switchport mode access
Switch(config-if)# switchport port-security
Switch(config-if)# switchport port-security maximum 10
Switch(config-if)# switchport port-security mac-address 0000.0000.0003 (Static secure MAC)
Switch(config-if)# end
Switch#show port address
Secure Mac Address Table
-----
```

Vlan	Mac Address	Type	Ports	Remaining Age (mins)
1	0000.0000.0003	SecureConfigured	Fa5/1	-

```
-----
Total Addresses in System (excluding one mac per port) : 2
Max Addresses limit in System (excluding one mac per port) : 3072
```

Example 6: Configuring Sticky Port Security

This example shows how to configure a sticky MAC address on Fast Ethernet interface 5/1 and to verify the configuration:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fa5/1
Switch(config-if)# switchport mode access
Switch(config-if)# switchport port-security
Switch(config-if)# switchport port-security mac-address sticky
Switch(config-if)# switchport port-security maximum 5
Switch(config-if)# end
```

Note

Sending traffic to the ports causes the system to configure the port with sticky secure addresses.

```
Switch# show port-security address
Secure Mac Address Table
-----
Vlan    Mac Address      Type                Ports    Remaining Age
(mins)
-----
1       0000.0000.0001   SecureSticky        Fa5/1    -
1       0000.0000.0002   SecureSticky        Fa5/1    -
1       0000.0000.0003   SecureSticky        Fa5/1    -
-----
Total Addresses in System (excluding one mac per port) : 2
Max Addresses limit in System (excluding one mac per port) : 3072
Switch# show running-config interface fastEthernet 5/1
Building configuration...

Current configuration : 344 bytes
!
interface FastEthernet5/1
 switchport mode access
 switchport port-security
 switchport port-security maximum 5
 switchport port-security mac-address sticky
 switchport port-security mac-address sticky 0000.0000.0001
 switchport port-security mac-address sticky 0000.0000.0002
 switchport port-security mac-address sticky 0000.0000.0003
end

Switch#
```

Example 7: Setting a Rate Limit for Bad Packets

The following example shows how to configure rate limit for invalid source packets on Fast Ethernet interface 5/1:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 5/1
Switch(config-if)# switchport port-security limit rate invalid-source-mac 100
Switch(config-if)# end
Switch#
```

The following example shows how to configure rate limit for invalid source packets on Fast Ethernet interface 5/1:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 5/1
Switch(config-if)# switchport port-security limit rate invalid-source-mac none
Switch(config-if)# end
Switch#
```

Example 8: Clearing Dynamic Secure MAC Addresses

The following example shows how to clear a dynamic secure MAC address:

```
Switch# clear port-security dynamic address 0000.0001.0001
```

The following example shows how to clear all dynamic secure MAC addresses on Fast Ethernet interface 2/1:

```
Switch# clear port-security dynamic interface fa2/1
```

The following example shows how to clear all dynamic secure MAC addresses in the system:

```
Switch# clear port-security dynamic
```

Configuring Port Security on PVLAN Ports

You can configure port security on a private VLAN port to take advantage of private VLAN functionality as well as to limit the number of MAC addresses.

Note

This section follows the same configuration model that was presented for access ports.

These sections describe how to configure trunk port security on host and promiscuous ports:

- [Configuring Port Security on an Isolated Private VLAN Host Port, page 55-14](#)
- [Example of Port Security on an Isolated Private VLAN Host Port, page 55-16](#)
- [Configuring Port Security on a Private VLAN Promiscuous Port, page 55-16](#)
- [Example of Port Security on a Private VLAN Promiscuous Port, page 55-17](#)

Configuring Port Security on an Isolated Private VLAN Host Port

[Figure 55-1](#) illustrates a typical topology for port security implemented on private VLAN host ports. In this topology, the PC connected through port a on the switch can communicate only with the router connected using the promiscuous port on the switch. The PC connected through port a cannot communicate with the PC connected through port b.

Figure 55-1 Port Security on Isolated Private VLAN Host Ports**Note**

Dynamic addresses secured on an isolated private VLAN host port on private VLANs are secured on the secondary VLANs, and not primary VLANs.

To configure port security on an isolated private VLAN host port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enter global configuration mode.
Step 2	Switch(config)# vlan sec_vlan_id	Specifies a secondary VLAN.
Step 3	Switch(config-vlan)# private-vlan isolated	Sets the private VLAN mode to isolated.
Step 4	Switch(config-vlan)# exit	Returns to global configuration mode.
Step 5	Switch(config)# vlan pri_vlan_id	Specifies a primary VLAN.
Step 6	Switch(config-vlan)# private-vlan primary	Specifies the VLAN as the primary private VLAN.
Step 7	Switch(config-vlan)# private-vlan association add sec_vlan_id	Creates an association between a secondary VLAN and a primary VLAN.
Step 8	Switch(config-vlan)# exit	Returns to global configuration mode.
Step 9	Switch(config)# interface interface_id	Enters interface configuration mode and specifies the physical interface to configure.
Step 10	Switch(config-if)# switchport mode private-vlan host	Specifies that the ports with a valid private VLAN trunk association become active host private VLAN trunk ports.
Step 11	Switch(config-if)# switchport private-vlan host-association primary_vlan secondary_vlan	Establishes a host association on an isolated host port.
Step 12	Switch(config-if)# [no] switchport port-security	Enables port security on the interface.
Step 13	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 14	Switch# show port-security address interface interface_id Switch# show port-security address	Verifies your entries.

Example of Port Security on an Isolated Private VLAN Host Port

The following example shows how to configure port security on an isolated private VLAN host port, Fast Ethernet interface 3/12:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vlan 6
Switch(config-vlan)# private-vlan isolated
Switch(config-vlan)# exit
Switch(config)# vlan 3
Switch(config-vlan)# private-vlan primary
Switch(config-vlan)# private-vlan association add 6
Switch(config-vlan)# exit
Switch(config)# interface fastethernet 3/12
Switch(config-if)# switchport mode private-vlan host
Switch(config-if)# switchport private-vlan association host 3 6
Switch(config-if)# switchport port-security
Switch(config-if)# end
```

Configuring Port Security on a Private VLAN Promiscuous Port

To configure port security on a private VLAN promiscuous port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# vlan <i>sec_vlan_id</i>	Specifies the VLAN.
Step 3	Switch(config-vlan)# private-vlan isolated	Sets the private VLAN mode to isolated.
Step 4	Switch(config-vlan)# exit	Returns to global configuration mode.
Step 5	Switch(config)# vlan <i>pri_vlan_id</i>	Specifies the VLAN.
Step 6	Switch(config-vlan)# private-vlan primary	Designates the VLAN as the primary private VLAN.
Step 7	Switch(config-vlan)# private-vlan association add <i>sec_vlan_id</i>	Creates an association between a secondary VLAN and a primary VLAN.
Step 8	Switch(config-vlan)# exit	Returns to global configuration mode.
Step 9	Switch(config)# interface <i>interface_id</i>	Enters interface configuration mode and specifies the physical interface to configure.
Step 10	Switch(config-if)# switchport mode private-vlan promiscuous	Specifies that the ports with a valid PVLAN mapping become active promiscuous ports.
Step 11	Switch(config-if)# switchport private-vlan mapping <i>primary_vlan secondary_vlan</i>	Configures a private VLAN for the promiscuous ports.
Step 12	Switch(config-if)# switchport port-security	Enables port security on the interface.
Step 13	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 14	Switch# show port-security address interface <i>interface_id</i> Switch# show port-security address	Verifies your entries.

Example of Port Security on a Private VLAN Promiscuous Port

The following example shows how to configure port security on a private VLAN promiscuous port, Fast Ethernet interface 3/12:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vlan 6
Switch(config-vlan)# private-vlan isolated
Switch(config-vlan)# exit
Switch(config)# vlan 3
Switch(config-vlan)# private-vlan primary
Switch(config-vlan)# private-vlan association add 6
Switch(config-vlan)# exit
Switch(config)# interface fastethernet 3/12
Switch(config-if)# switchport mode private-vlan promiscuous
Switch(config-if)# switchport mode private-vlan mapping 3 6
Switch(config-if)# switchport port-security
Switch(config-if)# end
```

Configuring Port Security on Trunk Ports

You might want to configure port security on trunk ports in metro aggregation to limit the number of MAC addresses per-VLAN. Trunk port security extends port security to trunk ports. It restricts the allowed MAC addresses or the maximum number of MAC addresses to individual VLANs on a trunk port. Trunk port security enables service providers to block the access from a station with a different MAC address than the ones specified for that VLAN on that trunk port. Trunk port security is also supported on private VLAN trunk ports.

Note

Port security can be enabled on a Layer 2 port channel interface configured in mode. The port security configuration on an EtherChannel is kept independent of the configuration of any physical member ports.

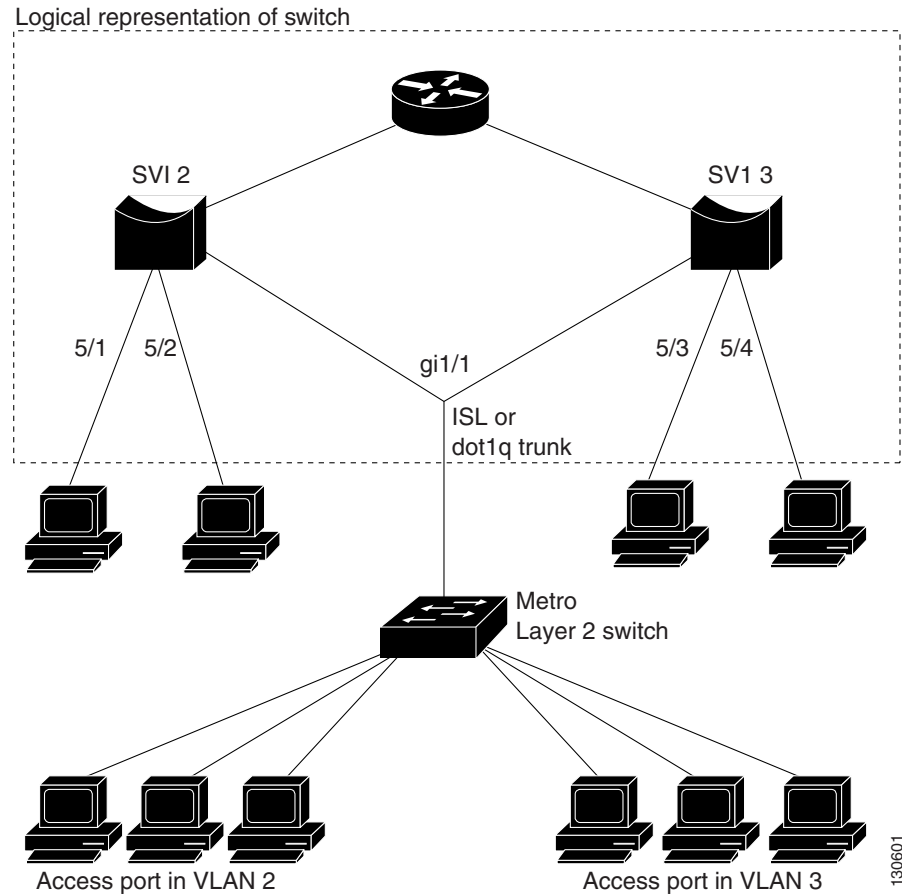

These sections describe how to configure trunk port security:

- [Configuring Trunk Port Security, page 55-17](#)
- [Examples of Trunk Port Security, page 55-19](#)
- [Trunk Port Security Configuration Guidelines and Restrictions, page 55-21](#)

Configuring Trunk Port Security

Trunk port security is used when a Catalyst 4500 series switch has a dot1q or isl trunk attached to a neighborhood Layer 2 switch. This may be used, for example, in metro aggregation networks ([Figure 55-2](#)).

Figure 55-2 Trunk Port Security

You can configure various port security related parameters on a per-port per-VLAN basis.

Note

The steps involved in configuring port security parameters is similar to those for access ports. In addition to those steps, the following per-port per-VLAN configuration steps are supported for trunk ports.

To configure port security related parameters on a per-VLAN per-port basis, perform this task:

Command	Purpose
Step 1 Switch(config)# interface <i>interface_id</i> interface <i>port-channel port_channel_number</i>	Enters interface configuration mode and specifies the interface to configure. Note The interface can be a Layer 2 port channel logical interface.
Step 2 Switch(config-if)# switchport trunk encapsulation dot1q	Sets the trunk encapsulation format to 802.1Q.
Step 3 Switch(config-if)# switchport mode trunk	Sets the interface mode. Note An interface in the default mode (dynamic auto) cannot be configured as a secure port.

	Command	Purpose
Step 4	Switch(config-if)# switchport port-security maximum value vlan	Configures a maximum number of secure mac-addresses for each VLAN on the interface that are not explicitly configured with a maximum mac-address limit. See the “Maximum Number of Secure MAC Addresses” section on page 55-4.
Step 5	Switch(config-if)# vlan-range range	Enters VLAN range sub-mode. Note You can specify single or multiple VLANs.
Step 6	Switch(config-if-vlan-range)# port-security maximum value	Configures a maximum number of secure MAC addresses for each VLAN.
Step 7	Switch(config-if-vlan-range)# no port-security maximum	Removes a maximum number of secure MAC addresses configuration for all the VLANs. Subsequently, the maximum value configured on the port will be used for all the VLANs.
Step 8	Switch(config-if-vlan-range)# [no] port-security mac-address mac_address	Configures a secure MAC-address on a range of VLANs.
Step 9	Switch(config-if-vlan-range)# [no] port-security mac-address sticky mac_address	Configures a sticky MAC-address on a range of VLANs.
Step 10	Switch(config-if-vlan-range)# end	Returns to interface configuration mode.
Step 11	Switch(config-if)# end	Returns to privileged EXEC mode.

Examples of Trunk Port Security

The following examples are provided:

- [Example 1: Configuring a Maximum Limit of Secure MAC Addresses for All VLANs, page 55-19](#)
- [Example 2: Configuring a Maximum Limit of Secure MAC Addresses for Specific VLANs, page 55-20](#)
- [Example 3: Configuring Secure MAC Addresses in a VLAN Range, page 55-20](#)

Example 1: Configuring a Maximum Limit of Secure MAC Addresses for All VLANs

This example shows how to configure a secure MAC-address and a maximum limit of secure MAC addresses on Gigabit Ethernet interface 1/1 for all VLANs:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface g1/1
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# sw mode trunk
Switch(config-if)# switchport port-security
Switch(config-if)# switchport port-security maximum 3

Switch# show port-security in g1/1 vlan
Default maximum: 3
VLAN  Maximum      Current
    1         3         0
    2         3         0
    3         3         0
    4         3         0
```

```

5          3          0
6          3          0
Switch#

Switch# show running interface g1/1
Building configuration...

Current configuration : 161 bytes
!
interface GigabitEthernet1/1
 switchport trunk encapsulation dot1q
 switchport mode trunk
 switchport port-security
 switchport port-security maximum 3 vlan
end

```

Example 2: Configuring a Maximum Limit of Secure MAC Addresses for Specific VLANs

This example shows how to configure a secure MAC-address on interface g1/1 in a specific VLAN or range of VLANs:

```

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface g1/1
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# sw mode trunk
Switch(config-if)# switchport port-security
Switch(config-if)# vlan-range 2-6
Switch(config-if-vlan-range)# port-security maximum 3
Switch(config-if-vlan-range)# exit

Switch# show port-security interface g1/1 vlan
Default maximum: not set, using 3072
VLAN  Maximum    Current
2          3          0
3          3          0
4          3          0
5          3          0
6          3          0
Switch#

```

Example 3: Configuring Secure MAC Addresses in a VLAN Range

This example shows how to configure a secure MAC-address in a VLAN on interface g1/1:

```

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface g1/1
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# sw mode trunk
Switch(config-if)# switchport port-security
Switch(config-if)# switchport port-security mac-address sticky
Switch(config-if)# vlan-range 2-6
Switch(config-if-vlan-range)# port-security mac-address 1.1.1
Switch(config-if-vlan-range)# port-security mac-address sticky 1.1.2
Switch(config-if-vlan-range)# port-security mac-address sticky 1.1.3
Switch(config-if-vlan-range)# exit

```

```
Switch# show port-security interface g1/1 address vlan 2-4
Secure Mac Address Table
```

Vlan	Mac Address	Type	Ports	Remaining Age (mins)
2	0001.0001.0001	SecureConfigured	Gi1/1	-
2	0001.0001.0002	SecureSticky	Gi1/1	-
2	0001.0001.0003	SecureSticky	Gi1/1	-

```

```
Switch#
```

Trunk Port Security Configuration Guidelines and Restrictions

When configuring port security related parameters on a per-port per-VLAN basis, consider these guidelines and restrictions:

- A secure MAC-address cannot be configured on a VLAN that is not allowed on a regular trunk port.
- The configuration on the primary VLAN on the private VLAN trunk is not allowed. The CLI is rejected and an error message is displayed.
- If a specific VLAN on a port is not configured with a maximum value (directly or indirectly), the maximum configured for the port is used for that VLAN. In this situation, the maximum number of addresses that can be secured on this VLAN is limited to the maximum value configured on the port.

Each VLAN can be configured with a maximum count that is greater than the value configured on the port. Also, the sum of the maximum configured values for all the VLANs can exceed the maximum configured for the port. In either of these situations, the number of MAC addresses secured on each VLAN is limited to the lesser of the VLAN configuration maximum and the port configuration maximum. Also, the number of addresses secured on the port across all VLANs cannot exceed a maximum that is configured on the port.

- For private VLAN trunk ports, the VLAN on which the configuration is being performed must be in either the allowed VLAN list of the private VLAN trunk or the secondary VLAN list in the association pairs. (The CLI is rejected if this condition is not met.) The allowed VLAN list on a private VLAN trunk is intended to hold the VLAN-IDs of all the regular VLANs that are allowed on the private VLAN trunk.
- Removal of an association pair from a PVLAN trunk causes all static and sticky addresses associated with the secondary VLAN of the pair to be removed from the running configuration. Dynamic addresses associated with the secondary VLAN are deleted from the system.

Similarly, when a VLAN is removed from the list of allowed PVLAN trunks, the addresses associated with that VLAN are removed.

Note

For a regular or private VLAN trunk port, if the VLAN is removed from the allowed VLAN list, all the addresses associated with that VLAN are removed.

Port Mode Changes

Generally, when a port mode changes, all dynamic addresses associated with that port are removed. All static or sticky addresses and other port security parameters configured on the native VLAN are moved to the native VLAN of the port in the new mode. All the addresses on the non-native VLANs are removed.

The native VLAN refers to the following VLAN on the specified port type:

Port Type	Native VLAN
access	access VLAN
trunk	native VLAN
isolated	secondary VLAN (from host association)
promiscuous	primary VLAN (from mapping)
private VLAN trunk	private VLAN trunk native VLAN
.1Q tunnel	access VLAN

For example, when the mode changes from access to private VLAN trunk, all the static or sticky addresses configured on the access VLAN of the access port are moved to the private VLAN native VLAN of the private VLAN trunk port. All other addresses are removed.

Similarly, when the mode changes from private VLAN trunk to access mode, all the static or sticky addresses configured on the private VLAN native VLAN are moved to the access VLAN of the access port. All other addresses are removed.

When a port is changed from trunk to private VLAN trunk, addresses associated with a VLAN on the trunk are retained if that VLAN is present in the allowed list of private VLAN trunk or the secondary VLAN of an association on the private VLAN trunk. If the VLAN is not present in either of them, the address is removed from the running configuration.

When a port is changed from private VLAN trunk to trunk, a static or sticky address is retained if the VLAN associated with the address is present in the allowed VLAN list of the trunk. If the VLAN is not present in the allowed list, the address is removed from running configuration.

Configuring Port Security on Voice Ports

You might want to configure port security in an IP phone environment when a port is configured with a data VLAN for a PC and a voice VLAN for a Cisco IP Phone.

These sections describe how to configure port security on voice ports:

- [Configuring Port Security on Voice Ports, page 55-23](#)
- [Examples of Voice Port Security, page 55-25](#)
- [Voice Port Security Configuration Guidelines and Restrictions, page 55-27](#)

Configuring Port Security on Voice Ports

To configure port security on a voice port, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface <i>interface_id</i>	Enters interface configuration mode and specifies the physical interface to configure.
Step 2	Switch(config-if)# switchport mode access	Sets the interface mode. Note An interface in the default mode (dynamic auto) cannot be configured as a secure port.
Step 3	Switch(config-if)# [no] switchport port-security	Enables port security on the interface. To return the interface to the default condition as not secured, use the no switchport port-security command.
Step 4	Switch(config-if)# [no] switchport port-security violation { restrict shutdown }	(Optional) Sets the violation mode, the action to be taken when a security violation is detected, as one of these: <ul style="list-style-type: none"> • restrict—A port security violation restricts data and causes the SecurityViolation counter to increment and send an SNMP trap notification. • shutdown—The interface is error-disabled when a security violation occurs. Note When a secure port is in the error-disabled state, you can bring it out of this state by entering the errdisable recovery cause psecure-violation global configuration command or you can manually reen able it by entering the shutdown and no shut down interface configuration commands. To return the violation mode to the default condition (shutdown mode), use the no switchport port-security violation shutdown command.
Step 5	Switch(config-if)# switchport port-security limit rate invalid-source-mac <i>packets_per_sec</i>	Sets the rate limit for bad packets. Default is 10 pps.

Command	Purpose
Step 6 Switch(config-if)# [no] switchport port-security mac-address <i>mac_address</i> [vlan { voice access }]	<p>(Optional) Specifies a secure MAC address for the interface.</p> <p>When you specify the vlan keyword, addresses are configured in the specified VLAN.</p> <ul style="list-style-type: none"> • voice—MAC address is configured in the voice VLAN. • access—MAC address is configured in the access VLAN. <p>You can use this command to configure secure MAC addresses. If you configure fewer secure MAC addresses than the maximum, the remaining MAC addresses are dynamically learned.</p> <p>To delete a MAC address from the address table, use the no switchport port-security mac-address <i>mac_address</i> command.</p> <p>Note This command only applies to access, PVLAN host, and PVLAN promiscuous mode. For more details on PVLAN, trunk, or regular trunk mode, refer to the “Configuring Port Security on Trunk Ports” section on page 55-17.</p>
Step 7 Switch(config-if)# [no] switchport port-security mac-address sticky	<p>(Optional) Enables sticky learning on the interface.</p> <p>To disable sticky learning on an interface, use the no switchport port-security mac-address sticky command. The interface converts the sticky secure MAC addresses to dynamic secure addresses.</p>
Step 8 Switch(config-if)# [no] switchport port-security mac-address <i>mac_address</i> sticky [vlan { voice access }]	<p>Specifies the sticky mac-address for the interface.</p> <p>When you specify the vlan keyword, the mac-address becomes sticky in the specified VLAN.</p> <ul style="list-style-type: none"> • voice—MAC address becomes sticky in the voice VLAN. • access—MAC address becomes sticky in the access VLAN. <p>To delete a sticky secure MAC addresses from the address table, use the no switchport port-security mac-address <i>mac_address</i> sticky command. To convert sticky to dynamic addresses, use the no switchport port-security mac-address sticky command.</p> <p>Note This command only applies to access, PVLAN host, and PVLAN promiscuous mode. For more details on PVLAN or trunk or regular trunk mode, refer to the “Configuring Port Security on Trunk Ports” section on page 55-17.</p>

	Command	Purpose
Step 9	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 10	Switch# show port-security address Switch# show port-security address Switch# show port-security address	Verifies your entries.

**Note**

To clear dynamically learned port security MAC addresses in the CAM table, use the **clear port-security dynamic** command. The **address** keyword enables you to clear a secure MAC addresses. The **interface** keyword enables you to clear all secure addresses on an interface (including any port channel interface). The **VLAN** keyword allows you to clear port security MACs on a per-VLAN per-port basis.

**Note**

Each port security-configured interface accepts one MAC-address by default. With port security port level port-security configuration takes precedence over VLAN level port-security configuration. To allow one MAC-address each for voice and data VLAN, configure the port for a maximum of greater than or equal to two addresses.

Examples of Voice Port Security

The following examples are provided:

- [Example 1: Configuring Maximum MAC Addresses for Voice and Data VLANs, page 55-25](#)
- [Example 2: Configuring Sticky MAC Addresses for Voice and Data VLANs, page 55-26](#)

Example 1: Configuring Maximum MAC Addresses for Voice and Data VLANs

This example shows how to designate a maximum of one MAC address for a voice VLAN (for a Cisco IP Phone, let's say) and one MAC address for the data VLAN (for a PC, let's say) on Fast Ethernet interface 5/1 and to verify the configuration:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fa5/1
Switch(config-if)# switchport mode access
Switch(config-if)# switchport port-security
Switch(config-if)# switchport port-security maximum 2
Switch(config-if)# switchport port-security mac-address sticky
Switch(config-if)# switchport port-security maximum 1 vlan voice
Switch(config-if)# switchport port-security maximum 1 vlan access
Switch(config-if)# end
```

**Note**

Sending traffic to the ports causes the system to configure the port with sticky secure addresses.

```
Switch# show port-security address
      Secure Mac Address Table

Voice Port Security Configuration Guidelines and Restrictions

Note

When a Catalyst 4500 series switch port is configured to support voice as well as port security, a security violation occurs on subsequent shut down when the number of MAC addresses on the port is equal to the maximum number of allowable secure MAC addresses. To avoid the security violation, configure the maximum number of secure MAC addresses to be more than the number of MAC addresses on the port.

Note

Port security as implemented on voice ports functions the same as port security on access ports.

When using (or configuring) voice port security, consider these guidelines and restrictions:

- You can configure sticky port security on voice ports. If sticky port security is enabled on a voice port, addresses secured on data and voice VLANs are secured as sticky addresses.
- You can configure maximum secure addresses per-VLAN. You can set a maximum for either the data VLAN or the voice VLAN. You can also set a maximum per-port, just as with access ports.
- You can configure port security MAC addresses on a per-VLAN basis on either the data or voice VLANs.
- Prior to Cisco IOS Release 12.2(31)SG, you required three MAC addresses as the maximum parameter to support an IP phone and a PC. With Cisco IOS Release 12.2(31)SG and later releases, the maximum parameter must be configured to two, one for the phone and one for the PC.

Displaying Port Security Settings

Use the **show port-security** command to display port security settings for an interface or for the switch.

To display traffic control information, perform one or more of these tasks:

Command	Purpose
Switch# show interface status err-disable	Displays interfaces that have been error-disabled along with the cause for which they were disabled.
Switch# show port-security [interface <i>interface_id</i> / interface <i>port_channel port_channel_number</i>]	Displays port security settings for the switch or for the specified interface, including the maximum allowed number of secure MAC addresses for each interface, the number of secure MAC addresses on the interface, the number of security violations that have occurred, and the violation mode. The interface can be a port channel logical interface.
Switch# show port-security [interface <i>interface_id</i> / interface <i>port_channel port_channel_number</i>] address	Displays all secure MAC addresses configured on all switch interfaces or on a specified interface with aging information for each address.
Switch# show port-security [interface <i>interface_id</i> / interface <i>port_channel port_channel_number</i>] vlan <i>vlan_list</i>	Displays the maximum allowed number of secure MAC addresses and the current number of secure MAC addresses on a specific VLAN-list and a specific interface.
Switch# show port-security [interface <i>interface_id</i> / interface <i>port_channel port_channel_number</i>] [address [vlan <i>vlan_list</i>]]	Displays all secure MAC addresses configured on a specific VLAN-list and a specific interface.

Examples of Security Settings

The following examples are provided:

- [Example 1: Displaying Security Settings for the Entire Switch, page 55-28](#)
- [Example 2: Displaying Security Settings for an Interface, page 55-29](#)
- [Example 3: Displaying All Secure Addresses for the Entire Switch, page 55-29](#)
- [Example 4: Displaying a Maximum Number of MAC Addresses on an Interface, page 55-30](#)
- [Example 5: Displaying Security Settings on an Interface for a VLAN Range, page 55-30](#)
- [Example 6: Displaying Secured MAC Addresses and Aging Information on an Interface, page 55-30](#)
- [Example 7: Displaying Secured MAC Addresses for a VLAN Range on an Interface, page 55-31](#)

Example 1: Displaying Security Settings for the Entire Switch

This example shows how to display port security settings for the entire switch:

```
Switch# show port-security
Secure Port  MaxSecureAddr  CurrentAddr  SecurityViolation  Security Action
          (Count)          (Count)          (Count)
-----
Fa3/1             2             2             0             Restrict
Fa3/2             2             2             0             Restrict

Fa3/10         1          0          0          Shutdown
Fa3/11         1          0          0          Shutdown
Fa3/12         1          0          0          Restrict
Fa3/13         1          0          0          Shutdown
Fa3/14         1          0          0          Shutdown
Fa3/15         1          0          0          Shutdown
Fa3/16         1          0          0          Shutdown
Po2            3          0          0          Shutdown
-----
Total Addresses in System (excluding one mac per port) :8
Max Addresses limit in System (excluding one mac per port) :3072
Global SNMP trap control for port-security :20 (traps per second)

```

Example 2: Displaying Security Settings for an Interface

This example shows how to display port security settings for Fast Ethernet interface 5/1:

```

Switch# show port-security interface fastethernet 5/1
Port Security          : Enabled
Port Status            : Secure-up
Violation Mode         : Shutdown
Aging Time             : 0 mins
Aging Type             : Absolute
SecureStatic Address Aging : Disabled
Maximum MAC Addresses  : 1
Total MAC Addresses    : 1
Configured MAC Addresses : 0
Sticky MAC Addresses   : 1
Last Source Address:Vlan : 0000.0001.001a:1
Security Violation Count : 0

```

Example 3: Displaying All Secure Addresses for the Entire Switch

This example shows how to display all secure MAC addresses configured on all switch interfaces:

```

Switch# show port-security address
Secure Mac Address Table
-----
Vlan    Mac Address      Type                Ports    Remaining Age
      (mins)
-----
1       0000.0001.0000   SecureConfigured    Fa3/1    15 (I)
1       0000.0001.0001   SecureConfigured    Fa3/1    14 (I)
1       0000.0001.0100   SecureConfigured    Fa3/2    -
1       0000.0001.0101   SecureConfigured    Fa3/2    -
1       0000.0001.0200   SecureConfigured    Fa3/3    -
1       0000.0001.0201   SecureConfigured    Fa3/3    -
1       0000.0001.0300   SecureConfigured    Fa3/4    -
1       0000.0001.0301   SecureConfigured    Fa3/4    -
1       0000.0001.1000   SecureDynamic       Fa3/5    -
1       0000.0001.1001   SecureDynamic       Fa3/5    -
1       0000.0001.1100   SecureDynamic       Fa3/6    -
1       0000.0001.1101   SecureDynamic       Fa3/6    -
1       0000.0001.1200   SecureSticky        Fa3/7    -

```

```

1      0000.0001.1201      SecureSticky      Fa3/7      -
1      0000.0001.1300      SecureSticky      Fa3/8      -
1      0000.0001.1301      SecureSticky      Fa3/8      -
1      0000.0001.2000      SecureSticky      Po2        -
-----
Total Addresses in System (excluding one mac per port)      :8
Max Addresses limit in System (excluding one mac per port) :3072

```

Example 4: Displaying a Maximum Number of MAC Addresses on an Interface

This example shows how to display the maximum allowed number of secure MAC addresses and the current number of secure MAC addressees on Gigabit Ethernet interface 1/1:

```

Switch# show port-security interface g1/1 vlan
Default maximum: 22
VLAN  Maximum      Current
2          22          3
3          22          3
4          22          3
5          22          1
6          22          2

```

Example 5: Displaying Security Settings on an Interface for a VLAN Range

This example shows how to display the port security settings on Gigabit Ethernet interface 1/1 for VLANs 2 and 3:

```

Switch# show port-security interface g1/1 vlan 2-3
Default maximum: 22
VLAN  Maximum      Current
2          22          3
3          22          3

```

Example 6: Displaying Secured MAC Addresses and Aging Information on an Interface

This example shows how to display all secure MAC addresses configured on Gigabit Ethernet interface 1/1 with aging information for each address.

```

Switch# show port-security interface g1/1 address

```

```

          Secure Mac Address Table
-----
Vlan      Mac Address      Type      Ports      Remaining Age(mins)
----      -
2      0001.0001.0001      SecureConfigured      Gi1/1      -
2      0001.0001.0002      SecureSticky      Gi1/1      -
2      0001.0001.0003      SecureSticky      Gi1/1      -
3      0001.0001.0001      SecureConfigured      Gi1/1      -
3      0001.0001.0002      SecureSticky      Gi1/1      -
3      0001.0001.0003      SecureSticky      Gi1/1      -

Configuring Port Security with Other Features/Environments

The following topics are discussed:

- [DHCP and IP Source Guard, page 55-31](#)
- [802.1X Authentication, page 55-32](#)
- [Configuring Port Security in a Wireless Environment, page 55-32](#)

DHCP and IP Source Guard

You might want to configure port security with DHCP and IP Source Guard to prevent IP spoofing by unsecured MAC addresses. IP Source Guard supports two levels of IP traffic filtering:

- Source IP address filtering
- Source IP and MAC address filtering

When used in source IP and MAC address filtering, IP Source Guard uses private ACLs to filter traffic based on the source IP address, and uses port security to filter traffic based on the source MAC address. Port security must be enabled on the access port in this mode.

When both features are enabled, the following limitations apply:

- The DHCP packet is not subject to port security dynamic learning.
- If multiple IP clients are connected to a single access port, port security cannot enforce exact binding of source IP and MAC address for each client.

For example, these clients reside on an access port with the following IP and MAC address:

- client1: MAC1 <---> IP1
 - client2: MAC2 <---> IP2
- Any combination of the source MAC and IP address traffic will be allowed as shown here:
- MAC1 <---> IP1, valid
 - MAC2 <---> IP2, valid

- MAC1 <---> IP2, invalid
- MAC2 <---> IP1, invalid

IP traffic with the correct source IP and MAC address binding will be permitted and port security will dynamically learn its MAC address. IP traffic with source addresses that are not in the binding will be treated as invalid packets and dropped by port security. To prevent a denial of service attack, you must configure port security rate limiting for the invalid source MAC address.

802.1X Authentication

You might want to configure port security with 802.1X authentication to prevent MAC spoofing. 802.1X is not supported on regular or private VLAN trunks. On access ports and PVLAN host or promiscuous ports, both port security and 802.1X can be configured simultaneously. When both are configured, hosts must be 802.1X authenticated before port security can secure the MAC address of the host. Both 802.1X and port security must approve of the host or a security violation will be triggered. The type of security violation will depend on which feature rejects the port: if the host is allowed by 802.1X (for example, because the port is in multihost mode) but is disallowed by port security, the port-security violation action will be triggered. If the host is allowed by port security but rejected by 802.1X (for example, because the host is not authorized on a single-host mode port) then the 802.1X security violation action will be triggered.

Note

802.1X, port-security and VVID can all be configured on the same port.

For more information on the interaction between 802.1X and port security, see “Using 802.1X with Port Security” on page 19.

Configuring Port Security in a Wireless Environment

If access points are connected to a secure port, do not configure a static MAC address for your users. A MAC address might move from one access point to another and might cause security violations if both the access points are connected on the same switch.

Figure 55-3 illustrates a typical topology of port security in a wireless environment.

Figure 55-3 Port Security in a Wireless Environment

Port Security Configuration Guidelines and Restrictions

When using (or configuring) port security, consider these guidelines and restrictions:

- After port security is configured on a port along with a "denying" PACL, the CPU will neither see any of the PACL packets denied from the given port nor learn the source MAC addresses from the denied packets. Therefore, the port security feature will not be aware of such packets.
- A secure port cannot be a destination port for the Switch Port Analyzer (SPAN).
- A secure port and a static MAC address configuration for an interface are mutually exclusive.
- When you enter a maximum secure address value for an interface, and the new value is greater than the previous value, the new value overwrites the previously configured value. If the new value is less than the previous value and the number of configured secure addresses on the interface exceeds the new value, the command is rejected.
- While configuring trunk port security on a trunk port, you do not need to account for the protocol packets such as CDP and BPDU) because they are not learned and secured.
- You cannot enable port security aging on sticky secure MAC addresses.
- To restrict MAC spoofing using port security, you must enable 802.1X authentication.
- You cannot configure port security on dynamic ports. You must change the mode to access before you enable port security.
- Port Security over EtherChannels is not supported.
- Wired guest access does not work on Supervisor Engine 8-E or 9-E, in multiple-host mode or in multi- authentication mode.

Configuring Auto Security

This chapter describes how to configure auto security on the Catalyst 4500 series switch.

It consists of these sections:

- [About Auto Security, page 56-1](#)
- [Feature Interaction, page 56-1](#)
- [Configuring Auto Security, page 56-2](#)
- [Guidelines and Restrictions, page 56-6](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Auto Security

Prior to Release IOS XE 3.6.0E and IOS 15.2(2)E, the Catalyst 4500 series switch offered IPv4 baseline security features (like Port Security), which must be enabled globally and on per port basis. Moreover, the baseline security feature CLIs for uplink ports differ from those for downlink CLIs.

Beginning with Release IOS XE 3.6.0E and IOS 15.2(2)E, the Catalyst 4500 series switch supports Auto Security (AS), which provides a single line CLI, to enable base line security features.

AS supports the IPv4 baseline security features: DHCP Snooping, Dynamic ARP Inspection, and Port Security.

Feature Interaction

Auto security interacts with Port Security, DHCP snooping, DAI modules.

DHCP Snooping

Auto Security (AS) enables DHCP Snooping globally (with the **ip dhcp snooping** command) and also on VLANs 2-1005 (with the **ip dhcp snooping vlan *vlanid*** command).

AS configures trunk or DHCP server-facing port(s) as trusted (with the **ip dhcp-snooping trust** command).

Dynamic ARP Inspection

AS enables this feature globally on all VLANs present on the switch (with the **ip arp inspection vlan vlanid** command).

AS configures the trunk port as trusted (with the **ip arp inspection trust** command).

Port Security

AS enables this feature on all the switch's access ports (with the **switchport port-security** command).]

Configuring Auto Security

Enabling auto security globally

To enable auto security globally, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# auto security	Enables auto security globally.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show running-config i security	(Optional) Saves your entries in the configuration file.

This example shows how to enable auto security globally:

```
Switch(config)# auto security
Switch# show running-config | i security
auto security
```

Relevant baseline security feature CLI as shown in the output of the show auto security command is applied on or removed from access and trunk ports.

Disabling auto security globally

To disable auto security globally, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# no auto security	Dis-enables auto security globally.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show running-config isecurity	(Optional) Saves your entries in the configuration file.

This example show how to dis-enable auto security globally:

```
Switch(config)# no auto security
Switch# show auto security
Auto Security is Disabled globally

AutoSecure is Enabled on below interface(s):
-----

Switch#
```

Enabling Auto Security Feature for Access (End Hosts) or Trunk (Uplink) Ports

Use the **auto security-port [host | uplink]** command, to enable auto security for access (end hosts) and uplink ports:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface interface	Enters interface mode
Step 3	Switch(config-if)# auto security-port [host uplink]	Enables auto security on host or uplink ports.
Step 4	Switch(config)# end	Returns to privileged EXEC mode.
Step 5	Switch# show auto security	Displays the status of auto security.

This example displays how to enable auto security for an uplink port:

This example shows how to configure a port as auto security-port uplink.

```
Switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# int g1/0/15
Switch(config-if)# switchport mode trunk
Switch(config-if)# auto security-port uplink
Switch(config-if)# end
```

Use the **show auto security** and **show running-config** commands confirm the prior configuration.

```
Switch# show auto security
Auto Security is Enabled globally

AutoSecure is Enabled on below interface(s):
-----
GigabitEthernet1/0/2
GigabitEthernet1/0/3
GigabitEthernet1/0/15

Switch# show running-config int g1/0/15
Building configuration...

Current configuration : 127 bytes
!
interface GigabitEthernet1/0/15
 switchport trunk encapsulation dot1q
 switchport mode trunk
 auto security-port uplink
end
```

This example shows how to configure a port as an auto-security port host.

```
Switch# conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch(config)# int g1/0/18
Switch(config-if)# switchport mode access
Switch(config-if)# auto security-port host
Switch(config-if)# end
Switch#
```

Use the **auto security** and **show running-config** commands to confirm the prior configuration.

```
Switch# show auto security
Auto Security is Enabled globally

AutoSecure is Enabled on below interface(s):
-----
    GigabitEthernet1/0/2
    GigabitEthernet1/0/3
    GigabitEthernet1/0/15
    GigabitEthernet1/0/18
```

```
Switch# show run int g1/0/18
Building configuration...

Current configuration : 165 bytes
!
interface GigabitEthernet1/0/18
 switchport access vlan 20
 switchport mode access
 switchport voice vlan 40
 auto security-port host
 spanning-tree portfast
```

Disabling Auto Security Feature for Access (End Hosts) or Uplink Ports

Use the **no auto security-port** command to disable auto security on a port:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface interface	Enters interface mode
Step 3	Switch(config-if)# no auto security-port	Disables auto security on a port.
Step 4	Switch(config-if)# end	Exits to EXEC mode.
Step 5	Switch(config)# do show run int interface	Verifies auto security-port being disabled.
Step 6	Switch(config)# end	Returns to privileged EXEC mode.

This example shows how to disable auto security:

```
Switch# show run int g1/0/15
Building configuration...

Current configuration : 137 bytes
!
interface GigabitEthernet1/0/15
 switchport trunk encapsulation dot1q
```

```

switchport mode trunk
auto security-port uplink
end
Switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# int g1/0/15
Switch(config-if)# no auto security-port
Switch(config-if)# end
Switch# show run int g1/0/15
Building configuration...

Current configuration : 110 bytes
!
interface GigabitEthernet1/0/15
switchport trunk encapsulation dot1q
switchport mode trunk
end

```

show command

Use the **show auto security** command, verify the status of auto-security on the interface and global level.

Use the **show auto security [configuration]** command, to view the CLIs that are applied with AS.

This example shows the output of the **show auto security** command when AS is enabled:

```

Switch# show auto security
Auto Security is Enabled globally
AutoSecurity is Enabled on below interface(s):
-----
GigabitEthernet2/0/2
GigabitEthernet2/0/3
GigabitEthernet2/0/4
GigabitEthernet2/0/5
GigabitEthernet2/0/6
GigabitEthernet2/0/7
GigabitEthernet2/0/8
GigabitEthernet2/0/9

```

This example shows the output of the **show auto security configuration** command when AS is enabled:

```

Switch# show auto security configuration
%AutoSecurity provides a single CLI config 'auto security'
to enable Base-line security Features like
DHCP snooping, ARP inspection and Port-Security
Auto Security CLIs applied globally:
-----
ip dhcp snooping
ip dhcp snooping vlan 2-1005
no ip dhcp snooping information option
ip arp inspection vlan 2-1005
ip arp inspection validate src-mac dst-mac ip

Auto Security CLIs applied on Access Port:
-----
switchport port-security
switchport port-security maximum 2
switchport port-security maximum vlan access 1
switchport port-security maximum vlan voice 1
switchport port-security violation restrict
switchport port-security aging time 2
switchport port-security aging type inactivity
ip arp inspection limit rate 100
ip dhcp snooping limit rate 100

```

```

Auto Security CLIs applied on Trunk Port:
-----
ip dhcp snooping trust
ip arp inspection trust
switchport port-security
switchport port-security maximum 100
switchport port-security violation restrict

```

Sample Output when Auto Security is Enabled

This example shows the output of the **show auto security** command when AS is enabled:

```

Switch# show auto security
Auto Security is Enabled globally

AutoSecure is Enabled on below interface(s):
-----
GigabitEthernet1/0/2
GigabitEthernet1/0/3
GigabitEthernet1/0/14

```

Sample Output when Auto Security is Disabled

This example shows the output of the **show auto security** command when AS is disabled:

```

Switch# show auto security
Auto Security is Disabled globally

AutoSecure is Enabled on below interface(s):
-----
none
Switch#

```

Guidelines and Restrictions

- The **auto security** command has no parameters.
- Base line security CLIs (like port security) are not individually nvgen'd on interfaces that have auto security-port configured. This allows you to maintain consistency over reboots.
- After auto security-port is enabled on a port, you cannot change the CLIs of the baseline security features (Port Security, DAI, and DHCP Snooping).

For example, if you enter the following:

```

interface GigabitEthernet2/0/24
switchport mode access
auto security-port host

```

The port security configuration is rejected on the auto security port:

```

Switch(config)# int g2/0/24
Switch(config-if)# switchport port-security maximum 4
%Command Rejected: 'auto security' enabled port

```

- Because you might need a different set of features on uplink ports, such as marking the port as a DHCP trusted port, you need to identify uplink and downlink ports and apply port mode specific configuration.

- Starting with Cisco IOS XE 3.6.0E (IOS 15.2.(2)E), all trunk ports are treated as uplink ports and all access port are treated as host ports.
- AS assumes that you will configure the port with data and voice VLANs.
- AS is not supported on routed or Layer 3 ports, dynamic ports, or VSL links.
- Enabling auto security should elicit system confirmation because the current baseline security configuration will be removed as the auto security configuration is applied. When auto security is globally enabled, existing configurations related to DAI, DHCP, and PSEC are removed and security violation may be triggered on the auto-security enabled port when incoming MACs exceed the limit.

When we issue **auto security** in global or interface config mode, any baseline security configuration on the interfaces or on the switch is removed and auto security configuration is applied. Disabling auto security does not restore the previous security configuration.

Configuring Control Plane Policing and Layer 2 Control Packet QoS

Note

CoPP is supported on Supervisor 6-E starting with Cisco IOS Release 12.2(50)SG; Supervisor 6L-E starting with Cisco IOS Release 12.2(52)X0; Supervisor Engine 7-E starting with Cisco IOS XE 3.1.0SG; Supervisor Engine 7L-E starting with Cisco IOS XE 3.2.0X0; Supervisor Engine 8-E starting with Cisco IOS XE 3.3.0SG; Supervisor 9-E starting with Cisco IOS XE 3.10.0E

This chapter contains information on how to protect your Catalyst 4500 series switch using control plane policing (CoPP). The information covered in this chapter is unique to the Catalyst 4500 series switches, and it supplements the network security information and procedures in [Chapter 62, “Configuring Network Security with ACLs.”](#) This information also supplements the network security information and procedures in these publications:

- *Cisco IOS Security Configuration Guide, Cisco IOS Release 12.4*, at this URL:
http://www.cisco.com/en/US/docs/ios/security/configuration/guide/12_4/sec_12_4_book.html
- *Cisco IOS Security Command Reference, Cisco IOS Release 12.4*, at this URL:
http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html

This chapter includes the following major sections:

About Control Plane Policing

Note

Catalyst 4500 switch support hardware CoPP for all IPv6 First Hop Security Features (DHCPv6 Inspection/Guard, DHCPv6 remote-ID option for Layer 2, IPv6 full RA Guard, ...) However, due to inability of VFE to match ICMP v6 packets for policing in the outward direction, hardware CoPP does not work on Supervisor 6-E and Supervisor 6L-E, because “wireless” is supported only in Supervisor 8-E and 9-E, wireless related CoPP will work only on Supervisor 8-E and 9-E in wireless mode.

The control plane policing (CoPP) feature increases security on the Catalyst 4500 series switch by protecting the CPU from unnecessary or DoS traffic and giving priority to important control plane and management traffic. The classification TCAM and QoS policers provide CoPP hardware support.

Traffic managed by the CPU is divided into three functional components or *planes*:

- Data plane
- Management plane
- Control plane

You can use CoPP to protect most of CPU-bound traffic and to ensure routing stability, reachability, and packet delivery. Most importantly, you can use CoPP to protect the CPU from a DoS attack.

By default, you receive a list of predefined ACLs matching a selected set of Layer 2 and Layer 3 control plane packets. You can further define your preferred policing parameters for each of these packets and modify the matching criteria of these ACLs.

The following table lists the predefined ACLs.

Predefined Named ACL	Description
system-cpp-dot1x	MAC DA = 0180.C200.0003
system-cpp-lddp	MAC DA = 0180.C200.000E
system-cpp-mcast-cfm	MAC DA = 0100.0CCC.CCCC - 0100.0CCC.CCCC7
system-cpp-ucast-cfm	MAC DA = 0100.0CCC.CCCC
system-cpp-bpdu-range	MAC DA = 0180.C200.0000 - 0180.C200.000F
system-cpp-cdp	MAC DA = 0100.0CCC.CCCC (UDLD/DTP/VTP/Pagp)

Predefined Named ACL	Description
system-cpp-sstp	MAC DA = 0100.0CCC.CCCD
system-cpp-cgmp	MAC DA = 01.00.0C.DD.DD.DD
system-cpp-hsrpv2	IP Protocol = UDP, IPDA = 224.0.0.102
system-cpp-ospf	IP Protocol = OSPF, IP DA matches 224.0.0.0/24
system-cpp-igmp	IP Protocol = IGMP, IP DA matches 224.0.0.0/3
system-cpp-pim	IP Protocol = PIM, IP DA matches 224.0.0.0/24
system-cpp-all-systems-on-subnet	IP DA = 224.0.0.1
system-cpp-all-routers-on-subnet	IP DA = 224.0.0.2
system-cpp-ripv2	IP DA = 224.0.0.9
system-cpp-ip-mcast-linklocal	IP DA = 224.0.0.0/24
system-cpp-dhcp-cs	IP Protocol = UDP, L4SrcPort = 68, L4DstPort = 67
system-cpp-dhcp-sc	IP Protocol = UDP, L4SrcPort = 67, L4DstPort = 68
system-cpp-dhcp-ss	IP Protocol = UDP, L4SrcPort = 67, L4DstPort = 67

For the data and management plane traffic, you can define your own ACLs to match the traffic class that you want to police.

CoPP uses MQC to define traffic classification criteria and to specify the configurable policy actions for the classified traffic. MQC uses class maps to define packets for a particular traffic class. After you have classified the traffic, you can create policy maps to enforce policy actions for the identified traffic. The **control-plane global** configuration command allows you to directly attach a CoPP service policy to the control plane.

The policy map `system-cpp-policy` must contain the predefined class maps in the predefined order at the beginning of the policy map. The policy map `system-cpp-wireless-policy` must contain the predefined class-maps in predefined order; adding user defined class-map to this policy-map is dis-advised. We recommend that you use the global macro `system-cpp` to create `system-cpp-policy` and `system-cpp-wireless-policy` policy maps.

The `system-cpp-policy` policy map contains the predefined class maps for the control plane traffic. The names of all system-defined CoPP class maps and their matching ACLs contain the prefix `system-cpp-`. By default, no action is specified for each traffic class. You can define your own class maps matching CPU-bound data plane and management plane traffic. You can also add your defined class maps to `system-cpp-policy`.

General Guidelines for Control Plane Policing

Guidelines for control plane policing include the following:

- If a given traffic class does not have a designated class map, and you want to protect this traffic, we recommend that you:
 - Create specific class maps for such unknown traffic packets and add the user-defined class maps to **system-cpp-policy**.
 - Or, rate-limit such traffic to prevent CPU hogging.

For instance, in a VSS setup, if you have defined class map *cpp-vsl-mgmt* for VSL management traffic (exclusively Layer 2 packets), do not use the *cpp-vsl-mgmt* class map to protect supervisor keep-alive traffic (IP packets), or BFD packets. This can cause VSL link failures. Instead, create separate class maps, such as *cpp-ip* for supervisor keep-alive traffic, and *cpp-bfd* for BFD packets. VSL link failures may also ensue if you enter *class-default* as the class name for traffic that does not have a designated class map.

- Port security might cancel the effect of CoPP for non-IP control packets.

Although source MAC learning on a Catalyst 4500 series switch is performed in software, learning control packets' source MAC addresses (for example, IEEE BPDU, CDP, SSTP BPDU, GARP/) is not allowed. After you configure port security on a port where you expect a high rate of potentially unanticipated control packets, the system generates a copy of the packet to the CPU (until the source address is learned), instead of forwarding it.

The current architecture of the Catalyst 4500 supervisor engine does not allow you to apply policing on the copy of packets sent to the CPU. You can only apply policing on packets that are forwarded to the CPU. Copies of packets are sent to the CPU at the same rate as control packets, and port security is not triggered because learning from control packets is not allowed. Policing is not applied because the packet copy, not the original, is sent to the CPU.

- ARP policing is not supported on either the classic series supervisor engines (i.e., supervisor engines prior to Supervisor Engine 7-E) or fixed configuration switches. It is supported on Supervisor Engine 6-E, and Supervisor Engine 6L-E (use “match protocol arp” to classify).
- Only ingress CoPP is supported; control-plane related CLIs support only the **input** keyword.
- Use ACLs and class-maps to identify data plane and management plane traffic that are handled by CPU.
- “police” is the only action supported in CoPP policy-map.
- Avoid using the **log** keyword in the CoPP policy ACLs.

Default Configuration

CoPP is disabled by default.

Configuring CoPP for Control Plane Traffic

To configure CoPP for control plane traffic, perform this task:

	Command	Purpose
Step 1	Switch# config terminal	Enters global configuration mode.
Step 2	Switch(config)# qos	(Optional) Enables QoS globally.
Step 3	Switch(config)# macro global apply system-cpp	(Optional) Creates the system-cpp-policy policy map and attaches it to the control plane.

	Command	Purpose
Step 4	<pre>Switch(config)# policy-map system-cpp-policy Switch(config-pmap)# class {system-cpp-dot1x system-cpp-bpdu-range system-cpp-cdp service system-cpp-sstp system-cpp-cgmp system-cpp-ospf system-cpp-igmp system-cpp-pim system-cpp-all-systems-on-subnet system-cpp-all-routers-on-subnet system-cpp-ripv2 system-cpp-hsrpv2 system-cpp-ip-mcast-linklocal system-cpp-dhcp-cs system-cpp-dhcp-sc system-cpp-dhcp-ss} Switch(config-pmap-c)# police [aggregate name] rate burst [conform-action {drop transmit}] [{exceed-action {drop transmit}}}]</pre>	Associates actions to one or multiple system-defined control plane traffic in the service policy map. Repeat this step if necessary.
Step 5	<pre>Switch# show policy-map system-cpp-policy</pre>	(Optional) Verifies the configuration.

The following example shows how to police CDP packets:

```
Switch# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# qos
Switch(config)# macro global apply system-cpp
Switch(config)# policy-map system-cpp-policy
Switch(config-pmap)# class system-cpp-cdp
Switch(config-pmap-c)# police 32000 1000 conform-action transmit exceed-action drop
Switch(config-pmap-c)# end
Switch# show policy-map system-cpp-policy
Policy Map system-cpp-policy
Class system-cpp-dot1x
Class system-cpp-bpdu-range
* Class system-cpp-cdp
  police 32000 bps 1000 byte conform-action transmit exceed-action drop
Class system-cpp-sstp
Class system-cpp-cgmp
Class system-cpp-ospf
Class system-cpp-hsrpv2
Class system-cpp-igmp
Class system-cpp-pim
Class system-cpp-all-systems-on-subnet
Class system-cpp-all-routers-on-subnet
Class system-cpp-ripv2
Class system-cpp-ip-mcast-linklocal
Class system-cpp-dhcp-cs
Class system-cpp-dhcp-sc
Class system-cpp-dhcp-ss
Switch#
```

Configuring CoPP for Data Plane and Management Plane Traffic

To configure CoPP for data plane and management plane traffic, perform this task:

	Command	Purpose
Step 1	Switch(config)# qos	(Optional) Enables QoS globally.
Step 2	Switch(config)# macro global apply system-cpp	(Optional) Attaches the system-cpp-policy policy map to the control plane and the system-cpp-wireless-policy policy to the wireless control plane.
Step 3	<p>Switch(config)# {ip mac} access-list extended {access-list-name}</p> <p>For an ip access list, issue Switch(config-ext-nacl)#{permit deny} {protocol} source {source-wildcard} destination {destination-wildcard}</p> <p>For a mac access list, issue Switch(config-ext-macl)#{permit deny} source {source-wildcard} destination {destination-wildcard} [protocol-family]</p> <p>OR</p> <p>Switch(config)# access-list {access-list-name} {permit deny} {type-code wild-mask address mask}</p>	<p>Defines ACLs to match traffic:</p> <ul style="list-style-type: none"> permit—Sets the conditions under which a packet passes a named ACL deny—Sets the conditions under which a packet does not pass a name ACL <p>Note You must configure ACLs in most cases to identify the important or unimportant traffic.</p> <ul style="list-style-type: none"> type-code—16-bit hexadecimal number written with a leading 0x; for example, 0x6000. Specify either a Link Service Access Point (LSAP) type code for 802-encapsulated packets or a SNAP type code for SNAP-encapsulated packets. (LSAP, sometimes called SAP, refers to the type codes found in the DSAP and SSAP fields of the 802 header.) wild-mask—16-bit hexadecimal number whose ones bits correspond to bits in the type-code argument. The wild-mask indicates which bits in the type-code argument should be ignored when making a comparison. (A mask for a DSAP/SSAP pair should always be 0x0101 because these two bits are used for purposes other than identifying the SAP code.) address—48-bit Token Ring address written as a dotted triple of four-digit hexadecimal numbers. This field is used for filtering by vendor code. mask—48-bit Token Ring address written as a dotted triple of four-digit hexadecimal numbers. The ones bits in the mask are the bits to be ignored in address. This field is used for filtering by vendor code.

	Command	Purpose
Step 4	Switch(config)# class-map { <i>traffic-class-name</i> } Switch(config-cmap)# match access-group { <i>access-list-number</i> <i>name</i> { <i>access-list-name</i> }}	Defines the packet classification criteria. To identify the traffic associated with the class, use the match statements.
Step 5	Switch(config-cmap)# exit	Returns to global configuration mode.
Step 6	Switch(config)# policy-map system-cpp-policy Switch(config-pmap)# class { <i>class-map-name</i> } Switch(config-pmap-c)# police [<i>aggregate name</i>] <i>rate burst</i> [conform-action { <i>drop</i> <i>transmit</i> }] [exceed-action { <i>drop</i> <i>transmit</i> }]	Adds the traffic classes to the CoPP policy map. Uses the police statement to associate actions to the traffic class.
Step 7	Switch(config)# end	Returns to privileged EXEC mode.
Step 8	Switch# show policy-map system-cpp-policy	Verifies your entries.

The following example shows how to configure trusted hosts with source addresses 10.1.1.1 and 10.1.1.2 to forward Telnet packets to the control plane without constraint, while allowing all remaining Telnet packets to be policed at the specific rate. This example assumes that global QoS is enabled and that the system-cpp-policy policy map was created.

```
Switch# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# qos
Switch(config)# macro global apply system-cpp

! Allow 10.1.1.1 trusted host traffic.
Switch(config)# access-list 140 deny tcp host 10.1.1.1 any eq telnet

! Allow 10.1.1.2 trusted host traffic.
Switch(config)# access-list 140 deny tcp host 10.1.1.2 any eq telnet

! Rate limit all other Telnet traffic.
Switch(config)# access-list 140 permit tcp any any eq telnet

! Define class-map "telnet-class."
Switch(config)# class-map telnet-class
Switch(config-cmap)# match access-group 140
Switch(config-cmap)# exit

! Add the class-map "telnet-class" to "system-cpp-policy" and define the proper action
Switch(config)# policy-map system-cpp-policy
Switch(config-pmap)# class telnet-class
Switch(config-pmap-c)# police 80000 1000 conform transmit exceed drop
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit

! Verify the above configuration steps
Switch# show policy-map system-cpp-policy
Policy Map system-cpp-policy
  Class system-cpp-dot1x
  Class system-cpp-bpdu-range

Control Plane Policing Configuration Guidelines and Restrictions

When using (or configuring) control plane policing, consider these guidelines and restrictions:

All supervisor engines

When configuring CoPP, consider these guidelines:

- Only ingress CoPP is supported. Only the **input** keyword is supported in control plane-related CLIs.
- Control plane traffic can be policed only through CoPP. Traffic cannot be policed at the input interface or VLAN even though a policy map containing the control plane traffic is accepted when the policy map is attached to an interface or VLAN.
- Use ACLs and class maps to identify data plane and management plane traffic that are handled by the CPU. User defined class maps should be added to the system-cpp-policy policy map for CoPP.
- The default system-cpp-policy policy map does not define actions for the system-defined class maps (no policing).
- The only action supported in system-cpp-policy is police.
- You can use both MAC and IP ACLs to define data plane and management plane traffic classes. However, if a packet also matches a predefined ACL for the control plane traffic, a police (or no police) action will operate on the control plane class because the control plane classes appear above the user-defined classes in the service policy.
- The exceeding action **policed-dscp-transmit** is not supported for CoPP.
- Do not use the **log** keyword in CoPP policy ACLs. Instead, if you want to determine if rogue packets are arriving, view the output of the **show policy-map interface** command or use the span feature.

Do not apply to Supervisor Engine 6-E, and Supervisor Engine 6L-E

- To police control plane traffic, use the system-defined class maps.
- System-defined class maps cannot be used in policy maps for regular QoS.
- The policy map named system-cpp-policy is dedicated for CoPP.
- CoPP is not enabled unless global QoS is enabled and a police action is specified.

Do not apply to Supervisor Engine 6-E, Supervisor Engine 6L-E, Supervisor 7-E and Supervisor 7L-E

- System-cpp-wireless-policy is generated only on Supervisor Engine 8-E and 9-E when booted in wireless mode.

Monitoring CoPP

You can enter the **show policy-map control-plane** command to develop site-specific policies, to monitor statistics for the control plane policy, and to troubleshoot CoPP. This command displays dynamic information about the actual policy applied, including rate information and the number of bytes (and packets) that conformed or exceeded the configured policies both in hardware and in software.

The output of the **show policy-map control-plane** command is similar to the following:

```
Switch# show policy-map control-plane

Control Plane

Service-policy input: system-cpp-policy

  Class-map: system-cpp-dot1x (match-all)
    0 packets

permit any host 0100.0ccc.cccd
```

To display one CoPP access list, enter the **show access-lists system-cpp-cdp** command:

```
Switch# show access-list system-cpp-cdp
Extended MAC access list system-cpp-cdp
permit any host 0100.0ccc.cccc
Switch#
```

Configuring Layer 2 Control Packet QoS

Layer 2 control packet QoS enables you to police control packets arriving on a physical port or LAN.

This section includes these topics:

- [Understanding Layer 2 Control Packet QoS, page 57-11](#)
- [Default Configuration, page 57-12](#)
- [Enabling Layer 2 Control Packet QoS, page 57-12](#)
- [Disabling Layer 2 Control Packet QoS, page 57-13](#)
- [Layer 2 Control Packet QoS Configuration Examples, page 57-14](#)
- [Layer 2 Control Packet QoS Guidelines and Restrictions, page 57-16](#)

Understanding Layer 2 Control Packet QoS

You might want to police incoming Layer 2 control packets such as STP, CDP, VTP, SSTP, BPDU, EAPOL and LLDP on a specific port before the packets reach CPU. This could serve as a first line of defense before aggregate traffic is subjected to policing (through CoPP). By default, policers cannot be applied to Layer 2 control packets in the input direction. This prevents users from inadvertently policing or dropping critical Layer 2 control packets.

While this approach protects a user who is wrongly policing control packets, it introduces a more serious problem. If a flood of Layer 2 control packets is received on any of the switch interfaces at a very high rate due to a DoS attack or to a loop introduced in the customer network because of misconfiguration, CPU utilization can increase quickly. This can have adverse impacts such as loss of protocol keep-alives and routing protocol updates. The Layer 2 control packet QoS feature allows you to police Layer 2 control packets at the port, VLAN, or port- VLAN level in the input direction.

Default Configuration

Layer 2 control packet QoS is disabled by default.

Enabling Layer 2 Control Packet QoS

To enable Layer 2 control packet QoS, perform this task:

	Command	Purpose
Step 1	Switch# config terminal	Enters configuration mode.
Step 2	Switch(config)# [no] qos control-packets [bpd-range cdp-vtp eapol sstp protocol-tunnel llbp]	Enables QoS on all or a specific packet type. Use the no keyword to disable QoS on all or a specific packet type.
Step 3	Switch(config)# end	Exits configuration mode.
Step 4	Switch# show run inc qos control-packets	Verifies the configuration.

Table 57-1 lists the types of packets impacted by this feature.

Table 57-1 Packet Type and Actionable Address Range

Type of Packet that the Feature is Enabled On	Range of Address the Feature Acts On
BPDURange	0180.C200.0000 BPDURange 0180.C200.0002 OAM, LACP 0180.C200.0003 EAPOL
CDP-VTP	0100.0CCC.CCCC
SSTP	0100.0CCC.CCCD
LLDP	0180.C200.000E

The following example shows how to enable QoS for CDP packets and to apply a policer to CDP packets arriving on interface gi3/1 and VLAN 1:

```
Switch# config terminal
Switch(config)# qos control-packets cdp-vtp
Switch(config)# end
Switch# show run | inc qos control-packets
qos control-packets cdp-vtp
Switch# show class-map
Class Map match-any system-control-packet-cdp-vtp (id 1)

      Match access-group name system-control-packet-cdp-vtp

Create a policy map and attach it to interface gi3/1 , vlan 1
Switch# config terminal
Switch(config)# policy-map police_cdp
Switch(config-pmap)# class system-control-packet-cdp-vtp
Switch(config-pmap-c)# police 32k
Switch(config-pmap-c)# end

Switch(config)# interface gi3/1
```

```

Switch(config-if)# vlan 1
Switch(config-if-vlan-range)# service-policy in police_cdp
Switch(config-if-vlan-range)# exit
Switch(config-if)# exit
Switch(config)# exit
Switch# show policy-map interface gi3/1

GigabitEthernet3/1 vlan 1

Service-policy input: police_cdp

Class-map: system-control-packet-cdp-vtp (match-any)
  0 packets
  Match: access-group name system-control-packet-cdp-vtp
    0 packets
  police:
    cir 32000 bps, bc 1500 bytes
    conformed 0 packets, 0 bytes; actions:
      transmit
    exceeded 0 packets, 0 bytes; actions:
      drop
    conformed 0000 bps, exceed 0000 bps

Class-map: class-default (match-any)
  0 packets

```

Disabling Layer 2 Control Packet QoS

The **no qos control-packet** command disables QoS for all packet types.

The following example shows how to disable QoS for CDP packets after QoS is enabled for all packet types:

```

Switch# show running-configuration | include qos control-packets
qos control-packets bpdu-range
qos control-packets cdp-vtp
qos control-packets llDP
qos control-packets eapOl
qos control-packets sstp
qos control-packets protocol-tunnel

```

Note

When all control packets (CDP/VTP, bpdu-range, Sstp, LLDP, and protocol-tunnel), are enabled only qos control-packets is nevgen'd. Individual protocol names mentioned in the previous output are nvegen'd only if the some of the control packets are configured.

```

Switch# config terminal
Switch(config)# no qos control-packets cdp-vtp
Switch(config)# end
Switch# show running-configuration | include qos control-packets
qos control-packets bpdu-range
qos control-packets llDP
qos control-packets sstp
qos control-packets protocol-tunnel

```

Note

When you unconfigure this feature for a specified protocol type, the user-configured policies handling that protocol type immediately become ineffective. To save TCAM resources, remove the policies as well as MACs and class maps (auto-generated or user-defined).

**Note**

TCAM resources are not consumed when the interface is in a down state.

Table 57-2 displays the auto-generated MACLs and class maps that are created when you enable the feature on the corresponding packet type.

Table 57-2 Packet Types and Auto-Generated MACL/Class Maps

Packet Type	Auto-Generated MACL/Class Map
BPDU-range	mac access-list extended system-control-packet-bpdu-range permit any 0180.c200.0000 0000.0000.000c class-map match-any system-control-packet-bpdu-range match access-group name system-control-packet-bpdu-range
SSTP	mac access-list extended system-control-packet-sstp permit any host 0100.0ccc.cccd class-map match-any system-control-packet-sstp match access-group name system-control-packet-sstp
CDP-VTP	mac access-list extended system-control-packet-cdp-vtp permit any host 0100.0ccc.cccc class-map match-any system-control-packet-cdp-vtp match access-group name system-control-packet-cdp-vtp
EAPOL	mac access-list extended system-control-packet-eapol permit any any 0x888E class-map match-any system-control-packet-eapol match access-group name system-control-packet-eapol
LLDP	mac access-list extended system-control-packet-lldp permit any host 0180.c200.000e class-map match-any system-control-packet-lldp match access-group name system-control-packet-lldp
PROTOCOL TUNNEL	mac access-list extended system-control-packet-protocol-tunnel permit any host 0100.0ccd.cdd0 class-map match-any system-control-packet-protocol-tunnel match access-group name system-control-packet-protocol-tunnel

Layer 2 Control Packet QoS Configuration Examples

You can use CoPP and Layer 2 control packet QoS together to prevent DoS attacks to the CPU. In the following example, BPDUs arriving on interface gi3/1, VLAN 1 and VLAN 2 are limited to 32 Kbps and 34 Kbps, respectively. Aggregate BPDU traffic to CPU then is further rate-limited to 50 Kbps using CoPP.

```
Switch(config)# qos control-packets
```

```
Switch(config)# policy-map police_bpdu_1
Switch(config-pmap)# class system-control-packet-bpdu-range
Switch(config-pmap-c)# police 32k 1000
Switch(config-pmap-c-police)# exit
Switch(config-pmap-c)# exit
Switch(config-pmap)# policy-map police_bpdu_2
Switch(config-pmap)# class system-control-packet-bpdu-range
Switch(config-pmap-c)# police 34k
Switch(config-pmap-c-police)# exit
```

Configuring Layer 2 Control Packet QoS

```
Switch(config)# interface gi3/1
Switch(config-if)# vlan-range 1
Switch(config-if-vlan-range)# service-policy in police_bpdu_1
Switch(config-if-vlan-range)# exit
Switch(config-if)# interface gi3/2
Switch(config-if)# vlan-range 2
Switch(config-if-vlan-range)# service-policy in police_bpdu_1
Switch(config-if-vlan-range)# exit
```

Configuring Control Plane Policy

```
Switch(config)# macro global apply system-cpp
Switch(config)# policy-map system-cpp-policy
Switch(config-pmap)# class system-cpp-bpdu-range
Switch(config-pmap-c)# police 50k
Switch(config-pmap-c-police)# exit
Switch(config-pmap-c)# exit
```

Note

To reduce the consumption of policer resources, you can also use named-aggregate policers applied to a group of ports or VLANs.

Note

Do not modify class maps and MACLs that are auto-generated by the system. This action can cause unexpected behavior when the switch reloads or when the running configuration is updated from a file.

To refine or modify system-generated class maps or MACLs, apply user-defined class maps and MACLs.

Note

User defined class map names must begin with the prefix system-control-packet. If not, certain hardware (Supervisor Engine II-Plus, Supervisor Engine II+10GE, Supervisor Engine V, and Supervisor Engine V-10GE) might not perform the configured QoS action.

For example, the following are valid user-defined class map names to police Layer 2 control packets because they begin with the prefix system-control-packet:

```
system-control-packet-bpdu1
system-control-packet-control-packet
```

No such restrictions exist on the names you can use for user-defined MACLs (access-groups).

The following example shows how to create user-defined MACLs and class maps to identify EAPOL and BPDU packets. Because the auto-generated class map system-control-packet-bpdu range matches three packet types (BPDU, EAPOL, and OAM), policing this traffic class affects all three packet types. To police BPDU and EAPOL packets at different rates, you can set user-defined MACL and class map as follows:

```
Switch(config)# mac access-list extended system-control-packet-bpdu
Switch(config-ext-macl)# permit any host 0180.c200.0000
Switch(config-ext-macl)# exit
```

```

Switch(config)# class-map match-any system-control-packet-bpdu
Switch(config-cmap)# match access-group name system-control-packet-bpdu
Switch(config-cmap)# exit

Switch(config)# mac access-list extended system-control-packet-eapol
Switch(config-ext-macl)# permit any host 0180.c200.0003
Switch(config-ext-macl)# exit
Switch(config)# class-map match-any system-control-packet-eapol
Switch(config-cmap)# match access-group name system-control-packet-eapol
Switch(config-cmap)# exit

```

Layer 2 Control Packet QoS Guidelines and Restrictions

When using (or configuring) Layer 2 control packet QoS, consider these guidelines and restrictions:

- When you enable Layer 2 control packet QoS, it applies to all ports on the switch. If Layer 2 control packets are not explicitly classified in the policy attached to port or VLAN, the actions in class-default will be applied as per normal QoS rules.
- Place classifiers that match control packets at the beginning of a policy map followed by other traffic classes, ensuring that Layer 2 control packets are not subjected to inadvertent QoS actions.
- The application of default class (class-default) actions depends on the type of supervisor engine:
 - Supervisor Engine V-10GE with NetFlow support—Actions associated with class-default are never applied on unmatched control packets; a default permit action is applied. Only actions associated with class maps that begin with system-control-packet are applied on control packets.
 - All other supervisor engines—Actions associated with class-default are applied on unmatched control packets.
- If you enable the feature on a BPDU range, EAPOL packets are policed only after the initial 802.1X authentication phase completes.

Policing IPv6 Control Traffic

On Supervisor Engine 6-E, and Supervisor Engine 6L-E, IPv6 control packets such as OSPF, PIM and MLD can be policed on a physical port, VLAN, or control plane by configuring IPv6 ACLs to classify such traffic and then applying a QoS policy to police such traffic.

The following examples show how to police OSPFv6, PIMv6 and MLD control traffic received on a port.

This example shows how to configure a traffic class to identify OSPFv6 control packets by its destination IP v6 address:

```

Switch# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ipv6 access-list ospfv6
Switch(config-ipv6-acl)# permit ipv6 any host ff02:5
Switch(config-ipv6-acl)# exit
Switch(config)# class-map ospfv6Class
Switch(config-camp)# match access-group name ospfv6
Switch(config-camp)# exit

```

The following example shows how to configure a traffic class to identify PIMv6 control packets by its destination IPv6 address:

```

Switch(config)# ipv6 access-list pimv6

```

```
Switch(config-ipv6-acl)# permit ipv6 any host ff02::d
Switch(config-ipv6-acl)# exit
Switch(config)# class-map pimv6Class
Switch(config-cmap)# match access-group name pimv6
Switch(config-cmap)# exit
```

The following example shows how to configure a traffic class to identify MLD protocol control packets:

```
Switch(config)# ipv6 access-list mldv1
Switch(config-ipv6-acl)# permit icmp any any mld-query
Switch(config-ipv6-acl)# permit icmp any any mld-report
Switch(config-ipv6-acl)# permit icmp any any mld-reduction
Switch(config-ipv6-acl)# exit
Switch(config)# class-map mldClass
Switch(config-cmap)# match access-group name mldv1
Switch(config-cmap)# exit
```

The following example shows how to configure a QoS policy to police OSPFv6, PIMv6 and MLD traffic classes:

```
Switch(config)# policy-map v6_control_packet_policy
Switch(config-pmap)# class mldClass
Switch(config-pmap-c)# police 32k
Switch(config-pmap-c-police)# class ospfv6Class
Switch(config-pmap-c)# police 32k
Switch(config-pmap-c)# class pimv6Class
Switch(config-pmap-c)# police 32k
Switch(config-pmap-c-police)# exit
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# exit
Switch# show policy-map
```

```
Policy Map v6_control_packet_policy
  Class mldClass
    police cir 32000 bc 1500
      conform-action transmit
      exceed-action drop
  Class ospfv6Class
    police cir 32000 bc 1500
      conform-action transmit
      exceed-action drop
  Class pimv6class
    police cir 32000 bc 1500
      conform-action transmit
      exceed-action drop
```

The following example shows how to policy to interface gi2/2 in the input direction:

```
Switch# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gi2/2
Switch(config-if)# service-policy in v6_control_packet_policy
Switch(config-if)# exit
```

Configuring Dynamic ARP Inspection

This chapter describes how to configure Dynamic ARP Inspection (DAI) on the Catalyst 4500 series switch.

This chapter includes the following major sections:

- [About Dynamic ARP Inspection, page 58-1](#)
- [Configuring Dynamic ARP Inspection, page 58-5](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Dynamic ARP Inspection

Dynamic ARP Inspection (DAI) is a security feature that validates Address Resolution Protocol (ARP) packets in a network. DAI allows a network administrator to intercept, log, and discard ARP packets with invalid MAC-IP pairs. This capability protects the network from certain “man-in-the-middle” attacks.

This section contains the following subsections:

- [ARP Cache Poisoning, page 58-2](#)
- [Purpose of Dynamic ARP Inspection, page 58-2](#)
- [Interface Trust State, Security Coverage and Network Configuration, page 58-3](#)
- [Relative Priority of Static Bindings and DHCP Snooping Entries, page 58-4](#)
- [Logging of Dropped Packets, page 58-4](#)
- [Rate Limiting of ARP Packets, page 58-4](#)
- [Port Channels Function, page 58-5](#)

ARP Cache Poisoning

You can attack hosts, switches, and routers connected to your Layer 2 network by “poisoning” their ARP caches. For example, a malicious user might intercept traffic intended for other hosts on the subnet by poisoning the ARP caches of systems connected to the subnet.

Figure 58-1 shows an example of cache poisoning.

Figure 58-1 ARP Cache Poisoning

Hosts HA, HB, and HC are connected to the switch on interfaces A, B and C, all of which are on the same subnet. Their IP and MAC addresses are shown in parentheses; for example, Host HA uses IP address IA and MAC address MA. When HA needs to communicate to HB at the IP Layer, HA broadcasts an ARP request for the MAC address associated with IB. As soon as HB receives the ARP request, the ARP cache on HB is populated with an ARP binding for a host with the IP address IA and a MAC address MA. When HB responds to HA, the ARP cache on HA is populated with a binding for a host with the IP address IB and a MAC address MB.

Host HC can “poison” the ARP caches of HA and HB by broadcasting forged ARP responses with bindings for a host with an IP address of IA (or IB) and a MAC address of MC. Hosts with poisoned ARP caches use the MAC address MC as the destination MAC address for traffic intended for IA or IB. This means that HC intercepts that traffic. Because HC knows the true MAC addresses associated with IA and IB, HC can forward the intercepted traffic to those hosts using the correct MAC address as the destination. HC has inserted itself into the traffic stream from HA to HB, the classic “man in the middle” attack.

Purpose of Dynamic ARP Inspection

To prevent ARP poisoning attacks, a switch must ensure that only valid ARP requests and responses are relayed. DAI prevents these attacks by intercepting all ARP requests and responses. Each of these intercepted packets is verified for valid MAC address to IP address bindings before the local ARP cache is updated or the packet is forwarded to the appropriate destination. Invalid ARP packets are dropped.

DAI determines the validity of an ARP packet based on valid MAC address to IP address bindings stored in a trusted database. This database is built at runtime by DHCP snooping, provided this feature is enabled on VLANs and on the switch. In addition, in order to handle hosts that use statically configured IP addresses, DAI can also validate ARP packets against user-configured ARP ACLs.

DAI can also be configured to drop ARP packets when the IP addresses in the packet are invalid or when the MAC addresses in the body of the ARP packet do not match the addresses specified in the Ethernet header.

Interface Trust State, Security Coverage and Network Configuration

DAI associates a trust state with each interface on the system. Packets arriving on trusted interfaces bypass all DAI validation checks, while those arriving on untrusted interfaces go using the DAI validation process. In a typical network configuration for DAI, all ports connected to host ports are configured as untrusted, while all ports connected to switches are configured as trusted. With this configuration, all ARP packets entering the network from a given switch pass the security check.

Figure 58-2 Validation of ARP Packets on a DAI-Enabled VLAN

Use the trust state configuration carefully. Configuring interfaces as untrusted when they should be trusted can result in a loss of connectivity. If we assume that both S1 and S2 (in Figure 58-2) run DAI on the VLAN ports that contains H1 and H2, and if H1 and H2 were to acquire their IP addresses from the DHCP server connected to S1, then only S1 binds the IP to MAC address of H1. If the interface between S1 and S2 is untrusted, the ARP packets from H1 get dropped on S2. This condition would result in a loss of connectivity between H1 and H2.

Configuring interfaces to be trusted when they are actually untrusted leaves a security hole in the network. If S1 were not running DAI, then H1 can easily poison the ARP of S2 (and H2, if the inter-switch link is configured as trusted). This condition can occur even though S2 is running DAI.

DAI ensures that hosts (on untrusted interfaces) connected to a switch running DAI do not poison the ARP caches of other hosts in the network. It does not, however, ensure that hosts from other portions of the network do not poison the caches of the hosts connected to it.

To handle cases in which some switches in a VLAN run DAI and other switches do not, the interfaces connecting such switches should be configured as untrusted. To validate the bindings of packets from non-DAI switches, however, the switch running DAI should be configured with ARP ACLs. When it is not feasible to determine such bindings, switches running DAI should be isolated from non-DAI switches at Layer 3.

Note

Depending on the set up of the DHCP server and the network, it may not be possible to perform validation of a given ARP packet on all switches in the VLAN.

Relative Priority of Static Bindings and DHCP Snooping Entries

As mentioned previously, DAI populates its database of valid MAC address to IP address bindings through DHCP snooping. It also validates ARP packets against statically configured ARP ACLs. It is important to note that ARP ACLs have precedence over entries in the DHCP snooping database. ARP packets are first compared to user-configured ARP ACLs. If the ARP ACL denies the ARP packet, then the packet is denied even if a valid binding exists in the database populated by DHCP snooping.

Logging of Dropped Packets

When the switch drops a packet, it places an entry in the log buffer and then generates system messages on a rate-controlled basis. After the message is generated, the switch clears the entry from the log buffer. Each log entry contains flow information, such as the receiving VLAN, the port number, the source and destination IP addresses, and the source and destination MAC addresses.

You use the **ip arp inspection log-buffer** global configuration command to configure the number of entries in the buffer and the number of entries needed in the specified interval to generate system messages. You specify the type of packets that are logged by using the **ip arp inspection vlan logging** global configuration command. For configuration information, see the [“Configuring the Log Buffer” section on page 58-14](#).

Rate Limiting of ARP Packets

DAI performs validation checks in the CPU, so the number of incoming ARP packets is rate-limited to prevent a denial of service attack. By default, the rate for untrusted interfaces is set to 15 pps second but trusted interfaces have no rate limit. When the rate of incoming ARP packets exceeds the configured limit, the port is placed in the error-disable state. The port remains in that state until an administrator intervenes. With the **errdisable recovery** global configuration command, you can enable error-disable recovery so that ports emerge from this state automatically after a specified timeout period.

You use the **ip arp inspection limit** global configuration command to limit the rate of incoming ARP requests and responses on the interface. Unless a rate limit is explicitly configured on an interface, changing the trust state of the interface also changes its rate limit to the default value for that trust state; that is, 15 packets per second for untrusted interfaces and unlimited for trusted interfaces. Once a rate limit is configured explicitly, the interface retains the rate limit even when its trust state is changed. At any time, the interface reverts to its default rate limit if the **no** form of the **rate limit** command is applied. For configuration information, see the [“Limiting the Rate of Incoming ARP Packets” section on page 58-16](#).

Note

When you enable DAI, all ARP packets are forwarded by CPU (software forwarding, the slow path). With this mechanism, whenever a packet exits through multiple ports, the CPU must create as many copies of the packet as there are egress ports. The number of egress ports is a multiplying factor for the CPU. When QoS policing is applied on egress packets that were forwarded by CPU, QoS must be applied in the CPU as well. (You cannot apply QoS in hardware on CPU generated packets because the hardware forwarding path is turned off for CPU generated packets.) Both factors can drive the CPU to a very high utilization level.

Port Channels Function

A given physical port can join a channel only when the trust state of the physical port and of the channel match. Otherwise, the physical port remains suspended in the channel. A channel inherits its trust state from the first physical port that joined the channel. Consequently, the trust state of the first physical port need not match the trust state of the channel.

Conversely, when the trust state is changed on the channel, the new trust state is configured on all the physical ports that comprise the channel.

The rate limit check on port channels is unique. The rate of incoming packets on a physical port is checked against the port channel configuration rather than the physical ports' configuration.

The rate limit configuration on a port channel is independent of the configuration on its physical ports.

The rate limit is cumulative across all physical ports; that is, the rate of incoming packets on a port channel equals the sum of rates across all physical ports.

When you configure rate limits for ARP packets on trunks, you must account for VLAN aggregation because a high rate limit on one VLAN can cause a denial of service attack to other VLANs when the port is error-disabled by software. Similarly, when a port channel is error-disabled, a high rate limit on one physical port can cause other ports in the channel to go down.

Configuring Dynamic ARP Inspection

These sections describe how to configure DAI on your switch:

- [Configuring Dynamic ARP Inspection in DHCP Environments, page 58-5](#) (required)
- [DAI Configuration Example, page 58-7](#)
- [Configuring ARP ACLs for Non-DHCP Environments, page 58-11](#) (optional)
- [Configuring the Log Buffer, page 58-14](#) (optional)
- [Limiting the Rate of Incoming ARP Packets, page 58-16](#) (optional)
- [Performing Validation Checks, page 58-19](#) (optional)

Configuring Dynamic ARP Inspection in DHCP Environments

This procedure shows how to configure dynamic ARP inspection when two switches support this feature. Host 1 is connected to Switch A, and Host 2 is connected to Switch B as shown in Figure 58-3. Both switches are running DAI on VLAN 100 where the hosts are located. A DHCP server is connected to Switch A. Both hosts acquire their IP addresses from the same DHCP server. Switch A has the bindings for Host 1, and Switch B has the bindings for Host 2.

Figure 58-3 ARP Packet Validation on a VLAN Enabled for DAI

Note

DAI depends on the entries in the DHCP snooping binding database to verify IP-to-MAC address bindings in incoming ARP requests and ARP responses. Make sure to enable DHCP snooping to permit ARP packets that have dynamically assigned IP addresses. For configuration information, see [Chapter 60, “Configuring DHCP Snooping, IP Source Guard, and IPSG for Static Hosts.”](#)

For information on how to configure DAI when only one switch supports the feature, see the [“Configuring ARP ACLs for Non-DHCP Environments”](#) section on page 58-11.

To configure DAI, perform this task on both switches:

	Command	Purpose
Step 1	Switch# show cdp neighbors	Verifies the connection between the switches.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# [no] ip arp inspection vlan <i>vlan-range</i>	<p>Enables DAI on a per-VLAN basis. By default, DAI is disabled on all VLANs.</p> <p>To disable DAI, use the no ip arp inspection vlan <i>vlan-range</i> global configuration command.</p> <p>For <i>vlan-range</i>, specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.</p> <p>Specify the same VLAN ID for both switches.</p>
Step 4	Switch(config)# interface <i>interface-id</i>	Specifies the interface connected to the other switch, and enter interface configuration mode.

	Command	Purpose
Step 5	Switch(config-if)# ip arp inspection trust	Configures the connection between the switches as trusted. To return the interfaces to an untrusted state, use the no ip arp inspection trust interface configuration command. By default, all interfaces are untrusted. The switch does not check ARP packets that it receives from the other switch on the trusted interface. It forwards the packets. For untrusted interfaces, the switch intercepts all ARP requests and responses. It verifies that the intercepted packets have valid IP-to-MAC address bindings before updating the local cache and before forwarding the packet to the appropriate destination. The switch drops invalid packets and logs them in the log buffer according to the logging configuration specified with the ip arp inspection vlan logging global configuration command. For more information, see the “Configuring the Log Buffer” section on page 58-14 .
Step 6	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 7	Switch# show ip arp inspection interfaces Switch# show ip arp inspection vlan <i>vlan-range</i>	Verifies the DAI configuration.
Step 8	Switch# show ip dhcp snooping binding	Verifies the DHCP bindings.
Step 9	Switch# show ip arp inspection statistics vlan <i>vlan-range</i>	Checks the DAI statistics.
Step 10	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

DAI Configuration Example

This example shows how to configure DAI on Switch A in VLAN 100. You would perform a similar procedure on Switch B.

Switch A

```
SwitchA# show cdp neighbors
```

```
Capability Codes: R - Router, T - Trans Bridge, B - Source Route Bridge  
S - Switch, H - Host, I - IGMP, r - Repeater, P - Phone

SwitchB#

Configuring ARP ACLs for Non-DHCP Environments

This procedure shows how to configure DAI when Switch B shown in Figure 58-3 does not support DAI or DHCP snooping.

If you configure port 1 on Switch A as trusted, a security hole is created because both Switch A and Host 1 could be attacked by either Switch B or Host 2. To prevent this possibility, you must configure port 1 on Switch A as untrusted. To permit ARP packets from Host 2, you must set up an ARP ACL and apply it to VLAN 100. If the IP address of Host 2 is not static, such that it is impossible to apply the ACL configuration on Switch A, you must separate Switch A from Switch B at Layer 3 and use a router to route packets between them.

To configure an ARP ACL (on switch A in a non-DHCP environment), perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# arp access-list <i>acl-name</i>	Defines an ARP ACL, and enter ARP access-list configuration mode. By default, no ARP access lists are defined. Note At the end of the ARP access list, there is an implicit deny ip any mac any command.
Step 3	Switch(config-arp-nac)# permit ip host <i>sender-ip</i> mac <i>host sender-mac</i> [log]	Permits ARP packets from the specified host (Host 2). <ul style="list-style-type: none"> For <i>sender-ip</i>, enter the IP address of Host 2. For <i>sender-mac</i>, enter the MAC address of Host 2. (Optional) Specify log to log a packet in the log buffer when it matches the access control entry (ACE). Matches are logged if you also configure the matchlog keyword in the ip arp inspection vlan logging global configuration command. For more information, see the “Configuring the Log Buffer” section on page 58-14.
Step 4	Switch(config-arp-nac)# exit	Returns to global configuration mode.

	Command	Purpose
Step 5	Switch(config)# ip arp inspection filter <i>arp-acl-name</i> vlan <i>vlan-range</i> [static]	<p>Applies the ARP ACL to the VLAN. By default, no defined ARP ACLs are applied to any VLAN.</p> <ul style="list-style-type: none"> For <i>arp-acl-name</i>, specify the name of the ACL created in Step 2. For <i>vlan-range</i>, specify the VLAN that the switches and hosts are in. You can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. (Optional) Specify static to treat implicit denies in the ARP ACL as explicit denies and to drop packets that do not match any previous clauses in the ACL. DHCP bindings are not used. <p>If you do not specify this keyword, it means that there is no explicit deny in the ACL that denies the packet, and DHCP bindings determine whether a packet is permitted or denied if the packet does not match any clauses in the ACL.</p> <p>ARP packets containing only IP-to-MAC address bindings are compared against the ACL. Packets are permitted only if the access list permits them.</p>
Step 6	Switch(config)# interface <i>interface-id</i>	Specifies the Switch A interface that is connected to Switch B, and enter interface configuration mode.
Step 7	Switch(config-if)# no ip arp inspection trust	<p>Configures the Switch A interface that is connected to Switch B as untrusted.</p> <p>By default, all interfaces are untrusted.</p> <p>For untrusted interfaces, the switch intercepts all ARP requests and responses. It verifies that the intercepted packets have valid IP-to-MAC address bindings before updating the local cache and before forwarding the packet to the appropriate destination. The switch drops invalid packets and logs them in the log buffer according to the logging configuration specified with the ip arp inspection vlan logging global configuration command. For more information, see the “Configuring the Log Buffer” section on page 58-14.</p>
Step 8	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 9	Switch# show arp access-list [<i>acl-name</i>] Switch# show ip arp inspection vlan <i>vlan-range</i> Switch# show ip arp inspection interfaces	Verifies the DAI configuration.
Step 10	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To remove the ARP ACL, use the **no arp access-list** global configuration command. To remove the ARP ACL attached to a VLAN, use the **no ip arp inspection filter arp-acl-name vlan vlan-range** global configuration command.

This example shows how to configure an ARP ACL called host2 on Switch A, to permit ARP packets from HostB (IP address 170.1.1.2 and MAC address 2.2.2), to apply the ACL to VLAN 100, and to configure port 1 on Switch A as untrusted:

```
SwitchA# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
SwitchA(config)# arp access-list hostB
SwitchA(config-arp-nacl)# permit ip host 170.1.1.2 mac host 2.2.2 log
SwitchA(config-arp-nacl)# exit
SwitchA(config)# ip arp inspection filter hostB vlan 100 static
SwitchA(config)# interface g3/48
SwitchA(config-if)# no ip arp inspection trust
SwitchA(config-if)# end
SwitchA# show arp access-list hostB
ARP access list hostB
    permit ip host 170.1.1.2 mac host 0002.0002.0002 log
```

```
SwitchA# show ip arp inspection interfaces
```

SwitchA#

Configuring the Log Buffer

When the switch drops a packet, it places an entry in the log buffer and then generates system messages on a rate-controlled basis. After the message is generated, the switch clears the entry from the log buffer. Each log entry contains flow information, such as the receiving VLAN, the port number, the source and destination IP addresses, and the source and destination MAC addresses.

A log-buffer entry can represent more than one packet. For example, if an interface receives many packets on the same VLAN with the same ARP parameters, the switch combines the packets as one entry in the log buffer and generates a single system message for the entry.

If the log buffer overflows, it means that a log event does not fit into the log buffer, and the display for the **show ip arp inspection log** privileged EXEC command is affected. No other statistics are provided for the entry.

To configure the log buffer, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ip arp inspection log-buffer {entries number logs number interval seconds}	<p>Configures the DAI logging buffer.</p> <p>By default, when DAI is enabled, denied or dropped ARP packets are logged. The number of log entries is 32. The number of system messages is limited to 5 per second. The logging-rate interval is 1 second.</p> <p>The keywords have these meanings:</p> <ul style="list-style-type: none"> For entries number, specify the number of entries to be logged in the buffer. The range is 0 to 1024. For logs number interval seconds, specify the number of entries to generate system messages in the specified interval. <p>For logs number, the range is 0 to 1024. A 0 value means that the entry is placed in the log buffer, but a system message is not generated.</p> <p>For interval seconds, the range is 0 to 86400 seconds (1 day). A 0 value means that a system message is immediately generated (and the log buffer is always empty).</p> <p>An interval setting of 0 overrides a log setting of 0.</p> <p>The logs and interval settings interact. If the logs number X is greater than interval seconds Y, X divided by Y (X/Y) system messages are sent every second. Otherwise, one system message is sent every Y divided by X (Y/X) seconds.</p>
Step 3	Switch(config)# [no] ip arp inspection vlan vlan-range logging {acl-match {matchlog none} dhcp-bindings {all none permit}}	<p>Controls the type of packets that are logged per-VLAN. By default, all denied or all dropped packets are logged. The term <i>logged</i> means the entry is placed in the log buffer and a system message is generated.</p> <p>The keywords have these meanings:</p> <ul style="list-style-type: none"> For vlan-range, specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. For acl-match matchlog, log packets based on the ACE logging configuration. If you specify the matchlog keyword in this command and the log keyword in the permit or deny ARP access-list configuration command, ARP packets permitted or denied by ACEs with log keyword are logged. For acl-match none, do not log packets that match ACLs. For dhcp-bindings all, log all packets that match DHCP bindings. For dhcp-bindings none, do not log packets that match DHCP bindings. For dhcp-bindings permit, log DHCP-binding permitted packets.
Step 4	Switch(config)# exit	Returns to privileged EXEC mode.

	Command	Purpose
Step 5	Switch# show ip arp inspection log	Verifies your settings.
Step 6	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To return to the default log buffer settings, use the **no ip arp inspection log-buffer** global configuration command. To return to the default VLAN log settings, use the **no ip arp inspection vlan *vlan-range* logging {acl-match | dhcp-bindings}** global configuration command. To clear the log buffer, use the **clear ip arp inspection log** privileged EXEC command.

This example shows how to configure the number of entries for the log buffer to 1024. It also shows how to configure your Catalyst 4500 series switch so that the logs must be generated from the buffer at the rate of 100 per 10 seconds.

```
SwitchB# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
SwitchB(config)# ip arp inspection log-buffer entries 1024
SwitchB(config)# ip arp inspection log-buffer logs 100 interval 10
SwitchB(config)# end
SwitchB# show ip arp inspection log
Total Log Buffer Size : 1024
Syslog rate : 100 entries per 10 seconds.
```

```

SwitchB#
```

Limiting the Rate of Incoming ARP Packets

The switch CPU performs DAI validation checks; therefore, the number of incoming ARP packets is rate-limited to prevent a denial-of-service attack.

Note

Unless you explicitly configure a rate limit on an interface, changing the trust state of the interface also changes its rate limit to the default value for that trust state. After you configure the rate limit, the interface retains the rate limit even when its trust state is changed. If you enter the **no ip arp-inspection limit** interface configuration command, the interface reverts to its default rate limit.

By default, the switch places the port in the error-disabled state when the rate of incoming ARP packets exceeds the configured limit. To prevent the port from shutting down, you can use the **errdisable detect cause arp-inspection action shutdown vlan** global configuration command to shut down just the offending VLAN on the port where the violation occurred.

When a port is in the error-disabled state, you can bring it out of this state automatically by configuring the **errdisable recovery cause arp-inspection** global configuration command or you can manually reenale it by entering the **shutdown** and **no shut down** interface configuration commands. If a port is in per-VLAN error-disable mode, you can also use **clear errdisable interface *name* *vlan range*** command to reenale the VLAN on the port.

To limit the rate of incoming ARP packets, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# errdisable detect cause arp-inspection [action shutdown vlan]	Enables per-VLAN error-disable detection. Note By default this command is enabled, and when a violation occurs the interface is shutdown.
Step 3	Switch(config)# interface interface-id	Specifies the interface to be rate-limited, and enters interface configuration mode.
Step 4	Switch(config-if)# [no] ip arp inspection limit {rate pps [burst interval second] none}	Limits the rate of incoming ARP requests and responses on the interface. The default rate is 15 pps on untrusted interfaces and unlimited on trusted interfaces. The burst interval is 1 second. The keywords have these meanings: <ul style="list-style-type: none"> For rate pps, specify an upper limit for the number of incoming packets processed per second. The range is 0 to 2048 pps. (Optional) For burst interval seconds, specify the consecutive interval in seconds, over which the interface is monitored for a high rate of ARP packets. The range is 1 to 15. For rate none, specify no upper limit for the rate of incoming ARP packets that can be processed.
Step 5	Switch(config-if)# exit	Returns to global configuration mode.
Step 6	Switch(config)# errdisable recovery {cause arp-inspection interval interval}	(Optional) Enables error recovery from the DAI error-disable state. By default, recovery is disabled, and the recovery interval is 300 seconds. For interval interval , specify the time in seconds to recover from the error-disable state. The range is 30 to 86400.
Step 7	Switch(config)# exit	Returns to privileged EXEC mode.
Step 8	Switch# show ip arp inspection interfaces	Verifies your settings.
Step 9	Switch# show errdisable recovery	Verifies your settings.
Step 10	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To return to the default rate-limit configuration, use the **no ip arp inspection limit** interface configuration command. To disable error recovery for DAI, use the **no errdisable recovery cause arp-inspection** global configuration command.

This example shows how to set an upper limit for the number of incoming packets (100 pps) and to specify a burst interval (1 second):

```
SwitchB# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
SwitchB(config)# interface g3/31
SwitchB(config-if)# ip arp inspection limit rate 100 burst interval 1
SwitchB(config-if)# exit
SwitchB(config)# errdisable recovery cause arp-inspection
SwitchB(config)# exit
```

SwitchB# **show ip arp inspection interfaces**

Performing Validation Checks

DAI intercepts, logs, and discards ARP packets with invalid IP-to-MAC address bindings. You can configure the switch to perform additional checks on the destination MAC address, the sender and target IP addresses, and the source MAC address.

To perform specific checks on incoming ARP packets, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ip arp inspection validate {[src-mac] [dst-mac] [ip]}	<p>Performs a specific check on incoming ARP packets. By default, no additional checks are performed.</p> <p>The keywords have these meanings:</p> <ul style="list-style-type: none"> For src-mac, check the source MAC address in the Ethernet header against the sender MAC address in the ARP body. This check is performed on both ARP requests and responses. When enabled, packets with different MAC addresses are classified as invalid and are dropped. For dst-mac, check the destination MAC address in the Ethernet header against the target MAC address in ARP body. This check is performed for ARP responses. When enabled, packets with different MAC addresses are classified as invalid and are dropped. For ip, check the ARP body for invalid and unexpected IP addresses. Addresses include 0.0.0.0, 255.255.255.255, and all IP multicast addresses. Sender IP addresses are checked in all ARP requests and responses, and target IP addresses are checked only in ARP responses. <p>You must specify at least one of the keywords. Each command overrides the configuration of the previous command; that is, if a command enables src and dst mac validations, and a second command enables IP validation only, the src and dst mac validations are disabled as a result of the second command.</p>
Step 3	Switch(config)# exit	Returns to privileged EXEC mode.
Step 4	Switch# show ip arp inspection vlan vlan-range	Verifies your settings.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To disable checking, use the **no ip arp inspection validate [src-mac] [dst-mac] [ip]** global configuration command. To display statistics for forwarded, dropped, MAC validation failure, and IP validation failure packets, use the **show ip arp inspection statistics** privileged EXEC command.

This example shows how to configure source mac validation. Packets are dropped and an error message may be generated when the source address in the Ethernet header does not match the sender hardware address in the ARP body.

```
SwitchB# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
SwitchB(config)# ip arp inspection validate src-mac
SwitchB(config)# exit
SwitchB# show ip arp inspection vlan 100

Source Mac Validation      : Enabled
Destination Mac Validation : Disabled
IP Address Validation      : Disabled
```

Configuring the Cisco IOS DHCP Server

Cisco devices running Cisco software include Dynamic Host Configuration Protocol (DHCP) server and the relay agent software. The Cisco IOS DHCP server is a full DHCP server implementation that assigns and manages IP addresses from specified address pools within the device to DHCP clients. The DHCP server can be configured to assign additional parameters such as the IP address of the Domain Name System (DNS) server and the default device.

This module describes the concepts and the tasks needed to configure the Cisco IOS DHCP server.

- [Prerequisites for Configuring the DHCP Server, page 59-1](#)
- [Information About Cisco IOS DHCP Server, page 59-2](#)
- [How to Configure the Cisco IOS DHCP Server, page 59-9](#)
- [Configuration Examples for the Cisco IOS DHCP Server, page 59-24](#)

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the [“Feature Information for the IOS DHCP Server”](#) section on page 59-34.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Configuring the DHCP Server

- Before you configure a Cisco Dynamic Host Control Protocol (DHCP) server, you must understand the concepts documented in the “Overview of the DHCP Server” section.
- The Cisco DHCP server and the relay agent services are enabled by default. Use the **no service dhcp** command to disable the Cisco DHCP server and the relay agent and the **service dhcp** command to reenble the functionality.

- Port 67 (the DHCP server port) is closed in the Cisco DHCP/BOOTP default configuration. There are two logical parts to the **service dhcp** command: service-enabled and service running. The DHCP service is enabled by default, but port 67 does not open until the DHCP service is running. If the DHCP service is running, the **show ip sockets details** or the **show sockets detail** command displays port 67 as open.
- The Cisco DHCP relay agent is enabled on an interface only when you configure the **ip helper-address** command. This command enables a DHCP broadcast to be forwarded to the configured DHCP server.

Information About Cisco IOS DHCP Server

Overview of the DHCP Server

The Cisco DHCP server accepts address assignment requests and renewals from the client and assigns the addresses from predefined groups of addresses within DHCP address pools. These address pools can also be configured to supply additional information to the requesting client such as the IP address of the Domain Name System (DNS) server, the default device, and other configuration parameters. The Cisco DHCP server can accept broadcasts from locally attached LAN segments or from DHCP requests that have been forwarded by other DHCP relay agents within the network.

DHCP Attribute Inheritance

The DHCP server database is organized as a tree. The root of the tree is the address pool for natural networks, branches are subnetwork address pools, and leaves are manual bindings to clients. Subnetworks inherit network parameters and clients inherit subnetwork parameters. Therefore, common parameters (for example, the domain name) should be configured at the highest (network or subnetwork) level of the tree.

Inherited parameters can be overridden. For example, if a parameter is defined in both the natural network and a subnetwork, the definition of the subnetwork is used.

Address leases are not inherited. If a lease is not specified for an IP address, by default, the DHCP server assigns a one-day lease for the address.

DHCP Server Address Allocation Using Option 82

The Cisco IOS DHCP server can allocate dynamic IP addresses based on the relay information option (option 82) sent by the relay agent.

DHCP provides a framework for passing configuration information to hosts on a TCP/IP network. Configuration parameters and other control information are carried in tagged data items that are stored in the options field of the DHCP message. The data items are also called options. Option 82 is organized as a single DHCP option that contains information known by the relay agent.

Automatic DHCP address allocation is based on an IP address. This IP address can either be the gateway address (giaddr field of the DHCP packet) or the IP address of an incoming interface. In some networks, it is necessary to use additional information to further determine which IP addresses to allocate. By using option 82, the Cisco IOS DHCP relay agent can include additional information about itself when forwarding client-originated DHCP packets to a DHCP server. The Cisco IOS DHCP server can also use option 82 to provide additional information to properly allocate IP addresses to DHCP clients. The information sent via option 82 is used to identify the port where the DHCP request arrives. Automatic DHCP address allocation does not parse out the individual suboptions contained in option 82. Rather, the address allocation is done by matching a configured pattern byte by byte.

This feature introduces a new DHCP class capability, which is a method to group DHCP clients based on some shared characteristics other than the subnet in which the clients reside.

For example, DHCP clients are connected to two ports of a single switch. Each port can be configured to be a part of two VLANs: VLAN1 and VLAN2. DHCP clients belong to either VLAN1 or VLAN2 and the switch can differentiate the VLAN that a particular DHCP Discover message belongs to (possibly through Layer 2 encapsulation). Each VLAN has its own subnet and all DHCP messages from the same VLAN (same switch) have the giaddr field set to the same value indicating the subnet of the VLAN.

Problems can occur while allocating IP addresses to DHCP clients that are connected to different ports of the same VLAN. These IP addresses must be part of the same subnet but the range of IP addresses must be different. In the preceding example, when a DHCP client that is connected to a port of VLAN1 must be allocated an IP address from a range of IP addresses within the VLAN's subnet, whereas a DHCP client connecting to port 2 of VLAN1 must be allocated an IP address from another range of IP addresses. The two range of IP addresses are part of the same subnet (and have the same subnet mask). Generally, during DHCP address allocation, the DHCP server refers only to the giaddr field and is unable to differentiate between the two ranges.

To solve this problem, a relay agent residing at the switch inserts the relay information option (option 82), which carries information specific to the port, and the DHCP server inspects both the giaddr field and the inserted option 82 during the address selection process.

When you enable option 82 on a device, the following sequence of events occurs:

1. The host (DHCP client) generates a DHCP request and broadcasts it on the network.
2. When the device receives the DHCP request, it adds the option 82 information in the packet. The option 82 information contains the device MAC address (the remote ID suboption) and the port identifier, vlan-mod-port, from which the packet is received (the circuit ID suboption).
3. The device adds the IP address of the relay agent to the DHCP packet.
4. The device forwards the DHCP request that includes the option 82 field to the DHCP server.
5. The DHCP server receives the packet. If the server is option 82 capable, it uses the remote ID, the circuit ID, or both to assign IP addresses and implement policies, such as restricting the number of IP addresses that can be assigned to a single remote ID or circuit ID. The DHCP server echoes the option 82 field in the DHCP reply.

6. The DHCP server unicasts the reply to the device if the request is relayed to the server by the device. The device verifies that it originally inserted the option 82 data by inspecting remote ID and possibly circuit ID fields. The device removes the option 82 field and forwards the packet to the interface that connects to the DHCP client that sent the DHCP request.

The Cisco software refers to a pool of IP addresses (giaddr or incoming interface IP address) and matches the request to a class or classes configured in the pool in the order the classes are specified in the DHCP pool configuration.

When a DHCP address pool is configured with one or more DHCP classes, the pool becomes a restricted access pool, which means that no addresses are allocated from the pool unless one or more classes in the pool matches. This design allows DHCP classes to be used either for access control (no default class is configured on the pool) or to provide further address range partitions within the subnet of the pool.

Multiple pools can be configured with the same class, eliminating the need to configure the same pattern in multiple pools.

The following capabilities are supported for DHCP class-based address allocation:

- Specifying the full relay agent information option value as a raw hexadecimal string by using the **relay-information hex** command in new relay agent information configuration mode.
- Support for bit-masking the raw relay information hexadecimal value.
- Support for a wildcard at the end of a hexadecimal string specified by the **relay-information hex** command.

If the relay agent inserts option 82 but does not set the giaddr field in the DHCP packet, the DHCP server interface must be configured as a trusted interface by using the **ip dhcp relay information trusted** command. This configuration prevents the server from dropping the DHCP message.

Disabling Conflict Logging

A DHCP database agent is any host (for example, an FTP, a TFTP, or a remote copy protocol [RCP] server) or storage media on a DHCP server (for example, disk0) that stores the DHCP bindings database. You can configure multiple DHCP database agents, and the interval between database updates and transfers for each agent.

Automatic bindings are IP addresses that are automatically mapped to the MAC addresses of hosts that are found in the DHCP database. Automatic binding information (such as lease expiration date and time, interface index, and VPN routing and forwarding [VRF] name) is stored in a database agent. The bindings are saved as text records for easy maintenance.

An address conflict occurs when two hosts use the same IP address. During address assignment, DHCP checks for conflicts by using ping and gratuitous Address Resolution Protocol (ARP). If a conflict is detected, the address is removed from the pool. The address is not assigned until the administrator resolves the conflict.

Note

We strongly recommend using database agents. However, the Cisco DHCP server can run without database agents. If you choose not to configure a DHCP database agent, disable the recording of DHCP address conflicts on the DHCP server by using the **no ip dhcp conflict logging** command in global configuration mode. If there is a conflict logging but no database agent is configured, bindings during a switchover are lost when a device reboots. Possible false conflicts can occur causing the address to be removed from the address pool.

DHCP Address Pools

You can configure a DHCP address pool with a name that is a string (such as “engineering”) or an integer (such as 0). Configuring a DHCP address pool also puts the device into DHCP pool configuration mode—identified by the `(dhcp-config)#` prompt—from which you can configure pool parameters (for example, the IP subnet number and default device list).

DHCP defines a process by which the DHCP server knows the IP subnet in which the DHCP client resides, and it can assign an IP address from a pool of valid IP addresses in that subnet. The process by which the DHCP server identifies the DHCP address pool to use for a client request is described in the Configuring Manual Bindings section.

The DHCP server identifies and uses DHCP address pools for a client request, in the following manner:

- If the client is not directly connected to the DHCP server (the `giaddr` field of the DHCPDISCOVER broadcast message is nonzero), the server matches the DHCPDISCOVER with the DHCP pool that has the subnet that contains the IP address in the `giaddr` field.
- If the client is directly connected to the DHCP server (the `giaddr` field is zero), the DHCP server matches the DHCPDISCOVER with DHCP pools that contain the subnets configured on the receiving interface. If the interface has secondary IP addresses, subnets associated with the secondary IP addresses are examined for possible allocation only after the subnet associated with the primary IP address (on the interface) is exhausted.

Cisco DHCP server software supports advanced capabilities for IP address allocation. See the Configuring DHCP Address Allocation Using Option 82 section for more information.

DHCP Address Pool with Secondary Subnets

Each subnet is a range of IP addresses that the device uses to allocate an IP address to a DHCP client. The DHCP server multiple subnet functionality enables a Cisco DHCP server address pool to manage additional IP addresses by adding the addresses to a secondary subnet of an existing DHCP address pool (instead of using a separate address pool).

Configuring a secondary DHCP subnetwork places the device in DHCP pool secondary subnet configuration mode—identified by the `(config-dhcp-subnet-secondary)#` prompt—where you can configure a default address list that is specific to the secondary subnet. You can also specify the utilization rate of the secondary subnet, which allows pools of IP addresses to dynamically increase or reduce in size depending on the address utilization level. This setting overrides the global utilization rate.

- If the DHCP server selects an address pool that contains multiple subnets, the DHCP server allocates an IP address from the subnets as follows:
- When the DHCP server receives an address assignment request, it looks for an available IP address in the primary subnet.
- When the primary subnet is exhausted, the DHCP server automatically looks for an available IP address in any of the secondary subnets maintained by the DHCP server (even though the `giaddr` does not necessarily match the secondary subnet). The server inspects the subnets for address availability in the order of subnets that were added to the pool.

**Note**

If the giaddr matches a secondary subnet in the pool, the DHCP server allocates an IP address from that particular secondary subnet (even if IP addresses are available in the primary subnet and irrespective of the order of secondary subnets that were added).

The secondary subnet in the pool is supported only for directly connected clients. To avoid multiple IP address allocation from multiple subnets, you should configure secondary IP address on the interface connected to clients. Note that the secondary subnets should not be used in pools that are used for servicing requests from DHCP relay.

Manual Bindings

An address binding is a mapping between the IP address and MAC address of a client. The IP address of a client can be assigned manually by an administrator or assigned automatically from a pool by a DHCP server.

Manual bindings are IP addresses that are manually mapped to MAC addresses of hosts that are found in the DHCP database. Manual bindings are stored in the NVRAM of the DHCP server. Manual bindings are just special address pools. There is no limit to the number of manual bindings, but you can configure only one manual binding per host pool.

Automatic bindings are IP addresses that have been automatically mapped to MAC addresses of hosts that are found in the DHCP database. Because the bindings are stored in the volatile memory of the DHCP server, binding information is lost in the event of power failures or on device reloads. To prevent the loss of automatic binding information, a copy of the automatic binding information is stored on a remote host called the DHCP database agent. The bindings are periodically written to the database agent. When the device reloads, the bindings are read from the database agent to the DHCP database in the DHCP server.

**Note**

We strongly recommend that you use database agents. However, Cisco DHCP server can function even without database agents.

Some DHCP clients send a client identifier (DHCP option 61) in the DHCP packet. To configure manual bindings for such clients, you must enter the client-identifier command with the hexadecimal values that identify the DHCP client. To configure manual bindings for clients that do not send a client identifier option, you must enter the hardware-address DHCP pool configuration command with the hexadecimal hardware address of the client.

Depending on your release, the DHCP server sends infinite lease time to the clients for which manual bindings are configured.

Depending on your release, the DHCP server sends lease time that is configured using the lease command to clients for which manual bindings are configured.

**Note**

You cannot configure manual bindings within the same pool that is configured with the network command in DHCP pool configuration mode. See the Configuring DHCP Address Pools section for information about DHCP address pools and the network command.

DHCP Static Mapping

The DHCP Static Mapping feature enables the assignment of static IP addresses (without creating numerous host pools with manual bindings) by using a customer-created text file that the DHCP server reads. The benefit of this feature is that it eliminates the need for a long configuration file and reduces the space required in NVRAM to maintain address pools.

A DHCP database contains the mappings between a client IP address and the hardware address, which is referred to as a binding. There are two types of bindings: manual bindings that map a single hardware address to a single IP address, and automatic bindings that dynamically map a hardware address to an IP address from a pool of IP addresses. Manual (also known as static) bindings can be configured individually directly on the device or by using the DHCP Static Mapping feature. These static bindings can be read from a separate static mapping text file. The static mapping text files are read when a device reloads or the DHCP service restarts. These files are read-only.

The read static bindings are treated just like the manual bindings, in that they are:

- Retained across DHCPRELEASEs from the clients.
- Not timed out.
- Deleted only upon deletion of the pool.
- Provided appropriate exclusions for the contained addresses, which are created at the time of the read.

Just like automatic bindings, manual (or static) bindings from the static mapping text file are also displayed by using the **show ip dhcp binding** command.

To create a static mapping text file, input your addresses in the text file that is stored in the DHCP database for the DHCP server to read. There is no limit to the number of addresses that can be stored in the file. The file format has the following elements:

- Database version number
- End-of-file designator
- Hardware type
- Hardware address
- IP address
- Lease expiration
- Time the file was created

The following is a sample static mapping text file:

```
*time* Jan 21 2005 03:52 PM
*version* 2
!IP address      Type      Hardware address      Lease expiration
10.0.0.4 /24     1         0090.bff6.081e        Infinite
10.0.0.5 /28     id        00b7.0813.88f1.66     Infinite
10.0.0.2 /21     1         0090.bff6.081d        Infinite
*end*
```

Table 59-1 Static Mapping Text File Field Descriptions

Field	Description
time	Specifies the time the file was created. This field allows DHCP to differentiate between the new and old database versions when multiple agents are configured. The valid format of the time is mm dd yyyy hh:mm AM/PM.
version 2	Specifies the database version number.
IP address	Specifies the static IP address. If the subnet mask is not specified, a mask is automatically assigned depending on the IP address. The IP address and the mask is separated by a space.
Type	Specifies the hardware type. For example, type “1” indicates Ethernet. The type “id” indicates that the field is a DHCP client identifier. Legal values can be found online at http://www.iana.org/assignments/arp-parameters in the “Number Hardware Type” list.
Hardware address	<p>Specifies the hardware address.</p> <p>When the type is numeric, the type refers to the hardware media. Legal values can be found online at http://www.iana.org/assignments/arp-parameters in the “Number Hardware Type” list.</p> <p>When the type is “id,” the type refers to a match on the client identifier.</p> <p>For more information about the client identifier, see RFC 2132, DHCP Options and BOOTP Vendor Extensions, section 9.14, located at http://www.ietf.org/rfc/rfc2132.txt, or the client-identifier command.</p> <p>If you are unsure about the client identifier to match with the hardware type, use the debug dhcp detail command to display the client identifier being sent to the DHCP server from the client.</p>

DHCP Server Operation

By default, the DHCP server pings a pool address twice before assigning a particular address to a requesting client. If the ping is unanswered, the DHCP server assumes (with a high probability) that the address is not in use and assigns the address to the requesting client.

By default, the DHCP server waits for 2 seconds before timing out a ping packet.

You can configure the DHCP server to ignore and not reply to any BOOTP requests that the server receives. This functionality is beneficial when there is a mix of BOOTP and DHCP clients in a network segment and there is a BOOTP server and a Cisco DHCP server servicing the network segment. The BOOTP server is configured with static bindings for the BOOTP clients and the BOOTP clients must obtain their addresses from the BOOTP server. However, DHCP servers can also respond to BOOTP requests and the DHCP server may offer an address that causes the BOOTP clients to boot with the address from the DHCP server, instead of the address from the BOOTP server. Configuring the DHCP server to ignore BOOTP requests ensures that the BOOTP clients will receive address information from the BOOTP server and will not accept an address from a DHCP server.

Cisco software can forward these ignored BOOTP request packets to another DHCP server if the **ip helper-address** command is configured on the incoming interface.

Static Route with the Next-Hop Dynamically Obtained Through DHCP

Static routes are updated in the routing table when the default gateway is assigned by the DHCP server. These routes remain in the routing table until the DHCP lease expires and then the routes are removed.

When a DHCP client releases an address, the corresponding static route (the route configured using the **ip route** command) is automatically removed from the routing table. If the DHCP router option (option 3 of the DHCP packet) changes during the client renewal, the DHCP default gateway changes to the new IP address supplied after the renewal.

This feature is particularly useful for VPN deployments such as Dynamic Multipoint VPNs (DMVPNs). It is useful when a nonphysical interface, such as a multipoint generic routing encapsulation (mGRE) tunnel, is configured on a device and certain traffic must be excluded from entering the tunnel interface.

Note

- If the DHCP client is not able to obtain an IP address or the default device IP address, the static route is not installed in the routing table.
- If the lease has expired and the DHCP client cannot renew the address, the DHCP IP address assigned to the client is released and any associated static routes are removed from the routing table

Configuring a DHCP Database Agent or Disabling Conflict Logging

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# ip dhcp database url [timeout seconds write-delay seconds] or Switch(config)# no ip dhcp conflict logging	Configures a DHCP server to save automatic bindings on a remote host called a database agent. Or Disables DHCP address conflict logging.
Step 4	Switch(config)# exit	Exits global configuration mode and returns to privileged EXEC mode.

Excluding IP Addresses

The IP address configured on a device interface is automatically excluded from the DHCP address pool. The DHCP server assumes that all other IP addresses in a DHCP address pool subnet are available for assigning to DHCP clients.

You must exclude addresses from the pool if the DHCP server does not allocate those IP addresses to DHCP clients. Consider a scenario where two DHCP servers are set up for the same network segment (subnet) for redundancy. If DHCP servers do not coordinate their services with each other using a protocol such as DHCP failover, each DHCP server must be configured to allocate addresses from a nonoverlapping set of addresses in the shared subnet. See the Example: Configuring Manual Bindings section for a configuration example.

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# ip dhcp excluded-address <i>low-address</i> [<i>high-address</i>]	Specifies IP addresses that the DHCP server should not assign to DHCP clients.
Step 4	Switch(config)# exit	Exits global configuration mode and returns to privileged EXEC mode.

Configuring DHCP Address Pools

- [Configuring a DHCP Address Pool, page 59-11](#)
- [Configuring a DHCP Address Pool with Secondary Subnets, page 59-13](#)
- [Troubleshooting Tips, page 59-15](#)
- [Verifying the DHCP Address Pool Configuration, page 59-16](#)

Configuring a DHCP Address Pool

On a per-address pool basis, specify DHCP options for the client as necessary.

Before you configure the DHCP address pool, you must:

- Identify DHCP options for devices where necessary, including the following:
 - Default boot image name
 - Default devices
 - Domain Name System (DNS) servers
 - Network Basic Input/Output System (NetBIOS) name server
 - Primary subnet
 - Secondary subnets and subnet-specific default device lists (see Configuring a DHCP Address Pool with Secondary Subnets section for information on secondary subnets).
- Decide on a NetBIOS node type (b, p, m, or h).
- Decide on a DNS domain name.

Note

You cannot configure manual bindings within the same pool that is configured with the network DHCP pool configuration command. To configure manual bindings, see the Configuring Manual Bindings section.

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# ip dhcp pool <i>name</i>	Assigns a name to a DHCP pool and enters DHCP configuration mode.
Step 4	Switch(dhcp-config)# utilization mark <i>high percentage-number</i> [log]	(Optional) Configures the high utilization mark of the current address pool size. <ul style="list-style-type: none"> • The log keyword enables the logging of a system message. A system message will be generated for a DHCP pool when the pool utilization exceeds the configured high utilization threshold.
Step 5	Switch(dhcp-config)# utilization mark low <i>percentage-number</i> [log]	(Optional) Configures the low utilization mark of the current address pool size. <ul style="list-style-type: none"> • The log keyword enables the logging of a system message. A system message will be generated for a DHCP pool when the pool utilization falls below the configured low utilization threshold.
Step 6	Switch(dhcp-config)# network <i>network-number</i> [<i>mask</i> <i>/prefix-length</i>] [secondary]	Specifies the subnet network number and mask of the DHCP address pool.
Step 7	Switch(dhcp-config)# domain-name <i>domain</i>	Specifies the domain name for the client.

	Command or Action	Purpose
Step 8	Switch(dhcp-config)# dns-server <i>address</i> [<i>address2</i> ... <i>address8</i>]	Specifies the IP address of a DNS server that is available to a DHCP client. <ul style="list-style-type: none"> One IP address is required; however, you can specify up to eight IP addresses in one command. Servers should be listed in order of preference.
Step 9	Switch(dhcp-config)# bootfile <i>filename</i>	(Optional) Specifies the name of the default boot image for a DHCP client. <ul style="list-style-type: none"> The boot file is used to store the boot image for the client. The boot image is generally the operating system that the client uses to load.
Step 10	Switch(dhcp-config)# next-server <i>address</i> [<i>address2</i> ... <i>address8</i>]	(Optional) Configures the next server in the boot process of a DHCP client. <ul style="list-style-type: none"> One address is required; however, you can specify up to eight addresses in one command line. If multiple servers are specified, DHCP assigns them to clients in a round-robin order. The first client gets address 1, the next client gets address 2, and so on. If this command is not configured, DHCP uses the server specified by the ip helper address command as the boot server.
Step 11	Switch(dhcp-config)# netbios-name-server <i>address</i> [<i>address2</i> ... <i>address8</i>]	(Optional) Specifies the NetBIOS WINS server that is available to a Microsoft DHCP client. <ul style="list-style-type: none"> One address is required; however, you can specify up to eight addresses in one command line. Servers should be listed in order of preference.
Step 12	Switch(dhcp-config)# netbios-node-type <i>type</i>	(Optional) Specifies the NetBIOS node type for a Microsoft DHCP client.
Step 13	Switch(dhcp-config)# default-router <i>address</i> [<i>address2</i> ... <i>address8</i>]	(Optional) Specifies the IP address of the default device for a DHCP client. <ul style="list-style-type: none"> The IP address should be on the same subnet as the client. One IP address is required; however, you can specify up to eight IP addresses in one command line. These default devices are listed in order of preference; that is, address is the most preferred device, address2 is the next most preferred device, and so on. When a DHCP client requests an IP address, the device—acting as a DHCP server—accesses the default device list to select another device that the DHCP client will use as the first hop for forwarding messages. After a DHCP client has booted, the client begins sending packets to its default device.
Step 14	Switch(dhcp-config)# option <i>code</i> [<i>instance number</i>] { <i>ascii string</i> <i>hex string</i> <i>ip-address</i> }	(Optional) Configures DHCP server options.

	Command or Action	Purpose
Step 15	Switch(dhcp-config)# lease {days [hours [minutes]] infinite }	Optional) Specifies the duration of the lease. <ul style="list-style-type: none"> The default is a one-day lease. The infinite keyword specifies that the duration of the lease is unlimited.
Step 16	Switch(dhcp-config)# end	Exits DHCP configuration mode and returns to privileged EXEC mode.

Configuring a DHCP Address Pool with Secondary Subnets

For any DHCP pool, you can configure a primary subnet and any number of secondary subnets.

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# ip dhcp pool name	Assigns a name to a DHCP pool and enters DHCP configuration mode.
Step 4	Switch(dhcp-config)# utilization mark high percentage-number [log]	(Optional) Configures the high utilization mark of the current address pool size. <ul style="list-style-type: none"> The log keyword enables the logging of a system message. A system message will be generated for a DHCP pool when the pool utilization exceeds the configured high utilization threshold.
Step 5	Switch(dhcp-config)# utilization mark low percentage-number [log]	(Optional) Configures the low utilization mark of the current address pool size. <ul style="list-style-type: none"> The log keyword enables the logging of a system message. A system message will be generated for a DHCP pool when the pool utilization falls below the configured low utilization threshold.
Step 6	Switch(dhcp-config)# network network-number [mask /prefix-length] [secondary]	Specifies the subnet network number and mask of the DHCP address pool.
Step 7	Switch(dhcp-config)# domain-name domain	Specifies the domain name for the client.
Step 8	Switch(dhcp-config)# dns-server address [address2 ... address8]	Specifies the IP address of a DNS server that is available to a DHCP client. <ul style="list-style-type: none"> One IP address is required; however, you can specify up to eight IP addresses in one command. Servers should be listed in order of preference.
Step 9	Switch(dhcp-config)# bootfile filename	(Optional) Specifies the name of the default boot image for a DHCP client. <ul style="list-style-type: none"> The boot file is used to store the boot image for the client. The boot image is generally the operating system that the client uses to load.

Command or Action	Purpose
Step 10 Switch(dhcp-config)# next-server <i>address</i> [<i>address2</i> ... <i>address8</i>]	(Optional) Configures the next server in the boot process of a DHCP client. <ul style="list-style-type: none"> One address is required; however, you can specify up to eight addresses in one command line. If multiple servers are specified, DHCP assigns them to clients in a round-robin order. The first client gets address 1, the next client gets address 2, and so on. If this command is not configured, DHCP uses the server specified by the ip helper address command as the boot server.
Step 11 Switch(dhcp-config)# netbios-name-server <i>address</i> [<i>address2</i> ... <i>address8</i>]	(Optional) Specifies the NetBIOS WINS server that is available to a Microsoft DHCP client. <ul style="list-style-type: none"> One address is required; however, you can specify up to eight addresses in one command line. Servers should be listed in order of preference.
Step 12 Switch(dhcp-config)# netbios-node-type <i>type</i>	(Optional) Specifies the NetBIOS node type for a Microsoft DHCP client.
Step 13 Switch(dhcp-config)# default-router <i>address</i> [<i>address2</i> ... <i>address8</i>]	(Optional) Specifies the IP address of the default device for a DHCP client. <ul style="list-style-type: none"> The IP address should be on the same subnet as the client. One IP address is required; however, you can specify up to eight IP addresses in one command line. These default devices are listed in order of preference; that is, address is the most preferred device, address2 is the next most preferred device, and so on. When a DHCP client requests an IP address, the device—acting as a DHCP server—accesses the default device list to select another device that the DHCP client will use as the first hop for forwarding messages. After a DHCP client has booted, the client begins sending packets to its default device.
Step 14 Switch(dhcp-config)# option <i>code</i> [<i>instance number</i>] { <i>ascii string</i> <i>hex string</i> <i>ip-address</i> }	(Optional) Configures DHCP server options.
Step 15 Switch(dhcp-config)# lease { <i>days</i> [<i>hours</i> [<i>minutes</i>]] infinite }	(Optional) Specifies the duration of the lease. <ul style="list-style-type: none"> The default is a one-day lease. The infinite keyword specifies that the duration of the lease is unlimited.

	Command or Action	Purpose
Step 16	Switch(dhcp-config)# network <i>network-number [mask /prefix-length]</i> [secondary]	(Optional) Specifies the network number and mask of a secondary DHCP server address pool. <ul style="list-style-type: none"> Any number of secondary subnets can be added to a DHCP server address pool. During execution of this command, the configuration mode changes to DHCP pool secondary subnet configuration mode, which is identified by (config-dhcp-subnet-secondary)# prompt. In this mode, the administrator can configure a default device list that is specific to the subnet. See Troubleshooting Tips section if you are using secondary IP addresses under a loopback interface with DHCP secondary subnets.
Step 17	Switch(config-dhcp-subnet-secondary)# override default-router <i>address [address2 ... address8]</i>	(Optional) Specifies the default device list that is used when an IP address is assigned to a DHCP client from a particular secondary subnet. <ul style="list-style-type: none"> If the subnet-specific override value is configured, this override value is used when assigning an IP address from the subnet; the network-wide default device list is used only to set the gateway device for the primary subnet. If this subnet-specific override value is not configured, the network-wide default device list is used when assigning an IP address from the subnet.
Step 18	Switch(config-dhcp-subnet-secondary)# override utilization high <i>percentage-number</i>	(Optional) Sets the high utilization mark of the subnet size. <ul style="list-style-type: none"> This command overrides the global default setting specified by the utilization mark high command.
Step 19	Switch(config-dhcp-subnet-secondary)# override utilization low <i>percentage-number</i>	(Optional) Sets the low utilization mark of the subnet size. <ul style="list-style-type: none"> This command overrides the global default setting specified by the utilization mark low command.
Step 20	Switch(config-dhcp-subnet-secondary)# end	Exits DHCP secondary subnet configuration mode and returns to privileged EXEC mode.

Troubleshooting Tips

If you are using secondary IP addresses under a single loopback interface and using secondary subnets under a DHCP pool, use one DHCP pool to configure networks for all the secondary subnets instead of using one pool per secondary subnet. The **network** *network-number [mask | /prefix-length] [secondary]* command must be configured under a single DHCP address pool rather than multiple DHCP address pools.

The following is the correct configuration:

```
ip dhcp pool dhcp_1
 network 172.16.1.0 255.255.255.0
 network 172.16.2.0 255.255.255.0 secondary
 network 172.16.3.0 255.255.255.0 secondary
 network 172.16.4.0 255.255.255.0 secondary
!
interface Loopback111
 ip address 172.16.1.1 255.255.255.255 secondary
```

```
ip address 172.16.2.1 255.255.255.255 secondary
ip address 172.16.3.1 255.255.255.255 secondary
ip address 172.16.4.1 255.255.255.255 secondary
```

The following is the incorrect configuration:

```
ip dhcp pool dhcp_1
network 172.16.1.0 255.255.255.0
lease 1 20 30
accounting default
!
ip dhcp pool dhcp_2
network 172.16.2.0 255.255.255.0
lease 1 20 30
accounting default
!
ip dhcp pool dhcp_3
network 172.16.3.0 255.255.255.0
lease 1 20 30
accounting default
!
ip dhcp pool dhcp_4
network 172.16.4.0 255.255.255.0
lease 1 20 30
accounting default
!
interface Loopback111
ip address 172.16.1.1 255.255.255.255 secondary
ip address 172.16.2.1 255.255.255.255 secondary
ip address 172.16.3.1 255.255.255.255 secondary
ip address 172.16.4.1 255.255.255.255 secondary
```

Verifying the DHCP Address Pool Configuration

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# show ip dhcp pool [<i>name</i>]	(Optional) Displays information about DHCP address pools.
Step 3	Switch(config)# show ip dhcp binding [<i>address</i>]	(Optional) Displays a list of all bindings created on a specific DHCP server. <ul style="list-style-type: none"> Use the show ip dhcp binding command to display the IP addresses that have already been assigned. Verify that the address pool is not exhausted. If necessary, recreate the pool to create a larger pool of addresses. Use the show ip dhcp binding command to display the lease expiration date and time of the IP address of the host.
Step 4	Switch(dhcp-config)# show ip dhcp conflict [<i>address</i>]	(Optional) Displays a list of all IP address conflicts.
Step 5	Switch(config)# show ip dhcp database [<i>url</i>]	(Optional) Displays recent activity on the DHCP database.
Step 6	Switch(config)# show ip dhcp server statistics [<i>type-number</i>]	(Optional) Displays count information about server statistics and messages sent and received.

Configuring Manual Bindings

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(dhcp-config)# ip dhcp pool <i>pool-name</i>	Assigns a name to a DHCP pool and enters DHCP configuration mode.
Step 4	Switch(dhcp-config)# host <i>address</i> [<i>mask</i> <i>/prefix-length</i>]	Specifies the IP address and subnet mask of the client. <ul style="list-style-type: none"> There is no limit to the number of manual bindings you can configure. However, you can configure only one manual binding per host pool.
Step 5	Switch(dhcp-config)# client-identifier <i>unique-identifier</i>	Specifies the unique identifier for DHCP clients. <ul style="list-style-type: none"> This command is used for DHCP requests. DHCP clients require client identifiers. You can specify the unique identifier for the client in either of the following ways: <ul style="list-style-type: none"> A 7-byte dotted hexadecimal notation. For example, 01b7.0813.8811.66, where 01 represents the Ethernet media type and the remaining bytes represent the MAC address of the DHCP client. A 27-byte dotted hexadecimal notation. For example, 7665.6e64.6f72.2d30.3032.342e.3937.6230.2e33.3734.312d.4661.302f.31. The equivalent ASCII string for this hexadecimal value is vendor-0024.97b0.3741-fa0/1, where vendor represents the vendor, 0024.97b0.3741 represents the MAC address of the source interface, and fa0/1 represents the source interface of the DHCP client. See the Troubleshooting section for information about how to determine the client identifier of the DHCP client. <div>  <p>Note The identifier specified here is considered for a DHCP client that sends a client identifier in the packet.</p> </div>
Step 6	Switch(dhcp-config)# hardware-address <i>hardware-address</i> [<i>protocol-type</i> <i>hardware-number</i>]	Specifies a hardware address for the client. <ul style="list-style-type: none"> This command is used for BOOTP requests. <div>  <p>Note The hardware address specified here is considered for a DHCP client that does not send a client identifier in the packet.</p> </div>

	Command or Action	Purpose
Step 7	Switch(dhcp-config)# client-name <i>name</i>	(Optional) Specifies the name of the client using any standard ASCII character. <ul style="list-style-type: none"> The client name should not include the domain name. For example, the name client1 should not be specified as client1.cisco.com.
Step 8	Switch(dhcp-config)# end	Exits DHCP configuration mode and returns to privileged EXEC mode.

Troubleshooting Tips

You can determine the client identifier by using the **debug ip dhcp server packet** command. In the following sample output, the client is identified by the value 0b07.1134.a029:

```
Switch# debug ip dhcp server packet
```

```
DHCPD:DHCPDISCOVER received from client 0b07.1134.a029 through relay 10.1.0.253.
DHCPD:assigned IP address 10.1.0.3 to client 0b07.1134.a029.
.
.
.
```

Configuring the DHCP Server to Read a Static Mapping Text File

Before You Begin

The administrator must create the static mapping text file in the correct format and configure the address pools before performing this task.

Before editing the file, you must disable the DHCP server using the **no service dhcp** command.

The static bindings must not be deleted when a DHCPRELEASE is received or must not be timed out by the DHCP timer. The static bindings should be created by using the **ip dhcp pool** command.

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# ip dhcp pool <i>pool-name</i>	Assigns a name to a DHCP pool and enters DHCP configuration mode. <div data-bbox="893 1501 1461 1753">  <p>Note If you have already configured the IP DHCP pool name using the ip dhcp pool command and the static file URL using the origin file command, you must perform a fresh read using the no service dhcp command and the service dhcp command.</p> </div>
Step 4	Switch(dhcp-config)# origin file <i>url</i>	Specifies the URL that the DHCP server can access to locate the text file.

	Command or Action	Purpose
Step 5	Switch(dhcp-config) # end	Exits DHCP configuration mode and returns to privileged EXEC mode.
Step 6	Switch# show ip dhcp binding [address]	(Optional) Displays a list of all bindings created on a specific DHCP server.

Customizing DHCP Server Operation

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config) # ip dhcp ping packets <i>number</i>	(Optional) Specifies the number of ping packets the DHCP server sends to a pool address before assigning the address to a requesting client. <ul style="list-style-type: none"> The default is two packets. Setting the <i>number</i> argument to a value of 0 disables the DHCP server ping operation.
Step 4	Switch(config) # ip dhcp ping timeout <i>milliseconds</i>	(Optional) Specifies the duration the DHCP server waits for a ping reply from an address pool.
Step 5	Switch(config) # ip dhcp bootp ignore	(Optional) Allows the DHCP server to selectively ignore and not reply to received BOOTP requests. <ul style="list-style-type: none"> The ip dhcp bootp ignore command applies to all DHCP pools configured on the device. BOOTP requests cannot be selectively ignored on a per-DHCP pool basis.
Step 6	Switch(config) # end	Exits global configuration mode and returns to privileged EXEC mode.

Configuring a Remote Device to Import DHCP Server Options from a Central DHCP Server

The Cisco DHCP server can dynamically configure options such as the Domain Name System (DNS) and Windows Internet Name Service (WINS) addresses to respond to DHCP requests from local clients behind the customer premises equipment (CPE). Earlier, network administrators configured the Cisco DHCP server on each device manually. Now, the Cisco DHCP server is enhanced to allow configuration information to be updated automatically. Network administrators can configure one or more centralized DHCP servers to update specific DHCP options within the DHCP pools. The remote servers can request or “import” these option parameters from centralized servers.

This section contains the following tasks:

- [Configuring the Central DHCP Server to Update DHCP Options, page 59-20](#)
- [Configuring a Remote Device to Import DHCP Server Options from a Central DHCP Server, page 59-19](#)

Configuring the Central DHCP Server to Update DHCP Options

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# ip dhcp pool <i>name</i>	Assigns a name to a DHCP pool and enters DHCP configuration mode.
Step 4	Switch(dhcp-config)# network <i>network-number</i> [<i>mask</i> <i>/prefix-length</i>]	Specifies the subnet number and mask of the DHCP address pool.
Step 5	Switch(dhcp-config)# dns-server <i>address</i> [<i>address2</i> ... <i>address8</i>]	(Optional) Specifies the IP address of a DNS server that is available to a DHCP client. <ul style="list-style-type: none"> One IP address is required; however, you can specify up to eight IP addresses in one command line. Servers should be listed in the order of preference.
Step 6	Switch(dhcp-config)# end	Exits DHCP configuration mode and returns to privileged EXEC mode.

Configuring the Remote Device to Import DHCP Options

Perform the following task to configure the remote device to import DHCP options:

Note

When two servers provide DHCP addresses to a single device configured with `ip address dhcp` on two different interfaces, the imported information is merged and, for those options that take a single value, the last known option value will be used.

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# ip dhcp pool <i>name</i>	Assigns a name to a DHCP pool and enters DHCP configuration mode.
Step 4	Switch(dhcp-config)# network <i>network-number</i> [<i>mask</i> <i>/prefix-length</i>]	Specifies the subnet number and mask of the DHCP address pool.
Step 5	Switch(dhcp-config)# import all	(Optional) Specifies the IP address of a DNS server that is available to a DHCP client. <ul style="list-style-type: none"> One IP address is required; however, you can specify up to eight IP addresses in one command line. Servers should be listed in the order of preference.
Step 6	Switch(dhcp-config)# exit	Exits DHCP configuration mode and returns to privileged EXEC mode.
Step 7	Switch(config)# interface <i>type number</i>	Configures an interface and enters interface configuration mode.
Step 8	Switch(config-if)# ip address dhcp	Specifies that the interface acquires an IP address through DHCP.

	Command or Action	Purpose
Step 9	Switch(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.
Step 10	Switch# show ip dhcp import	Displays the options that are imported from the central DHCP server.

Configuring DHCP Address Allocation Using Option 82

- [Enabling Option 82 for DHCP Address Allocation, page 59-21](#)
- [Defining the DHCP Class and Relay Agent Information Patterns, page 59-21](#)

Enabling Option 82 for DHCP Address Allocation

By default, the Cisco DHCP server uses information provided by option 82 to allocate IP addresses. If the DHCP address allocation is disabled, perform the task described in this section to reenable this capability.

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# ip dhcp use class	Controls DHCP classes that are used for address allocation. <ul style="list-style-type: none"> • This functionality is enabled by default. • Use the no form of this command to disable this functionality without deleting the DHCP class configuration.
Step 4	Switch(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

Troubleshooting Tips

If DHCP classes are configured in the pool, but the DHCP server does not use the classes, verify if the **no ip dhcp use class** command was configured.

Defining the DHCP Class and Relay Agent Information Patterns

Before You Begin

You must know the hexadecimal value of each byte location in option 82 to configure the relay-information hex command. The option 82 format may vary from product to product. Contact the relay agent vendor for this information.

Perform this task to define the DHCP class and relay agent information patterns.

■ Configuring DHCP Address Pools

Step 1	Switch> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# ip dhcp class name	Defines a DHCP class and enters DHCP class configuration mode.
Step 4	Switch(dhcp-class)# relay agent information	Enters relay agent information option configuration mode. • If you omit this step, the DHCP class matches any relay agent information option, whether the relay agent information option value is available or not.
Step 5	Switch(dhcp-class-relayinfo)# relay-information hex pattern [*] [bitmask mask]	(Optional) Specifies a hexadecimal value for full relay information option. • The pattern argument creates a pattern that is used to match the DHCP class. • If you omit this step, no pattern is configured and it is considered a match to any relay agent information option value, but the relay information option must be available in the DHCP packet. • You can configure multiple relay-information hex commands in a DHCP class.
Step 6	Repeat Steps 3 through 5 for each DHCP class you need to configure.	—
Step 7	Switch(dhcp-class-relayinfo)# end	Exits relay agent information option mode and returns to privileged EXEC mode.

Troubleshooting Tips

Use the **debug ip dhcp server class** command to display the class matching results.

Defining the DHCP Address Pool

Step 1	Switch> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# ip dhcp pool name	Assigns a name to a DHCP pool and enters DHCP configuration mode. • Multiple pools can be configured with the same class, eliminating the need to configure the same pattern in multiple pools.
Step 4	Switch(dhcp-config)# network network-number [mask /prefix-length]	Configures the subnet and mask for a DHCP address pool on a Cisco IOS DHCP server.

Step 5	Switch(dhcp-config)# class <i>class-name</i>	Associates a class with a pool and enters DHCP pool class configuration mode. <ul style="list-style-type: none"> This command also creates a DHCP class if the DHCP class is not yet defined.
Step 6	Switch(dhcp-pool-class)# address range <i>start-ip end-ip</i>	(Optional) Sets an address range for the DHCP class in a DHCP server address pool. <ul style="list-style-type: none"> If this command is not configured for a class, the default value is the entire subnet of the pool. Each class in the DHCP pool is examined for a match in the order configured.
Step 7	Repeat Steps 5 and 6 for each DHCP class you need to associate with the DHCP pool.	—
Step 8	Switch(dhcp-pool-class)# end	Exits DHCP pool class option mode and returns to privileged EXEC mode.

Configuring Static Route with the Next-Hop Dynamically Obtained Through DHCP

This task enables static routes to be assigned using a DHCP default gateway as the next-hop device. Without this feature the gateway IP address is not known until after the DHCP address assignment. You cannot configure a static route with the CLI without knowing that DHCP-supplied address.

Before You Begin

Verify all DHCP client and server configuration steps. Ensure that the DHCP client and server are properly defined to supply a DHCP device option 3 of the DHCP packet.

Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# ip route <i>prefix mask</i> { <i>ip-address</i> <i>interface-type interface-number</i> [<i>ip-address</i>]} dhcp [<i>distance</i>]	Assigns a static route for the default next-hop device when the DHCP server is accessed for an IP address. <ul style="list-style-type: none"> If more than one interface is configured to obtain an IP address from a DHCP server, use the ip route prefix mask interface-type interface-number dhcp command for each interface. If the interface is not specified, the route is added to the routing table as soon as any of the interfaces obtain an IP address and a default device.
Step 4	Switch(config)# end	Exits global configuration mode and returns to privileged EXEC mode.
Step 5	Switch# show ip route	(Optional) Displays the current state of the routing table.

Clearing DHCP Server Variables

Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# clear ip dhcp binding {address *}	Deletes an automatic address binding from the DHCP database. <ul style="list-style-type: none"> Specifying the address argument clears the automatic binding for a specific (client) IP address, whereas specifying an asterisk (*) clears all automatic bindings.
Step 3	Switch# clear ip dhcp conflict {address *}	Clears an address conflict from the DHCP database. <ul style="list-style-type: none"> Specifying the address argument clears the conflict for a specific IP address, whereas specifying an asterisk (*) clears conflicts for all addresses.
Step 4	Switch# clear ip dhcp server statistics	Resets all DHCP server counters to 0.

Configuration Examples for the Cisco IOS DHCP Server

- [Example: Configuring a DHCP Database Agent or Disabling Conflict Logging, page 59-24](#)
- [Example: Excluding IP Addresses, page 59-24](#)
- [Example: Configuring a DHCP Address Pool, page 59-25](#)
- [Example: Configuring Manual Bindings, page 59-27](#)
- [Example: Configuring Static Mapping, page 59-28](#)
- [Example: Customizing DHCP Server Operation, page 59-29](#)
- [Example: Configuring a Remote Device to Import DHCP Server Options from a Central DHCP Server, page 59-30](#)
- [Example: Configuring DHCP Address Allocation Using Option 82, page 59-31](#)
- [Example: Configuring a Static Route with the Next-Hop Dynamically Obtained Through DHCP, page 59-32](#)

Example: Configuring a DHCP Database Agent or Disabling Conflict Logging

The following example shows how to store bindings on host 172.16.4.253. The file transfer protocol is FTP. The server waits for 2 minutes (120 seconds) before performing database changes.

```
Switch> enable
Switch# configure terminal
Switch(config)# ip dhcp database ftp://user:password@172.16.4.253/router-dhcp write-delay 120
Switch(config)# exit
```

Example: Excluding IP Addresses

In the following example, server A and server B service the subnet 10.0.20.0/24. If the subnet is split equally between the two servers, server A is configured to allocate IP addresses 10.0.20.1 to 10.0.20.125 and server B is configured to allocate IP addresses 10.0.20.126 to 10.0.20.254.

Server A

```
Switch# configure terminal
switch(config)# ip dhcp excluded-address 10.0.20.126 10.0.20.255
Switch(config)# ip dhcp pool A
Switch(dhcp-config)# network 10.0.20.0 255.255.255.0
```

Server B

```
Switch# configure terminal
switch(config)# ip dhcp excluded-address 10.0.20.0 10.0.20.125
Switch(config)# ip dhcp pool B
Switch(dhcp-config)# network 10.0.20.0 255.255.255.0
```

Example: Configuring a DHCP Address Pool

In the following example, three DHCP address pools are created: one in network 172.16.0.0, one in subnetwork 172.16.1.0, and one in subnetwork 172.16.2.0. Attributes from network 172.16.0.0—such as the domain name, Domain Name System (DNS) server, (Network Basic Input/Output System) NetBIOS name server, and NetBIOS node type—are inherited in subnetworks 172.16.1.0 and 172.16.2.0. In each pool, clients are granted 30-day leases and all addresses in each subnetwork, except the excluded addresses, are available to the DHCP server for assigning to clients. The table below lists the IP addresses for the devices in three DHCP address pools.

Table 59-2 *DHCP Address Pool Configuration*

	Pool 0 (Network 172.16.0.0)	Pool 1 (Subnetwork 172.16.1.0)	Pool 2 (Subnetwork 172.16.2.0)
Device Type	IP Address	IP Address	IP Address
Default Devices		172.16.1.100 172.16.1.101	172.16.2.100 172.16.2.101
DNS Server	172.16.1.102 172.16.2.102		
NetBIOS Name Server	172.16.1.103 172.16.2.103		
NetBIOS Node Type	h-node		

```
Switch(config)# ip dhcp database ftp://user:password@172.16.4.253/router-dhcp write-delay 120
Switch(config)# ip dhcp excluded-address 172.16.1.100 172.16.1.103
Switch(config)# ip dhcp excluded-address 172.16.2.100 172.16.2.103
!
Switch(config)# ip dhcp pool 0
Switch(dhcp-config)# network 172.16.0.0 /16
Switch(dhcp-config)# domain-name cisco.com
Switch(dhcp-config)# dns-server 172.16.1.102 172.16.2.102
Switch(dhcp-config)# netbios-name-server 172.16.1.103 172.16.2.103
Switch(dhcp-config)# netbios-node-type h-node
!
Switch(config)# ip dhcp pool 1
Switch(dhcp-config)# network 172.16.1.0 /24
Switch(dhcp-config)# default-router 172.16.1.100 172.16.1.101
Switch(dhcp-config)# lease 30
```

```

!
Switch(config)# ip dhcp pool 2
Switch(dhcp-config)# network 172.16.2.0 /24
Switch(dhcp-config)# default-router 172.16.2.100 172.16.2.101
Switch(dhcp-config)# lease 30

```

Example: Configuring a DHCP Address Pool with Multiple Disjoint Subnets

Multiple disjoint subnets in a DHCP pool can be used in any of the following network topologies:

- IP address pooling—The DHCP client and server reside on the same subnet.
- DHCP relay—The DHCP client and DHCP server communicate through a DHCP relay agent where the relay interface is configured with secondary IP addresses.
- Hierarchical DHCP—The DHCP server is configured as the DHCP subnet allocation server. The DHCP client and DHCP subnet allocation server communicate through an on-demand address pool (ODAP) router.

In the following example, one DHCP address pool named pool3 is created; the primary subnet is 172.16.0.0/16, one secondary subnet is 172.16.1.0/24, and the other secondary subnet is 172.16.2.0/24.

- When IP addresses in the primary subnet are exhausted, the DHCP server inspects the secondary subnets in the order in which the subnets were added to the pool.
- When the DHCP server allocates an IP address from the secondary subnet 172.16.1.0/24, the server uses the subnet-specific default device list that consists of IP addresses 172.16.1.100 and 172.16.1.101. However, when the DHCP server allocates an IP address from the subnet 172.16.2.0/24, the server uses the pool-wide list that consists of the four IP addresses from 172.16.0.100 to 172.16.0.103.
- Other attributes from the primary subnet 172.16.0.0/16—such as the domain name, DNS server, NetBIOS name server, and NetBIOS node type—are inherited in both the secondary subnets.
- DHCP clients are granted 30-day leases on IP addresses in the pool. All addresses in each subnet, except the excluded addresses, are available to the DHCP server for assigning to clients.

The table below lists the IP addresses for the devices in the DHCP address pool that consists of three disjoint subnets.

Table 59-3 **DHCP Address Pool Configuration**

	Primary Subnet (172.16.0.0/16)	First Secondary Subnet (172.16.1.0/24)	Second Secondary Subnet (172.16.2.0/24)
Device Type	IP Address	IP Address	IP Address

Example: Configuring Manual Bindings

The following example shows how to create a manual binding for a client named example1.abc.com that sends a client identifier in the DHCP packet. The MAC address of the client is 02c7.f800.0422 and the IP address of the client is 172.16.2.254.

```
Switch(config)# ip dhcp pool pool1
Switch(dhcp-config)# host 172.16.2.254
Switch(dhcp-config)# client-identifier 01b7.0813.8811.66
Switch(dhcp-config)# client-name example1
```

The following example shows how to create a manual binding for a client named example2.abc.com that does not send a client identifier in the DHCP packet. The MAC address of the client is 02c7.f800.0422 and the IP address of the client is 172.16.2.253.

```
Switch(config)# ip dhcp pool pool2
Switch(dhcp-config)# host 172.16.2.253
Switch(dhcp-config)# hardware-address 02c7.f800.0422 ethernet
Switch(dhcp-config)# client-name example1
```

Because attributes are inherited, the two preceding configurations are equivalent to the following:

```
Switch(config)# ip dhcp pool pool1
Switch(dhcp-config)# host 172.16.2.254 255.255.255.0
Switch(dhcp-config)# hardware-address 02c7.f800.0422 ieee802
Switch(dhcp-config)# client-name client1
Switch(dhcp-config)# default-router 172.16.2.100 172.16.2.101
Switch(dhcp-config)# domain-name abc.com
Switch(dhcp-config)# dns-server 172.16.1.102 172.16.2.102
Switch(dhcp-config)# netbios-name-server 172.16.1.103 172.16.2.103
Switch(dhcp-config)# netbios-node-type h-node
```

Example: Configuring Static Mapping

The following example shows how to restart the DHCP server, configure the pool, and specify the URL where the static mapping text file is stored:

```
Switch# configure terminal
Switch(config)# no service dhcp
Switch(config)# service dhcp
Switch(config)# ip dhcp pool pool1
Switch(dhcp-config)# origin file tftp://10.1.0.1/static-bindings
Switch(dhcp-config)# end
```

Note

The static mapping text file can be copied to flash memory on the device and served by the TFTP process of the device. In this case, the IP address in the original file line must be an address owned by the device and one additional line of configuration is required on the device: tftp-server flash static-filename.

The following sample output from the **show ip dhcp binding** command displays address bindings that are configured:

```
Device# show ip dhcp binding

00:05:14:%SYS-5-CONFIG_I: Configured from console by console
Bindings from all pools not associated with VRF:
IP address  Client-ID/          Ls expir   Type    Hw address        User name
10.9.9.4/8   0063.7363.2d30.3036.  Infinite   Static   302e.3762.2e39.3634.  632d.4574.8892.
10.9.9.1/24  0063.6973.636f.2d30.  Infinite   Static   3036.302e.3437.3165.  2e64.6462.342d.
```

The following sample output displays each entry in the static mapping text file

```
*time* Jan 21 2005 22:52 PM
!IP address      Type      Hardware address          Lease expiration
10.19.9.1 /24    id        0063.6973.636f.2d30.3036.302e.3437
10.9.9.4         id        0063.7363.2d30.3036.302e.3762.2e39.3634.632d  Infinite
*end*
```

The following sample debug output shows the reading of the static mapping text file from the TFTP server:

```
Switch# debug ip dhcp server

Loading abc/static_pool from 10.19.192.33 (via Ethernet0):

```

Example: Customizing DHCP Server Operation

```
Switch# configure terminal
Switch(config)# ip dhcp ping packets 5
Switch(config)# ip dhcp ping timeout 850
Switch(config)# ip dhcp bootp ignore
Switch(config)# end
```

Example: Configuring the Option to Ignore all BOOTP Requests

The following example shows two DHCP pools that are configured on the device and that the device's DHCP server is configured to ignore all received BOOTP requests. If a BOOTP request is received from subnet 10.0.18.0/24, the request will be dropped by the device (because the `ip helper-address` command is not configured). If there is a BOOTP request from subnet 192.168.1.0/24, the request will be forwarded to 172.16.1.1 via the `ip helper-address` command.

Example: Configuring a Remote Device to Import DHCP Server Options from a Central DHCP Server

- [Example: Importing DHCP Options, page 59-30](#)
- [Example: Configuring the Remote Device to Import DHCP Options, page 59-31](#)

Example: Importing DHCP Options

The following example shows how to configure a remote and central server to support the importing of DHCP options. The central server is configured to automatically update DHCP options, such as DNS and WINS addresses, within the DHCP pools. In response to a DHCP request from a local client behind CPE equipment, the remote server can request or “import” these option parameters from the centralized server. See the figure below for a diagram of the network topology.

Central Device

```

!do not assign this range to DHCP clients
ip dhcp-excluded address 10.0.0.1 10.0.0.5
!
ip dhcp pool central
! Specifies network number and mask for DHCP clients
network 10.0.0.0 255.255.255.0
! Specifies the domain name for the client

```

```
domain-name central
! Specifies DNS server that will respond to DHCP clients when they need to correlate host
! name to ip address
dns-server 10.0.0.2
! Specifies the NETBIOS WINS server
netbios-name-server 10.0.0.2
!
interface FastEthernet0/0
 ip address 10.0.0.1 255.255.255.0
 duplex auto
 speed auto
```

Remote Device

```
ip dhcp pool client
! Imports DHCP option parameters into DHCP server database
import all
 network 172.16.2.254 255.255.255.0
!
interface FastEthernet0/0
 ip address dhcp
 duplex auto
 speed auto
```

Example: Configuring the Remote Device to Import DHCP Options

```
Switch# configure terminal
Switch(config)# ip dhcp pool 1
Switch(dhcp-config)# network 172.16.0.0 /16
Switch(dhcp-config)# import all
Switch(dhcp-config)# exit
Switch(config)# interface FastEthernet 0/0
Switch(config-if)# ip address dhcp
Switch(config-if)# end
Switch# show ip dhcp import
```

Example: Configuring DHCP Address Allocation Using Option 82

This example shows how to configure two DHCP classes. CLASS1 defines the group of DHCP clients whose address requests contain the relay agent information option with the specified hexadecimal values. CLASS2 defines the group of DHCP clients whose address requests contain the configured relay agent information suboptions. CLASS3 has no pattern configured and is treated as a “match to any” class. This type of class is useful for specifying a “default” class.

The subnet of pool ABC has been divided into three ranges without further subnetting the 10.0.20.0/24 subnet. If there is a DHCP Discover message from the 10.0.20.0/24 subnet with option 82 matching that of class CLASS1, an available address in the range from 10.0.20.1 to 10.0.20.100 will be allocated. If there is no free address in CLASS address range, the DHCP Discover message will be matched against CLASS2, and so on.

Therefore, each class in the DHCP pool will be examined for a match in the order configured by the user. In pool ABC, the order of matching is CLASS1, CLASS2, and finally CLASS3. In pool DEF, class CLASS2 does not have any address range configured. By default, the address range for a particular class is the pool’s entire subnets. Therefore, clients matching CLASS2 may be allocated addresses from 10.0.20.1 to 10.0.20.254.

Multiple pools can be configured with the same class, eliminating the need to configure the same patterns in multiple pools. For example, there may be a need to specify that one or more pools must be used only to service a particular class of devices (for example, cable modems and IP phones).

```
! Defines the DHCP classes and relay information patterns
ip dhcp class CLASS1
  relay agent information
    relay-information hex 01030a0b0c02050000000123
    relay-information hex 01030a0b0c02*
    relay-information hex 01030a0b0c02050000000000 bitmask 00000000000000000000FF
ip dhcp class CLASS2
  relay agent information
    relay-information hex 01040102030402020102
    relay-information hex 01040101030402020102
ip dhcp class CLASS3
  relay agent information
! Associates the DHCP pool with DHCP classes
ip dhcp pool ABC
  network 10.0.20.0 255.255.255.0
  class CLASS1
    address range 10.0.20.1 10.0.20.100
class CLASS2
  address range 10.0.20.101 10.0.20.200
class CLASS3
  address range 10.0.20.201 10.0.20.254
ip dhcp pool DEF
  network 172.64.2.2 255.255.255.0
  class CLASS1
    address range 172.64.2.3 172.64.2.10
  class CLASS2
```

Example: Configuring a Static Route with the Next-Hop Dynamically Obtained Through DHCP

The following example shows how to configure two Ethernet interfaces to obtain the next-hop device IP address from the DHCP server:

```
Switch(config)# ip route 10.10.10.0 255.255.255.0 dhcp 200
Switch(config)# ip route 10.10.20.1 255.255.255.255 ethernet 1 dhcp
```

Feature Information for the IOS DHCP Server

Table 4 lists the features in this module and provides links to specific configuration information.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

Table 4 lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 4 Feature Information for the IOS DHCP Server

Feature Name	Feature Information
DHCP Server Import All Enhancement	The DHCP Server Import All Enhancement feature is an enhancement to the import all command. Prior to this feature, the options imported through the import all command were overwritten by those imported by another subsystem. Through this feature, options imported by multiple subsystems can coexist in the DHCP address pool. When the session is terminated or the lease is released, the imported options are cleared.
DHCP Server Multiple Subnet	The DHCP Server Multiple Subnet feature enables multiple subnets to be configured under the same DHCP address pool. The following commands were introduced or modified: network(DHCP), override default-router.
DHCP Server Option to Ignore all BOOTP Requests	The DHCP Server Option to Ignore all BOOTP Requests feature allows the Cisco IOS DHCP server to selectively ignore and not reply to received Bootstrap Protocol (BOOTP) request packets. The following command was introduced or modified: ip dhcp bootp ignore.

Configuring DHCP Snooping, IP Source Guard, and IPSPG for Static Hosts

This chapter describes how to configure Dynamic Host Configuration Protocol (DHCP) snooping, IP source guard, and IP source guard (IPSPG) for static hosts on Catalyst 4500 series switches. It provides guidelines, procedures, and configuration examples.

This chapter consists of the following major sections:

- [About DHCP Snooping, page 60-1](#)
- [Configuring DHCP Snooping, page 60-6](#)
- [Displaying DHCP Snooping Information, page 60-18](#)
- [Displaying IP Source Binding Information, page 60-23](#)
- [Configuring IP Source Guard, page 60-20](#)
- [Displaying IP Source Binding Information, page 60-23](#)
- [Configuring IP Source Guard for Static Hosts, page 60-24](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About DHCP Snooping

DHCP snooping is a DHCP security feature that provides security by filtering untrusted DHCP messages and by building and maintaining a DHCP snooping binding table. An untrusted message is a message that is received from outside the network or firewall and that can cause traffic attacks within your network.

The DHCP snooping binding table contains the MAC address, IP address, lease time, binding type, VLAN number, and interface information that corresponds to the local untrusted interfaces of a switch; it does not contain information regarding hosts interconnected with a trusted interface. An untrusted interface is an interface that is configured to receive messages from outside the network or firewall. A trusted interface is an interface that is configured to receive only messages from within the network.

DHCP snooping acts such as a firewall between untrusted hosts and DHCP servers. It also gives you a way to differentiate between untrusted interfaces connected to the end-user and trusted interfaces connected to the DHCP server or another switch.

**Note**

In order to enable DHCP snooping on a VLAN, you must enable DHCP snooping on the switch.

You can configure DHCP snooping for switches and VLANs. When you enable DHCP snooping on a switch, the interface acts as a Layer 2 bridge, intercepting and safeguarding DHCP messages going to a Layer 2 VLAN. When you enable DHCP snooping on a VLAN, the switch acts as a Layer 2 bridge within a VLAN domain.

This section includes these topics:

- [Trusted and Untrusted Sources, page 60-2](#)
- [About the DHCP Snooping Database Agent, page 60-2](#)
- [Option 82 Data Insertion, page 60-3](#)

Trusted and Untrusted Sources

The DHCP snooping feature determines whether traffic sources are trusted or untrusted. An untrusted source may initiate traffic attacks or other hostile actions. To prevent such attacks, the DHCP snooping feature filters messages and rate-limits traffic from untrusted sources.

In an enterprise network, devices under your administrative control are trusted sources. These devices include the switches, routers and servers in your network. Any device beyond the firewall or outside your network is an untrusted source. Host ports are generally treated as untrusted sources.

In a service provider environment, any device that is not in the service provider network is an untrusted source (such as a customer switch). Host ports are untrusted sources.

In the Catalyst 4500 series switch, you indicate that a source is trusted by configuring the trust state of its connecting interface.

The default trust state of all interfaces is untrusted. You must configure DHCP server interfaces as trusted. You can also configure other interfaces as trusted if they connect to devices (such as switches or routers) inside your network. You usually do not configure host port interfaces as trusted.

**Note**

For DHCP snooping to function properly, all DHCP servers must be connected to the switch through trusted interfaces, as untrusted DHCP messages will be forwarded only to trusted interfaces.

About the DHCP Snooping Database Agent

To retain the bindings across switch reloads, you must use the DHCP snooping database agent. Without this agent, the bindings established by DHCP snooping are lost upon switch reload. Connectivity is lost as well.

The mechanism for the database agent stores the bindings in a file at a configured location. Upon reload, the switch reads the file to build the database for the bindings. The switch keeps the file current by writing to the file as the database changes.

The format of the file that contains the bindings is as follows:

```
<initial-checksum>
TYPE DHCP-SNOOPING
VERSION 1
BEGIN
<entry-1> <checksum-1>
<entry-2> <checksum-1-2>
...
...
<entry-n> <checksum-1-2-...-n>
END
```

Each entry in the file is tagged with a checksum that is used to validate the entries whenever the file is read. The <initial-checksum> entry on the first line helps distinguish entries associated with the latest write from entries that are associated with a previous write.

it is a sample bindings file:

```
3ebe1518
TYPE DHCP-SNOOPING
VERSION 1
BEGIN
10.1.1.1 512 0001.0001.0005 3EBE2881 Gi1/1 e5e1e733
10.1.1.1 512 0001.0001.0002 3EBE2881 Gi1/1 4b3486ec
10.1.1.1 1536 0001.0001.0004 3EBE2881 Gi1/1 f0e02872
10.1.1.1 1024 0001.0001.0003 3EBE2881 Gi1/1 ac41adf9
10.1.1.1 1 0001.0001.0001 3EBE2881 Gi1/1 34b3273e
END
```

Each entry holds an IP address, VLAN, MAC address, lease time (in hex), and the interface associated with a binding. At the end of each entry is a checksum that accounts for all the bytes from the start of the file through all the bytes associated with the entry. Each entry consists of 72 bytes of data, followed by a space, followed by a checksum.

Upon bootup, when the calculated checksum equals the stored checksum, a switch reads entries from the file and adds the bindings to the DHCP snooping database. When the calculated checksum does not equal the stored checksum, the entry read from the file is ignored and so are all the entries following the failed entry. The switch also ignores all those entries from the file whose lease time has expired. (This situation is possible because the lease time might indicate an expired time.) An entry from the file is also ignored if the interface referred to in the entry no longer exists on the system or if it is a router port or a DHCP snooping-trusted interface.

When a switch learns of new bindings or when it loses some bindings, the switch writes the modified set of entries from the snooping database to the file. The writes are performed with a configurable delay to batch as many changes as possible before the actual write happens. Associated with each transfer is a timeout after which a transfer is aborted if it is not completed. These timers are referred to as the write delay and abort timeout.

Option 82 Data Insertion

In residential, metropolitan Ethernet-access environments, DHCP can centrally manage the IP address assignments for a large number of subscribers. When the DHCP Option 82 feature is enabled on the switch, a subscriber device is identified by the switch port through which it connects to the network (in addition to its MAC address). Multiple hosts on the subscriber LAN can be connected to the same port on the access switch and are uniquely identified.

**Note**

The DHCP Option 82 feature is supported only when DHCP snooping is globally enabled and on the VLANs to which subscriber devices using this feature are assigned.

Figure 60-1 is an example of a metropolitan Ethernet network in which a centralized DHCP server assigns IP addresses to subscribers connected to the switch at the access layer. Because the DHCP clients and their associated DHCP server do not reside on the same IP network or subnet, a DHCP relay agent (the Catalyst switch) is configured with a helper address to enable broadcast forwarding and to transfer DHCP messages between the clients and the server.

Figure 60-1 DHCP Relay Agent in a Metropolitan Ethernet Network

When you enable the DHCP snooping information Option 82 on the switch, this sequence of events occurs:

- The host (DHCP client) generates a DHCP request and broadcasts it on the network.
- When the switch receives the DHCP request, it adds the Option 82 information in the packet. By default, the remote ID suboption is the switch MAC address, and the circuit ID suboption is the port identifier, **vlan-mod-port**, from which the packet is received. Beginning with Cisco IOS Release 12.2(40)SG, you can configure the remote ID and circuit ID. For information on configuring these suboptions, see the [“Enabling DHCP Snooping and Option 82”](#) section on page 60-10.
- If the IP address of the relay agent is configured, the switch adds this IP address in the DHCP packet.
- The switch forwards the DHCP request that includes the Option 82 field to the DHCP server.
- The DHCP server receives the packet. If the server is Option 82-capable, it can use the remote ID, the circuit ID, or both to assign IP addresses and implement policies, such as restricting the number of IP addresses that can be assigned to a single remote ID or circuit ID. The DHCP server then echoes the Option 82 field in the DHCP reply.
- The DHCP server unicasts the reply to the switch if the request was relayed to the server by the switch. The switch verifies that it originally inserted the Option 82 data by inspecting the remote ID and possibly the circuit ID fields. The switch removes the Option 82 field and forwards the packet to the switch port that connects to the DHCP client that sent the DHCP request.

In the default suboption configuration, when the described sequence of events occurs, the values in these fields in [Figure 60-2](#) do not change:

- Circuit ID suboption fields
 - Suboption type
 - Length of the suboption type
 - Circuit ID type
 - Length of the circuit ID type
- Remote ID suboption fields
 - Suboption type
 - Length of the suboption type
 - Remote ID type
 - Length of the remote ID type

[Figure 60-2](#) shows the packet formats for the remote ID suboption and the circuit ID suboption when the default suboption configuration is used. For the circuit ID suboption, the module number corresponds to the switch module number. The switch uses the packet formats when you globally enable DHCP snooping and enter the **ip dhcp snooping information option** global configuration command.

Figure 60-2 Suboption Packet Formats

Circuit ID Suboption Frame Format

Remote ID Suboption Frame Format

[Figure 60-3](#) shows the packet formats for user-configured remote ID and circuit ID suboptions. The switch uses these packet formats when DHCP snooping is globally enabled and when the **ip dhcp snooping information option format remote-id** global configuration command and the **ip dhcp snooping vlan information option format-type circuit-id string** interface configuration command are entered.

The values for these fields in the packets change from the default values when you configure the remote ID and circuit ID suboptions:

- Circuit ID suboption fields
 - The circuit ID type is 1.
 - The length values are variable, depending on the length of the string that you configure.
- Remote ID suboption fields
 - The remote ID type is 1.
 - The length values are variable, depending on the length of the string that you configure.

Figure 60-3 User-Configured Suboption Packet Formats

Circuit ID Suboption Frame Format (for user-configured string):

Remote ID Suboption Frame Format (for user-configured string):

Configuring DHCP Snooping

When you configure DHCP snooping on your switch, you are enabling the switch to differentiate untrusted interfaces from trusted interfaces. You must enable DHCP snooping globally before you can use DHCP snooping on a VLAN. You can enable DHCP snooping independently from other DHCP features.

These sections describe how to configure DHCP snooping:

- [Default Configuration for DHCP Snooping, page 60-7](#)
- [Enabling DHCP Snooping, page 60-7](#)
- [Enabling DHCP Snooping on the Aggregation Switch, page 60-9](#)
- [Enabling DHCP Snooping and Option 82, page 60-10](#)
- [Enabling DHCP Snooping on Private VLAN, page 60-12](#)
- [Configuring DHCP Snooping on Private VLAN, page 60-12](#)

- [Configuring DHCP Snooping with an Ethernet Channel Group](#), page 60-12
- [Enabling the DHCP Snooping Database Agent](#), page 60-13
- [Limiting the Rate of Incoming DHCP Packets](#), page 60-13
- [Configuration Examples for the Database Agent](#), page 60-15

**Note**

For DHCP server configuration information, refer to “Configuring DHCP” in the *Cisco IOS IP and IP Routing Configuration Guide* at:

http://www.cisco.com/en/US/docs/ios/12_2/ip/configuration/guide/1cfdhcp.html

Default Configuration for DHCP Snooping

DHCP snooping is disabled by default. [Table 60-1](#) shows all the default configuration values for each DHCP snooping option.

Table 60-1 **Default Configuration Values for DHCP Snooping**

Option	Default Value/State
DHCP snooping	Disabled
DHCP snooping information option	Enabled
DHCP snooping information option allow-untrusted	Disabled
DHCP snooping limit rate	Infinite (functions as if rate limiting were disabled)
DHCP snooping trust	Untrusted
DHCP snooping vlan	Disabled

If you want to change the default configuration values, see the “[Enabling DHCP Snooping](#)” section.

Enabling DHCP Snooping

**Note**

When DHCP snooping is enabled globally, DHCP requests are dropped until the ports are configured. Consequently, you should probably configure this feature during a maintenance window and not during production.

To enable DHCP snooping, perform this task:

	Command	Purpose
Step 1	Switch(config)# ip dhcp snooping	Enables DHCP snooping globally. You can use the no keyword to disable DHCP snooping.
Step 2	Switch(config)# ip dhcp snooping vlan <i>number</i> [<i>number</i>] vlan { <i>vlan range</i> }	Enables DHCP snooping on your VLAN or VLAN range.

	Command	Purpose
Step 3	Switch(config)# errdisable recovery {cause dhcp-rate-limit interval interval}	(Optional) Configures the amount of time required for recovery from a specified errdisable cause.
Step 4	Switch(config)# errdisable detect cause dhcp-rate-limit {action shutdown vlan}	(Optional) Enables per-VLAN errdisable detection. Note By default this command is enabled, and when a violation occurs the interface is shutdown.
Step 5	Switch(config-if)# ip dhcp snooping trust	Configures the interface as trusted or untrusted. You can use the no keyword to configure an interface to receive messages from an untrusted client.
Step 6	Switch(config-if)# ip dhcp snooping limit rate rate	Configures the number of DHCP packets per second (pps) that an interface can receive. ¹
Step 7	Switch(config)# end	Exits configuration mode.
Step 8	Switch# show ip dhcp snooping	Verifies the configuration.

1. We recommend not configuring the untrusted interface rate limit to more than 100 packets per second. The recommended rate limit for each untrusted client is 15 packets per second. Normally, the rate limit applies to untrusted interfaces. If you want to set up rate limiting for trusted interfaces, keep in mind that trusted interfaces aggregate all DHCP traffic in the switch, and you will need to adjust the rate limit to a higher value. You should fine tune this threshold depending on the network configuration. The CPU should not receive DHCP packets at a sustained rate of more than 1,000 packets per second.

You can configure DHCP snooping for a single VLAN or a range of VLANs. To configure a single VLAN, enter a single VLAN number. To configure a range of VLANs, enter a beginning and an ending VLAN number or a dash and range of VLANs.

The number of incoming DHCP packets is rate-limited to prevent a denial-of-service attack. When the rate of incoming DHCP packets exceeds the configured limit, the switch places the port in the errdisabled state. To prevent the port from shutting down, you can use the **errdisable detect cause dhcp-rate-limit action shutdown vlan** global configuration command to shut down just the offending VLAN on the port where the violation occurred.

When a secure port is in the errdisabled state, you can bring it out of this state automatically by configuring the **errdisable recovery cause dhcp-rate-limit** global configuration command or you can manually reenabel it by entering the **shutdown** and **no shutdown** interface configuration commands. If a port is in per-VLAN errdisable mode, you can also use **clear errdisable interface name vlan range** command to reenabel the VLAN on the port.

This example shows how to enable DHCP snooping on VLAN 500 through 555:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip dhcp snooping
Switch(config)# ip dhcp snooping vlan 500 555
Switch(config)# ip dhcp snooping information option format remote-id string switch123
Switch(config)# interface GigabitEthernet 5/1
Switch(config-if)# ip dhcp snooping trust
Switch(config-if)# ip dhcp snooping limit rate 100
Switch(config-if)# ip dhcp snooping vlan 555 information option format-type circuit-id
string customer-555
Switch(config-if)# interface FastEthernet 2/1
Switch(config-if)# ip dhcp snooping vlan 555 information option format-type circuit-id
string customer-500
Switch(config)# end
Switch# show ip dhcp snooping
Switch DHCP snooping is enabled
DHCP snooping is configured on following VLANs:
500,555
```

DHCP snooping is operational on following VLANs:
500,555

DHCP snooping is configured on the following L3 Interfaces:

Insertion of option 82 is enabled

circuit-id default format: vlan-mod-port

remote-id: switch123 (string)

Option 82 on untrusted port is not allowed Verification of hwaddr field is enabled DHCP snooping trust/rate is configured on the following Interfaces:

Interface	Trusted	Rate limit (pps)
-----	-----	-----
FastEthernet5/1	yes	100
Custom circuit-ids:		
VLAN 555: customer-555		
FastEthernet2/1	no	unlimited
Custom circuit-ids:		
VLAN 500: customer-500		

Switch#

The following configuration describes the DHCP snooping configuration steps if routing is defined on another Catalyst switch (for example, a Catalyst 6500 series switch):

```
// Trust the uplink gigabit Ethernet trunk port
```

```
interface range GigabitEthernet 1/1 - 2
switchport mode trunk
switchport trunk encapsulation dot1q
ip dhcp snooping trust
```

```
!
```

```
interface VLAN 14
ip address 10.33.234.1 255.255.254.0
ip helper-address 10.5.1.2
```

Note

If you are enabling trunking on uplink gigabit interfaces, and the above routing configuration is defined on a Catalyst 6500 series switch, you must configure the “trust” relationship with downstream DHCP snooping (on a Catalyst 4500 series switch) which adds Option 82. On a Catalyst 6500 series switch, this task is accomplished with the **ip dhcp relay information trusted** VLAN configuration command.

Enabling DHCP Snooping on the Aggregation Switch

To enable DHCP snooping on an aggregation switch, configure the interface connecting to a downstream switch as a snooping untrusted port. If the downstream switch (or a device such as a DSLAM in the path between the aggregation switch and the DHCP clients) adds DHCP information Option 82 to the DHCP packets, the DHCP packets would be dropped on arriving on a snooping untrusted port. If you configure the **ip dhcp snooping information option allow-untrusted** global configuration command on the aggregation switch, the aggregation switch can accept DHCP requests with Option 82 information from any snooping untrusted port.

Enabling DHCP Snooping and Option 82

To enable DHCP snooping and Option 82 on the switch, perform the following steps:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ip dhcp snooping	Enables DHCP snooping globally.
Step 3	Switch(config)# ip dhcp snooping vlan <i>vlan-range</i>	Enables DHCP snooping on a VLAN or range of VLANs. The range is 1 to 4094. You can enter a single VLAN ID identified by VLAN ID number, a series of VLAN IDs separated by commas, a range of VLAN IDs separated by hyphens, or a range of VLAN IDs separated by entering the starting and ending VLAN IDs separated by a space.
Step 4	Switch(config)# ip dhcp snooping information option	Enables the switch to insert and remove DHCP relay information (Option 82 field) in forwarded DHCP request messages to the DHCP server. It is the default setting.
Step 5	Switch(config)# ip dhcp snooping information option format remote-id [string <i>ASCII-string</i> <i>hostname</i>]	(Optional) Configures the remote ID suboption. You can configure the remote ID to be: <ul style="list-style-type: none"> String of up to 63 ASCII characters (no spaces) Configured hostname for the switch If the hostname is longer than 63 characters, it is truncated to 63 characters in the remote ID configuration. The default remote ID is the switch MAC address.
Step 6	Switch(config)# ip dhcp snooping information option allow-untrusted	(Optional) If the switch is an aggregation switch connected to an edge switch, enables the switch to accept incoming DHCP snooping packets with Option 82 information from the edge switch. The default setting is disabled. Note Enter this command only on aggregation switches that are connected to trusted devices.
Step 7	Switch(config)# interface <i>interface-id</i>	Specifies the interface to be configured, and enter interface configuration mode.
Step 8	Switch(config-if)# ip dhcp snooping vlan <i>vlan</i> information option format-type circuit-id [override] string <i>ASCII-string</i>	(Optional) Configures the circuit ID suboption for the specified interface. Specify the VLAN and port identifier, using a VLAN ID in the range of 1 to 4094. The default circuit ID is the port identifier, in the format vlan-mod-port . You can configure the circuit ID to be a string of 3 to 63 ASCII characters (no spaces). Optional) Use the override keyword when you do not want the circuit-ID suboption inserted in TLV format to define subscriber information.
Step 9	Switch(config-if)# ip dhcp snooping trust	(Optional) Configures the interface as trusted or untrusted. You can use the no keyword to configure an interface to receive messages from an untrusted client. The default setting is untrusted.

	Command	Purpose
Step 10	Switch(config-if)# ip dhcp snooping limit rate rate	(Optional) Configures the number of DHCP packets per second that an interface can receive. The range is 1 to 2048. By default, no rate limit is configured. Note We recommend an untrusted rate limit of not more than 100 packets per second. If you configure rate limiting for trusted interfaces, you might need to increase the rate limit if the port is a trunk port assigned to more than one VLAN on which DHCP snooping is enabled.
Step 11	Switch(config-if)# exit	Returns to global configuration mode.
Step 12	Switch(config)# ip dhcp snooping verify mac-address	(Optional) Configures the switch to verify that the source MAC address in a DHCP packet that is received on untrusted ports matches the client hardware address in the packet. The default is to verify that the source MAC address matches the client hardware address in the packet.
Step 13	Switch(config)# end	Returns to privileged EXEC mode.
Step 14	Switch# show running-config	Verifies your entries.
Step 15	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To disable DHCP snooping, use the **no ip dhcp snooping** global configuration command. To disable DHCP snooping on a VLAN or range of VLANs, use the **no ip dhcp snooping vlan vlan-range** global configuration command. To disable the insertion and removal of the Option 82 field, use the **no ip dhcp snooping information option** global configuration command. To configure an aggregation switch to drop incoming DHCP snooping packets with Option 82 information from an edge switch, use the **no ip dhcp snooping information option allow-untrusted** global configuration command.

This example shows how to enable DHCP snooping globally and on VLAN 10 and to configure a rate limit of 100 packets per second on a port:

```
Switch(config)# ip dhcp snooping
Switch(config)# ip dhcp snooping vlan 10
Switch(config)# ip dhcp snooping information option
Switch(config)# interface gigabitethernet0/1
Switch(config-if)# ip dhcp snooping limit rate 100
```

The following example shows how to enable DHCP snooping on VLAN 500 through 555 and option 82 circuit-id:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip dhcp snooping
Switch(config)# ip dhcp snooping vlan 500 555
Switch(config)# ip dhcp snooping information option format remote-id string switch123
Switch(config)# interface GigabitEthernet 5/1
Switch(config-if)# ip dhcp snooping trust
Switch(config-if)# ip dhcp snooping limit rate 100
Switch(config-if)# ip dhcp snooping vlan 555 information option format-type circuit-id
string customer-555
Switch(config-if)# interface FastEthernet 2/1
Switch(config-if)# ip dhcp snooping vlan 555 information option format-type circuit-id
string customer-500
Switch(config)# end
```

This example shows how to configure the Option 82 circuit-ID override suboption:

```
Switch(config-if)# ip dhcp snooping vlan 250 information option format-type circuit-id
```

```
override string testcustomer
```

Enabling DHCP Snooping on Private VLAN

DHCP snooping can be enabled on private VLANs, which provide isolation between Layer 2 ports within the same VLAN. If DHCP snooping is enabled (or disabled), the configuration is propagated to both the primary VLAN and its associated secondary VLANs. You cannot enable (or disable) DHCP snooping on a primary VLAN without reflecting this configuration change on the secondary VLANs.

Configuring DHCP snooping on a secondary VLAN is still allowed, but it does not take effect if the associated primary VLAN is already configured. If the associated primary VLAN is configured, the effective DHCP snooping mode on the secondary VLAN is derived from the corresponding primary VLAN. Manually configuring DHCP snooping on a secondary VLAN causes the switch to issue this warning message:

```
DHCP Snooping configuration may not take effect on secondary vlan XXX
```

The **show ip dhcp snooping** command displays all VLANs (both primary and secondary) that have DHCP snooping enabled.

Configuring DHCP Snooping on Private VLAN

DHCP snooping, IPSG, and DAI are Layer 2-based security features that can be enabled and disabled on an individual VLAN, including auxiliary or voice VLAN. You need to enable DHCP snooping on a voice VLAN for a Cisco IP phone to function properly.

Configuring DHCP Snooping with an Ethernet Channel Group

When you configure DHCP snooping, you need to configure trunk interfaces that transmit DHCP packets as trusted interfaces by adding **ip dhcp snooping trust** to the physical interface configuration. However, if DHCP packets will be transmitted over an Ethernet channel group, you must configure **ip dhcp snooping trust** on the logical port channel interface, for example:

```
Switch# show run int port-channel150
Building configuration...

Current configuration : 150 bytes
!
interface Port-channel150
  switchport
  switchport trunk native vlan 4092
  switchport mode trunk
  switchport nonegotiate
  ip dhcp snooping trust
end

Switch#
```

Enabling the DHCP Snooping Database Agent

To configure the database agent, perform one or more of the following tasks:

Command	Purpose
Switch(config)# ip dhcp snooping database {url write-delay seconds timeout seconds}	(Required) Configures a URL for the database agent (or file) and the related timeout values.
Switch(config)# no ip dhcp snooping database [write-delay timeout]	
Switch# show ip dhcp snooping database [detail]	(Optional) Displays the current operating state of the database agent and statistics associated with the transfers.
Switch# clear ip dhcp snooping database statistics	(Optional) Clears the statistics associated with the database agent.
Switch# renew ip dhcp snooping database [validation none] [url]	(Optional) Requests the read entries from a file at the given URL.
Switch# ip dhcp snooping binding mac-addr vlan vlan ipaddr interface ifname expiry lease-in-seconds	(Optional) Adds or deletes bindings to the snooping database.
Switch# no ip dhcp snooping binding mac-addr vlan vlan ipaddr interface ifname	

Note

Because both NVRAM and bootflash have limited storage capacity, you should use TFTP or network-based files. If you use flash to store the database file, new updates (by the agent) result in the creation of new files (flash fills quickly). Moreover, because of the nature of the file system used on flash, a large number of files can cause slow access. When a file is stored in a remote location accessible through TFTP, an RPR or SSO standby supervisor engine can take over the binding list when a switchover occurs.

Note

Network-based URLs (such as TFTP and FTP) require that you create an empty file at the configured URL before the switch can write the set of bindings for the first time.

Limiting the Rate of Incoming DHCP Packets

The switch CPU performs DHCP validation checks; therefore, the number of incoming DHCP packets is rate-limited to prevent a denial-of-service attack.

When the rate of incoming DHCP packets exceeds the configured limit, the switch places the port in the errdisabled state. The port remains in that state until you intervene or you enable errdisable recovery so that ports automatically emerge from this state after a specified timeout period.

Note

Unless you explicitly configure a rate limit on an interface, changing the trust state of the interface also changes its rate limit to the default value for that trust state. After you configure the rate limit, the interface retains the rate limit even when its trust state is changed. If you enter the **no ip dhcp snooping limit rate** interface configuration command, the interface reverts to its default rate limit.

To prevent the port from shutting down, you can use the **errdisable detect cause dhcp-rate-limit action shutdown vlan** global configuration command to shut down just the offending VLAN on the port where the violation occurred.

To limit the rate of incoming DHCP packets, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# errdisable detect cause dhcp-rate-limit [action shutdown vlan]	Enables per-VLAN errdisable detection.
Step 3	Switch(config)# interface interface-id	Specifies the interface to be rate-limited, and enter interface configuration mode.
Step 4	Switch(config-if)# [no] ip dhcp snooping limit rate	Limits the rate of incoming DHCP requests and responses on the interface. The default rate is disabled.
Step 5	Switch(config-if)# exit	Returns to global configuration mode.
Step 6	Switch(config)# errdisable recovery {cause dhcp-rate-limit interval interval}	(Optional) Enables error recovery from the DHCP errdisable state. By default, recovery is disabled, and the recovery interval is 300 seconds. For interval interval , specify the time in seconds to recover from the errdisable state. The range is 30 to 86400.
Step 7	Switch(config)# exit	Returns to privileged EXEC mode.
Step 8	Switch# show interfaces status	Verifies your settings.
Step 9	Switch# show errdisable recovery	Verifies your settings.
Step 10	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To return to the default rate-limit configuration, use the **no ip dhcp-rate-limit** interface configuration command. To disable error recovery for DHCP inspection, use the **no errdisable recovery cause dhcp-rate-limit** global configuration command.

This example shows how to set an upper limit for the number of incoming packets (100 pps) and to specify a burst interval (1 second):

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface g3/31
Switch(config-if)# ip dhcp-rate-limit rate 100 burst interval 1
Switch(config-if)# exit
Switch(config)# errdisable recovery cause dhcp-rate-limit
Switch(config)# exit
Switch# show interfaces status
```

Port	Name	Status	Vlan	Duplex	Speed	Type
Tel1/1		connected	1	full	10G	10GBase-LR
Tel1/2		connected	vl-err-dis	full	10G	10GBase-LR

```

SwitchB# show errdisable recovery

Configuration Examples for the Database Agent

The following examples show how to configuration commands in the previous procedure:

Example 1: Enabling the Database Agent

The following example shows how to configure the DHCP snooping database agent to store the bindings at a given location and to view the configuration and operating state:

```

Switch# configure terminal
Switch(config)# ip dhcp snooping database tftp://10.1.1.1/directory/file
Switch(config)# end

```

```

Switch# show ip dhcp snooping database detail
Agent URL : tftp://10.1.1.1/directory/file
Write delay Timer : 300 seconds
Abort Timer : 300 seconds

Agent Running : No
Delay Timer Expiry : 7 (00:00:07)
Abort Timer Expiry : Not Running

Last Succeeded Time : None
Last Failed Time : 17:14:25 UTC Sat Jul 7 2001
Last Failed Reason : Unable to access URL.

Total Attempts      :      21   Startup Failures :      0
Successful Transfers :      0   Failed Transfers :     21
Successful Reads    :      0   Failed Reads   :      0
Successful Writes   :      0   Failed Writes  :     21
Media Failures      :      0

First successful access: Read

Last ignored bindings counters :
Binding Collisions   :      0   Expired leases   :      0
Invalid interfaces   :      0   Unsupported vlans :      0
Parse failures       :      0
Last Ignored Time : None

Total ignored bindings counters:
Binding Collisions   :      0   Expired leases   :      0
Invalid interfaces   :      0   Unsupported vlans :      0
Parse failures       :      0

Switch#

```

The first three lines of output show the configured URL and related timer configuration values. The next three lines show the operating state and the amount of time left for expiry of write delay and abort timers.

Among the statistics shown in the output, startup failures indicate the number of attempts the read or create of the file has failed upon bootup.

Note

Because the location is based off in the network, you must create a temporary file on the TFTP server. You can create a temporary file on a typical UNIX workstation by creating a 0 byte file “file” in the directory “directory” that can be referenced by the TFTP server daemon. With some server implementations on UNIX workstations, the file should be provided with full (777) permissions for write access to the file.

DHCP snooping bindings are keyed on the MAC address and VLAN combination. If an entry in the remote file has an entry for a given MAC address and VLAN set, for which the switch already has a binding, the entry from the remote file is ignored when the file is read. This condition is referred to as the binding collision.

An entry in a file may no longer be valid because the lease indicated by the entry may have expired by the time it is read. The expired leases counter indicates the number of bindings ignored because of this condition. The Invalid interfaces counter refers to the number of bindings that have been ignored when the interface referred by the entry either does not exist on the system or is a router or DHCP snooping trusted interface if it exists, when the read happened. Unsupported VLANs refers to the number of entries that have been ignored because the indicated VLAN is not supported on the system. The Parse failures counter provides the number of entries that have been ignored when the switch is unable to interpret the meaning of the entries from the file.

The switch maintains two sets of counters for these ignored bindings. One provides the counters for a read that has at least one binding ignored by at least one of these conditions. These counters are shown as the “Last ignored bindings counters.” The total ignored bindings counters provides a sum of the number of bindings that have been ignored because of all the reads since the switch bootup. These two set of counters are cleared by the **clear** command. The total counter set may indicate the number of bindings that have been ignored since the last clear.

Example 2: Reading Binding Entries from a TFTP File

To manually read the entries from a TFTP file, perform this task:

	Command	Purpose
Step 1	Switch# show ip dhcp snooping database	Displays the DHCP snooping database agent statistics.
Step 2	Switch# renew ip dhcp snoop data url	Directs the switch to read the file from given URL.
Step 3	Switch# show ip dhcp snoop data	Displays the read status.
Step 4	Switch# show ip dhcp snoop bind	Verifies whether the bindings were read successfully.

it is an example of how to manually read entries from the tftp://10.1.1.1/directory/file:

```
Switch# show ip dhcp snooping database
Agent URL :
Write delay Timer : 300 seconds
Abort Timer : 300 seconds

Agent Running : No
Delay Timer Expiry : Not Running
Abort Timer Expiry : Not Running

Last Succeeded Time : None
Last Failed Time : None
Last Failed Reason : No failure recorded.

Total Attempts      :      0   Startup Failures :      0

```
Switch#
```

Example 3: Adding Information to the DHCP Snooping Database

To manually add a binding to the DHCP snooping database, perform this task:

	Command	Purpose
Step 1	Switch# show ip dhcp snooping binding	Views the DHCP snooping database.
Step 2	Switch# ip dhcp snooping binding <i>binding-id</i> vlan <i>vlan-id</i> interface <i>interface</i> expiry <i>lease-time</i>	Adds the binding using the ip dhcp snooping EXEC command.
Step 3	Switch# show ip dhcp snooping binding	Checks the DHCP snooping database.

This example shows how to manually add a binding to the DHCP snooping database:

```
Switch# show ip dhcp snooping binding
```

MacAddress	IpAddress	Lease(sec)	Type	VLAN	Interface
------------	-----------	------------	------	------	-----------

```
Switch#
```

```
Switch# ip dhcp snooping binding 1.1.1 vlan 1 10.1.1.1 interface gi1/1 expiry 1000
```

```
Switch# show ip dhcp snooping binding
```

MacAddress	IpAddress	Lease(sec)	Type	VLAN	Interface
------------	-----------	------------	------	------	-----------

00:01:00:01:00:01	10.1.1.1	992	dhcp-snooping	1	GigabitEthernet1/1
-------------------	----------	-----	---------------	---	--------------------

```
Switch#
```

Displaying DHCP Snooping Information

You can display a DHCP snooping binding table and configuration information for all interfaces on a switch.

Displaying a Binding Table

The DHCP snooping binding table for each switch contains binding entries that correspond to untrusted ports. The table does not contain information about hosts interconnected with a trusted port because each interconnected switch has its own DHCP snooping binding table.

This example shows how to display the DHCP snooping binding information for a switch:

```
Switch# show ip dhcp snooping binding
-----
MacAddress      IpAddress      Lease(sec)    Type           VLAN    Interface
-----
00:02:B3:3F:3B:99  55.5.5.2      6943          dhcp-snooping  10      FastEthernet6/10
Switch#
```

Table 60-2 describes the fields in the `show ip dhcp snooping binding` command output.

Table 60-2 *show ip dhcp snooping binding Command Output*

Field	Description
MAC Address	Client hardware MAC address
IP Address	Client IP address assigned from the DHCP server
Lease (seconds)	IP address lease time
Type	Binding type; dynamic binding learned by DHCP snooping or statically-configured binding.
VLAN	VLAN number of the client interface
Interface	Interface that connects to the DHCP client host

Displaying the DHCP Snooping Configuration

This example shows how to display the DHCP snooping configuration for a switch:

```
Switch# show ip dhcp snooping
Switch DHCP snooping is enabled.
DHCP Snooping is configured on the following VLANs:
  10 30-40 100 200-220
Insertion of option 82 is enabled
Option82 on untrusted port is not allowed
Verification of hwaddr field is enabled
Interface      Trusted      Rate limit (pps)
-----
FastEthernet2/1  yes         10
FastEthernet3/1  yes         none
GigabitEthernet1/1 no          20
Switch#
```

About IP Source Guard

The IP source guard feature is enabled on a DHCP snooping untrusted Layer 2 port. Initially, all IP traffic on the port is blocked except for DHCP packets that are captured by the DHCP snooping process. When a client receives a valid IP address from the DHCP server, or when you configure a static IP source binding, a per-port and VLAN access control list (VACL) is installed on the port. This process restricts

the client IP traffic to those source IP addresses configured in the binding; any IP traffic with a source IP address other than that in the IP source binding is filtered out. This filtering limits the ability of a host to attack the network by claiming a neighbor host's IP address.

**Note**

If IP source guard is enabled on a trunk port with a large number of VLANs that have DHCP snooping enabled, you might exhaust ACL hardware resources, and some packets might be switched in software instead.

**Note**

When IP source guard is enabled, you might want to designate an alternative scheme for ACL hardware programming. For more information, see the “TCAM Programming and ACLs” section in [Chapter 62, “Configuring Network Security with ACLs”](#).

IP source guard supports the Layer 2 port only, including both access and trunk. For each untrusted Layer 2 port, there are two levels of IP traffic security filtering:

- Source IP address filter

IP traffic is filtered based on its source IP address. Only IP traffic with a source IP address that matches the IP source binding entry is permitted.

An IP source address filter is changed when a new IP source entry binding is created or deleted on the port. The port VACL is recalculated and reapplied in the hardware to reflect the IP source binding change. By default, if the IP filter is enabled without any IP source binding on the port, a default PVACL that denies all IP traffic is installed on the port. Similarly, when the IP filter is disabled, any IP source filter PVACL is removed from the interface.

- Source IP and MAC address filter

IP traffic is filtered based on its source IP address as well as its MAC address; only IP traffic with source IP and MAC addresses matching the IP source binding entry are permitted.

**Note**

When IP source guard is enabled in IP and MAC filtering mode, the DHCP snooping Option 82 must be enabled to ensure that the DHCP protocol works properly. Without Option 82 data, the switch cannot locate the client host port to forward the DHCP server reply. Instead, the DHCP server reply is dropped, and the client cannot obtain an IP address.

Configuring IP Source Guard

To enable IP source guard, perform this task:

	Command	Purpose
Step 1	Switch(config)# ip dhcp snooping	Enables DHCP snooping globally. You can use the no keyword to disable DHCP snooping.
Step 2	Switch(config)# ip dhcp snooping vlan <i>number</i> [<i>number</i>]	Enables DHCP snooping on your VLANs.
Step 3	Switch(config-if)# no ip dhcp snooping trust	Configures the interface as trusted or untrusted. You can use the no keyword of to configure an interface to receive only messages from within the network.

	Command	Purpose
Step 4	Switch(config-if)# ip verify source vlan dhcp-snooping port-security	Enables IP source guard, source IP, and source MAC address filtering on the port.
Step 5	Switch(config-if)# switchport port-security limit rate invalid-source-mac N	Enables security rate limiting for learned source MAC addresses on the port. Note This limit only applies to the port where IP source guard is enabled as filtering both IP and MAC addresses.
Step 6	Switch(config)# ip source binding mac-address Vlan vlan-id ip-address interface interface-name	Configures a static IP binding on the port.
Step 7	Switch(config)# end	Exits configuration mode.
Step 8	Switch# show ip verify source interface interface-name	Verifies the configuration.

If you want to stop IP source guard with static hosts on an interface, use the following commands in interface configuration submode:

```
Switch(config-if)# no ip verify source
Switch(config-if)# no ip device tracking max
```

If the **no ip device tracking** command is used in interface configuration submode, it actually runs in global configuration mode and causes IP device tracking to be disabled globally. Disabling IP device tracking globally causes IP source guard with static hosts to deny all IP traffic on interfaces using the **ip verify source tracking [port-security]** command.

Note

The static IP source binding can only be configured on switch port. If you enter the **ip source binding vlan interface** command on a Layer 3 port, you receive this error message:

```
Static IP source binding can only be configured on switch port.
```

This example shows how to enable per-Layer 2 port IP source guard on VLAN 10 through 20:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip dhcp snooping
Switch(config)# ip dhcp snooping vlan 10 20
Switch(config)# interface fa6/1
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# switchport trunk native vlan 10
Switch(config-if)# switchport trunk allowed vlan 11-20
Switch(config-if)# no ip dhcp snooping trust
Switch(config-if)# ip verify source vlan dhcp-snooping
Switch(config)# end
Switch# show ip verify source interface f6/1
```

Interface	Filter-type	Filter-mode	IP-address	Mac-address	Vlan
Fa6/1	ip-mac	active	10.0.0.1		10
Fa6/1	ip-mac	active	deny-all		11-20

```
Switch#
```

The output shows that there is one valid DHCP binding to VLAN 10.

Configuring IP Source Guard on Private VLANs

For IP source guard to be effective on PVLAN ports, you must enable DHCP snooping on primary VLANs. IP source guard on a primary VLAN is automatically propagated to a secondary VLAN. You can configure static IP source binding on a secondary VLAN, but it does not work. When manually configuring a static IP source binding on a secondary VLAN, you receive the following message:

IP source filter may not take effect on a secondary VLAN where IP source binding is configured. If the private VLAN feature is enabled, IP source filter on the primary VLAN will automatically propagate to all secondary VLAN.

Note

IP Source Guard is supported on private VLAN host ports only.

Displaying IP Source Guard Information

You can display IP source guard PVACL information for all interfaces on a switch using the **show ip verify source** command, as the following examples show:

- This example shows displayed PVACLs if DHCP snooping is enabled on VLAN 10 through 20, if interface fa6/1 is configured for IP filtering, and if there is an existing IP address binding 10.0.0.1 on VLAN 10:

Interface	Filter-type	Filter-mode	IP-address	Mac-address	Vlan
fa6/1	ip	active	10.0.0.1		10
fa6/1	ip	active	deny-all		11-20

Note

The second entry shows that a default PVACL (deny all IP traffic) is installed on the port for those snooping-enabled VLANs that do not have a valid IP source binding.

- This example shows displayed PVACL for a trusted port:

Interface	Filter-type	Filter-mode	IP-address	Mac-address	Vlan
fa6/2	ip	inactive-trust-port			

- This example shows displayed PVACL for a port in a VLAN not configured for DHCP snooping:

Interface	Filter-type	Filter-mode	IP-address	Mac-address	Vlan
fa6/3	ip	inactive-no-snooping-vlan			

- This example shows displayed PVACLs for a port with multiple bindings configured for an IP-to-MAC filtering:

Interface	Filter-type	Filter-mode	IP-address	Mac-address	Vlan
fa6/4	ip-mac	active	10.0.0.2	aaaa.bbbb.cccc	10
fa6/4	ip-mac	active	11.0.0.1	aaaa.bbbb.cccd	11
fa6/4	ip-mac	active	deny-all	deny-all	12-20

- This example shows displayed PVACLs for a port configured for IP-to-MAC filtering but not for port security:

Interface	Filter-type	Filter-mode	IP-address	Mac-address	Vlan
fa6/5	ip-mac	active	10.0.0.3	permit-all	10

```
fa6/5      ip-mac      active      deny-all      permit-all      11-20
```

Note The MAC filter shows permit-all because port security is not enabled, so the MAC filter cannot apply to the port or VLAN and is effectively disabled. Always enable port security first.

- This example shows displayed error message when entering the **show ip verify source** command on a port that does not have an IP source filter mode configured:

```
IP Source Guard is not configured on the interface fa6/6.
```

You can also use the **show ip verify source** command to display all interfaces on the switch that have IP source guard enabled, as follows:

```
Switch# show ip verify source
Interface  Filter-type  Filter-mode  IP-address      Mac-address      Vlan
-----
fa6/1      ip           active       10.0.0.1        10
fa6/1      ip           active       deny-all       11-20
fa6/2      ip           inactive-trust-port
fa6/3      ip           inactive-no-snooping-vlan
fa6/4      ip-mac       active       10.0.0.2        aaaa.bbbb.cccc  10
fa6/4      ip-mac       active       11.0.0.1        aaaa.bbbb.cccd  11
fa6/4      ip-mac       active       deny-all       deny-all        12-20
fa6/5      ip-mac       active       10.0.0.3        permit-all      10
fa6/5      ip-mac       active       deny-all       permit-all      11-20
```

Displaying IP Source Binding Information

You can display all IP source bindings configured on all interfaces on a switch using the **show ip source binding** command.

```
Switch# show ip source binding
MacAddress      IpAddress      Lease(sec)  Type           VLAN  Interface
-----
00:02:B3:3F:3B:99  55.5.5.2      6522        dhcp-snooping  10    FastEthernet6/10
00:00:00:0A:00:0B  11.0.0.1      infinite    static         10    FastEthernet6/10
Switch#
```

Table 60-3 describes the fields in the **show ip source binding** command output.

Table 60-3 *show ip source binding Command Output*

Field	Description
MAC Address	Client hardware MAC address
IP Address	Client IP address assigned from the DHCP server
Lease (seconds)	IP address lease time
Type	Binding type; static bindings configured from CLI to dynamic binding learned from DHCP snooping
VLAN	VLAN number of the client interface
Interface	Interface that connects to the DHCP client host

Configuring IP Source Guard for Static Hosts

**Note**

IPSG for static hosts should not be used on uplink ports.

IP source guard (IPSG) for static hosts extends the IPSG capability to non-DHCP and static environments.

This section includes these topics:

- [About IP Source Guard for Static Hosts, page 60-24](#)
- [Configuring IPSG for Static Hosts on a Layer 2 Access Port, page 60-24](#)
- [Configuring IPSG for Static Hosts on a PVLAN Host Port, page 60-28](#)

About IP Source Guard for Static Hosts

The prior feature, IPSG, uses the entries created by the DHCP snooping feature to validate the hosts connected to a switch. Any traffic received from a host without a valid DHCP binding entry is dropped. A DHCP environment is a prerequisite for IPSG to work. The IPSG for static hosts feature removes IPSG's dependency on DHCP. The switch creates static entries based on ARP requests or other IP packets and uses them to maintain the list of valid hosts for a given port. In addition, you can specify the number of hosts that would be allowed to send traffic to a given port. It is equivalent to port security at Layer 3.

**Note**

Some IP hosts with multiple network interfaces may inject some invalid packets into a network interface. Those invalid packets contain the IP-to-MAC address for another network interface of that host as the source address. It may cause IPSG for static hosts in the switch, which connects to the host, to learn the invalid IP-to-MAC address bindings and reject the valid bindings. You should consult the vendor of the corresponding operating system and the network device of that host to prevent it from injecting invalid packets.

IPSG for static hosts initially learns IP-to-MAC bindings dynamically through an ACL-based snooping method. IP-to-MAC bindings are learned from static hosts by using ARP and IP packets and are stored using the device tracking database. Once the number of IP addresses that have been dynamically learned or statically configured on a given port reaches a maximum limit, any packet with a new IP address is dropped in hardware. To handle hosts that have moved or gone away for any reason, the IPSG for static hosts feature uses the IP device tracking functionality to age out dynamically learned IP address bindings. This feature can be used in conjunction with DHCP snooping. Multiple bindings will be established on a port that is connected to both DHCP and static hosts (that is, bindings will be stored in both the device tracking database as well as the DHCP snooping binding database).

Configuring IPSG for Static Hosts on a Layer 2 Access Port

You can configure IPSG for static hosts on a Layer 2 access port.

To enable IPSG for static hosts with IP filters on a Layer 2 access port, perform this task:

	Command	Purpose
Step 1	Switch(config)# ip device tracking	Turns on the IP host table.
Step 2	Switch(config)# interface fastEthernet a/b	Enters IP configuration mode.
Step 3	Switch(config-if)# switchport mode access	Configures a port as access.
Step 4	Switch(config-if)# switchport access vlan n	Configures the VLAN for this port.
Step 5	Switch(config-if)# ip device tracking maximum n	Establishes a maximum limit for the bindings on this port. Upper bound for the maximum is 10. Note Starting from Cisco IOS XE Release 3.10.1E, the following IPDT commands are deprecated; there are no replacement commands: [no] ip device tracking probe count [no] ip device tracking probe delay . For more related information, see the <i>Configuring SISF-Based Device Tracking</i> chapter in this guide.
Step 6	Switch(config-if)# switchport port-security	(Optional) Activates port security for this port.
Step 7	Switch(config-if)# switchport port-security maximum n	(Optional) Establishes a maximum number of MAC addresses for this port.
Step 8	Switch(config-if)# ip verify source tracking [port-security]	Activates IPSG for static hosts on this port.
Step 9	Switch(config-if)# end	Exits configuration interface mode.
Step 10	Switch# show ip verify source interface-name	Verifies the configuration.
Step 11	Switch# show ip device track all [active inactive] count	Verifies the configuration by displaying the IP-to-MAC binding for a given host on the switch interface. <ul style="list-style-type: none"> • all active—Displays only the active IP-to-MAC binding entries. • all inactive—Displays only the inactive IP-to-MAC binding entries. • all—Displays the active and inactive IP-to-MAC binding entries.

To stop IPSG with static hosts on an interface, use the following commands in interface configuration submode:

```
Switch(config-if)# no ip verify source
Switch(config-if)# no ip device tracking max"
```

To enable IPSG with static hosts on a port, enter the following commands:

```
Switch(config)# ip device tracking ****enable IP device tracking globally
Switch(config)# ip device tracking max <n> ****set an IP device tracking maximum on int
Switch(config-if)# ip verify source tracking [port-security] ****activate IPSG on the port
```

Caution

If you only configure the **ip verify source tracking [port-security]** interface configuration command on a port without enabling IP device tracking globally or setting an IP device tracking maximum on that interface, IPSG with static hosts will reject all the IP traffic from that interface.

This issue also applies to IPSG with static hosts on a PVLAN host port.

This example shows how to enable IPSG for static hosts with IP filters on a Layer 2 access port and to verify the three valid IP bindings on the interface Fa4/3:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip device tracking
Switch(config)# interface fastEthernet 4/3
Switch(config-if)# switchport mode access
Switch(config-if)# switchport access vlan 10
Switch(config-if)# ip device tracking maximum 5
Switch(config-if)# ip verify source tracking
Switch(config-if)# end

Switch# show ip verify source
```

Interface	Filter-type	Filter-mode	IP-address	Mac-address	Vlan
Fa4/3	ip trk	active	40.1.1.24		10
Fa4/3	ip trk	active	40.1.1.20		10
Fa4/3	ip trk	active	40.1.1.21		10

The following example shows how to enable IPSG for static hosts with IP MAC filters on a Layer 2 access port, to verify the five valid IP-MAC bindings on the interface Fa4/3, and to verify that the number of bindings on this interface has reached the maximum limit:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip device tracking
Switch(config)# interface fastEthernet 4/3
Switch(config-if)# switchport mode access
Switch(config-if)# switchport access vlan 1
Switch(config-if)# ip device tracking maximum 5
Switch(config-if)# switchport port-security
Switch(config-if)# switchport port-security maximum 5
Switch(config-if)# ip verify source tracking port-security
Switch(config-if)# end

Switch# show ip verify source
```

Interface	Filter-type	Filter-mode	IP-address	Mac-address	Vlan
Fa4/3	ip-mac trk	active	40.1.1.24	00:00:00:00:03:04	1
Fa4/3	ip-mac trk	active	40.1.1.20	00:00:00:00:03:05	1
Fa4/3	ip-mac trk	active	40.1.1.21	00:00:00:00:03:06	1
Fa4/3	ip-mac trk	active	40.1.1.22	00:00:00:00:03:07	1
Fa4/3	ip-mac trk	active	40.1.1.23	00:00:00:00:03:08	1

The following example displays all IP-to-MAC binding entries for all interfaces. The CLI displays all active as well as inactive entries. When a host is learned on a interface, the new entry is marked as active. When the same host is disconnected from the current interface and connected to a different interface, a new IP-to-MAC binding entry is displayed as active as soon as the host is detected. The old entry for this host on the previous interface is now marked as inactive.

```
Switch# show ip device tracking all
Global IP Device Tracking for clients = Enabled
Global IP Device Tracking Probe Count = 3
Global IP Device Tracking Probe Interval = 300
Global IP Device Tracking Probe Delay Interval = 10
```

IP Address	MAC Address	Vlan	Interface	STATE
200.1.1.8	0001.0600.0000	8	GigabitEthernet3/1	INACTIVE
200.1.1.9	0001.0600.0000	8	GigabitEthernet3/1	INACTIVE
200.1.1.10	0001.0600.0000	8	GigabitEthernet3/1	INACTIVE
200.1.1.1	0001.0600.0000	9	GigabitEthernet4/1	ACTIVE
200.1.1.1	0001.0600.0000	8	GigabitEthernet3/1	INACTIVE
200.1.1.2	0001.0600.0000	9	GigabitEthernet4/1	ACTIVE
200.1.1.2	0001.0600.0000	8	GigabitEthernet3/1	INACTIVE
200.1.1.3	0001.0600.0000	9	GigabitEthernet4/1	ACTIVE
200.1.1.3	0001.0600.0000	8	GigabitEthernet3/1	INACTIVE
200.1.1.4	0001.0600.0000	9	GigabitEthernet4/1	ACTIVE
200.1.1.4	0001.0600.0000	8	GigabitEthernet3/1	INACTIVE
200.1.1.5	0001.0600.0000	9	GigabitEthernet4/1	ACTIVE
200.1.1.5	0001.0600.0000	8	GigabitEthernet3/1	INACTIVE
200.1.1.6	0001.0600.0000	8	GigabitEthernet3/1	INACTIVE
200.1.1.7	0001.0600.0000	8	GigabitEthernet3/1	INACTIVE

The following example displays all active IP-to-MAC binding entries for all interfaces:

```
Switch# show ip device tracking all active
IP Device Tracking = Enabled
IP Device Tracking Probe Count = 3
IP Device Tracking Probe Interval = 30
```

IP Address	MAC Address	Vlan	Interface	STATE
200.1.1.1	0001.0600.0000	9	GigabitEthernet4/1	ACTIVE
200.1.1.2	0001.0600.0000	9	GigabitEthernet4/1	ACTIVE
200.1.1.3	0001.0600.0000	9	GigabitEthernet4/1	ACTIVE
200.1.1.4	0001.0600.0000	9	GigabitEthernet4/1	ACTIVE
200.1.1.5	0001.0600.0000	9	GigabitEthernet4/1	ACTIVE

The following example displays all inactive IP-to-MAC binding entries for all interfaces. The host was first learned on GigabitEthernet 3/1 then moved to GigabitEthernet 4/1. The IP-to-MAC binding entries learned on GigabitEthernet 3/1 are marked as inactive.

```
Switch# show ip device tracking all inactive
IP Device Tracking = Enabled
IP Device Tracking Probe Count = 3
IP Device Tracking Probe Interval = 30
```

IP Address	MAC Address	Vlan	Interface	STATE
200.1.1.8	0001.0600.0000	8	GigabitEthernet3/1	INACTIVE
200.1.1.9	0001.0600.0000	8	GigabitEthernet3/1	INACTIVE
200.1.1.10	0001.0600.0000	8	GigabitEthernet3/1	INACTIVE
200.1.1.1	0001.0600.0000	8	GigabitEthernet3/1	INACTIVE
200.1.1.2	0001.0600.0000	8	GigabitEthernet3/1	INACTIVE
200.1.1.3	0001.0600.0000	8	GigabitEthernet3/1	INACTIVE

```

200.1.1.4      0001.0600.0000  8  GigabitEthernet3/1  INACTIVE
200.1.1.5      0001.0600.0000  8  GigabitEthernet3/1  INACTIVE
200.1.1.6      0001.0600.0000  8  GigabitEthernet3/1  INACTIVE
200.1.1.7      0001.0600.0000  8  GigabitEthernet3/1  INACTIVE

```

The following example displays the count of all IP device tracking host entries for all interfaces:

```

Switch# show ip device tracking all count
Total IP Device Tracking Host entries: 5
-----
Interface                Maximum Limit      Number of Entries
-----
Fa4/3                     5

```

Configuring IPSG for Static Hosts on a PVLAN Host Port

You can configure IPSG for static hosts on a PVLAN host port.

To enable IPSG for static hosts with IP filters on a PVLAN host port, perform this task:

	Command	Purpose
Step 1	Switch(config)# vlan <i>n1</i>	Enters configuration VLAN mode.
Step 2	Switch(config-vlan)# private-vlan primary	Establishes a primary VLAN on a PVLAN port.
Step 3	Switch(config-vlan)# exit	Exits VLAN configuration mode.
Step 4	Switch(config)# vlan <i>n2</i>	Enters configuration VLAN mode.
Step 5	Switch(config-vlan)# private-vlan isolated	Establishes an isolated VLAN on a PVLAN port.
Step 6	Switch(config-vlan)# exit	Exits VLAN configuration mode.
Step 7	Switch(config)# vlan <i>n1</i>	Enters configuration VLAN mode.
Step 8	Switch(config-vlan)# private-vlan association <i>201</i>	Associates the VLAN on an isolated PVLAN port.
Step 9	Switch(config-vlan)# exit	Exits VLAN configuration mode.
Step 10	Switch(config)# interface fastEthernet <i>a/b</i>	Enters interface configuration mode.
Step 11	Switch(config-if)# switchport mode private-vlan host	(Optional) Establishes a port as a PVLAN host.
Step 12	Switch(config-if)# switchport private-vlan host-association <i>a b</i>	(Optional) Associates this port with the corresponding PVLAN.
Step 13	Switch(config-if)# ip device tracking maximum <i>n</i>	Establishes a maximum limit for the bindings on this port.
Step 14	Switch(config-if)# ip verify source tracking [port-security]	Activates IPSG for static hosts on this port.
Step 15	Switch(config-if)# end	Exits configuration interface mode.
Step 16	Switch# show ip device tracking all	Verifies the configuration.
Step 17	Switch# show ip verify source <i>interface-name</i>	Verifies the configuration.

This example shows how to enable IPSG for static hosts with IP filters on a PVLAN host port:

```

Switch(config)# vlan 200
Switch(config-vlan)# private-vlan primary
Switch(config-vlan)# exit
Switch(config)# vlan 201

```

```

Switch(config-vlan)# private-vlan isolated
Switch(config-vlan)# exit
Switch(config)# vlan 200
Switch(config-vlan)# private-vlan association 201
Switch(config-vlan)# exit
Switch(config)# int fastEthernet 4/3
Switch(config-if)# switchport mode private-vlan host
Switch(config-if)# switchport private-vlan host-association 200 201
Switch(config-if)# ip device tracking maximum 8
Switch(config-if)# ip verify source tracking

```

```

Switch# show ip device tracking all
Global IP Device Tracking for clients = Enabled
Global IP Device Tracking Probe Count = 3
Global IP Device Tracking Probe Interval = 300
Global IP Device Tracking Probe Delay Interval = 10

```

IP Address	MAC Address	Vlan	Interface	STATE
40.1.1.24	0000.0000.0304	200	FastEthernet4/3	ACTIVE
40.1.1.20	0000.0000.0305	200	FastEthernet4/3	ACTIVE
40.1.1.21	0000.0000.0306	200	FastEthernet4/3	ACTIVE
40.1.1.22	0000.0000.0307	200	FastEthernet4/3	ACTIVE
40.1.1.23	0000.0000.0308	200	FastEthernet4/3	ACTIVE

The output shows the five valid IP-to-MAC bindings that have been learned on the interface Fa4/3. For the PVLAN, the bindings are associated with primary VLAN ID. In this example, the primary VLAN ID, 200, is shown in the table.

```

Switch# show ip verify source

```

Interface	Filter-type	Filter-mode	IP-address	Mac-address	Vlan
Fa4/3	ip trk	active	40.1.1.23		200
Fa4/3	ip trk	active	40.1.1.24		200
Fa4/3	ip trk	active	40.1.1.20		200
Fa4/3	ip trk	active	40.1.1.21		200
Fa4/3	ip trk	active	40.1.1.22		200
Fa4/3	ip trk	active	40.1.1.23		201
Fa4/3	ip trk	active	40.1.1.24		201
Fa4/3	ip trk	active	40.1.1.20		201
Fa4/3	ip trk	active	40.1.1.21		201
Fa4/3	ip trk	active	40.1.1.22		201

The output shows that the five valid IP-to-MAC bindings are on both the primary and secondary VLAN.

DHCPv6 Options Support

This module describes the Dynamic Host Control Protocol Version 6 (DHCPv6) Relay Agent, DHCPv6 Interface-ID, Lightweight DHCPv6 Relay Agent (LRDA), and CAPWAP Access Controller DHCP Option 52 features.

This module consists of these sections:

- [Restrictions for DHCPv6 Options Support, page 61-1](#)
- [Information About DHCPv6 Options Support, page 61-2](#)
- [How to Configure DHCPv6 Options Support, page 61-5](#)
- [Configuration Examples for DHCPv6 Options Support, page 61-9](#)
- [Additional References for DHCPv6 Options Support, page 61-10](#)
- [Feature Information for DHCPv6 Options Support, page 61-12](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see publications at this location:

[*Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch*](#)

If a command is not in the *Catalyst 4500 Series Switch Command Reference*, you can locate it in the Cisco IOS library, at this location:

[*Cisco IOS Master Command List, All Releases*](#)

Restrictions for DHCPv6 Options Support

The following restrictions apply to the Lightweight DHCPv6 Relay Agent (LDRA) feature:

- An interface or port cannot be configured as both client facing and server facing at the same time.
- Access nodes implementing LDRA do not support IPv6 control or routing.
- Unlike a DHCPv6 relay agent, an LDRA does not implement any IPv6 control functions (like Internet Control Message Protocol Version 6 [ICMPv6] functions), nor does it have any routing capability in the node.

Information About DHCPv6 Options Support

- [DHCPv6 Relay Agent Overview, page 61-2](#)

- [LDRA for VLANs and Interfaces, page 61-4](#)
- [CAPWAP Access Controller DHCPv6 Option, page 61-4](#)

DHCPv6 Relay Agent Overview

A DHCPv6 relay agent is any host that forwards DHCP packets between clients and servers. Relay agents are used to forward requests and replies between clients and servers when they are not on the same physical subnet.

A DHCPv6 relay agent, which may reside on the client's link, is used to relay messages between the client and the server. The DHCPv6 relay agent operation is transparent to the client. A DHCPv6 client locates a DHCPv6 server using a reserved, link-scoped multicast address. For direct communication between the DHCPv6 client and the DHCPv6 server, both of them must be attached to the same link. However, in some situations where ease of management, economy, or scalability is a concern, it is desirable to allow a DHCPv6 client to send a message to a DHCPv6 server that is not connected to the same link.

DHCPv6 Relay Options: Remote-ID

The DHCPv6 Remote ID Option feature adds the remote identification (remote-ID) option to relayed (RELAY-FORWARD) DHCPv6 packets.

The remote-ID option provides information to the DHCPv6 server, which includes port information, the system's DHCP Unique Identifier (DUID), and the virtual LAN (VLAN) ID. This information can be used to uniquely identify both the relay and the port on the relay through which the client packet arrived. The DHCPv6 server uses this information to select parameters specific to a particular user, host, or subscriber modem.

The addition of the remote-ID option to the RELAY-FORWARD packet occurs automatically and no user configuration is necessary.

The DHCPv6 server does not need to echo the remote-ID option in the RELAY-REPLY packet. The Internet Assigned Numbers Authority (IANA) has assigned the DHCPv6 option code 37 for the relay agent remote-ID option.

If the remote-ID option is included in the RELAY-REPLY packet, the option is removed from the packet before it is relayed to the client.

DHCPv6 Interface-ID

The interface-ID option is used by relay agents to decide which interface should be used when forwarding a RELAY-REPLY packet. If a relay agent receives a RELAY-REPLY message with an interface-ID option, the message is relayed to the client through the interface identified by the option.

The server must copy the interface-ID option from the RELAY-FORWARD message into the RELAY-REPLY message the server sends to the relay agent in response to the RELAY-FORWARD message. This option must not appear in any message except a RELAY-FORWARD or a RELAY-REPLY message.

Servers can use the interface-ID for parameter assignment policies. The interface-ID must be considered as an opaque value, with policies based on exact match only; that is, interface-ID must not be internally parsed by the server. The interface-ID value for an interface must be stable and remain unchanged, for example, after the relay agent is restarted; if the interface-ID changes, a server will not be able to use it reliably in parameter assignment policies.

Lightweight DHCPv6 Relay Agent

The Lightweight DHCPv6 Relay Agent feature allows relay agent information to be inserted by an access node that performs a link-layer bridging (non-routing) function. Lightweight DHCPv6 Relay Agent (LDRA) functionality can be implemented in existing access nodes, such as DSL access multiplexers (DSLAMs) and Ethernet switches, that do not support IPv6 control or routing functions. LDRA is used to insert relay-agent options in DHCPv6 message exchanges primarily to identify client-facing interfaces. LDRA functionality can be enabled on an interface and a VLAN.

An LDRA device or interface has the following features:

- Maintains interoperability with existing DHCPv6 relay agents and servers.
- Is functionally the equivalent of a Layer 2 relay agent, without routing capabilities.

**Note**

LDRA is a device or interface on which LDRA functionality is configured.

Background

A variety of different link-layer network topologies exist for the aggregation of IPv6 nodes into one or more devices. In Layer 2 aggregation networks (IEEE 802.1D bridging or similar) that have many nodes on a single link, a DHCPv6 server or DHCP relay agent normally does not recognize how a DHCP client is attached to a network. LDRA allows relay-agent information, including the Interface-ID option, to be inserted by the access node so that the information may be used by the DHCPv6 server for client identification.

Interoperability between DHCPv6 Relay Agents and LDRA

DHCPv6 relay agents are used to forward DHCPv6 messages between a client and a server when the client and server are not on the same IPv6 link. A DHCPv6 relay agent also adds an interface ID option in the upstream DHCPv6 message (from client-to-server) to identify the interface on which the client is connected. This information is used by the DHCPv6 relay agent while forwarding the downstream DHCPv6 message to the DHCPv6 client. The DHCPv6 relay agent is implemented alongside the routing functionality on the common node.

To maintain interoperability with existing DHCP relays and servers, LDRA implements the same message types (RELAY-FORWARD and RELAY-REPLY) as a DHCPv6 relay agent. LDRA allows relay-agent information to be inserted by an access node that performs a link-layer bridging (that is, non-routing) function. The LDRA resides on the same IPv6 link as the client and a DHCPv6 relay agent or server.

LDRA for VLANs and Interfaces

You can configure LDRA on VLANs and interfaces. LDRA is not enabled by default. You must enable it on the VLAN or interface first.

In a typical deployment, a majority of the interfaces or ports on a device are client facing. In such a scenario, you can configure LDRA functionality on the VLAN. When you configure LDRA on a VLAN, the functionality is configured on all ports or interfaces within the VLAN. Instead of configuring LDRA functionality individually on interfaces and ports within a VLAN, you can configure LDRA on the entire VLAN. As a result, all ports or interfaces associated with the VLAN will be configured as client facing.

You can also configure LDRA functionality on a specific interface or port. An interface or port can be configured as client-facing trusted, client-facing untrusted, or server facing.

The LDRA configuration on a VLAN has to be configured as trusted or untrusted. An LDRA must implement a configuration setting for all client-facing interfaces, marking them as trusted or as untrusted.

By default, any interface that is configured as client facing will be configured as an untrusted interface. When a client-facing interface is deemed untrusted, LDRA will discard any message of type RELAY-FORWARD received from the client-facing interface.

CAPWAP Access Controller DHCPv6 Option

The Control And Provisioning of Wireless Access Points (CAPWAP) protocol allows lightweight access points to use DHCPv6 to discover a Wireless Controller to which it can connect. CAPWAP is a standard, interoperable protocol that enables a controller to manage a collection of wireless access points.

Wireless access points use the DHCPv6 option 52 (RFC 5417) to supply the IPv6 management interface addresses of the primary, secondary, and tertiary Wireless Controllers.

Both stateless and stateful DHCPv6 addressing modes are supported. In stateless mode, access points obtain IPv6 address using the Stateless Address AutoConfiguration (SLAAC), while additional network information (not obtained from router advertisements) is obtained from a DHCPv6 server. In stateful mode, access points obtain both IPv6 addressing and additional network information exclusively from the DHCPv6 server. In both modes, a DHCPv6 server is required to provide option 52 if Wireless Controller discovery using DHCPv6 is required.

How to Configure DHCPv6 Options Support

- [Configuring the DHCPv6 Relay Agent, page 61-5](#)
- [Configuring LDRA Functionality on a VLAN, page 61-5](#)
- [Configuring LDRA Functionality on an Interface, page 61-6](#)
- [Verifying the LRDA Configuration, page 61-7](#)
- [Verifying the LRDA Configuration, page 61-7](#)

Configuring the DHCPv6 Relay Agent

	Command or Action	Purpose
Step 1	Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	Device# configure terminal	Enters global configuration mode.
Step 3	Device(config)# interface <i>type number</i>	Configures an interface and enters interface configuration mode.
Step 4	Device(config-if)# ipv6 dhcp relay destination <i>ipv6-address</i> [<i>interface-type</i> <i>interface-number</i>]	Specifies a destination address to which client packets are forwarded and enables the DHCPv6 relay service on the interface.
Step 5	Device(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.

Configuring LDRA Functionality on a VLAN

	Command or Action	Purpose
Step 1	Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	Device# configure terminal	Enters global configuration mode.
Step 3	Device(config)# ipv6 dhcp-ldra { enable disable remote-id }	Enables LDRA functionality globally. <div>  <p>Note You must enable the LDRA functionality in global configuration mode before configuring it on an interface.</p> </div>
Step 4	Device(config)# vlan configuration <i>vlan-number</i>	Specifies a VLAN number and enters VLAN configuration mode.

	Command or Action	Purpose
Step 5	Device(config-vlan-config)# ipv6 dhcp ldra attach-policy { client-facing-trusted client-facing-untrusted }	Enables the LDRA functionality on a specified VLAN. <ul style="list-style-type: none"> The client-facing-trusted keyword configures all ports or interfaces associated with the VLAN as client facing, trusted ports. The client-facing-untrusted keyword configures all ports or interfaces associated with the VLAN as client facing, untrusted ports.
Step 6	Device(config-vlan-config)# exit	Exits VLAN configuration mode and returns to global configuration mode.
Step 7	Device(config)# interface <i>type number</i>	Configures an interface and enters interface configuration mode.
Step 8	Device(config-if)# switchport	Switches an interface that is in Layer 3 mode into Layer 2 mode for Layer 2 configuration.
Step 9	Device(config-if)# switchport access vlan <i>vlan-number</i>	Specifies that an interface operates in the specified VLAN instead of the default VLAN in interface configuration mode.
Step 10	Device(config-if)# ipv6 dhcp ldra attach-policy { client-facing-trusted client-facing-untrusted client-facing-disable server-facing }	Enables LDRA functionality on a specified interface or port. <ul style="list-style-type: none"> The server-facing keyword specifies an interface or port as server facing.
Step 11	Device(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.

Configuring LDRA Functionality on an Interface

	Command or Action	Purpose
Step 1	Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Device# configure terminal	Enters global configuration mode.
Step 3	Device(config)# ipv6 dhcp ldra { enable disable remote-id }	Enables LDRA functionality globally. <div>  <div> Note You must enable the LDRA functionality in global configuration mode before configuring it on an interface. </div> </div>
Step 4	Device(config)# interface <i>type number</i>	Configures an interface and enters interface configuration mode.
Step 5	Device(config-if)# switchport	Switches an interface that is in Layer 3 mode into Layer 2 mode for Layer 2 configuration.
Step 6	Device(config-if)# ipv6 dhcp ldra interface-id <i>interface-id</i>	Configures LDRA interface ID on a port or an interface.
Step 7	Device(config-if)# end	Exits VLAN configuration mode and returns to privileged EXEC mode.

Verifying the LRDA Configuration

Step 1 **show ipv6 dhcp interface**

Displays DHCPv6 interface information.

Example:

```
Device# show ipv6 dhcp interface

GigabitEthernet0/1 is in relay mode
Relay destinations:
  3FFB:C00:C18:6:A8BB:CCFF:FE03:2701
Serial3/0 is in relay mode
Relay destinations:
  3FFB:C00:C18:6:A8BB:CCFF:FE03:2600
  FE80::A8BB:CCFF:FE03:2801 on Serial3/0
  FF05::1:3
```

Step 2 **show ipv6 dhcp-ldra**

Displays LDRA configuration details. The fields in the example given below are self-explanatory.

Example:

```
Device# show ipv6 dhcp-ldra

DHCPv6 LDRA is Enabled.
DHCPv6 LDRA policy: client-facing-disable
Target: none
DHCPv6 LDRA policy: client-facing-trusted
Target: vlan 5
DHCPv6 LDRA policy: client-facing-untrusted
Target: none
DHCPv6 LDRA policy: server-facing
Target: Gi1/0/7
```

Step 3 **show ipv6 dhcp-ldra statistics**

Displays LDRA configuration statistics before and after initiating a DHCP session. The fields in the examples below are self-explanatory.

Example:

```
Device# show ipv6 dhcp-ldra statistics

DHCPv6 LDRA client facing statistics.
Messages received 2
Messages sent 2
Messages discarded 0
Messages Received
SOLICIT 1
REQUEST 1
Messages Sent
RELAY-FORWARD 2
DHCPv6 LDRA server facing statistics.
Messages received 2
Messages sent 2
Messages discarded 0
Messages Received
RELAY-REPLY 2
Messages Sent
```

```
ADVERTISE 1
REPLY 1
```

Step 4 **debug ipv6 dhcp-ldra all**

Enables all LDRA debugging flows. The fields in the example below are self-explanatory.

Example:

```
Device# debug ipv6 dhcp-ldra all

05:44:10: DHCPv6 LDRA API: Entered ipv6_dhcp_ldra_post_processor.
05:44:10: DHCPv6 LDRA EVENT: [Gi1/0/3 Vlan 5] Received SOLICIT from 2001:DB8:1::1 to
FF02::1:2.
05:44:10:
05:44:10:
05:44:10:
05:44:10:
05:44:10: 000300010015F906981B
05:44:10: option ORO(6), len 4
05:44:10: DNS-SERVERS,DOMAIN-LIST
05:44:10: option IA-NA(3), len 12
05:44:10: IAID 0x00040001, T1 0, T2 0
05:44:10: DHCPv6 LDRA API: Entered dhcpv6_ldra_client_facing_new_pak.
05:44:10: DHCPv6 LDRA EVENT: [Vlan 5] Sending RELAY-FORWARD from 2001:DB8:1::1
to FF02::1:2.
!
!
!
```

Configuring CAPWAP Access Points

	Command or Action	Purpose
Step 1	Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	Device# configure terminal	Enters global configuration mode.
Step 3	Device(config)# ipv6 dhcp pool <i>poolname</i>	Configures a DHCPv6 server configuration information pool and enters DHCPv6 pool configuration mode.
Step 4	Device(config-dhcpv6)# capwap-ac address <i>ipv6-address</i>	Configures CAPWAP access controller address.
Step 5	Device(config-dhcpv6)# end	Exits DHCPv6 pool mode and returns to privileged EXEC mode.

Configuration Examples for DHCPv6 Options Support

- [Example: Configuring the DHCPv6 Relay Agent, page 61-9](#)
- [Example: Configuring LDRA Functionality on a VLAN, page 61-9](#)
- [Example: Configuring LDRA Functionality on an Interface, page 61-9](#)
- [Example: Configuring CAPWAP Access Points, page 61-10](#)

Example: Configuring the DHCPv6 Relay Agent

```
Device> enable
Device# configure terminal
Device(config)# interface gigabitethernet 1/1
Device(config-if)# ipv6 dhcp relay destination FE80::250:A2FF:FEBF:A056 gigabitethernet
0/1
Device(config-if)# end
```

Example: Configuring LDRA Functionality on a VLAN

The following example shows how to configure Lightweight DHCPv6 Relay Agent (LDRA) on a VLAN numbered 5.

```
Device> enable
Device# configure terminal
Device(config)# ipv6 dhcp-ldra enable
Device(config)# vlan configuration 5
Device(config-vlan-config)# ipv6 dhcp ldra attach-policy client-facing-trusted
Device(config-vlan-config)# exit
Device(config)# interface gigabitethernet 0/0
Device(config-if)# switchport
Device(config-if)# switchport access vlan 5
Device(config-if)# ipv6 dhcp-ldra attach-policy client-facing-trusted
Device(config-if)# exit
Device(config)# interface gigabitethernet 1/0
Device(config-if)# switchport
Device(config-if)# switchport access vlan 5
Device(config-if)# ipv6 dhcp-ldra attach-policy server-facing
Device(config-if)# end
```

Example: Configuring LDRA Functionality on an Interface

In the following example, LDRA is configured on the interfaces GigabitEthernet 0/0:

```
Device> enable
Device# configure terminal
Device(config)# ipv6 dhcp-ldra enable
Device(config)# interface gigabitethernet 0/0
Device(config-if)# switchport
Device(config-if)# ipv6 dhcp-ldra interface-id 2
Device(config-if)# end
```

Example: Configuring CAPWAP Access Points

```
Device> enable
Device# configure terminal
Device(config)# ipv6 dhcp pool pool1
Device(config-dhcpv6)# capwap-ac address 2001:DB8::1
Device(config-dhcpv6)# end
Device#
```

Feature Information for DHCPv6 Options Support

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 1 Feature Information for DHCPv6 Options Support

Feature Name	Releases	Feature Information
CAPWAP Access Controller DHCP Option 52	Cisco IOS Release 15.2(5)E2	The Control And Provisioning of Wireless Access Points (CAPWAP) protocol allows Lightweight Access Points to use DHCPv6 to discover a Wireless Controller to which it can connect.
DHCPv6 Interface-ID	Cisco IOS Release 15.2(5)E2	The interface-ID option is used by relay agents to decide which interface should be used when forwarding a RELAY-REPLY packet.
DHCPv6 Relay Agent	Cisco IOS Release 15.2(5)E2	A DHCP relay agent, which may reside on the client's link, is used to relay messages between the client and server.

Configuring Network Security with ACLs

This chapter describes how to use access control lists (ACLs) to configure network security on the Catalyst 4500 series switches.

Note

Catalyst 4500 series switches supports time-based ACLs.

This chapter consists of the following major sections:

- [About ACLs, page 62-2](#)
- [Hardware and Software ACL Support, page 62-6](#)
- [Troubleshooting High CPU Due to ACLs, page 62-7](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About ACLs

This section includes these topics:

- [Overview, page 62-2](#)
- [Supported Features That Use ACLs, page 62-3](#)
- [Router ACLs, page 62-3](#)
- [Port ACLs, page 62-4](#)
- [Dynamic ACLs, page 62-5](#)
- [VLAN Maps, page 62-5](#)

Overview

An ACL is a collection of sequential permit and deny conditions that applies to packets. When a packet is received on an interface, the switch compares the fields in the packet against any applied ACLs to verify that the packet has the permissions required to be forwarded, based on the conditions specified in the access lists. It tests the packets against the conditions in an access list one-by-one. The first match determines whether the switch accepts or rejects the packets. Because the switch stops testing conditions after the first match, the order of conditions in the list is critical. If no conditions match, the switch drops the packet. If no restrictions exist, the switch forwards the packet; otherwise, the switch drops the packet.

Switches traditionally operate at Layer 2, switching traffic within a VLAN. Routers route traffic between VLANs at Layer 3. The Catalyst 4500 series switch can accelerate packet routing between VLANs by using Layer 3 switching. The Layer 3 switch bridges the packet, and then routes the packet internally without going to an external router. The packet is then bridged again and sent to its destination. During this process, the switch can control all packets, including packets bridged within a VLAN.

You configure access lists on a router or switch to filter traffic and provide basic security for your network. If you do not configure ACLs, all packets passing using the switch could be allowed on all parts of the network. You can use ACLs to control which hosts can access different parts of a network or to decide which types of traffic are forwarded or blocked at router interfaces. For example, you can allow e-mail traffic to be forwarded but not Telnet traffic. ACLs can be configured to block inbound traffic, outbound traffic, or both. However, on Layer 2 interfaces, you can apply ACLs only in the inbound direction.

An ACL contains an ordered list of access control entries (ACEs). Each ACE specifies permit or deny and a set of conditions the packet must satisfy in order to match the ACE. The meaning of permit or deny depends on the context in which the ACL is used. Negative TCP flags such as -syn, -psh or -fin in ACEs are not considered when you apply IP ACLs. We recommend that you use positive TCP flags in ACEs.

**Note**

The Catalyst 4500 series switch does not support non-contiguous ports on the same ACE or on a download able ACE.

The Catalyst 4500 series switch supports three types of ACLs:

- IP ACLs, which filter IP traffic, including TCP, the User Datagram Protocol (UDP), Internet Group Management Protocol (IGMP), and Internet Control Message Protocol (ICMP)
- IPv6 ACLs
- MAC ACLs which match based on Ethernet addresses and Ether Type

Supported Features That Use ACLs

The switch supports three applications of ACLs to filter traffic:

- Router ACLs are applied to Layer 3 interfaces. They control the access of routed traffic between VLANs. All Catalyst 4500 series switches can create router ACLs, but you must have a Cisco IOS software image on your switch to apply an ACL to a Layer 3 interface and filter packets routed between VLANs.
- Port ACLs perform access control on traffic entering a Layer 2 interface. If insufficient hardware CAM entries exist, the output port ACL is not applied to the port and a warning message is given to user. (This restriction applies to all access group modes for output port ACLs.) When sufficient CAM entries exist, the output port ACL may be reapplied.

If there is any output port ACL configured on a Layer 2 port, then no VACL or router ACL can be configured on the VLANs that the Layer 2 port belongs to. Also, the reverse is true: port ACLs and VLAN-based ACLs (VACLs and router ACLs) are mutually exclusive on a Layer 2 port. This restriction applies to all access group modes. On the input direction, port ACLs, VLAN-based ACLs, and router ACLs can co-exist.

You can apply one IPv4 access list, one IPv6 access list and one MAC access list for a Layer 2 interface.

- You can use VLAN maps to filter traffic between devices in the same VLAN. You do not need the enhanced image to create or apply VLAN maps. VLAN maps are configured to control access based on Layer 3 addresses for IP. MAC addresses using Ethernet ACEs control the access of unsupported protocols. After you apply a VLAN map to a VLAN, all packets (routed or bridged) entering the VLAN are checked against that map. Packets can either enter the VLAN through a switch port or through a routed port after being routed.

You can use both router ACLs and VLAN maps on the same switch.

Router ACLs

You can apply one access list of each supported type to an interface.

Note

Catalyst 4500 series switches running Cisco IOS Release 12.2(40)SG do *not* support IPv6 port ACLs (PACLs).

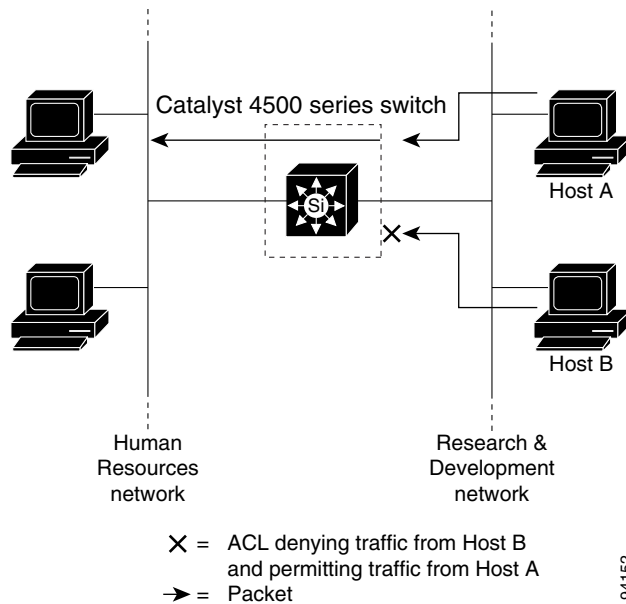

Multiple features can use one ACL for a given interface, and one feature can use multiple ACLs. When a single router ACL is used by multiple features, it is examined multiple times. The access list type determines the input to the matching operation:

- Standard IP access lists use source addresses for matching operations.
- Extended IP access lists use source and destination addresses and optional protocol type information for matching operations.

The switch examines ACLs associated with features configured on a given interface and a direction. As packets enter the switch on an interface, ACLs associated with all inbound features configured on that interface are examined. After packets are routed and before they are forwarded to the next hop, all ACLs associated with outbound features configured on the egress interface are examined.

ACLs permit or deny packet forwarding based on how the packet matches the entries in the ACL. For example, you can use access lists to allow one host to access a part of a network, but prevent another host from accessing the same part. In [Figure 62-1](#), ACLs applied at the router input allow Host A to access the Human Resources network, but prevent Host B from accessing the same network.

Figure 62-1 Using ACLs to Control Traffic to a Network

94152

Note

Starting IOS XE 3.11.0, Catalyst 4500 series switches do not support egress ACLs on a tunnel interface and on the source interface of the tunnel.

Port ACLs

You can also apply ACLs to Layer 2 interfaces on a switch. Port ACLs are supported on physical interfaces and EtherChannel interfaces. The following access lists are supported on Layer 2 interfaces:

- Standard IP access lists using source addresses
- Extended IP access lists using source and destination addresses and optional protocol type information
- IPv6 access lists using source and destination addresses and optional protocol type information
- MAC extended access lists using source and destination MAC addresses and optional protocol type information

Note

Negative TCP flags such as -syn, -psh or -fin in ACEs are not considered when you apply port ACLs. We recommend that you use positive TCP flags in ACEs.

As with router ACLs, the switch examines ACLs associated with features configured on a given interface and permits or denies packet forwarding based on how the packet matches the entries in the ACL. In the example in [Figure 62-1](#), if all workstations were in the same VLAN, ACLs applied at the Layer 2 input would allow Host A to access the Human Resources network, but prevent Host B from accessing the same network.

When you apply a port ACL to a trunk port, the ACL filters traffic on all VLANs present on the trunk port. When you apply a port ACL to a port with voice VLAN, the ACL filters traffic on both data and voice VLANs.

With port ACLs, you can filter IP traffic by using IP access lists and non-IP traffic by using MAC addresses. You can filter both IP and non-IP traffic on the same Layer 2 interface by applying both an IP access list and a MAC access list to the interface.

With port ACLs, you can filter IPv4 traffic with IPv4 access lists, IPv6 traffic with IPv6 access lists, and non-IP traffic with MAC access lists. You can filter multiple types of traffic simultaneously by applying ACLs of the appropriate type to the Layer 2 interface simultaneously.

**Note**

You cannot simultaneously apply more than one access list of a given type to a Layer 2 interface. If an IPv4, IPv6, or MAC access list is already configured on a Layer 2 interface, and you apply a new IPv4, IPv6 or MAC access list to the interface, the new ACL replaces the previously configured ACL of the same type.

Dynamic ACLs

Various security features, such as 802.1X, NAC and Web Authentication, are capable of downloading ACLs from a central server and applying them to interfaces. Prior to Cisco IOS Release 12.2(54)SG, these features required the explicit configuration of a standard port ACL

Starting with Cisco IOS Release 12.2(54)SG, a port ACL does not require configuration. For more details refer to the [“Removing the Requirement for a Port ACL”](#) section on [page 62-32](#).

VLAN Maps

VLAN maps can control the access of all traffic in a VLAN. You can apply VLAN maps on the switch to all packets that are routed into or out of a VLAN or are bridged within a VLAN. VLAN maps are not defined by direction (input or output).

**Note**

Negative TCP flags such as -syn, -psh or -fin in ACEs are not considered when you apply VLAN ACLs. We recommend that you use positive TCP flags in ACEs.

You can configure VLAN maps to match Layer 3 addresses for IP traffic. Access of all non-IP protocols is controlled with a MAC address and an Ethertype using MAC ACLs in VLAN maps. (IP traffic is not controlled by MAC ACLs in VLAN maps.) You can enforce VLAN maps only on packets heading to the switch; you cannot enforce VLAN maps on traffic between hosts on a hub or on another switch connected to this switch.

With VLAN maps, forwarding packets is permitted or denied, based on the action specified in the map. [Figure 62-2](#) illustrates how a VLAN map is applied to deny a specific type of traffic from Host A in VLAN 10 from being forwarded.

Figure 62-2 Using VLAN Maps to Control Traffic

Hardware and Software ACL Support

This section describes how to determine whether ACLs are processed in hardware or in software:

- Flows that match a *deny* statement in standard and extended ACLs are dropped in hardware if ICMP unreachable messages are disabled.
- Flows that match a *permit* statement in standard ACLs are processed in hardware.
- The following ACL types are not supported in software:
 - Standard Xerox Network Systems (XNS) Protocol access list
 - Extended XNS access list
 - DECnet access list
 - Protocol type-code access list
 - Standard Internet Packet Exchange (IPX) access list
 - Extended IPX access list

Note

Packets that require logging are processed in software. A copy of the packets is sent to the CPU for logging while the actual packets are forwarded in hardware so that non-logged packet processing is not impacted.

By default, the Catalyst 4500 series switch sends ICMP unreachable messages when a packet is denied by an access list; these packets are not dropped in hardware but are forwarded to the switch so that it can generate the ICMP unreachable message.

To drop access list denied packets in hardware on the input interface, you must disable ICMP unreachable messages using the **no ip unreachables** interface configuration command. The **ip unreachables** command is enabled by default.

Note

Cisco IOS Release 12.2(40)SG does not support disabling IP unreachables on interfaces routing IPv6 traffic.

Note

If you set the **no ip unreachable** command on all Layer 3 interfaces, output ACL denied packets do not come to the CPU.

Troubleshooting High CPU Due to ACLs

Packets that match entries in fully programmed ACLs are processed in hardware.

Packets that match entries in partially programmed ACLs are processed in software using the CPU. This may cause high CPU utilization and packets to be dropped.

CPU spikes and connectivity loss may be observed when an ACL applied to a VLAN interface blocks HSRP management multicast traffic. In this scenario where both HSRP member devices may become Active, the resulting high number of IPv6 Neighbor Discovery packets being lifted to the CPU may cause a spike. To avoid this, ensure that the active and the standby devices in HSRP can communicate. Additionally, do not configure the IPv6 HSRP multicast address in the ACL.

To determine whether packets are being dropped due to high CPU utilization, reference the following:

http://www.cisco.com/en/US/products/hw/switches/ps663/products_tech_note09186a00804cef15.shtml

If the ACL and/or IPSG configuration is partially programmed in hardware, upgrading to Cisco IOS Release 12.2(31)SGA or later and resizing the TCAM regions may enable the ACLs to be fully programmed.

**Note**

Removal of obsolete TCAM entries can take several CPU process review cycles to complete. This process may cause some packets to be switched in software if the TCAM entry or mask utilization is at or near 100 percent.

Selecting Mode of Capturing Control Packets

In some deployments, you might want to bridge control packets in hardware rather than globally capture and forward them in software (at the expense of the CPU). The per-VLAN capture mode feature allows a Catalyst 4500 series switch to capture control packets only on selected VLANs and bridge traffic in hardware on all other VLANs.

When you use per-VLAN capture mode on your switch, it partially disables the global TCAM capture entries internally and attaches feature-specific capture ACLs on those VLANs that are enabled for snooping features. (All IP capture entries, and other non-IP entries are still captured through global TCAM.)

Because this feature controls specific control packets, they are captured only on the VLANs on which the internal ACLs are installed. On all other VLANs, the control traffic is bridged in hardware rather than forwarded to CPU.

The per-VLAN capture mode allows you to apply user-defined ACLs and QoS policers (in hardware) on control packets. You can also subject the aggregate control traffic ingressing the CPU to control plane policing.

When you use per-VLAN capture mode, the following four protocol groups are selectable per-VLAN. The breakdown of protocols intercepted by each group is as follows:

- IGMP Snooping—Cgmp, Ospf, Igmp, RipV2, Pim, 224.0.0.1, 224.0.0.2, 224.0.0.*
- DHCP Snooping—Client to Server, Server to Client, Server to Server

Because some of the groups have multiple overlapping ACEs (for example, 224.0.0.* is present in all the groups except for DHCP Snooping), turning on a certain group will also trigger the interception of some protocols from other groups.

Following are the programming triggers for the four protocol groups per-VLAN:

- IGMP Snooping should be enabled globally on a given VLAN.
- DHCP Snooping should be enabled globally on a given VLAN.

Guidelines and Restrictions

Note

Before configuring per-VLAN capture mode, you should examine your configuration to ensure that only the necessary features are enabled on the desired VLANs.

The following guidelines and restrictions apply to per-VLAN capture mode:

- Starting with Cisco IOS Release 15.0(2)SG on Supervisor Engine 6-E, 6L-E
Starting with Cisco IOS XE Release 3.2.0 on Supervisor Engine 7-E
Starting with Cisco IOS XE Release 3.2.0XO on Supervisor Engine 7L-E
Starting with Cisco IOS XE Release 3.6.0 on Supervisor Engine 8-E
Starting with Cisco IOS XE Release 3.10.0E on Supervisor Engine 9-E
globally reserved static ACL entries in the TCAM region for Layer 3 control packets are removed. The per-VLAN CTI command is not needed and does not apply for Layer 3 control packets because these packets are captured in per-VLAN fashion by default.

The following still function:

- Global static capture and CTI commands for IGMP or PIM packets (both use MAC addresses 224.0.0.1 and 224.0.0.2)
- Global and per-VLAN CTI for DHCP packets

With Cisco IOS Release 15.0(2)SG, per-VLAN capture of Layer 3 control packets is driven by SVI configuration. Except for IGMP, PIM, or DHCP, no special configuration is required.

Enabling per-VLAN capture mode consumes additional entries in the ACL/feature TCAM. The number of available TCAM entries depends on the type of supervisor engine. The entry and mask count further limits the utilization of the ACL/feature TCAM.

- On Supervisor Engines IV, V and V-10 GE a maximum of 32 action entries are supported at ingress and 64 entries are supported at egress. To avoid high CPU utilization, move ACEs with a 'log' action towards end of the ACL so that the available action index can be used optimally to process other ACE actions.
- Certain configurations can exhaust TCAM resource earlier in per-VLAN capture mode than in global capture mode (such as, when IP Source Guard is enabled on several interfaces or on a user-configured PACL).

You can resize TCAM regions to make more entries available to the PortAndVlan or PortOrVlan region based on the configuration. This allows more entries to be programmed in hardware before reaching the limit. When TCAM resources are exhausted, the packets are forwarded in software.

- In per-VLAN capture mode, you can configure ACLs to permit or deny control traffic on a VLAN or port.

Because security ACLs are terminated by an *implicit deny*, you must ensure that the ACLs are configured to permit the control packets necessary for the feature (protocol) to operate. However, this rule does not differ from the default behavior.

- CPU spikes and connectivity loss may be observed when an ACL applied to a VLAN interface blocks HSRP management multicast traffic. In this scenario where both HSRP member devices may become Active, the resulting high number of IPv6 Neighbor Discovery packets being lifted to the CPU may cause a spike. To avoid this, ensure that the active and the standby devices in HSRP can communicate. Additionally, do not configure the IPv6 HSRP multicast address in the ACL.

Selecting Control Packet Capture

To select the mode of capturing control packets, perform this task:

	Command	Purpose
Step 1	Switch# conf terminal	Enters configuration mode.
Step 2	Switch(config)# [no] access-list hardware capture mode [vlan global]	Selects mode of capturing control packets. The no form of the access-list hardware capture mode command restores the capture mode to the default, which is global.
Step 3	Switch(config)# end	Returns to enable mode.

This example shows how to configure a Catalyst 4500 series switch to capture control packets only on VLANs where features are enabled:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# access-list hardware capture mode vlan
Switch(config)# end
Switch#
```

This example shows how to configure a Catalyst 4500 series switch to capture control packets globally across all VLANs (using static ACL, the default mode):

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# access-list hardware capture mode global
Switch(config)# end
Switch#
```

When the capture mode changes from global to VLAN, the static CAM entries are invalidated. This creates a window during which control packets may pass through a Catalyst 4500 series switch without being intercepted to the CPU. This temporary situation is restored when the new per-VLAN capture entries are programmed in the hardware.

When you configure per-VLAN capture mode, you should examine the **show** commands for individual features to verify the appropriate behavior. In per-VLAN capture mode, the invalidated static CAM entries will appear as inactive in the output of the **show platform hardware acl input entries static** command. For example, the hit count for inactive entries will remain frozen because those entries are invalidated and applied per-VLAN where the feature is enabled. The following table lists the CamIndex entry types and the Cam regions.

CamIndex Entry Type	Active	Hit Count	CamRegion
50 PermitSharedStp	Y	3344	ControlPktsTwo
51 PermitLoopbackTest	Y	0	ControlPktsTwo

CamIndex Entry Type	Active	Hit Count	CamRegion
52 PermitProtTunnel	Y	0	ControlPktsTwo
53 CaptureCgmp	N	440	ControlPktsTwo
55 CaptureIgmpp	N	0	ControlPktsTwo
0 IgmppImv1ToCpu	N	N/A	0 (estimate)
0 IgmppGeneralQueryToCpu	N	N/A	0 (estimate)
2 IgmppToCpu	N	N/A	0 (estimate)
3 IgmppImv2ToCpu	N	N/A	0 (estimate)
2048 Ipv6MldGeneralQueryCopyToCpu	N	N/A	0 (estimate)
2050 Ipv6MldGeneralQueryCopyToCpu	N	N/A	0 (estimate)
2052 Ipv6MldQueryOrReportV1ToCpu	N	N/A	0 (estimate)
2054 Ipv6MldQueryOrReportV1ToCpu	N	N/A	0 (estimate)
2056 Ipv6MldReportV2ToCpu	N	N/A	0 (estimate)
2058 Ipv6MldReportV2ToCpu	N	N/A	0 (estimate)
2060 Ipv6MldDoneToCpu	N	N/A	0 (estimate)
2064 Ipv6MldImv2ToCpu	N	N/A	0 (estimate)

TCAM Programming and ACLs

You apply three types of hardware resources when you program ACLs and ACL-based features: mapping table entries (MTEs), profiles, and TCAM value/mask entries. If any of these resources are exhausted, packets are sent to the CPU for software-based processing.

Note

Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, 7-E, 6L-E, and 6-E automatically manage the available resources. Because masks are not shared on the supervisor engines, only one programming algorithm exists. No regions exist so region resizing is not needed.

If you exhaust resources on the supervisor engine, you should consider reducing the complexity of your configuration.

Note

When an interface is in down state, TCAMs are not consumed for RACLs, but are for PACLs.

Note

TCAM resources are replicated or shared based on the feature combinations applied on the interfaces. For example, if the same ACL and flow monitor configurations are applied on two different interfaces, TCAM resources are shared between the two interfaces. But if multicast routing is added on any one of the interfaces, then TCAM resources are replicated and not shared.

Layer 4 Operators in ACLs

The following sections provide guidelines and restrictions for configuring ACLs that include Layer 4 port operations:

- [Restrictions for Layer 4 Operations, page 62-11](#)
- [Configuration Guidelines for Layer 4 Operations, page 62-12](#)
- [Using ACLs to Filter TCP Flags and How ACL Processing Impacts CPU, page 62-13](#)

Restrictions for Layer 4 Operations

Note

Cisco IOS XE Release 3.7.0E and Cisco IOS Release 15.2(3)E do not support the configuration of named ACLs for noncontiguous ports on an ACE.

You can specify these operator types, each of which uses one Layer 4 operation in the hardware:

- gt (greater than)
- lt (less than)
- neq (not equal)
- range (inclusive range)

The limits on the number of Layer 4 operations differ for each type of ACL, and can also vary based on other factors: whether an ACL is applied to incoming or outgoing traffic, whether the ACL is a security ACL or is used as a match condition for a QoS policy, and whether IPv6 ACLs are being programmed using the compressed flow label format.

Note

The IPv6 compressed flow label format uses the Layer 2 Address Table to compress a portion of the IPv6 source address of each ACE in the ACL. The extra space freed in the flow label can then be used to support more Layer 4 operations. For this compression to be used, the IPv6 ACL cannot contain any ACEs that mask in only a portion of the bottom 48 bits of the source IPv6 address.

Generally, you will receive at most the following number of Layer 4 operations on the same ACL:

Direction	Protocol	Type	Operations
Input	IPv4	Security	14
Input	IPv6	Compressed Security	16
Input	IPv6	Uncompressed Security	2
Input	IPv4	QoS	4
Input	IPv6	Compressed QoS	10
Input	IPv6	Uncompressed QoS	4
Output	IPv4	Security	16
Output	IPv6	Compressed Security	18
Output	IPv6	Uncompressed Security	4
Output	IPv4	QoS	4
Output	IPv6	Compressed QoS	10
Output	IPv6	Uncompressed QoS	4

Note

Where up to 16 operations are supported, the seventeenth will trigger an expansion.

If you exceed the number of available Layer 4 operations, each new operation might cause the affected ACE to be translated into multiple ACEs in the hardware. If this translation fails, packets are sent to the CPU for software processing.

When you globally enable the **ipv6 multicast-routing** and **ipv6 routing** global configuration commands, a reduced number of Layer 4 operations are available for use in IPv6 ACL or QoS. Additionally, the "eq" operator consumes a Layer 4 Operation if it is used to match a source port.

Configuration Guidelines for Layer 4 Operations

When using Layer 4 operators, consider these guidelines:

- Layer 4 operations are considered different if the operator or operand differ. For example, the following ACL contains three different Layer 4 operations because gt 10 and gt 11 are considered two different Layer 4 operations:

```
... gt 10 permit
... lt 9 deny
... gt 11 deny
```

Note The eq operator can be used an unlimited number of times because eq does not use a Layer 4 operation in hardware.

- Layer 4 operations are considered different if the same operator/operand couple applies once to a source port and once to a destination port, as in the following example:

```
... Src gt 10....
... Dst gt 10
```

A more detailed example follows:

```
access-list 101
... (dst port) gt 10 permit
... (dst port) lt 9 deny
... (dst port) gt 11 deny
... (dst port) neq 6 permit
... (src port) neq 6 deny
... (dst port) gt 10 deny

access-list 102
... (dst port) gt 20 deny
... (src port) lt 9 deny
... (src port) range 11 13 deny
... (dst port) neq 6 permit
```

Access lists 101 and 102 use the following Layer 4 operations:

- Access list 101 Layer 4 operations: 5
 - gt 10 permit and gt 10 deny both use the same operation because they are identical and both operate on the destination port.
- Access list 102 Layer 4 operations: 4
- Total Layer 4 operations: 8 (due to sharing between the two access lists)
 - neq6 permit is shared between the two ACLs because they are identical and both operate on the same destination port.
- A description of the Layer 4 operations usage is as follows:

- Layer 4 operation 1 stores gt 10 permit and gt 10 deny from ACL 101
- Layer 4 operation 2 stores lt 9 deny from ACL 101
- Layer 4 operation 3 stores gt 11 deny from ACL 101
- Layer 4 operation 4 stores neg 6 permit from ACL 101 and 102
- Layer 4 operation 5 stores neg 6 deny from ACL 101
- Layer 4 operation 6 stores gt 20 deny from ACL 102
- Layer 4 operation 7 stores lt 9 deny from ACL 102
- Layer 4 operation 8 stores range 11 13 deny from ACL 102

Using ACLs to Filter TCP Flags and How ACL Processing Impacts CPU

You can use IPv4 or IPv6 ACLs to filter TCP flags. You do this by configuring ACEs that make up an access list to allow matching on a flag that is set.

You use a combination of flags on which to filter; these combinations are processed in hardware. Only the following combinations are supported (applicable to IPv4 and IPv6 ACLs) and the flags must be used in the specified combination:

- **rst** and **ack**—equivalent to the keyword **established**.
 - **rst**—The reset flag indicates that the receiver should delete the connection without further interaction.
 - **ack**—The acknowledge flag indicates that the acknowledgment field of a segment specifies the next sequence number the sender of this segment is expecting to receive.
- **syn** and **fin** and **rst**
 - **syn**—The synchronize flag is used to establish connections.
 - **fin**—The finish flag is used to clear connections.
 - **rst**—See above
- **psh**—The push flag indicates the data in the call should be immediately pushed through to the receiving user.
- **urg**—The urgent flag indicates that the urgent field is meaningful and must be added to the segment sequence number

Note Match-all is not supported. Match-any is supported only when used in the following combinations of positive flags: "rst and ack" (must be combined), "syn and fin and rst" (must be combined), "psh" and "urg".

ACL processing can impact the CPU in two ways:

- For some packets, when the hardware runs out of resources, the software must perform the ACL matches:
 - The TCP flag combinations rst ack, syn fin rst, urg and psh are processed in hardware. Other TCP flag combinations are supported in software.
 - If the total number of Layer 4 operations in an ACL is less than six, you can distribute the operations in any way you choose.

To create an ACL (IPv4 or IPv6) to filter TCP tags, perform the following task:

	Command	Purpose
Step 1	configure terminal Example Switch# configure terminal	Blocks all traffic to or from the configured unicast MAC address in the specified VLAN. To clear MAC address-based blocking, use the no form of this command without the drop keyword.
Step 2	ip access-list extended <i>access-list-name</i> Example Switch(config)# ip access-list extended kmd1 Switch(config-ext-nacl)#	Specifies the IP access list by name and enters named access list configuration mode.
Step 3	[sequence-number] permit tcp <i>source source-wildcard</i> [<i>operator</i> [<i>port</i>]] <i>destination destination-wildcard</i> [<i>operator</i> [<i>port</i>]] [<i>established</i> { match-any match-all } {+ -} [<i>flag-name</i>] [<i>precedence precedence</i>] [<i>tos tos</i>] [log] [<i>time-range time-range-name</i>] [<i>fragments</i>] Example (IPv4-specific) Switch(config-ext-nacl)# permit tcp host 10.1.1.1 host 2.2.2.2 established Example (IPv6-specific) Switch(config-ext-nacl)# permit tcp host 2001:2:25:1::1 host 2001:2:25:1::10 established	Specifies a permit statement in named IP access list mode. This access list happens to use a permit statement first, but a deny statement could appear first, depending on the order of statements you need. Use the TCP command syntax of the permit command. Match-all is not supported. Match-any is supported only when used in the following combinations of positive flags: "rst and ack" (must be combined), "sync and fin and rst" (must be combined), "psh" and "urg"
Step 4	[sequence-number] deny tcp <i>source source-wildcard</i> [<i>operator</i> [<i>port</i>]] <i>destination destination-wildcard</i> [<i>operator</i> [<i>port</i>]] [<i>established</i> { match-any match-all } {+ -} [<i>flag-name</i>] [<i>precedence precedence</i>] [<i>tos tos</i>] [log] [<i>time-range time-range-name</i>] [<i>fragments</i>] Example (IPv4-specific) Switch(config-ext-nacl)# deny tcp host 3.3.3.3 host 4.4.4.4 fin rst syn Example (IPv6-specific) Switch(config-ext-nacl)# deny tcp host 2001:2:25:1::2 host 2001:2:25:1::20 fin rst syn	(Optional) Specifies a deny statement in named IP access list mode. This access list happens to use a permit statement first, but a deny statement could appear first, depending on the order of statements you need. Use the TCP command syntax of the deny command. See the deny (IP) command for additional command syntax to permit upper-layer protocols (ICMP, IGMP, TCP, and UDP). Match-all is not supported. Match-any is supported only when used in the following combinations of positive flags: "rst and ack" (must be combined), "sync and fin and rst" (must be combined), "psh" and "urg".
Step 5	Repeat Step 3 or Step 4 as necessary, adding statements by sequence number where you planned. Use the no sequence-number command to delete an entry.	Allows you to revise the access list.

	Command	Purpose
Step 6	end Example Switch(config-ext-nacl)# end	(Optional) Exits the configuration mode and returns to privileged EXEC mode.
Step 7	show ip access-lists <i>access-list-name</i> Example Switch# show ip access-lists kmd1	(Optional) Displays the contents of the IP access list. Review the output to confirm that the access list includes the new entry.

Examples

The following access lists are processed completely in hardware:

```
access-list 104 permit tcp any any established
access-list 105 permit tcp any any rst ack
access-list 107 permit tcp any syn fin rst
```

Access lists 104 and 105 are identical; established is shorthand for rst and ack.

Access list 101, is processed completely in software:

```
access-list 101 permit tcp any any syn
```

Because four source and two destination operations exist, access list 106 is processed in hardware:

```
access-list 106 permit tcp any range 100 120 any range 120 140
access-list 106 permit tcp any range 140 160 any range 180 200
access-list 106 permit tcp any range 200 220
access-list 106 deny tcp any range 220 240
```

In the following code, the Layer 4 operations for the third ACE trigger an attempt to translate dst lt 1023 into multiple ACEs in hardware, because three source and three destination operations exist. If the translation attempt fails, the third ACE is processed in software.

```
access-list 102 permit tcp any lt 80 any gt 100
access-list 102 permit tcp any range 100 120 any range 120 1024
access-list 102 permit tcp any gt 1024 any lt 1023
```

Similarly, for access list 103, the third ACE triggers an attempt to translate dst gt 1023 into multiple ACEs in hardware. If the attempt fails, the third ACE is processed in software. Although the operations for source and destination ports look similar, they are considered different Layer 4 operations.

```
access-list 103 permit tcp any lt 80 any lt 80
access-list 103 permit tcp any range 100 120 any range 100 120
access-list 103 permit tcp any gt 1024 any gt 1023
```

Note Remember that source port lt 80 and destination port lt 80 are considered different operations.

- Some packets must be sent to the CPU for accounting purposes, but the action is still performed by the hardware. For example, if a packet must be logged, a copy is sent to the CPU for logging, but the forwarding (or dropping) is performed in the hardware. Although logging slows the CPU, it does not affect the forwarding rate. This sequence of events would happen under the following conditions:
 - When a log keyword is used
 - When an output ACL denies a packet
 - When an input ACL denies a packet, and on the interface where the ACL is applied, **ip unreachable** is enabled (**ip unreachable** is enabled by default on all the interfaces)

Configuring Unicast MAC Address Filtering

To block all unicast traffic to or from a MAC address in a specified VLAN, perform this task:

Command	Purpose
Switch(config)# mac-address-table static <i>mac_address</i> vlan <i>vlan_ID</i> drop	Blocks all traffic to or from the configured unicast MAC address in the specified VLAN. To clear MAC address-based blocking, use the no form of this command without the drop keyword.

This example shows how to block all unicast traffic to or from MAC address 0050.3e8d.6400 in VLAN 12:

```
Switch# configure terminal
Switch(config)# mac-address-table static 0050.3e8d.6400 vlan 12 drop
```

Configuring Named MAC Extended ACLs

You can filter non-IPv4, non-IPv6 traffic on a VLAN and on a physical Layer 2 port by using MAC addresses and named MAC extended ACLs. The procedure is similar to that of configuring other extended named ACLs. You can use a number to name the access list, but MAC access list numbers from 700 to 799 are not supported.

Note

Named MAC extended ACLs cannot be applied to Layer 3 interfaces.

For more information about the supported non-IP protocols in the **mac access-list extended** command, refer to the *Catalyst 4500 Series Switch Cisco IOS Command Reference*.

To create a named MAC extended ACL, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# [no] mac access-list extended name	Defines an extended MAC access list using a name. To delete the entire ACL, use the no mac access-list extended name global configuration command. You can also delete individual ACEs from named MAC extended ACLs.
Step 3	Switch(config-ext-macl)# {deny permit} {any host source MAC address source MAC address mask} {any host destination MAC address destination MAC address mask} [protocol-family {appletalk arp-non-ipv4 decnet ipx ipv6 (not supported on Sup 6-E and 6L-E) rarp-ipv4 rarp-non-ipv4 vines xns}]	In extended MAC access-list configuration mode, specify to permit or deny any source MAC address, a source MAC address with a mask, or a specific host source MAC address and any destination MAC address, destination MAC address with a mask, or a specific destination MAC address. Note IPv6 packets do <i>not</i> generate Layer 2 ACL lookup keys.
Step 4	Switch(config-ext-macl)# end	Returns to privileged EXEC mode.
Step 5	Switch# show access-lists [number name]	Shows the access list configuration.
Step 6	Switch(config)# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to create and display an access list named `mac1`, denying only EtherType DECnet Phase IV traffic, but permitting all other types of traffic:

```
Switch(config)# mac access-list extended mac1
Switch(config-ext-macl)# deny any any decnet-iv (old) protocol-family decnet (new)
Switch(config-ext-macl)# permit any any
Switch(config-ext-macl)# end
Switch # show access-lists
Extended MAC access list mac1
    deny any any decnet-iv (old) protocol-family decnet (new)
    permit any any
```

The following example shows how to enable or disable hardware statistics while configuring ACEs in the access list:

```
Switch# config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# mac access-list extended mac1
Switch(config-ext-nacl)# hardware statistics
Switch(config-ext-nacl)# end
Switch# show access-lists
Extended MAC access list mac1
    deny any any decnet-iv (old) protocol-family decnet (new)
    permit any any
    hardware statistics
```

Configuring EtherType Matching

You can classify non-IP traffic based on the EtherType value using the existing MAC access list commands. When you classify non-IP traffic by EtherType, you can apply security ACLs and QoS policies to traffic that carry the same EtherType.

EtherType matching allows you to classify tagged and untagged IP packets based on the EtherType value. Tagged packets present a potential operation problem:

- While single-tagged packets are supported on the access and trunk ports, double-tagged packets are not.
- Single and double-tagged packets are not supported if the port mode is dot1qtunnel.

For more information about the **mac access-list extended** command, refer to the *Catalyst 4500 Series Switch Cisco IOS Command Reference*.

To create a named MAC extended ACL, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# [no] mac access-list extended name	Defines an extended MAC access list using a name. To delete the entire ACL, use the no mac access-list extended name global configuration command. You can also delete individual ACEs from named MAC extended ACLs.
Step 3	Switch(config-ext-macl)# {deny permit} {any host source MAC address source MAC address mask} {any host destination MAC address destination MAC address mask} [protocol-family {appletalk arp-non-ipv4 decnet ipx ipv6 (not supported on Sup 6-E and 6L-E) rarp-ipv4 rarp-non-ipv4 vines xns} ethertype]	In extended MAC access-list configuration mode, specify to permit or deny any based upon the EtherTypes value, valid values are 15636-65535. Note You can specify matching by either EtherType or protocol family but not both.
Step 4	Switch(config-ext-macl)# end	Returns to privileged EXEC mode.
Step 5	Switch# show access-lists [number name]	Shows the access list configuration.
Step 6	Switch(config)# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to create and display an access list named matching, permitting the 0x8863 and 0x8040 EtherType values:

```
Switch(config)# mac access-list extended matching
Switch(config-ext-macl)# permit any any 0x8863
Switch(config-ext-macl)# permit any any 0x8040
Switch(config-ext-macl)# end
Switch # show access-lists matching
Extended MAC access list matching
    permit any any 0x8863
    permit any any netbios
Switch #
```

Configuring Named IPv6 ACLs

Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, 7-E, 6L-E, and 6-E support hardware-based IPv6 ACLs to filter unicast, multicast and broadcast IPv6 traffic on Layer 2 and Layer 3 interfaces. You can only configure such access lists on Layer 3 interfaces that are configured with an IPv6 address.

Beginning with IOS XE 3.7.0, you can employ IPv6 wildcard masking when specifying the Layer 3 address of a IPv6 ACL entry. Scale and performance issues that might be introduced by this feature are captured in the following:

<http://www.cisco.com/c/en/us/products/switches/catalyst-4500-series-switches/datasheet-listing.html>

The following document covers all security related hardware TCAM resources: “Cisco Catalyst 4500E Supervisor Engine 8-E: Wired and Wireless Convergence Data Sheet”

http://www.cisco.com/c/en/us/products/collateral/switches/catalyst-4500-series-switches/data_sheet_c78-728191.html

Note

routing-type/mobility-type extension header options in an IPv6 ACL have never been supported, but were previously configurable. As of Release IOS XE 3.4.0SG and IOS 15.1(2)SG, configuration of these options has been removed.

To create a named IPv6 ACLs, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ipv6 access-list name	Defines an IPv6 access list using a name and enters access-list configuration mode. To delete the IPv6 ACL, use the no form of the command. You can also delete individual ACEs from the IPv6 access list.
Step 3	Switch(config-ipv6-acl)# { deny permit } { any proto object-group service-object-group-name } { host ipv6-addr ipv6-prefix ipv6-addr ipv6-wildcard-bits object-group source-network-object-group-name } { host ipv6-addr ipv6-prefix ipv6-addr ipv6-wildcard-bits object-group dest-network-object-group-name }	Specifies one or more IPv6 ACEs. Repeat this step to define multiple ACEs. You can specify an IPv6 address or use a wildcard mask to specify addresses. If you use a wildcard, the address should be specified in hexadecimal format, using 16-bit values between colons. (See RFC 2373).
		 Note 0 is the care bit and must match; 1 is the <i>don't care</i> bit and the system does not care whether it matches.
Step 4	Switch(config-ipv6-acl)# hardware statistics	(Optional) Enables hardware statistics for the IPv6 ACL.
Step 5	Switch(config-ipv6-acl)# end	Returns to privileged EXEC mode.
Step 6	Switch# show ipv6 access-list	Display the IPv6 access list configuration.

The following example shows how to create and display an IPv6 access list named v6test, denying only one IPv6 traffic with one particular source and destination address, but permitting all other types of IPv6 traffic:

```
Switch(config)# ipv6 access-list v6test
Switch(config-ipv6-acl)# deny ipv6 host 2020::10 host 2040::10
Switch(config-ipv6-acl)# permit any any
Switch(config-ipv6-acl)# end
Switch# show ipv6 access-list
IPv6 access list v6test
  deny ipv6 host 2020::10 host 2040::10 sequence 10
  permit ipv6 any any sequence 20
```

The following example show various ways of configuring ACEs in IPv6 ACL:

```
Switch(config)#ipv6 access-list v6test
```

The permit entry specifies the source and destination IPv6 addresses using wildcard masks:
 Switch(config-ipv6-acl)#permit 1:2::3 FF:0:FFFF:AA:20:: 4:5::6 0:FFFF:2233::FFFF

Here the permit entry allows all packets that have a source UDP port, and specifies the permit conditions for a destination IPv6 addresses using prefix/ prefix-length:

```
Switch(config-ipv6-acl)#permit udp any 3:8::5/64
```

Here the permit entry allows all packets that have a source TCP port and the IPv6 addresses (that has been specified using a wildcard mask), and allows destination addresses that have IPv6 prefix ::/0.

```
Switch(config-ipv6-acl)#permit tcp 1:2::3 FFFF:FFFF:: any
```

Here the permit entry allows all packets (source and destination) that have IPv6 prefix ::/0. This is necessary because an implicit deny -all condition is at the end of each IPv6 access list.

```
Switch(config-ipv6-acl)#permit any any
```

To enable hardware statistics, enter the following commands while configuring ACEs in the access list:

```
Switch(config)# ipv6 access-list v6test
Switch(config-ipv6-acl)# hardware statistics
Switch(config-ipv6-acl)# end
```

Note

Hardware statistics is disabled by default.

Applying IPv6 ACLs to Layer 2 and 3 Interface

To apply an IPv6 ACL to a Layer 3 interface, perform the following task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-type slot/interface</i>	Specifies the interface to be configured. Note <i>interface-type</i> must be a Layer 3 interface.
Step 3	Switch(config-if)# ipv6 traffic-filter <i>ipv6-acl {in out}</i>	Applies the IPv6 ACL to a Layer 3 interface.

Note

IPv6 ACLs are supported on Layer 3 interfaces and on Layer 2 ports using the **ipv6 traffic-filter** command.

The following example applies the extended-named IPv6 ACL simple-ipv6-acl to SVI 300 routed ingress traffic:

```
Switch# configure terminal
Switch(config)# interface vlan 300
Switch(config-if)# ipv6 traffic-filter simple-ipv6-acl in
```

**Note**

Output IPv6 ACLs with ACE to match on the ICMP option fail on a switch.

The following conditions may cause a RACL to malfunction (no workaround):

- ACLs are applied on the output direction of the interface.
- IPv6 ACL contain Ace to match on the ICMP option fields (ICMP Type or ICMP Code).

The following examples of nonfunctioning RACLs:

```
IPv6 access list a1
  permit icmp any any nd-ns sequence 10
  deny ipv6 any any sequence 20

IPv6 access list a2
  permit icmp 2020::/96 any nd-ns sequence 10
  deny ipv6 any any sequence 20
```

Configuring VLAN Maps

This section includes these topics:

- [VLAN Map Configuration Guidelines, page 62-22](#)
- [Creating and Deleting VLAN Maps, page 62-22](#)
- [Applying a VLAN Map to a VLAN, page 62-25](#)
- [Using VLAN Maps in Your Network, page 62-25](#)

This section describes how to configure VLAN maps, which is the only way to control filtering within a VLAN. VLAN maps have no direction. To filter traffic in a specific direction by using a VLAN map, you need to include an ACL with specific source or destination addresses. If there is a match clause for that type of packet (IP or MAC) in the VLAN map, the default action is to drop the packet if the packet does not match any of the entries within the map. If there is no match clause for that type of packet, the default is to forward the packet.

To create a VLAN map and apply it to one or more VLANs, follow these steps:

Step 1 Create the standard or extended IP ACLs or named MAC extended ACLs that you want to apply to the VLAN.

Step 2 Enter the **vlan access-map** global configuration command to create a VLAN ACL map entry.

In access map configuration mode, you have the option to enter an **action** (**forward** [the default] or **drop**) and enter the **match** command to specify an IP packet or a non-IP packet and to match the packet against one or more ACLs (standard or extended). If a match clause is not specified, the action is applied to all packets. The match clause can be used to match against multiple ACLs. If a packet matches any of the specified ACLs, the action is applied.

**Note**

If the VLAN map has a match clause for the type of packet (IP or MAC) and the packet does not match the type, the default is to drop the packet. If there is no match clause in the VLAN map for that type of packet, and no action specified, the packet is forwarded.

Step 3 Use the **vlan filter** global configuration command to apply a VLAN map to one or more VLANs.

**Note**

You cannot apply a VLAN map to a VLAN on a switch that has ACLs applied to Layer 2 interfaces (port ACLs).

VLAN Map Configuration Guidelines

When configuring VLAN maps, consider these guidelines:

- VLAN maps do not filter IPv4 ARP packets.
- If there is no router ACL configured to deny traffic on a routed VLAN interface (input or output), and no VLAN map configured, all traffic is permitted.
- Each VLAN map consists of a series of entries. The order of entries in a VLAN map is important. A packet that comes into the switch is tested against the first entry in the VLAN map. If it matches, the action specified for that part of the VLAN map is taken. If there is no match, the packet is tested against the next entry in the map.
- If the VLAN map has at least one match clause for the type of packet (IP or MAC) and the packet does not match any of these match clauses, the default is to drop the packet. If there is no match clause for that type of packet in the VLAN map, the default is to forward the packet.
- The system might take longer to boot if you have configured a very large number of ACLs.

Creating and Deleting VLAN Maps

Each VLAN map consists of an ordered series of entries. To create, add to, or delete a VLAN map entry, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# vlan access-map <i>name</i> [<i>number</i>]	Creates a VLAN map, and give it a name and (optionally) a number. The number is the sequence number of the entry within the map. When you create VLAN maps with the same name, numbers are assigned sequentially in increments of 10. When modifying or deleting maps, you can enter the number of the map entry that you want to modify or delete. This command enables access-map configuration mode.
Step 3	Switch(config-access-map)# action { drop forward }	(Optional) Sets the action for the map entry. The default is to forward.

	Command	Purpose
Step 4	Switch(config-access-map)# match { ip ipv6 mac } address { <i>name</i> <i>number</i> } [<i>name</i> <i>number</i>]	Matches the packet (using either the IP, IPv6, or MAC address) against one or more standard or extended access lists. Note that packets are matched only against access lists of the correct protocol type. IP packets are compared with standard or extended IP access lists. Non-IP packets are only compared with named MAC extended access lists. If a match clause is not specified, the action is taken on all packets.
Step 5	Switch(config-access-map)# end	Returns to global configuration mode.
Step 6	Switch(config)# show running-config	Displays the access list configuration.
Step 7	Switch(config)# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

You can use the **no vlan access-map** *name* global configuration command to delete a map. You can use the **no vlan access-map** *name number* global configuration command to delete a single sequence entry from within the map. You can use the **no action** access-map configuration command to enforce the default action, which is to forward.

VLAN maps do not use the specific **permit** or **deny** keywords. To deny a packet by using VLAN maps, create an ACL that would match the packet, and then set the action to drop. A permit in the ACL is the same as a match. A deny in the ACL means no match.

Examples of ACLs and VLAN Maps

These examples show how to create ACLs and VLAN maps for specific purposes.

Example 1

This example shows how to create an ACL and a VLAN map to deny a packet. In the first map, any packets that match the ip1 ACL (TCP packets) would be dropped. You first create the ip1 ACL to permit any TCP packet and no other packets. Because there is a match clause for IP packets in the VLAN map, the default action is to drop any IP packet that does not match any of the match clauses.

```
Switch(config)# ip access-list extended ip1
Switch(config-ext-nacl)# permit tcp any any
Switch(config-ext-nacl)# exit

Switch(config)# vlan access-map map_1 10
Switch(config-access-map)# match ip address ip1
Switch(config-access-map)# action drop
```

This example shows how to create a VLAN map to permit a packet. ACL ip2 permits UDP packets; and any packets that match the ip2 ACL are forwarded.

```
Switch(config)# ip access-list extended ip2
Switch(config-ext-nacl)# permit udp any any
Switch(config-ext-nacl)# exit
Switch(config)# vlan access-map map_1 20
Switch(config-access-map)# match ip address ip2
Switch(config-access-map)# action forward
```

In this map, any IP packets that did not match any of the previous ACLs (that is, packets that are not TCP packets or UDP packets) would get dropped.

Example 2

In this example, the VLAN map is configured to drop IP packets and to forward MAC packets by default. By applying standard ACL 101 and the extended named access lists **igmp-match** and **tcp-match**, the VLAN map is configured to do the following:

- Forward all UDP packets
- Drop all IGMP packets
- Forward all TCP packets
- Drop all other IP packets
- Forward all non-IP packets

```
Switch(config)# access-list 101 permit udp any any
Switch(config)# ip access-list extended igmp-match
Switch(config-ext-nacl)# permit igmp any any
Switch(config)# ip access-list extended tcp-match
Switch(config-ext-nacl)# permit tcp any any
Switch(config-ext-nacl)# exit
Switch(config)# vlan access-map drop-ip-default 10
Switch(config-access-map)# match ip address 101
Switch(config-access-map)# action forward
Switch(config-access-map)# exit
Switch(config)# vlan access-map drop-ip-default 20
Switch(config-access-map)# match ip address igmp-match
Switch(config-access-map)# action drop
Switch(config-access-map)# exit
Switch(config)# vlan access-map drop-ip-default 30
Switch(config-access-map)# match ip address tcp-match
Switch(config-access-map)# action forward
```

Example 3

In this example, the VLAN map is configured to drop MAC packets and forward IP packets by default. By applying MAC extended access lists, **good-hosts** and **good-protocols**, the VLAN map is configured to do the following:

- Forward MAC packets from hosts 0000.0c00.0111 and 0000.0c00.0211
- Forward MAC packets of DECnet or VINES (Virtual Integrated Network Service) protocol-family
- Drop all other non-IP packets
- Forward all IP packets

```
Switch(config)# mac access-list extended good-hosts
Switch(config-ext-nacl)# permit host 000.0c00.0111 any
Switch(config-ext-nacl)# permit host 000.0c00.0211 any
Switch(config-ext-nacl)# exit
Switch(config)# mac access-list extended good-protocols
Switch(config-ext-nacl)# permit any any protocol-family decnet
Switch(config-ext-nacl)# permit any any protocol-family vines
Switch(config-ext-nacl)# exit
Switch(config)# vlan access-map drop-mac-default 10
Switch(config-access-map)# match mac address good-hosts
Switch(config-access-map)# action forward
Switch(config-access-map)# exit
Switch(config)# vlan access-map drop-mac-default 20
Switch(config-access-map)# match mac address good-protocols
Switch(config-access-map)# action forward
```

Example 4

In this example, the VLAN map is configured to drop all packets (IP and non-IP). By applying access lists **tcp-match** and **good-hosts**, the VLAN map is configured to do the following:

- Forward all TCP packets
- Forward MAC packets from hosts 0000.0c00.0111 and 0000.0c00.0211
- Drop all other IP packets
- Drop all other MAC packets

```
Switch(config)# vlan access-map drop-all-default 10
Switch(config-access-map)# match ip address tcp-match
Switch(config-access-map)# action forward
Switch(config-access-map)# exit
Switch(config)# vlan access-map drop-all-default 20
Switch(config-access-map)# match mac address good-hosts
Switch(config-access-map)# action forward
```

Applying a VLAN Map to a VLAN

To apply a VLAN map to one or more VLANs, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# vlan filter <i>mapname</i> vlan-list <i>list</i>	Applies the VLAN map to one or more VLAN IDs. The list can be a single VLAN ID (22), a consecutive list (10-22), or a string of VLAN IDs (12, 22, 30). Spaces around comma, and dash, are optional.
Step 3	Switch(config)# show running-config	Displays the access list configuration.
Step 4	Switch(config)# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Note

You cannot apply a VLAN map to a VLAN on a switch that has ACLs applied to Layer 2 interfaces (port ACLs).

This example shows how to apply VLAN map 1 to VLANs 20 through 22:

```
Switch(config)# vlan filter map 1 vlan-list 20-22
```

Using VLAN Maps in Your Network

Figure 62-3 shows a typical wiring closet configuration. Host X and Host Y are in different VLANs, connected to wiring closet switches A and C. Traffic moving from Host X to Host Y is routed by Switch B. Access to traffic moving from Host X to Host Y can be controlled at the entry point of Switch A. In the following configuration, the switch can support a VLAN map and a QoS classification ACL.

Figure 62-3 Wiring Closet Configuration

For example, if you do not want HTTP traffic to be switched from Host X to Host Y, you could apply a VLAN map on Switch A to drop all HTTP traffic moving from Host X (IP address 10.1.1.32) to Host Y (IP address 10.1.1.34) at Switch A and not bridge the traffic to Switch B. To configure this scenario, you would do the following.

First, define an IP access list HTTP to permit (match) any TCP traffic on the HTTP port, as follows:

```
Switch(config)# ip access-list extended http
Switch(config-ext-nacl)# permit tcp host 10.1.1.32 host 10.1.1.34 eq www
Switch(config-ext-nacl)# exit
```

Next, create a VLAN access map named map2 so that traffic that matches the HTTP access list is dropped and all other IP traffic is forwarded, as follows:

```
Switch(config)# vlan access-map map2 10
Switch(config-access-map)# match ip address http
Switch(config-access-map)# action drop
Switch(config-access-map)# exit

Switch(config)# ip access-list extended match_all
Switch(config-ext-nacl)# permit ip any any
Switch(config-ext-nacl)# exit
Switch(config)# vlan access-map map2 20
Switch(config-access-map)# match ip address match_all
Switch(config-access-map)# action forward
```

You then apply the VLAN access map named map2 to VLAN 1, as follows:

```
Switch(config)# vlan filter map2 vlan 1
```

Denying Access to a Server on Another VLAN

Figure 62-4 shows how to restrict access to a server on another VLAN. In this example, server 10.1.1.100 in VLAN 10 has the following access restrictions:

- Hosts in subnet 10.1.2.0/8 in VLAN 20 should not have access.
- Hosts 10.1.1.4 and 10.1.1.8 in VLAN 10 should not have access.

Figure 62-4 Deny Access to a Server on Another VLAN

This procedure configures ACLs with VLAN maps to deny access to a server on another VLAN. The VLAN map SERVER1_ACL denies access to hosts in subnet 10.1.2.0/8, host 10.1.1.4, and host 10.1.1.8. Then it permits all other IP traffic. In Step 3, VLAN map SERVER1 is applied to VLAN 10. To configure this scenario, follow these steps:

Step 1 Define the IP ACL to match and permit the correct packets.

```
Switch(config)# ip access-list extended SERVER1_ACL
Switch(config-ext-nacl)# permit ip 10.1.2.0 0.0.0.255 host 10.1.1.100
Switch(config-ext-nacl)# permit ip host 10.1.1.4 host 10.1.1.100
Switch(config-ext-nacl)# permit ip host 10.1.1.8 host 10.1.1.100
Switch(config-ext-nacl)# exit
```

Step 2 Define a VLAN map using the ACL to drop IP packets that match SERVER1_ACL and forward IP packets that do not match the ACL.

```
Switch(config)# vlan access-map SERVER1_MAP
Switch(config-access-map)# match ip address SERVER1_ACL
Switch(config-access-map)# action drop
Switch(config)# vlan access-map SERVER1_MAP 20
Switch(config-access-map)# action forward
Switch(config-access-map)# exit
```

Step 3 Apply the VLAN map to VLAN 10.

```
Switch(config)# vlan filter SERVER1_MAP vlan-list 10.
```

Displaying VLAN Access Map Information

To display information about VLAN access maps or VLAN filters, perform one of these commands:

Command	Purpose
Switch# show vlan access-map [<i>mapname</i>]	Shows information about all VLAN access maps or the specified access map.
Switch# show vlan filter [access-map <i>name</i> / vlan <i>vlan-id</i>]	Shows information about all VLAN filters or about a specified VLAN or VLAN access map.

it is a sample output of the **show vlan access-map** command:

```
Switch# show vlan access-map
Vlan access-map "map_1" 10
  Match clauses:
    ip address: ip1
  Action:
    drop
Vlan access-map "map_1" 20
  Match clauses:
    mac address: mac1
  Action:
    forward
Vlan access-map "map_1" 30
  Match clauses:
  Action:
    drop
```

Note

Sequence 30 does not have a match clause. All packets (IP as well as non-IP) are matched against it and dropped.

it is a sample output of the **show vlan filter** command:

```
Switch# show vlan filter
VLAN Map map_1 is filtering VLANs:
  20-22
```

Using VLAN Maps with Router ACLs

If the VLAN map has a match clause for a packet type (IP or MAC) and the packet does not match the type, the default is to drop the packet. If there is no match clause in the VLAN map, and no action is specified, the packet is forwarded if it does not match any VLAN map entry.

Note

You cannot combine VLAN maps or input router ACLs with port ACLs on a switch.

Topics include:

- [Guidelines for Using Router ACLs and VLAN Maps on the Same VLAN, page 62-29](#)
- [Examples of Router ACLs and VLAN Maps Applied to VLANs, page 62-29](#)

Guidelines for Using Router ACLs and VLAN Maps on the Same VLAN

Because the switch hardware performs one lookup for each direction (input and output), you must merge a router ACL and a VLAN map when they are configured on the same VLAN. Merging the router ACL with the VLAN map can significantly increase the number of ACEs.

When possible, try to write the ACL so that all entries have a single action except for the final, default action. You should write the ACL using one of these two forms:

```
permit...
permit...
permit...
deny ip any any
```

or

```
deny...
deny...
deny...
permit ip any any
```

To define multiple permit or deny actions in an ACL, group each action type together to reduce the number of entries.

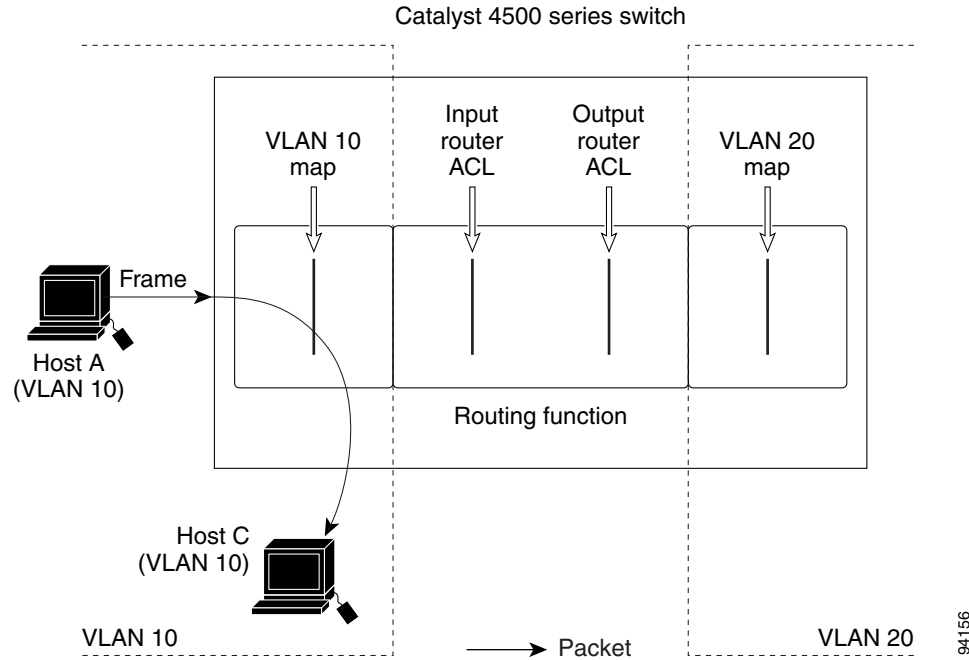

If you need to specify the full-flow mode and the ACL contains both IP ACEs and TCP/UDP/ICMP ACEs with Layer 4 information, put the Layer 4 ACEs at the end of the list. Doing this gives priority to the filtering of traffic based on IP addresses.

Examples of Router ACLs and VLAN Maps Applied to VLANs

These examples show how router ACLs and VLAN maps are applied on a VLAN to control the access of switched, bridged, routed, and multicast packets. Although the following illustrations show packets being forwarded to their destination, each time a packet crosses a line indicating a VLAN map or an ACL, the packet could be dropped rather than forwarded.

ACLs and Switched Packets

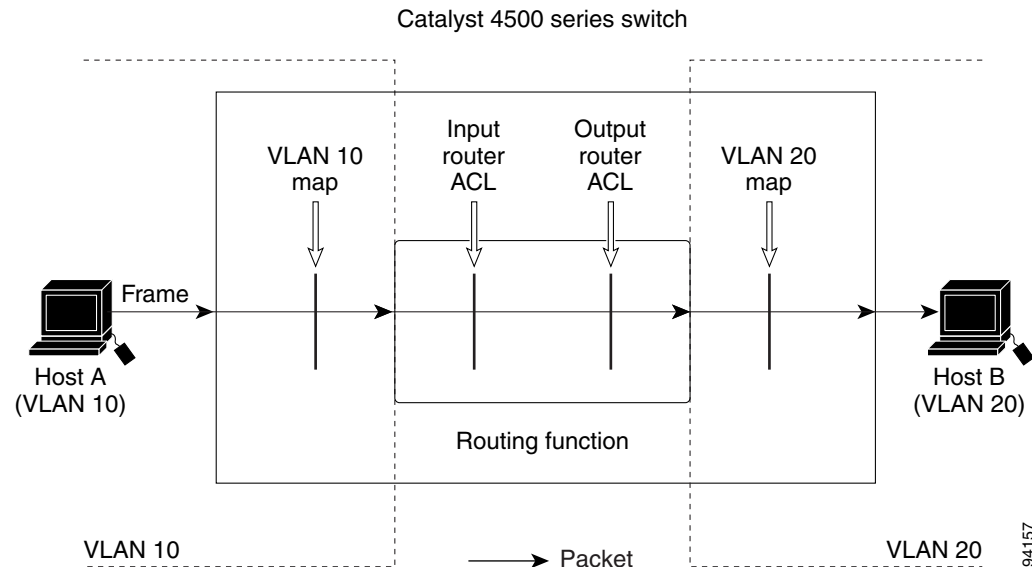

Figure 62-5 shows how an ACL processes packets that are switched within a VLAN. Packets switched within the VLAN are not processed by router ACLs.

Figure 62-5 Applying ACLs on Switched Packets

ACLs and Routed Packets

Figure 62-6 shows how ACLs are applied on routed packets. For routed packets, the ACLs are applied in this order:

1. VLAN map for input VLAN
2. Input router ACL
3. Output router ACL
4. VLAN map for output VLAN

Figure 62-6 Applying ACLs on Routed Packets

Configuring PACLS

This section describes how to configure PACLS, which are used to control filtering on Layer 2 interfaces. PACLS can filter traffic to or from Layer 2 interfaces based on Layer 3 information, Layer 4 head information or non-IP Layer 2 information.

This section includes these topics:

- [Creating a PACL, page 62-31](#)
- [PACL Configuration Guidelines, page 62-32](#)
- [Removing the Requirement for a Port ACL, page 62-32](#)
- [Webauth Fallback, page 62-33](#)
- [Configuring IPv4, IPv6, and MAC ACLs on a Layer 2 Interface, page 62-33](#)
- [Using PACL with Access-Group Mode, page 62-34](#)
- [Configuring Access-group Mode on Layer 2 Interface, page 62-35](#)
- [Applying ACLs to a Layer 2 Interface, page 62-35](#)
- [Displaying an ACL Configuration on a Layer 2 Interface, page 62-36](#)

Creating a PACL

To create a PACL and apply it to one or more interfaces, follow these steps:

- Step 1** Create the standard or extended IPv4 ACLs, IPv6 ACLs, or named MAC extended ACLs that you want to apply to the interface.

- Step 2** Use the `IP access-group`, `IPv6 traffic-filter`, or `mac access-group interface` command to apply IPv4, IPv6, or MAC ACLs to one or more Layer 2 interfaces.
-

PACL Configuration Guidelines

When configuring PACLS, consider these guidelines:

- There can be at most one IPv4, one IPv6, and one MAC access list applied to the same Layer 2 interface per direction.
- The IPv4 access list filters only IPv4 packets, the IPv6 access list filters only IPv6 packets, and the MAC access list filters only non-IP packets.
- The number of ACLs and ACEs that can be configured as part of a PACL are bounded by the hardware resources on the switch. Those hardware resources are shared by various ACL features (for example, RACL, VACL) that are configured on the system. If insufficient hardware resources to program PACL exist in hardware, the actions for input and output PACLS differ:
 - For input PACLS, some packets are sent to CPU for software forwarding.
 - For output PACLS, the PACL is disabled on the port.
- If insufficient hardware resources exist to program the PACL, the output PACL is not applied to the port, and you receive a warning message.
- The input ACL logging option is supported, although logging is not supported for output ACLs.
- The access group mode can change the way PACLS interact with other ACLs. To maintain consistent behavior across Cisco platforms, use the default access group mode.
- If a PACL is removed when there are active sessions on a port, a hole (permit ip any any) is installed on the port.

Removing the Requirement for a Port ACL

Prior to Cisco IOS Release 12.2(54)SG, a standard port ACL was necessary if you planned to download an ACL from a AAA server. This was because ACL infrastructure was insufficient to provide dynamic creation of access control entries without associating an ACL with the port.

Starting with Cisco IOS Release 12.2(54)SG, configuring a port ACL is not mandatory. If a port ACL is not configured on the port (by entering the `ip access-group number in` command), a default ACL (AUTH-DEFAULT-ACL) is attached automatically to the port when an ACL is downloaded. It allows only DHCP traffic and consists of the following ACEs:

```
permit udp any range bootps 65347 any range bootpc 65348
permit udp any any range bootps 65347
deny ip any any.
```

AUTH-DEFAULT-ACL is automatically created. To modify it, enter the following command:

```
ip access-list extended AUTH-DEFAULT-ACL
```

This ACL is not nvgened. AUTH-DEFAULT-ACL is attached provided there are sessions applying dynamic ACLs (Per-user/Filter-Id/DACL). AUTH-DEFAULT-ACL is removed when the last authenticated session with policies is cleared. It remains attached to the port provided at least one session is applying dynamic policies.

Configuration Restrictions

The following restrictions apply:

- Starting with Cisco IOS Release 12.2(54)SG, the port ACL does not require configuration; the default ACL is created automatically.
- Even if AUTH-DEFAULT-ACL is modified, it is not nvgened.

Debugging Considerations

Syslog messages appear when AUTH-DEFAULT-ACL is attached or detached from an interface provided you enter the **epm logging** command in configuration mode.

The following syslog displays when the default ACL is attached:

```
%EPM-6-AUTH_ACL: POLICY Auth-Default-ACL| EVENT CREATE-ATTACH-SUCCESS
```

The following syslog displays when the ACL is detached:

```
%EPM-6-AUTH_ACL: POLICY Auth-Default-ACL| EVENT DETACH-SUCCESS  
%EPM-6-AUTH_ACL: POLICY Auth-Default-ACL| EVENT DELETE-SUCCESS
```

Webauth Fallback

Many authentication methods require specific capabilities on the end-point device to respond to the network authenticating device with its identity or credentials. If the end-point lacks the required capability, the authenticator must fallback to alternative methods to gather host or user credentials. If the 802.1X/MAB authentication mechanism fails, a fallback to webauth might occur.

Prior to Cisco IOS Release 12.2(54)SG, webauth fallback implementation required a fallback profile configured on the authenticating device. As part of this profile, an admission rule must be configured along with the access policies (the fallback ACL).

Consider a situation where no port ACL is configured on a port. The first few hosts authenticated through 802.1X/MAB do not download any ACLs. All traffic from these hosts is allowed through. Now, suppose a host connects to the port, and there is a fallback to webauth to authenticate the host. The fallback ACL will be installed on the port, and traffic from previously authenticated hosts will also be restricted by this fallback ACL.

Starting with Cisco IOS Release 12.2(54)SG, Cisco uses a different approach to address this issue. When a host falls back to webauth for authentication, the ACE entries in the fallback ACL are converted into entries with Host IP insertion for a host that has fallen back and will be applied until the host authenticates. Once the host successfully authenticates, the fallback ACL is removed. The resultant host ACLs will be: dynamic ACLs and Port ACL/AUTH-DEFAULT-ACL. Refer to the previous section for an explanation of AUTH-DEFAULT -ACL.

Configuring IPv4, IPv6, and MAC ACLs on a Layer 2 Interface

Note

Only IPv4, IPv6 and MAC ACLs can be applied to Layer 2 physical interfaces.

Standard (numbered, named), Extended (numbered, named) IP ACLs, and Extended Named MAC ACLs are also supported.

To apply IPv4 or MAC ACLs on a Layer 2 interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface interface	Enters interface configuration mode.
Step 3	Switch(config-if)# [no] {ip mac} access-group {name number} {in out}	Applies numbered or named ACL to the Layer 2 interface. The no form deletes the IP or MAC ACL from the Layer 2 interface.
Step 4	Switch(config)# show running-config	Displays the access list configuration.

To apply IPv6 ACLs on a Layer 2 interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface interface	Enters interface configuration mode.
Step 3	Switch(config-if)# [no] ipv6 traffic-filter name {in out}	Applied the specified IPv6 ACL to the Layer 2 interface. The no form deletes the IPv6 ACL from the Layer 2 interface.
Step 4	Switch(config)# show running-config	Displays the access list configuration.

The following example shows how to configure the Extended Named IP ACL `simple-ip-acl` to permit all TCP traffic and implicitly deny all other IP traffic:

```
Switch(config)# interface Gi3/1
Switch(config-if)# ip access-list extended simple-ip-acl
Switch(config-ext-nacl)# permit tcp any any
Switch(config-ext-nacl)# end
```

The following example shows how to configure the Extended Named MACL `simple-mac-acl` to permit source host 000.000.011 to any destination host:

```
Switch(config)# interface Gi3/1
Switch(config-if)# mac access-list extended simple-mac-acl
Switch(config-ext-macl)# permit host 000.000.011 any
Switch(config-ext-macl)# end
```

Using PACL with Access-Group Mode

You can use the access group mode to change the way PACLS interact with other ACLs. For example, if a Layer 2 interface belongs to VLAN100, VACL (VLAN filter) V1 is applied on VLAN100, and PACL P1 is applied on the Layer 2 interface. In this situation, you must specify how P1 and V1 impact the traffic with the Layer 2 interface on VLAN100. In a per-interface method, you can use the **access-group mode** command to specify one of the following desired modes:

- **prefer port mode**—If PACL is configured on a Layer 2 interface, then PACL takes effect and overwrites the effect of other ACLs (Router ACL and VACL). If no PACL feature is configured on the Layer 2 interface, other features applicable to the interface are merged and applied on the interface. it is the default access group mode.

- prefer VLAN mode—VLAN-based ACL features take effect on the port if they have been applied on the port and no PACLs are in effect. If no VLAN-based ACL features are applicable to the Layer 2 interface, then the PACL feature already on the interface is applied.
- merge mode—Merges applicable ACL features before they are programmed into the hardware.

Configuring Access-group Mode on Layer 2 Interface

To configure an access mode on a Layer 2 interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface</i>	Enters interface configuration mode.
Step 3	Switch(config-if)# [no] access-group mode { prefer { port vlan } merge }	Applies numbered or named ACL to the Layer 2 interface. The no form deletes the IP or MAC ACL from the Layer 2 interface.
Step 4	Switch(config)# show running-config	Displays the access list configuration.

This example shows how to merge and apply features other than PACL on the interface:

```
Switch# configure terminal
Switch(config)# interface fast 6/1
Switch(config-if)# access-group mode prefer port
```

This example shows how to merge applicable ACL features before they are programmed into hardware:

```
Switch# configure terminal
Switch(config)# interface fast 6/1
Switch(config-if)# access-group mode merge
```

Applying ACLs to a Layer 2 Interface

To apply IPv4, IPv6, and MAC ACLs to a Layer 2 interface, perform one of these tasks:

Command	Purpose
Switch(config-if)# ip access-group <i>ip-acl</i> { in out }	Applies an IPv4 ACL to the Layer 2 interface.
Switch(config-if)# ipv6 traffic-filter <i>ipv6-acl</i> { in out }	Applies an IPv6 ACL to the Layer 2 interface.
Switch(config-if)# mac access-group <i>mac-acl</i> { in out }	Applies a MAC ACL to the Layer 2 interface.

This example applies the extended named IP ACL simple-ip-acl to interface FastEthernet 6/1 ingress traffic:

```
Switch# configure terminal
Switch(config)# interface fast 6/1
Switch(config-if)# ip access-group simple-ip-acl in
```

This example applies the IPv6 ACL simple-ipv6-acl to interface FastEthernet 6/1 ingress traffic:

```
Switch# configure terminal
Switch(config)# interface fast 6/1
Switch(config-if)# ipv6 traffic-filter simple-ipv6-acl in
```

This example applies the extended named MAC ACL `simple-mac-acl` to interface FastEthernet 6/1 egress traffic:

```
Switch# configure terminal
Switch(config)# interface fast 6/1
Switch(config-if)# mac access-group simple-mac-acl out
```

Displaying an ACL Configuration on a Layer 2 Interface

To display information about an ACL configuration on Layer 2 interfaces, perform one of these tasks:

Command	Purpose
Switch# show ip interface [<i>interface-name</i>]	Shows the IP access group configuration on the interface.
Switch# show mac access-group interface [<i>interface-name</i>]	Shows the MAC access group configuration on the interface.
Switch# show access-group mode interface [<i>interface-name</i>]	Shows the access group mode configuration on the interface.

This example shows that the IP access group `simple-ip-acl` is configured on the inbound direction of interface `fa6/1`:

```
Switch# show ip interface fast 6/1
FastEthernet6/1 is up, line protocol is up
  Inbound access list is simple-ip-acl
  Outgoing access list is not set
```

This example shows that MAC access group `simple-mac-acl` is configured on the inbound direction of interface `fa6/1`:

```
Switch# show mac access-group interface fast 6/1
Interface FastEthernet6/1:
  Inbound access-list is simple-mac-acl
  Outbound access-list is not set
```

This example shows that access group merge is configured on interface `fa6/1`:

```
Switch# show access-group mode interface fast 6/1
Interface FastEthernet6/1:
  Access group mode is: merge
```

Using PACL with VLAN Maps and Router ACLs

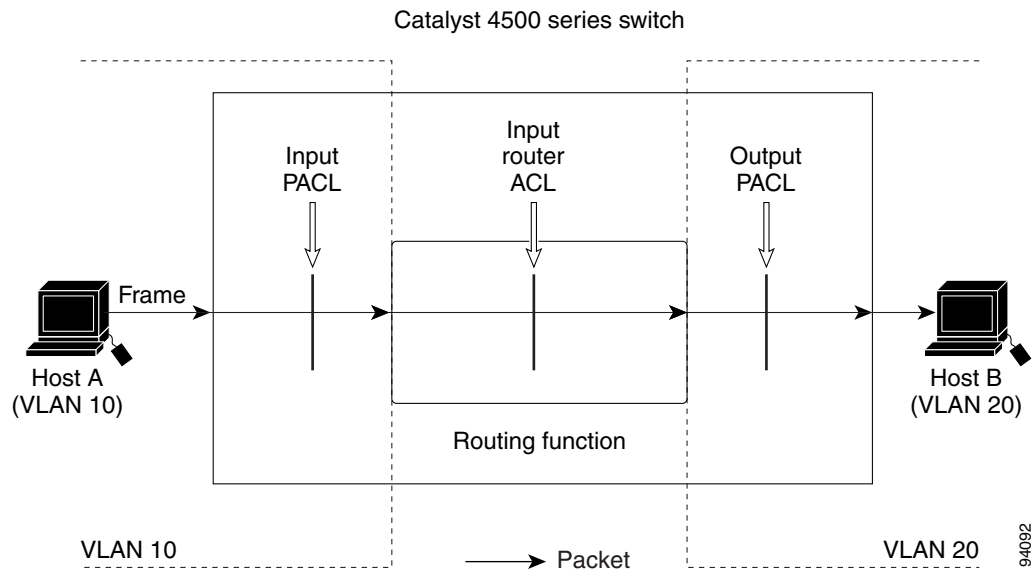

For PACLs, the interaction with Router ACLs and VACLs depends on the interface access group mode as shown in [Table 62-1](#).

Table 62-1 Interaction between PACLs, VACLs, and Router ACLs

ACL Type(s)	Input PACL		
	prefer port mode	prefer vlan mode	merge mode
1. Input Router ACL	PACL applied	Input Router ACL applied	PACL, Input Router ACL (merged) applied in order (ingress)
2. VACL	PACL applied	VACL applied	PACL, VACL (merged) applied in order (ingress)
3. VACL + Input Router ACL	PACL applied	VACL + Input Router ACL applied	PACL, VACL, Input Router ACL (merged) applied in order (ingress)

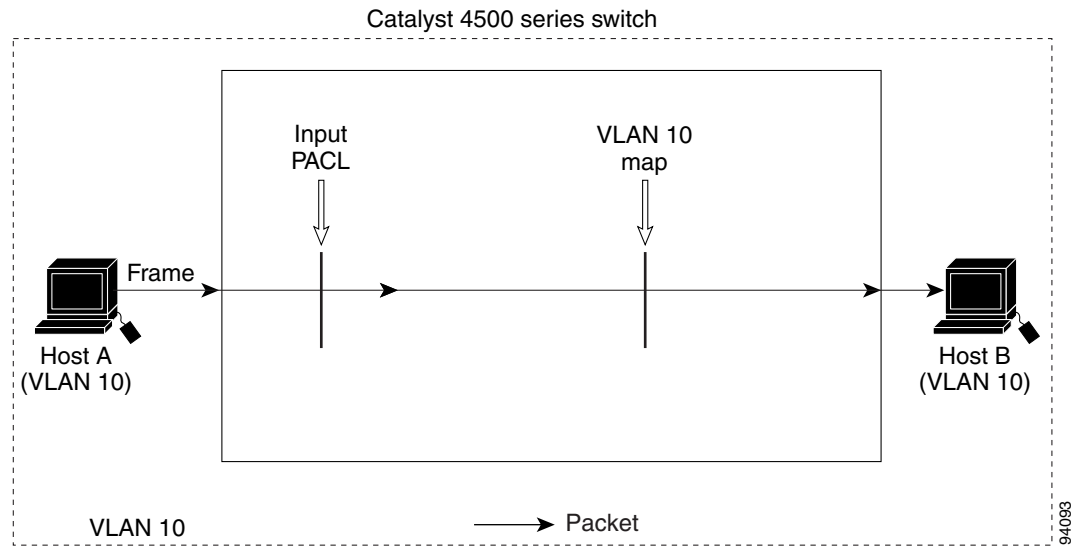

Each ACL type listed in [Table 62-1](#) corresponds with these scenarios:

Scenario 1: Host A is connected to an interface in VLAN 20, which has an SVI configured. The interface has input PACL configured, and the SVI has input Router ACL configured as shown in [Figure 62-7](#):

Figure 62-7 Scenario 1: PACL Interaction with an Input Router ACL

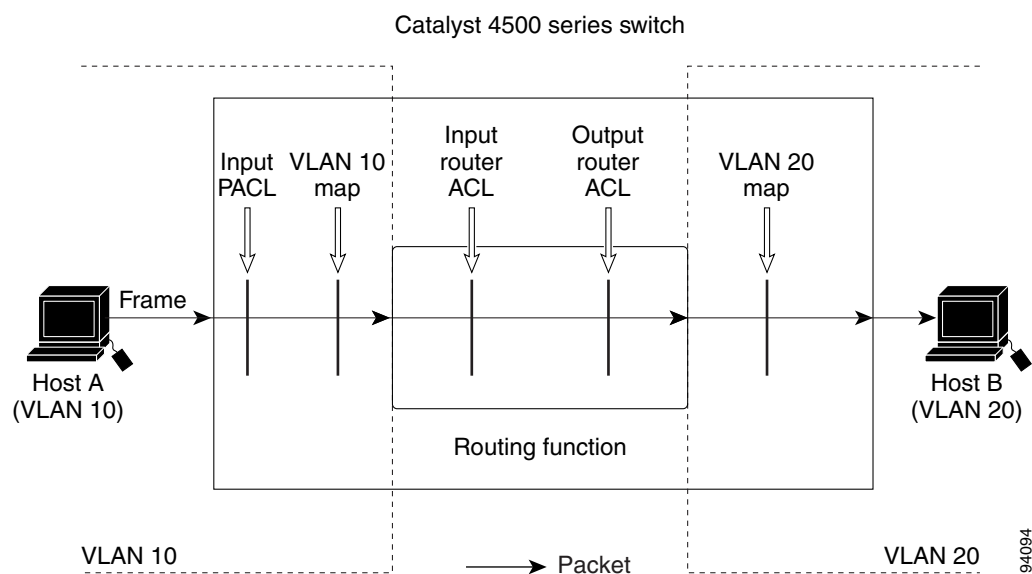

If the interface access group mode is prefer port, then only the input PACL is applied on the ingress traffic from Host A. If the mode is prefer VLAN, then only the input Router ACL is applied to ingress traffic from Host A that requires routing. If the mode is merge, then the input PACL is first applied to the ingress traffic from Host A, and the input Router ACL is applied on the traffic that requires routing.

Scenario 2: Host A is connected to an interface in VLAN 10, which has a VACL (VLAN Map) configured and an input PACL configured as shown in [Figure 62-8](#):

Figure 62-8 Scenario 2: PACL Interaction with a VACL

If the interface access group mode is prefer port, then only the input PACL is applied on the ingress traffic from Host A. If the mode is prefer VLAN, then only the VACL is applied to the ingress traffic from Host A. If the mode is merge, the input PACL is first applied to the ingress traffic from Host A, and the VACL is applied on the traffic.

Scenario 3: Host A is connected to an interface in VLAN 10, which has a VACL and an SVI configured. The SVI has an input Router ACL configured and the interface has an input PACL configured, as shown in Figure 62-9:

Figure 62-9 Scenario 3: VACL and Input Router ACL

If the interface access group mode is prefer port, then only the input PACL is applied on the ingress traffic from Host A. If the mode is prefer VLAN, then the merged results of the VACL and the input Router ACL are applied to the ingress traffic from Host A. If the mode is merge, the input PACL is first

applied to the ingress traffic from Host A, the VACL is applied on the traffic and finally, and the input Router ACL is applied to the traffic that needs routing. (that is, the merged results of the input PACL, VACL, and input Router ACL are applied to the traffic).

Configuring Object Group ACLs

Object groups provide an alternative way of dealing with ACLs.

Instead of allowing or disallowing individual IP addresses, protocols, and ports (which are used in conventional ACLs), you can use each ACE to allow or disallow an entire group of users to access a group of servers or services.

Object groups enable you to group ACE entries and add or remove entries while keeping your ACL structure more readable. Object group ACLs (OG ACLs) are especially suited to help you manage large ACLs that require frequent changing. Cisco IOS Firewall benefits from object groups, because they simplify policy creation (for example, group A has access to group A services).

Beginning with Cisco IOS XE Release 3.7.1E, object groups are supported for IPv4 ACLs (IPv4 OG ACLs), and with Cisco IOS XE Release 3.9.2E, for IPv6 ACLs (IPv6 OG ACLs).

The feature is supported only on Cisco Catalyst 4500E Series Switches with Supervisor Engine 9-E, 8-E, 7-LE, and 7-E, and Cisco Catalyst 4500-X Series Switches.

See the following sections for more information:

- [Overview, page 62-39](#)
- [Configuring IPv4 OG ACLs, page 62-40](#)
- [Configuring IPv6 OG ACLs, page 62-46](#)

Overview

All features that use or reference conventional ACLs are compatible with OG ACLs. This feature extends the conventional ACLs to support OG ACLs and also adds new keywords and the source and destination addresses and ports.

To configure OG ACLs, you first create one or more object groups. These can be any combination of network object groups or service object groups. You then create ACEs that apply a policy (such as permit or deny) to those object groups.

A network object group includes the following objects:

- Host IP addresses
- Network address of group members
- Nested object groups

A service object group includes the following objects:

- Source and destination protocol ports (such as Telnet or Simple Network Management Protocol [SNMP])
- Internet Control Message Protocol (ICMP) types (such as echo, echo-reply, or host-unreachable)
- Top-level protocols (such as Encapsulating Security Payload [ESP], TCP, or UDP)
- Other service object groups

You can configure an OG ACL multiple times with a source group only, a destination group only, or both source and destination groups.

You can add, delete, or change objects in an object group membership list dynamically (without deleting and redefining the object group), and without redefining the ACL ACE that uses the object group.

When you add a member to a group, delete a member from a group, or modify the policy statements in an ACE that uses an access group, the system updates the ACEs in the TCAM. An ACE that is defined using a group name, is equivalent to multiple ACEs (one applied to each entry in the object group). The system expands the object group ACL ACEs into multiple Cisco IOS ACEs (one ACE for each entry in the group) and populates the ACEs in the TCAM. Therefore, the object group ACL feature reduces the number of entries you need to configure but does not reduce TCAM usage.

You cannot delete an object group that is used within an ACL or a class-based policy language (CPL) policy.

Configuring IPv4 OG ACLs

- [Guidelines and Restrictions for Configuring IPv4 OG ACLs, page 62-40](#)
- [Creating a Network Object Group, page 62-40](#)
- [Creating a Service Object Group, page 62-42](#)
- [Configuring an IPv4 OG ACL, page 62-43](#)
- [Applying an IPv4 OG ACL to an Interface, page 62-44](#)
- [Verifying IPv4 OG ACLs, page 62-45](#)

Guidelines and Restrictions for Configuring IPv4 OG ACLs

- The object groups can be used only in extended named and numbered ACLs.
- IPv4 OG ACLs support only Layer 3 interfaces (such as routed interfaces and VLAN interfaces). They do not support Layer 2 features such as VLAN ACLs (VACLs) or port ACLs (PACLs).
- IPv4 OG ACLs are not supported with IPsec.
- IPv4 OG ACLs are not supported on management interfaces, such as FastEthernet1, and on GRE tunnels.
- The maximum number of object group-based ACEs supported in an ACL is 2048.
- IPv4 OG ACEs are used only while processing hardware-switched packets.

ACL statements using object groups are ignored on those packets that are sent to the Route Processor, and such ACL statements are not used for filtering. To match such packets, regular ACEs (without object groups) need to be created in the same ACL.

Creating a Network Object Group

To create a network object group, perform this task:

	Command or Action	Purpose
Step 1	configure terminal Example: Switch# configure terminal	Enters global configuration mode.
Step 2	object-group network <i>object-group-name</i> Example: Switch(config)# object-group network my-network-object-group	Defines the object group name and enters network object-group configuration mode.
Step 3	description <i>description-text</i> Example: Switch(config-network-group)# description test engineers	(Optional) Specifies a description of the object group. You can use up to 200 characters.
Step 4	host {<i>host-address</i> <i>host-name</i>} Example: Switch(config-network-group)# host 209.165.200.237	(Optional) Specifies the IP address or name of a host. If you specify a host address, you must use an IPv4 address.
Step 5	network-address {/nn <i>network-mask</i>} Example: Switch(config-network-group)# 209.165.200.241 255.255.255.224	(Optional) Specifies a subnet object. You must specify an IPv4 address for the network address. The default network mask is 255.255.255.255.
Step 6	group-object <i>nested-object-group-name</i> Example: Switch(config-network-group)# group-object my-nested-object-group	(Optional) Specifies a nested (child) object group to be included in the current (parent) object group. The child object group type must match that of the parent (for example, if you are creating a network object group, you must specify another network object group as the child). You can use duplicated objects in an object group only by nesting group objects. For example, if object 1 is in both group A and group B, you can define a group C that includes both A and B. However, you cannot include a group object that causes the group hierarchy to become circular (for example, you cannot include group A in group B and then also include group B in group A). While you can have an unlimited number of nested levels we recommend a maximum of two levels.
Step 7	Repeat the steps until you have specified objects on which you want to base your object group.	—
Step 8	end Example: Switch(config-network-group)# end	Exits network object-group configuration mode and returns to privileged EXEC mode.

Creating a Service Object Group

	Command or Action	Purpose
Step 1	configure terminal Example: Switch# configure terminal	Enters global configuration mode.
Step 2	object-group service <i>object-group-name</i> Example: Switch(config)# object-group service my-service-object-group	Defines the object group name and enters network object-group configuration mode.
Step 3	description <i>description-text</i> Example: Switch(config-service-group)# description test engineers	(Optional) Specifies a description of the object group. You can use up to 200 characters.
Step 4	<i>protocol</i> Example: Switch(config-service-group)# ahp	(Optional) Specifies an IP protocol number or name.
Step 5	{tcp udp tcp-udp} [source {[eq] lt gt} port1 range port1 port2}] [[eq] lt gt] port1 range port1 port2] Example: Switch(config-service-group)# tcp-udp range 2000 2005	(Optional) Specifies TCP, UDP, or both.
Step 6	icmp <i>icmp-type</i> Example: Switch(config-service-group)# icmp conversion-error	(Optional) Specifies the decimal number or name of an Internet Control Message Protocol (ICMP) type.

	Command or Action	Purpose
Step 7	group-object <i>nested-object-group-name</i> Example: Switch(config-service-group)# group-object my-nested-object-group	(Optional) Specifies a nested (child) object group to be included in the current (parent) object group. The child object group type must match that of the parent (for example, if you are creating a network object group, you must specify another network object group as the child). You can use duplicate objects in an object group only by nesting group objects. For example, if object 1 is in both group A and group B, you can define a group C that includes both A and B. However, you cannot include a group object that causes the group hierarchy to become circular (for example, you cannot include group A in group B and then also include group B in group A). While you can have an unlimited number of nested levels we recommend a maximum of two levels.
Step 8	Repeat the steps until you have specified objects on which you want to base your object group.	—
Step 9	end Example: Switch(config-network-group)# end	Exits network object-group configuration mode and returns to privileged EXEC mode.

Configuring an IPv4 OG ACL

When creating an object group ACL, configure an ACL that references one or more object groups. As with conventional ACLs, you can associate the same access policy with one or more interfaces.

You can define multiple ACEs that reference object groups within the same object group ACL. You can also reuse a specific object group in multiple ACEs. To create an object group ACL, perform the following task:

	Command or Action	Purpose
Step 1	configure terminal Example: Switch# configure terminal	Enters global configuration mode.
Step 2	ip access-list extended <i>access-list-name</i> Example: Switch(config)# ip access-list extended my-ogacl-policy	Defines an extended IP access list using a name and enters extended access-list configuration mode.

	Command or Action	Purpose
Step 3	remark <i>remark</i> Example: Switch(config-ext-nacl)# remark my-ogacl-policy is to provide the marketing network access to the server	(Optional) Adds a comment about the configured access list entry. A remark can precede or follow an access list entry. In this example, the remark reminds the network administrator that the subsequent entry denies the Marketing network access to the interface.
Step 4	permit <i>protocol source [source-wildcard] destination [destination-wildcard] [option option-name] [precedence precedence] [tos tos] [established] [log log-input] [time-range time-range-name] [fragments]</i> Example: Switch(config-ext-nacl)# permit object-group my-service-object-group object-group my-network-object-group any	Permits any packet that matches all conditions specified in the statement. Every access list needs at least one permit statement. Optionally use the object-group <i>service-object-group-name</i> keyword and argument as a substitute for the protocol. Optionally use the object-group <i>source-network-object-group-name</i> keyword and argument as a substitute for the source <i>source-wildcard</i> . Optionally use the object-group <i>destination-network-object-group-name</i> keyword and argument as a substitute for the destination <i>destination-wildcard</i> . If <i>source-wildcard</i> or <i>destination-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, which matches on all bits of the source or destination address, respectively. Optionally use the any keyword as a substitute for the source <i>source-wildcard</i> or destination <i>destination-wildcard</i> to specify the address and wildcard of 0.0.0.0 255.255.255.255. Use the log-input keyword to include input interface, source MAC address, or virtual circuit in the logging output.
Step 5	Repeat the steps to specify the fields and values on which you want to base your access list.	Remember that all sources not specifically permitted are denied by an implicit deny statement at the end of the access list.
Step 6	end Example: Device(config-ext-nacl)# end	Exits extended access-list configuration mode and returns to privileged EXEC mode.

Applying an IPv4 OG ACL to an Interface

An object group ACL can be used to control traffic on the interface it is applied to. To apply an object group ACL to an interface, perform the following task:

	Command or Action	Purpose
Step 1	configure terminal Example: Switch# configure terminal	Enters the global configuration mode.
Step 2	interface type number Example: Switch(config)# interface vlan 100	Specifies the interface and enters interface configuration mode.
Step 3	ip access-group {access-list-name access-list-number} {in out} Example: Switch(config-if)# ip access-group my-ogacl-policy in	Applies the ACL to the interface and specifies whether to filter inbound or outbound packets.
Step 4	end Example: Device(config-ext-nacl)# end	Exits interface configuration mode and returns to privileged EXEC mode.

Verifying IPv4 OG ACLs

Enter the **show object-group** *[object-group-name]* command, to display the configuration in the named or numbered object group (or in all object groups if no name is entered). For example:

```
Switch# show object-group
Network object group auth-proxy-acl-deny-dest
  host 209.165.200.235
Service object group auth-proxy-acl-deny-services
  tcp eq www
  tcp eq 443
Network object group auth-proxy-acl-permit-dest
  209.165.200.226 255.255.255.224
  209.165.200.227 255.255.255.224
  209.165.200.228 255.255.255.224
  209.165.200.229 255.255.255.224
  209.165.200.246 255.255.255.224
  209.165.200.230 255.255.255.224
  209.165.200.231 255.255.255.224
  209.165.200.232 255.255.255.224
  209.165.200.233 255.255.255.224
  209.165.200.234 255.255.255.224
Service object group auth-proxy-acl-permit-services
  tcp eq www
  tcp eq 443
```

Enter the **show ip access-list** *[access-list-name]* command, to display the contents of the named or numbered access list or object group ACL (or for all access lists and object group ACLs if no name is entered). For example:

```
Switch# show ip access-list my-ogacl-policy
Extended IP access list my-ogacl-policy
10 permit object-group my-service-object-group my-network-object-group any
```

Configuring IPv6 OG ACLs

- [Guidelines and Restrictions for Configuring IPv6 OG ACLs, page 62-46](#)
- [Creating a IPv6 Address Network Object Group, page 62-46](#)
- [Creating an IPv6 Service Object Group, page 62-47](#)
- [Configuring an IPv6 OG ACL, page 62-48](#)
- [Applying an IPv6 OG ACL to an Interface, page 62-49](#)
- [Verifying IPv6 OG ACLs, page 62-49](#)

Guidelines and Restrictions for Configuring IPv6 OG ACLs

- IPv6 OG ACLs are supported only on Layer 3 interfaces (such as routed interfaces and VLAN interfaces).
- Only Cisco IOS ACLs are supported. It is not supported with any other features. The **reflexive** and **evaluate** keywords are not supported.
- Only named extended Cisco IOS ACLs are supported. Numbered ACLs are not supported. As with regular ACEs, you can associate the same access policy with one or more interfaces.
- Feature interactions for IPv6 OG ACLs are the same as for Cisco IOS ACLs.
- The maximum number of object group-based ACEs supported in an IPv6 OG ACL is 2048.
- IPv6 OG ACEs are used only while processing hardware-switched packets.

ACL statements using object groups are ignored on those packets that are sent to the Route Processor, and such ACL statements are not used for filtering. To match such packets, regular ACEs (without object groups) need to be created in the same ACL.

Creating a IPv6 Address Network Object Group

To create an IPv6 address network object group, perform this task:

	Command or Action	Purpose
Step 1	configure terminal Example: Switch# configure terminal	Enters global configuration mode.
Step 2	object-group v6-network <i>object-group-name</i> Example: Switch(config)# object-group v6-network myOG	Defines the object group name and enters IPv6-address network object-group configuration mode.

	Command or Action	Purpose
Step 3	<p><code>{ ipv6-source-prefix ipv6-source-prefix description description-text exit group-object host { host-address host-name } no</code></p> <p>Example:</p> <pre>Switch(config-service-group)# description example of network object group Switch(config-v6network-group)# host 2001::1</pre>	<p>(Optional) Configures a member of the group and specifies a description of the object group.</p> <p>For the object group, you can configure a network address plus mask or a host (identified by host name or IPv6 address).</p>
Step 4	<p>Repeat the steps until you have specified all objects on which you want to base your object group.</p> <p>Example:</p> <pre>Switch(config-v6network-group)# 2002::1/64</pre>	—
Step 5	<p><code>{ end } { exit }</code></p> <p>Example:</p> <pre>Switch(config-network-group)# end</pre>	<p>To exit the configuration mode, enter the end command.</p> <p>To exit the IPv6-address object-group configuration mode, enter the exit command.</p>

Creating an IPv6 Service Object Group

To create an IPv6 service object group , perform this task:

	Command or Action	Purpose
Step 1	<p>configure terminal</p> <p>Example:</p> <pre>Switch# configure terminal</pre>	Enters global configuration mode.
Step 2	<p>object-group v6-service object-group-name</p> <p>Example:</p> <pre>Switch(config)# object-group v6-service mySG</pre>	Defines object group name and enters the service object-group configuration mode.
Step 3	<p><code>{ 0-255 ahp description description-text esp exit group-object hbh icmp ipv6 no pcp setp tcp tcp-udp udp }</code></p> <p>Example:</p> <pre>Switch(config-v6service-group)# description example of service object group Switch(config-v6service-group)# esp</pre>	<p>(Optional) Configures a member of the group and specifies a description of the object group.</p> <p>For the object group, you can configure a network address plus mask or a host (identified by host name or IPv6 address)</p>

	Command or Action	Purpose
Step 4	Repeat the steps until you have specified all objects on which you want to base your object group. Example: Switch(config-v6service-group)# ahp	—
Step 5	{ end } { exit } Example: Switch(config-v6service-group)# end	To exit the configuration mode, enter the end command. To exit the IPv6-address object-group configuration mode, enter the exit command.

Configuring an IPv6 OG ACL

	Command or Action	Purpose
Step 1	configure terminal Example: Switch# configure terminal	Enters global configuration mode.
Step 2	ipv6 access-list <i>access-list-name</i> Example: Switch(config)# ipv6 access-list example-ipv6-acl	Defines an OG ACL with the specified name and enters IPv6-ACL configuration mode.
Step 3	{ deny permit } { any proto object-group <i>service-object-group-name</i> } { host <i>ipv6-addr</i> <i>ipv6-prefix</i> <i>ipv6-addr</i> <i>ipv6-wildcard-bits</i> object-group <i>source-network-object-group-name</i> } { host <i>ipv6-addr</i> <i>ipv6-prefix</i> <i>ipv6-addr</i> <i>ipv6-wildcard-bits</i> object-group <i>dest-network-object-group-name</i> } Example: Switch(config-ext-nacl)# permit object-group mySG object-group myOG any sequence 10	(Optional) Permits any packet that matches all conditions specified in the statement. In this example, the service object group my SG, allows network object groups from myOG with any destination.
Step 4	Repeat the steps to specify the fields and values on which you want to base your access list.	Remember that all sources not specifically permitted are denied by an implicit deny statement at the end of the access list.
Step 5	{ end } { exit } Example: Switch(config-v6service-group)# end	To exit the configuration mode, enter the end command. To exit the IPv6-address object-group configuration mode, enter the exit command.

Applying an IPv6 OG ACL to an Interface

	Command or Action	Purpose
Step 1	configure terminal Example: Switch# configure terminal	Enters the global configuration mode.
Step 2	interface type / slot Example: Switch(config)# interface vlan 100	Specifies the interface and enters interface configuration mode. The interface-type must be a Layer 3 interface.
Step 3	ipv6 traffic-filter access-list-name {in out} Example: Switch(config-if)# ipv6 traffic-filter example-ipv6-acl in	Applies the ACL to the interface and specifies whether to filter inbound or outbound packets.
Step 4	end Example: Device(config-ext-nacl)# end	Exits interface configuration mode and returns to privileged EXEC mode.

Verifying IPv6 OG ACLs

Enter the **show ipv6 access-list [access-list-name]** command, to display the contents of the named access list or object group ACL (or for all access lists and object group ACLs if no name is entered). For example:

```
Switch# show ipv6 access-list example-ipv6-acl
IPv6 access list og-acl
permit object-group mySG object-group myOG any sequence 10
```

```
Switch# show ipv6 access-list example-ipv6-acl expanded
IPv6 access list og-acl
  permit tcp host 2001::1 any eq www sequence 10
  permit udp host 2001::1 any eq xdmcp sequence 10
  permit esp host 2001::1 any sequence 10
  permit hbh host 2001::1 any sequence 10
  permit tcp host 2002::1 any eq www sequence 10
  permit udp host 2002::1 any eq xdmcp sequence 10
  permit esp host 2002::1 any sequence 10
  permit hbh host 2002::1 any sequence 10
  permit tcp host 2003::1 any eq www sequence 10
  permit udp host 2003::1 any eq xdmcp sequence 10
  permit esp host 2003::1 any sequence 10
  permit hbh host 2003::1 any sequence 10
  permit tcp host 2001::255 any eq www sequence 10
  permit udp host 2001::255 any eq xdmcp sequence 10
  permit esp host 2001::255 any sequence 10
  permit hbh host 2001::255 any sequence 10
  permit tcp 2002::1/64 any eq www sequence 10
  permit udp 2002::1/64 any eq xdmcp sequence 10
  permit esp 2002::1/64 any sequence 10
  permit hbh 2002::1/64 any sequence 10
```

Configuring RA Guard

This section includes these topics:

- [Introduction, page 62-50](#)
- [Deployment, page 62-51](#)
- [Configuring RA Guard, page 62-51](#)
- [Examples, page 62-52](#)
- [Usage Guidelines, page 62-53](#)

Introduction

When deploying IPv6 networks, routers are configured to use IPv6 Router Advertisements to convey configuration information to hosts onlink. Router Advertisement is a critical part of the autoconfiguration process. The conveyed information includes the implied default router address obtained from the observed source address of the Router-Advertisement (RA) message. However, in some networks, invalid RAs are observed. This may happen because of misconfigurations or a malicious attacks on the network.

Devices acting as rogue routers may send illegitimate RAs. When using IPv6 within a single Layer 2 network segment, you can enable Layer 2 devices to drop rogue RAs before they reach end-nodes.

Beginning with Cisco IOS Release 54(SG)SG on Supervisor Engine 6-E (and 6L-E); Cisco IOS XE Release 3.3.0SG on Supervisor Engine 7-E; Cisco IOS XE Release 3.2.0XO on Supervisor Engine 7L-E, Cisco IOS XE Release 3.2.0XO on Supervisor Engine 8-E, and Cisco IOS XE Release 3.10.0E on Supervisor Engine 9-E, the Catalyst 4500 Series Switch supports RA Guard. This feature examines incoming Router-Advertisement and Router-Redirect packets and decides whether to switch or block them based solely on information found in the message and in the Layer 2 device configuration.

You can configure RA Guard in two modes (host and router) based on the device connected to the port.

- Host mode—All the Router-Advertisement and Router-Redirect messages are disallowed on the port.
- Router mode—All messages (RA/RS/Redirect) are allowed on the port; only host mode is supported.

You can configure Catalyst 4500 host ports to allow or disallow RA messages. Once a port is configured to disallow the Router-Advertisement and Router-Redirect packets, it filters the content of the received frames on that port and blocks Router-Advertisement or Router-Redirect frames.

When RA Guard is configured on a port, the following packets are dropped in hardware:

- Router-Advertisement packets —IPv6 ICMP packets with ICMP type = 134
- Router-Redirect packets—IPv6 ICMP packets with ICMP type = 137

Router Solicitation packets are sent out on the ports that are configured with RA Guard policy that defines the device role as a router.

Per port RA Guard ACL statistics are supported and displayed when you enter a **show ipv6 snooping counters interface** command. The statistics output displays the number of packets that have been dropped per port due to the RA Guard.

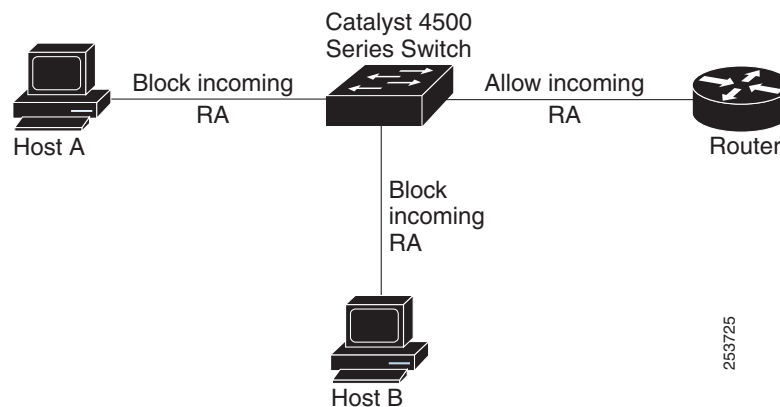

**Note**

Beginning with Cisco IOS Release 15.0(2)SG, per port RA Guard ACL statistics are supported and displayed when you enter a **show ipv6 snooping counters interface** command. (Previous to this release, you enter the **show ipv6 first-hop counters interface** command.)

Deployment

Figure 62-10 illustrates a deployment scenario for RA Guard. We drop RA packets from ports that are connected to hosts and permit RA packets from ports connected to the Router.

Figure 62-10 Typical RA Guard Deployment

Configuring RA Guard

To configure RA Guard, perform this step:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 1	Switch(config)# interface interface	Enters interface mode.
Step 2	Switch(config-if)# [no] ipv6 nd raguard	Enables RA Guard on the switch.
Step 3	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 4	Switch# show ipv6 nd raguard policy policy_name	Shows the policy on which RA Guard has been enabled.
		Note With Cisco Release IOS XE 3.4.0SG and IOS 15.1(2)SG, the show ipv6 nd raguard policy command replaces the show ipv6 first-hop policies command.

	Command	Purpose
Step 5	Switch# show ipv6 first-hop counters <i>interface</i>	Shows the number of packets dropped per port due to RA Guard. The counters can be displayed for a particular interface by using the <i>interface</i> option. Note If counters are not enabled for the port, the counter value is zero.
Step 6	Switch# clear ipv6 snooping counters <i>interface</i>	Clears RA Guard counters on a particular interface. The counters on all interfaces are cleared if the <i>interface</i> option is absent.

Examples

This examples shows how to enable RA Guard on the switch:

```
Switch(config)# int gi1/1
Switch(config-if)# ipv6 nd raguard
Switch(config-if)# end
Switch# show running-configuration interface gi1/1
```

Building configuration...

Current configuration : 53 bytes

!

```
interface GigabitEthernet1/1
```

```
    ipv6 nd raguard
```

```
end
```

The following example shows a sample output of the **show ipv6** commands:

```
Switch# show ipv6 snooping counters int gi 2/48
Received messages on gi 2/48 :
Protocol                Protocol message
NDP                      RS[9] RA[131] NS[7] NA[2]
DHCPv6                  SOL[24] ADV[2] REQ[1] REP[1]

Bridged messages from gi 2/48 :
Protocol                Protocol message
NDP                      RS[9] NS[7] NA[2]
DHCPv6                  SOL[24] ADV[1] REQ[1] REP[1]

Dropped messages on gi 2/48 :
Feature                Protocol Msg [Total dropped]
Snooping               NDP      RA  [131]
                        reason:  Packet not authorized on port [131]

                        NS   [2]
                        reason:  Packet accepted but not forwarded [2]

Switch#
```

Note

Beginning with Cisco IOS Release 15.0(2)SG, per port RA Guard ACL statistics are supported and displayed when you enter a **show ipv6 snooping counters** *interface* command. (Previous to this release, you enter the **show ipv6 first-hop counters** *interface* command.)

**Note**

Be aware that only RA (Router Advertisement) and REDIR (Router Redirected packets) counters are supported in 12.2(54)SG.

```
Switch# show ipv6 nd raguard policy RA_GUARD
Policy RA_GUARD configuration:
  device-role router
Policy RA_GUARD is applied on the following targets:
Target      Type  Policy      Feature      Target range
Gi 1/1      PORT RA_GUARD    RA guard     vlan all
```

Switch#

**Note**

With Cisco Release IOS XE 3.4.0SG and IOS 15.1(2)SG, the **show ipv6 nd raguard policy** command replaces the **show ipv6 first-hop policies** command.

Usage Guidelines

Observe the following restrictions:

- It is an ingress feature; only IPv6 Router-Advertisement and Router-Redirect packets entering through the port are filtered.
- RA Guard does not offer protection in environments where IPv6 traffic is tunneled.
- Starting with IOS XE 3.4.0SG/15.1(2)SG, RA Guard is supported in software. In prior releases, this Feature is supported only in hardware; packets are not punted to software except under resource exhaustion (for example, TCAM memory exhaustion).
- RA Guard is purely an Layer 2 port based feature and can be configured only on switchports. It works irrespective of whether IPv6 routing is enabled. It is supported on switchports and VLANs.
- RA Guard is supported on trunk ports and VLANs; filtering is performed on packets arriving from all the allowed VLANs.
- Starting with IOS XE 3.4.0SG/15.1(2)SG, RA Guard is not supported on EtherChannel. In prior releases, RA Guard is supported on EtherChannel; the RA Guard configuration (whether present or not) on the EtherChannel overrides the RA Guard configuration on the member ports.
- RA Guard is supported on ports that belong to PVLANS (for example, isolated secondary host ports, community secondary host ports, promiscuous primary host ports, (primary/secondary) trunk ports. Primary VLAN features are inherited and merged with port features.
- Starting with IOS XE 3.4.0SG/15.1(2)SG, RA Guard is supported on Supervisor Engine 8-E, 7-LE, and 7-E, 4500X-32, and 4500X-16 platforms. In prior releases, because of hardware limitations, it may not be possible for Supervisor Engine 6-E, Supervisor Engine 6L-E, Supervisor Engine 7-E and Supervisor Engine 7L-E to collect statistics for RA Guard in hardware. If so, an error message is displayed. Starting with Cisco IOS XE Release 3.10.0E, supported is extended to Supervisor Engine 9-E.

The **show ipv6 snooping counter** *interface* command displays the estimated counters.

**Note**

Beginning with Cisco IOS Release 15.0(2)SG, per port RA Guard ACL statistics are supported and displayed when you enter a **show ipv6 snooping counters** *interface* command. (Previous to this release, you enter the **show ipv6 first-hop counters** *interface* command.)

Configuring Authorization and Revocation of Certificates in a PKI

This module describes how to configure authorization and revocation of certificates in a public key infrastructure (PKI). It includes information on high-availability support for the certificate server.

Note

Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the Next Generation Encryption (NGE) white paper.

Prerequisites for Authorization and Revocation of Certificates

Plan Your PKI Strategy

Tip

It is strongly recommended that you plan your entire PKI strategy before you begin to deploy actual certificates.

Authorization and revocation can occur only after you or a network administrator have completed the following tasks:

- Configured the certificate authority (CA).
- Enrolled peer devices with the CA.
- Identified and configured the protocol (such as IP Security [IPsec] or secure socket layer [SSL]) that is to be used for peer-to-peer communication.

You should decide which authorization and revocation strategy you are going to configure before enrolling peer devices because the peer device certificates might have to contain authorization and revocation-specific information.

“crypto ca” to “crypto pki” CLI Change

As of Cisco IOS Release 12.3(7)T, all commands that begin as “crypto ca” have been changed to begin as “crypto pki.” Although the router will still accept crypto ca commands, all output will be read back as crypto pki.

High Availability

For high availability, IPsec-secured Stream Control Transmission Protocol (SCTP) must be configured on both the active and the standby routers. For synchronization to work, the redundancy mode on the certificate servers must be set to ACTIVE/STANDBY after you configure SCTP.

Restrictions for Authorization and Revocation of Certificates

PKI High Availability (HA) support of intra-chassis stateful switchover (SSO) redundancy is currently not supported on all switches running the Cisco IOS Release 12.2 S software. See Cisco bug CSCtb59872 for more information.

?Depending on your Cisco IOS release, Lightweight Directory Access Protocol (LDAP) is supported.

Information About Authorization and Revocation of Certificates

PKI Authorization

PKI authentication does not provide authorization. Current solutions for authorization are specific to the router that is being configured, although a centrally managed solution is often required.

There is not a standard mechanism by which certificates are defined as authorized for some tasks and not for others. This authorization information can be captured in the certificate itself if the application is aware of the certificate-based authorization information. But this solution does not provide a simple mechanism for real-time updates to the authorization information and forces each application to be aware of the specific authorization information embedded in the certificate.

When the certificate-based ACL mechanism is configured as part of the trustpoint authentication, the application is no longer responsible for determining this authorization information, and it is no longer possible to specify for which application the certificate is authorized. In some cases, the certificate-based ACL on the router gets so large that it cannot be managed. Additionally, it is beneficial to retrieve certificate-based ACL indications from an external server.

Current solutions to the real-time authorization problem involve specifying a new protocol and building a new server (with associated tasks, such as management and data distribution).

PKI and AAA Server Integration for Certificate Status

Integrating your PKI with an authentication, authorization, and accounting (AAA) server provides an alternative online certificate status solution that leverages the existing AAA infrastructure. Certificates can be listed in the AAA database with appropriate levels of authorization. For components that do not explicitly support PKI-AAA, a default label of “all” from the AAA server provides authorization. Likewise, a label of “none” from the AAA database indicates that the specified certificate is not valid. (The absence of any application label is equivalent, but “none” is included for completeness and clarity). If the application component does support PKI-AAA, the component may be specified directly; for example, the application component could be “ipsec”, “ssl”, or “ocsp.” (ipsec=IP Security, ssl=Secure Sockets Layer, and osp=Open Settlement Protocol.)

**Note**

Currently, no application component supports specification of the application label.

- There may be a time delay when accessing the AAA server. If the AAA server is not available, the authorization fails.

RADIUS or TACACS+ Choosing a AAA Server Protocol

The AAA server can be configured to work with either the RADIUS or TACACS+ protocol. When you are configuring the AAA server for the PKI integration, you must set the RADIUS or TACACS attributes that are required for authorization.

If the RADIUS protocol is used, the password that is configured for the username in the AAA server should be set to Cisco, which is acceptable because the certificate validation provides authentication and the AAA database is only being used for authorization. When the TACACS protocol is used, the password that is configured for the username in the AAA server is irrelevant because TACACS supports authorization without requiring authentication (the password is used for authentication).

In addition, if you are using TACACS, you must add a PKI service to the AAA server. The custom attribute “cert-application=all” is added under the PKI service for the particular user or usergroup to authorize the specific username.

Attribute-Value Pairs for PKI and AAA Server Integration

The table below lists the attribute-value (AV) pairs that are to be used when setting up PKI integration with a AAA server. (Note the values shown in the table are possible values.) The AV pairs must match the client configuration. If they do not match, the peer certificate is not authorized.

**Note**

Users can sometimes have AV pairs that are different from those of every other user. As a result, a unique username is required for each user. The **all** parameter (within the **authorization username** command) specifies that the entire subject name of the certificate will be used as the authorization username.

Table 63-1 AV Pairs that Must Match

AV Pair	Value
cisco-avpair=pki:cert-application=all	Valid values are “all” and “none.”
cisco-avpair=pki:cert-trustpoint=msca	<p>The value is a Cisco IOS command-line interface (CLI) configuration trustpoint label.</p> <div>  <p>Note The cert-trustpoint AV pair is normally optional. If it is specified, the Cisco IOS router query must be coming from a certificate trustpoint that has a matching label, and the certificate that is authenticated must have the specified certificate serial number.</p> </div>

Table 63-1 AV Pairs that Must Match

AV Pair	Value
cisco-avpair=pki:cert-serial=16318DB7000100001671	<p>The value is a certificate serial number.</p> <div>  Note </div> <p>The cert-serial AV pair is normally optional. If it is specified, the Cisco IOS router query must be coming from a certificate trustpoint that has a matching label, and the certificate that is authenticated must have the specified certificate serial number.</p>
cisco-avpair=pki:cert-lifetime-end=1:00 jan 1, 2003	<p>The cert-lifetime-end AV pair is available to artificially extend a certificate lifetime beyond the time period that is indicated in the certificate itself. If the cert-lifetime-end AV pair is used, the cert-trustpoint and cert-serial AV pairs must also be specified. The value must match the following form: hours:minutes month day, year.</p> <div>  Note </div> <p>Only the first three characters of a month are used: Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, Dec. If more than three characters are entered for the month, the remaining characters are ignored (for example Janxxxx).</p>

CRLs or OCSP Server Choosing a Certificate Revocation Mechanism

After a certificate is validated as a properly signed certificate, a certificate revocation method is performed to ensure that the certificate has not been revoked by the issuing CA. Cisco IOS software supports two revocation mechanisms--certificate revocation lists (CRLs) and Online Certificate Status Protocol (OCSP). Cisco IOS software also supports AAA integration for certificate checking; however, additional authorization functionality is included. For more information on PKI and AAA certificate authorization and status check, see the PKI and AAA Server Integration for Certificate Status section.

The following sections explain how each revocation mechanism works:

What Is a CRL

A certificate revocation list (CRL) is a list of revoked certificates. The CRL is created and digitally signed by the CA that originally issued the certificates. The CRL contains dates for when each certificate was issued and when it expires.

CAs publish new CRLs periodically or when a certificate for which the CA is responsible has been revoked. By default, a new CRL is downloaded after the currently cached CRL expires. An administrator may also configure the duration for which CRLs are cached in router memory or disable CRL caching completely. The CRL caching configuration applies to all CRLs associated with a trustpoint.

When the CRL expires, the router deletes it from its cache. A new CRL is downloaded when a certificate is presented for verification; however, if a newer version of the CRL that lists the certificate under examination is on the server but the router is still using the CRL in its cache, the router does not know that the certificate has been revoked. The certificate passes the revocation check even though it should have been denied.

When a CA issues a certificate, the CA can include in the certificate the CRL distribution point (CDP) for that certificate. Cisco IOS client devices use CDPs to locate and load the correct CRL. The Cisco IOS client supports multiple CDPs, but the Cisco IOS CA currently supports only one CDP; however, third-party vendor CAs may support multiple CDPs or different CDPs per certificate. If a CDP is not specified in the certificate, the client device uses the default Simple Certificate Enrollment Protocol (SCEP) method to retrieve the CRL. (The CDP location can be specified through the **cdp-url** command.)

When implementing CRLs, you should consider the following design considerations:

- CRL lifetimes and the security association (SA) and Internet Key Exchange (IKE) lifetimes.
- The CRL lifetime determines the length of time between CA-issued updates to the CRL. The default CRL lifetime value, which is 168 hours [1 week], can be changed through the **lifetime crl** command.
- The method of the CDP determines how the CRL is retrieved; some possible choices include HTTP, Lightweight Directory Access Protocol (LDAP), SCEP, or TFTP. HTTP, TFTP, and LDAP are the most commonly used methods. Although Cisco IOS software defaults to SCEP, an HTTP CDP is recommended for large installations using CRLs because HTTP can be made highly scalable.
- The location of the CDP determines from where the CRL is retrieved; for example, you can specify the server and file path from which to retrieve the CRL.

Querying All CDPs During Revocation Check

When a CDP server does not respond to a request, the Cisco IOS software reports an error, which may result in the peer's certificate being rejected. To prevent a possible certificate rejection and if there are multiple CDPs in a certificate, the Cisco IOS software will attempt to use the CDPs in the order in which they appear in the certificate. The router will attempt to retrieve a CRL using each CDP URL or directory specification. If an error occurs using a CDP, an attempt will be made using the next CDP.

Note

Prior to Cisco IOS Release 12.3(7)T, the Cisco IOS software makes only one attempt to retrieve the CRL, even when the certificate contains more than one CDP.

Tip

Although the Cisco IOS software will make every attempt to obtain the CRL from one of the indicated CDPs, it is recommended that you use an HTTP CDP server with high-speed redundant HTTP servers to avoid application timeouts because of slow CDP responses.

What Is OCSP

OCSP is an online mechanism that is used to determine certificate validity and provides the following flexibility as a revocation mechanism:

- OCSP can provide real-time certificate status checking.
- OCSP allows the network administrator to specify a central OCSP server, which can service all devices within a network.
- OCSP also allows the network administrator the flexibility to specify multiple OCSP servers, either per client certificate or per group of client certificates.
- OCSP server validation is usually based on the root CA certificate or a valid subordinate CA certificate, but may also be configured so that external CA certificates or self-signed certificates may be used. Using external CA certificates or self-signed certificates allows the OCSP servers certificate to be issued and validated from an alternative PKI hierarchy.

A network administrator can configure an OCSP server to collect and update CRLs from different CA servers. The devices within the network can rely on the OCSP server to check the certificate status without retrieving and caching each CRL for every peer. When peers have to check the revocation status of a certificate, they send a query to the OCSP server that includes the serial number of the certificate in question and an optional unique identifier for the OCSP request, or a nonce. The OCSP server holds a copy of the CRL to determine if the CA has listed the certificate as being revoked; the server then responds to the peer including the nonce. If the nonce in the response from the OCSP server does not match the original nonce sent by the peer, the response is considered invalid and certificate verification fails. The dialog between the OCSP server and the peer consumes less bandwidth than most CRL downloads.

If the OCSP server is using a CRL, CRL time limitations will be applicable; that is, a CRL that is still valid might be used by the OCSP server although a new CRL has been issued by the CRL containing additional certificate revocation information. Because fewer devices are downloading the CRL information on a regular basis, you can decrease the CRL lifetime value or configure the OCSP server not to cache the CRL. For more information, check your OCSP server documentation.

**Note**

OCSP multiple response handling: Support has been enabled for handling of multiple OCSP single responses from an OCSP responder in a response packet.

In addition to the debug log messages the following debug log message will be displayed:

CRYPTO_PKI: Number of single Responses in OCSP response:1 (this value can change depending upon the number of responses).

When to Use an OCSP Server

OCSP may be more appropriate than CRLs if your PKI has any of the following characteristics:

- Real-time certificate revocation status is necessary. CRLs are updated only periodically and the latest CRL may not always be cached by the client device. For example, if a client does not yet have the latest CRL cached and a newly revoked certificate is being checked, that revoked certificate will successfully pass the revocation check.
- There are a large number of revoked certificates or multiple CRLs. Caching a large CRL consumes large portions of Cisco IOS memory and may reduce resources available to other processes.
- CRLs expire frequently, causing the CDP to handle a larger load of CRLs.

**Note**

As of Cisco IOS Release 12.4(9)T or later, an administrator may configure CRL caching, either by disabling CRL caching completely or setting a maximum lifetime for a cached CRL per trustpoint.

When to Use Certificate-Based ACLs for Authorization or Revocation

Certificates contain several fields that are used to determine whether a device or user is authorized to perform a specified action.

Because certificate-based ACLs are configured on the device, they do not scale well for large numbers of ACLs; however, certificate-based ACLs do provide very granular control of specific device behavior. Certificate-based ACLs are also leveraged by additional features to help determine when PKI components such as revocation, authorization, or a trustpoint should be used. They provide a general mechanism allowing users to select a specific certificate or a group of certificates that are being validated for either authorization or additional processing.

Certificate-based ACLs specify one or more fields within the certificate and an acceptable value for each specified field. You can specify which fields within a certificate should be checked and which values those fields may or may not have.

There are six logical tests for comparing the field with the value--equal, not equal, contains, does not contain, less than, and greater than or equal. If more than one field is specified within a single certificate-based ACL, the tests of all of the fields within the ACL must succeed to match the ACL. The same field may be specified multiple times within the same ACL. More than one ACL may be specified, and ACL will be processed in turn until a match is found or all of the ACLs have been processed.

Ignore Revocation Checks Using a Certificate-Based ACL

Certificate-based ACLs can be configured to instruct your router to ignore the revocation check and expired certificates of a valid peer. Thus, a certificate that meets the specified criteria can be accepted regardless of the validity period of the certificate, or if the certificate meets the specified criteria, revocation checking does not have to be performed. You can also use a certificate-based ACL to ignore the revocation check when the communication with a AAA server is protected with a certificate.

Ignoring Revocation Lists

To allow a trustpoint to enforce CRLs except for specific certificates, enter the **match certificate** command with the **skip revocation-check** keyword. This type of enforcement is most useful in a hub-and-spoke configuration in which you also want to allow direct spoke-to-spoke connections. In pure hub-and-spoke configurations, all spokes connect only to the hub, so CRL checking is necessary only on the hub. For one spoke to communicate directly with another spoke, the **match certificate** command with the **skip revocation-check** keyword can be used for neighboring peer certificates instead of requiring a CRL on each spoke.

Ignoring Expired Certificates

To configure your router to ignore expired certificates, enter the **match certificate** command with the **allow expired-certificate** keyword. This command has the following purposes:

- If the certificate of a peer has expired, this command may be used to “allow” the expired certificate until the peer can obtain a new certificate.

- If your router clock has not yet been set to the correct time, the certificate of a peer will appear to be not yet valid until the clock is set. This command may be used to allow the certificate of the peer even though your router clock is not set.

**Note**

If Network Time Protocol (NTP) is available only via the IPsec connection (usually via the hub in a hub-and-spoke configuration), the router clock can never be set. The tunnel to the hub cannot be brought up because the certificate of the hub is not yet valid.

- "Expired" is a generic term for a certificate that is expired or that is not yet valid. The certificate has a start and end time. An expired certificate, for purposes of the ACL, is one for which the current time of the router is outside the start and end times specified in the certificate.

Skipping the AAA Check of the Certificate

If the communication with an AAA server is protected with a certificate, and you want to skip the AAA check of the certificate, use the **match certificate** command with the **skip authorization-check** keyword. For example, if a virtual private network (VPN) tunnel is configured so that all AAA traffic goes over that tunnel, and the tunnel is protected with a certificate, you can use the **match certificate** command with the **skip authorization-check** keyword to skip the certificate check so that the tunnel can be established.

The **match certificate** command and the **skip authorization-check** keyword should be configured after PKI integration with an AAA server is configured.

**Note**

If the AAA server is available only via an IPsec connection, the AAA server cannot be contacted until after the IPsec connection is established. The IPsec connection cannot be "brought up" because the certificate of the AAA server is not yet valid.

PKI Certificate Chain Validation

A certificate chain establishes a sequence of trusted certificates --from a peer certificate to the root CA certificate. Within a PKI hierarchy, all enrolled peers can validate the certificate of one another if the peers share a trusted root CA certificate or a common subordinate CA. Each CA corresponds to a trustpoint.

When a certificate chain is received from a peer, the default processing of a certificate chain path continues until the first trusted certificate, or trustpoint, is reached. In Cisco IOS Release 12.4(6)T and later releases, an administrator may configure the level to which a certificate chain is processed on all certificates including subordinate CA certificates.

Configuring the level to which a certificate chain is processed allows for the reauthentication of trusted certificates, the extension of a trusted certificate chain, and the completion of a certificate chain that contains a gap.

Reauthentication of Trusted Certificates

The default behavior is for the router to remove any trusted certificates from the certificate chain sent by the peer before the chain is validated. An administrator may configure certificate chain path processing so that the router does not remove CA certificates that are already trusted before chain validation, so that all certificates in the chain are re-authenticated for the current session.

Extending the Trusted Certificate Chain

The default behavior is for the router to use its trusted certificates to extend the certificate chain if there are any missing certificates in the certificate chain sent by the peer. The router will validate only certificates in the chain sent by the peer. An administrator may configure certificate chain path processing so that the certificates in the peer's certificate chain and the router's trusted certificates are validated to a specified point.

Completing Gaps in a Certificate Chain

An administrator may configure certificate chain processing so that if there is a gap in the configured Cisco IOS trustpoint hierarchy, certificates sent by the peer can be used to complete the set of certificates to be validated.

**Note**

If the trustpoint is configured to require parent validation and the peer does not provide the full certificate chain, the gap cannot be completed and the certificate chain is rejected and invalid.

**Note**

It is a configuration error if the trustpoint is configured to require parent validation and there is no parent trustpoint configured. The resulting certificate chain gap cannot be completed and the subordinate CA certificate cannot be validated. The certificate chain is invalid.

High-Availability Support

High-availability support for the certificate server is provided by:

- Synchronizing revoke commands with the standby certificate server.
- Sending serial-number commands when new certificates are issued.

This means that the standby certificate server is ready to issue certificates and certificate revocation lists (CRLs) if it becomes active.

Further high-availability support is provided by the following synchronizations with the standby:

- Certificate-server configuration.
- Pending requests.
- Grant and reject commands.
- For box-to-box high availability, which does not support configuration synchronization, a basic configuration synchronization mechanism is layered over a redundancy facility.
- Trustpoint configuration synchronization support.

How to Configure Authorization and Revocation of Certificates for Your PKI

Configuring PKI Integration with a AAA Server

Perform this task to generate a AAA username from the certificate presented by the peer and specify which fields within a certificate should be used to build the AAA database username.

The following restrictions should be considered when using the **all** keyword as the subject name for the **authorization username** command:

Some AAA servers limit the length of the username (for example, to 64 characters). As a result, the entire certificate subject name cannot be longer than the limitation of the server.

Some AAA servers limit the available character set that may be used for the username (for example, a space [] and an equal sign [=] may not be acceptable). You cannot use the **all** keyword for a AAA server having such a character-set limitation.

The **subject-name** command in the trustpoint configuration may not always be the final AAA subject name. If the fully qualified domain name (FQDN), serial number, or IP address of the router are included in a certificate request, the subject name field of the issued certificate will also have these components. To turn off the components, use the **fqdn**, **serial-number**, and **ip-address** commands with the **none** keyword.

CA servers sometimes change the requested subject name field when they issue a certificate. For example, CA servers of some vendors switch the relative distinguished names (RDNs) in the requested subject names to the following order: CN, OU, O, L, ST, and C. However, another CA server might append the configured LDAP directory root (for example, O=cisco.com) to the end of the requested subject name.

Depending on the tools you choose for displaying a certificate, the printed order of the RDNs in the subject name could be different. Cisco IOS software always displays the least significant RDN first, but other software, such as Open Source Secure Socket Layer (OpenSSL), does the opposite. Therefore, if you are configuring a AAA server with a full distinguished name (DN) (subject name) as the corresponding username, ensure that the Cisco IOS software style (that is, with the least significant RDN first) is used.

or

radius server host hostname [**key** string]

Note

Beginning with Cisco IOS XE Release 3.11.3aE, the legacy command **tacacs-server** is deprecated. Use the **tacacs server** command if the software running on your device is Cisco IOS XE Release 3.11.3aE or later releases.

	Command	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	aaa new-model Example: Router(config)# aaa new-model	Enables the AAA access control model.
Step 4	aaa authorization network <i>listname</i> [<i>method</i>] Example: Router (config)# aaa authorization network maxaaa group tacacs+	Sets the parameters that restrict user access to a network. ? <i>method</i> --Can be group radius , group tacacs+ , or group group-name .
Step 5	crypto pki trustpoint <i>name</i> Example: Route (config)# crypto pki trustpoint msca	Declares the trustpoint and a given name and enters ca-trustpoint configuration mode.

	Command	Purpose
Step 6	enrollment [mode] [retry period <i>minutes</i>] [retry count <i>number</i>] url <i>url</i> [pem] Example: <pre>Router (ca-trustpoint)# enrollment url http://caserver.myexample.com - or- Router (ca-trustpoint)# enrollment url http://[2001:DB8:1:1::1]:80</pre>	<p>Specifies the following enrollment parameters of the CA:</p> <p>(Optional) The mode keyword specifies the registration authority (RA) mode, if your CA system provides an RA. By default, RA mode is disabled.</p> <ul style="list-style-type: none"> • (Optional) The retry period keyword and minutes argument specifies the period, in minutes, in which the router waits before sending the CA another certificate request. Valid values are from 1 to 60. The default is 1. • (Optional) The retry count keyword and number argument specifies the number of times a router will resend a certificate request when it does not receive a response from the previous request. Valid values are from 1 to 100. The default is 10. • The url argument is the URL of the CA to which your router should send certificate requests. <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p> Note With the introduction of Cisco IOS Release 15.2(1)T, an IPv6 address can be added to the http: enrolment method. For example: http://[ipv6-address]:80. The IPv6 address must be enclosed in brackets in the URL. See the enrollment url (ca-trustpoint) command page for more information on the other enrollment methods that can be used.</p> </div> <ul style="list-style-type: none"> • (Optional) The pem keyword adds privacy-enhanced mail (PEM) boundaries to the certificate request.
Step 7	revocation-check <i>method</i> Example: <pre>Router (ca-trustpoint)# revocation-check crl</pre>	<p>(Optional) Checks the revocation status of a certificate.</p>
Step 8	exit Example: <pre>Router (ca-trustpoint)# exit</pre>	<p>Exits ca-trustpoint configuration mode and returns to global configuration mode.</p>

	Command	Purpose
Step 9	authorization username subjectname subjectname Example: Router (config)# authorization username subjectname serialnumber	Sets parameters for the different certificate fields that are used to build the AAA username. The <i>subjectname</i> argument can be any of the following: ? all --Entire distinguished name (subject name) of the certificate. ? commonname --Certification common name. ? country --Certificate country. • email --Certificate e-mail. ? ipaddress --Certificate IP address. ? locality --Certificate locality. ? organization --Certificate organization. ? organizationalunit --Certificate organizational unit. ? postalcode --Certificate postal code. ? serialnumber --Certificate serial number. ? state --Certificate state field. ? streetaddress --Certificate street address. ? title --Certificate title. ? unstructuredname --Certificate unstructured name.
Step 10	authorization list listname Example: Route (config)# authorization list maxaaa	Specifies the AAA authorization list.
Step 11	tacacs server servername Example: Router(config)# tacacs server newserver Router(config-tacacs-server)# key another_secret_key radius server host hostname [key string] Example: Router(config)# radius server host 192.0.2.1 key another_secret_key	Specifies a TACACS+ host. or Specifies a RADIUS host.

Troubleshooting Tips

To display debug messages for the trace of interaction (message type) between the CA and the router, use the debug crypto **pki transactions** command. (See the sample output, which shows a successful PKI integration with AAA server exchange and a failed PKI integration with AAA server exchange.)

Successful Exchange

```
Router# debug crypto pki transactions
Apr 22 23:15:03.695: CRYPTO_PKI: Found a issuer match
Apr 22 23:15:03.955: CRYPTO_PKI: cert revocation status unknown.
Apr 22 23:15:03.955: CRYPTO_PKI: Certificate validated without revocation check
Each line that shows "CRYPTO_PKI_AAA" indicates the state of the AAA authorization checks. Each
of the AAA AV pairs is indicated, and then the results of the authorization check are shown.

Apr 22 23:15:04.019: CRYPTO_PKI_AAA: checking AAA authorization (ipsecca_script_aalist,
PKIAAA-L, <all>)
Apr 22 23:15:04.503: CRYPTO_PKI_AAA: reply attribute ("cert-application" = "all")
Apr 22 23:15:04.503: CRYPTO_PKI_AAA: reply attribute ("cert-trustpoint" = "CA1")
Apr 22 23:15:04.503: CRYPTO_PKI_AAA: reply attribute ("cert-serial" = "15DE")
Apr 22 23:15:04.503: CRYPTO_PKI_AAA: authorization passed
Apr 22 23:12:30.327: CRYPTO_PKI: Found a issuer match
```

Failed Exchange

```
Router# debug crypto pki transactions
Apr 22 23:11:13.703: CRYPTO_PKI_AAA: checking AAA authorization =
Apr 22 23:11:14.203: CRYPTO_PKI_AAA: reply attribute ("cert-application" = "all")
Apr 22 23:11:14.203: CRYPTO_PKI_AAA: reply attribute ("cert-trustpoint" = "CA1")
Apr 22 23:11:14.203: CRYPTO_PKI_AAA: reply attribute ("cert-serial" = "233D")
Apr 22 23:11:14.203: CRYPTO_PKI_AAA: parsed cert-lifetime-end as: 21:30:00
Apr 22 23:11:14.203: CRYPTO_PKI_AAA: timezone specific extended
Apr 22 23:11:14.203: CRYPTO_PKI_AAA: cert-lifetime-end is expired
Apr 22 23:11:14.203: CRYPTO_PKI_AAA: cert-lifetime-end check failed.
Apr 22 23:11:14.203: CRYPTO_PKI_AAA: authorization failed
```

In the above failed exchange, the certificate has expired.

Configuring a Revocation Mechanism for PKI Certificate Status Checking

Perform this task to set up a CRL as the certificate revocation mechanism--CRLs or OCSP--that is used to check the status of certificates in a PKI.

The revocation-check Command

Use the **revocation-check** command to specify at least one method (OCSP, CRL, or skip the revocation check) that is to be used to ensure that the certificate of a peer has not been revoked. For multiple methods, the order in which the methods are applied is determined by the order specified via this command.

If your router does not have the applicable CRL and is unable to obtain one or if the OCSP server returns an error, your router will reject the peer's certificate--unless you include the **none** keyword in your configuration. If the **none** keyword is configured, a revocation check will not be performed and the certificate will always be accepted.

Nonces and Peer Communications with OCSP Servers

When using OCSP, nonces, unique identifiers for OCSP requests, are sent by default during peer communications with your OCSP server. The use of nonces offers a more secure and reliable communication channel between the peer and OCSP server.

If your OCSP server does not support nonces, you may disable the sending of nonces. For more information, check your OCSP server documentation.

Before You Begin

- Before issuing any client certificates, the appropriate settings on the server (such as setting the CDP) should be configured.
- When configuring an OCSP server to return the revocation status for a CA server, the OCSP server must be configured with an OCSP response signing certificate that is issued by that CA server. Ensure that the signing certificate is in the correct format, or the router will not accept the OCSP response. See your OCSP manual for additional information.

Note

OCSP transports messages over HTTP, so there may be a time delay when you access the OCSP server.

If the OCSP server depends on normal CRL processing to check revocation status, the same time delay that affects CRLs will also apply to OCSP.

Configuring a Revocation Mechanism for PKI Certificate Status Checking

	Command	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto pki trustpoint <i>name</i> Example: Router(config)# crypto pki trustpoint hazel	Declares the trustpoint and a given name and enters ca-trustpoint configuration mode.

	Command	Purpose
Step 4	ocsp url <i>url</i> Example: Router(ca-trustpoint)# ocsp url http://ocsp-server - or - Router(ca-trustpoint)# ocsp url http://10.10.10.1:80 - or - Router(ca-trustpoint)# ocsp url http://[2001DB8:1:1::2]:80	The <i>url</i> argument specifies the URL of an OCSP server so that the trustpoint can check the certificate status. This URL overrides the URL of the OCSP server (if one exists) in the Authority Info Access (AIA) extension of the certificate. All certificates associated with a configured trustpoint are checked by the OCSP server. The - or - URL can be a hostname, IPv4 address, or an IPv6 address.
Step 5	revocation-check <i>method1</i> [<i>method2</i> <i>method3</i>] Example: Router(ca-trustpoint)# revocation-check ocsp none	Checks the revocation status of a certificate. ? crl --Certificate checking is performed by a CRL. This is the default option. ? none --Certificate checking is ignored. ? ocsp --Certificate checking is performed by an OCSP server. If a second and third method are specified, each method will be used only if the previous method returns an error, such as a server being down.
Step 6	ocsp disable-nonce Example: Router(ca-trustpoint)# ocsp disable-nonce	(Optional) Specifies that a nonce, or an OCSP request unique identifier, will not be sent during peer communications with the OCSP server.
Step 7	exit Example: Router(ca-trustpoint)# exit	Returns to global configuration mode.
Step 8	exit Example: Router(config)# exit	Returns to privileged EXEC mode.
Step 9	show crypto pki certificates Example: Router# show crypto pki certificates	(Optional) Displays information about your certificates.
Step 10	show crypto pki trustpoints [<i>status</i> <i>label</i> [<i>status</i>]] Example: Router# show crypto pki trustpoints	Displays information about the trustpoint configured in router.

Configuring Certificate Authorization and Revocation Settings

Perform this task to specify a certificate-based ACL, to ignore revocation checks or expired certificates, to manually override the default CDP location, to manually override the OCSP server setting, to configure CRL caching, or to set session acceptance or rejection based on a certificate serial number, as appropriate.

Configuring Certificate-Based ACLs to Ignore Revocation Checks

To configure your router to use certificate-based ACLs to ignore revocation checks and expired certificates, perform the following steps:

- Identify an existing trustpoint or create a new trustpoint to be used when verifying the certificate of the peer. Authenticate the trustpoint if it has not already been authenticated. The router may enroll with this trustpoint if you want. Do not set optional CRLs for the trustpoint if you plan to use the **match certificate** command and **skip revocation-check** keyword.
- Determine the unique characteristics of the certificates that should not have their CRL checked and of the expired certificates that should be allowed.
- Define a certificate map to match the characteristics identified in the prior step.
- You can add the **match certificate** command and **skip revocation-check** keyword and the **match certificate** command and **allow expired-certificate** keyword to the trustpoint that was created or identified in the first step.

Note

Certificate maps are checked even if the peer's public key is cached. For example, when the public key is cached by the peer, and a certificate map is added to the trustpoint to ban a certificate, the certificate map is effective. This prevents a client with the banned certificate, which was once connected in the past, from reconnecting.

Manually Overriding CDPs in a Certificate

Users can override the CDPs in a certificate with a manually configured CDP. Manually overriding the CDPs in a certificate can be advantageous when a particular server is unavailable for an extended period of time. The certificate's CDPs can be replaced with a URL or directory specification without reissuing all of the certificates that contain the original CDP.

Manually Overriding the OCSP Server Setting in a Certificate

Administrators can override the OCSP server setting specified in the Authority Information Access (AIA) field of the client certificate or set by the issuing the **ocsp url** command. One or more OCSP servers may be manually specified, either per client certificate or per group of client certificates by the **match certificate override ocsp** command. The **match certificate override ocsp** command overrides the client certificate AIA field or the **ocsp url** command setting if a client certificate is successfully matched to a certificate map during the revocation check.

Note

Only one OCSP server can be specified per client certificate.

Configuring CRL Cache Control

By default, a new CRL will be downloaded after the currently cached CRL expires. Administrators can either configure the maximum amount of time in minutes a CRL remains in the cache by issuing the **crl cache delete-after** command or disable CRL caching by issuing the **crl cache none** command. Only the **crl-cache delete-after** command or the **crl-cache none** command may be specified. If both commands are entered for a trustpoint, the last command executed will take effect and a message will be displayed.

Neither the **crl-cache none** command nor the **crl-cache delete-after** command affects the currently cached CRL. If you configure the **crl-cache none** command, all CRLs downloaded after this command is issued will not be cached. If you configure the **crl-cache delete-after** command, the configured lifetime will only affect CRLs downloaded after this command is issued.

This functionality is useful is when a CA issues CRLs with no expiration date or with expiration dates days or weeks ahead.

Configuring Certificate Serial Number Session Control

A certificate serial number can be specified to allow a certificate validation request to be accepted or rejected by the trustpoint for a session. A session may be rejected, depending on certificate serial number session control, even if a certificate is still valid. Certificate serial number session control may be configured by using either a certificate map with the serial-number field or an AAA attribute, with the **cert-serial-not** command.

Using certificate maps for session control allows an administrator to specify a single certificate serial number. Using the AAA attribute allows an administrator to specify one or more certificate serial numbers for session control.

Before You Begin

- The trustpoint should be defined and authenticated before attaching certificate maps to the trustpoint.
- The certificate map must be configured before the CDP override feature can be enabled or the **serial-number** command is issued.
- The PKI and AAA server integration must be successfully completed to use AAA attributes as described in “PKI and AAA Server Integration for Certificate Status.”

	Command	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example: Router> enable	<ul style="list-style-type: none"> • Enter your password if prompted
Step 2	configure terminal	Enters global configuration mode.
	Example: Router# configure terminal	

Command	Purpose
Step 3 crypto pki certificate map label sequence-number Example: <pre>Router(config)# crypto pki certificate map Group 10</pre>	Defines values in a certificate that should be matched or not matched and enters ca-certificate-map configuration mode.
Step 4 <i>field-name match-criteria match-value</i> Example: <pre>Router(ca-certificate-map)# subject-name co MyExample</pre>	<p>Specifies one or more certificate fields together with their matching criteria and the value to match.</p> <p>The <i>field-name</i> is one of the following case-insensitive name strings or a date:</p> <ul style="list-style-type: none"> ? alt-subject-name ? expires-on ? issuer-name ? name ? serial-number ? subject-name ? unstructured-subject-name ? valid-start <p>Date field format is dd mm yyyy hh:mm:ss or mmm dd yyyy hh:mm:ss.</p> <div data-bbox="862 1066 911 1136">  Note </div> <div data-bbox="951 1108 1487 1598"> <p>The <i>match-criteria</i> is one of the following logical operators:</p> <ul style="list-style-type: none"> • co --contains (valid only for name fields and serial number field) • eq --equal (valid for name, serial number, and date fields) • ge --greater than or equal (valid only for date fields) • lt --less than (valid only for date fields) • nc --does not contain (valid only for name fields and serial number field) • ne --not equal (valid for name, serial number, and date fields) <p>The match-value is the name or date to test with the logical operator assigned by match-criteria.</p> </div> <div data-bbox="862 1629 911 1698">  Note </div> <div data-bbox="951 1671 1487 1812"> <p>Use this command only when setting up a certificate-based ACL--not when setting up a certificate-based ACL to ignore revocation checks or expired certificates.</p> </div>

	Command	Purpose
Step 5	exit Example: Router(ca-certificate-map)# exit	Returns to global configuration mode.
Step 6	crypto pki trustpoint <i>name</i> Example: Router(config)# crypto pki trustpoint Access2	Declares the trustpoint, given name and enters ca-trustpoint configuration mode.
Step 7	Do one of the following: <ul style="list-style-type: none"> crl-cache none crl-cache none <i>time</i> Example: Router(ca-trustpoint)# crl-cache none Example: Router(ca-trustpoint)# crl-cache delete-after 20	(Optional) Disables CRL caching completely for all CRLs associated with the trustpoint. The crl-cache none command does not affect any currently cached CRLs. All CRLs downloaded after this command is configured will not be cached. (Optional) Specifies the maximum time CRLs will remain in the cache for all CRLs associated with the trustpoint. ? <i>time</i> --The amount of time in minutes before the CRL is deleted. The crl-cache delete-after command does not affect any currently cached CRLs. The configured lifetime will only affect CRLs downloaded after this command is configured.
Step 8	match certificate <i>certificate-map-label</i> [allow expired-certificate skip revocation-check skip authorization-check Example: Router(ca-trustpoint)# match certificate Group skip revocation-check	(Optional) Associates the certificate-based ACL (that was defined via the crypto pki certificate map command) to a trustpoint. <i>certificate-map-label</i> --Must match the label argument specified via the crypto pki certificate map command. allow expired-certificate --Ignores expired certificates. skip revocation-check --Allows a trustpoint to enforce CRLs except for specific certificates. skip authorization-check --Skips the AAA check of a certificate when PKI integration with an AAA server is configured.

Command	Purpose
<p>Step 9</p> <p>match certificate <i>certificate-map-label</i> override cdp {<i>url</i> <i>directory</i>} <i>string</i></p> <p>Example:</p> <pre>Router(ca-trustpoint)# match certificate Group1 override cdp url http://server.cisco.com</pre>	<p>(Optional) Manually overrides the existing CDP entries for a certificate with a URL or directory specification.</p> <p><i>certificate-map-label</i> --A user-specified label that must match the label argument specified in a previously defined crypto pki certificate map command.</p> <ul style="list-style-type: none"> • url --Specifies that the certificate's CDPs will be overridden with an HTTP or LDAP URL. • directory --Specifies that the certificate's CDPs will be overridden with an LDAP directory specification. • <i>string</i> --The URL or directory specification. <div data-bbox="862 646 911 688"></div> <p>Note Some applications may time out before all CDPs have been tried and will report an error message. The error message will not affect the router, and the Cisco IOS software will continue attempting to retrieve a CRL until all CDPs have been tried.</p>
<p>Step 10</p> <p>match certificate <i>certificate-map-label</i> override oosp [<i>trustpoint trustpoint-label</i>] <i>sequence-number url oosp-url</i></p> <p>Example:</p> <pre>Router(ca-trustpoint)# match certificate mycertmapname override oosp trustpoint mytp 15 url http://192.0.2.2</pre>	<p>(Optional) Specifies an OOSP server, either per client certificate or per group of client certificates, and may be issued more than once to specify additional OOSP servers and client certificate settings including alternative PKI hierarchies.</p> <ul style="list-style-type: none"> • <i>certificate-map-label</i> --The name of an existing certificate map. • trustpoint --The trustpoint to be used when validating the OOSP server certificate. • <i>sequence-number</i> --The order the match certificate override oosp command statements apply to the certificate being verified. Matches are performed from the lowest sequence number to the highest sequence number. If more than one command is issued with the same sequence number, it overwrites the previous OOSP server override setting. • url --The URL of the OOSP server. <p>When the certificate matches a configured certificate map, the AIA field of the client certificate and any previously issued oosp url command settings are overwritten with the specified OOSP server.</p> <p>If no map-based match occurs, one of the following two cases will continue to apply to the client certificate.</p> <ul style="list-style-type: none"> • If OOSP is specified as the revocation method, the AIA field value will continue to apply to the client certificate. • If the oosp url configuration exists, the oosp url configuration settings will continue to apply to the client certificates.
<p>Step 11</p> <p>exit</p> <p>Example:</p> <pre>Router(ca-trustpoint)# exit</pre>	<p>Returns to global configuration mode.</p>

	Command	Purpose
Step 12	aaa new-model Example: Router(config)# aaa new-model	(Optional) Enables the AAA access control model.
Step 13	aaa attribute list list-name Example: Router(config)# aaa attribute list crl	(Optional) Defines an AAA attribute list locally on a router and enters config-attr-list configuration mode.
Step 14	attribute type {name} {value} Example: Router(config-attr-list)# attribute type cert-serial-not 6C4A	(Optional) Defines an AAA attribute type that is to be added to an AAA attribute list locally on a router. To configure certificate serial number session control, an administrator may specify a specific certificate in the value field to be accepted or rejected based on its serial number where name is set to cert-serial-not . If the serial number of the certificate matches the serial number specified by the attribute type setting, the certificate will be rejected. For a full list of available AAA attribute types, execute the show aaa attributes command.
Step 15	exit Example: Router(ca-trustpoint)# exit Example: Router(config-attr-list)# exit	Returns to global configuration mode.
Step 16	exit Example: Router(config)# exit	Returns to privileged EXEC mode.
Step 17	show crypto pki certificates Example: Router# show crypto pki certificates	(Optional) Displays the components of the certificates installed on the router if the CA certificate has been authenticated.

Example

The following is a sample certificate. The OCSP-related extensions are shown using exclamation points.

Certificate:

Data:

```

Version: v3
Serial Number:0x14
Signature Algorithm:SHAwithRSA - 1.2.840.113549.1.1.4
Issuer:CN=CA server,OU=PKI,O=Cisco Systems
Validity:
    Not Before:Thursday, August 8, 2002 4:38:05 PM PST
    Not After:Tuesday, August 7, 2003 4:38:05 PM PST
Subject:CN=OCSP server,OU=PKI,O=Cisco Systems

```

```

Subject Public Key Info:
  Algorithm:RSA - 1.2.840.113549.1.1.1
  Public Key:
    Exponent:65537
    Public Key Modulus:(2048 bits) :
      <snip>
Extensions:
  Identifier:Subject Key Identifier - 2.5.29.14
    Critical:no
    Key Identifier:
      <snip>
  Identifier:Authority Key Identifier - 2.5.29.35
    Critical:no
    Key Identifier:
      <snip>
!
  Identifier:OCSP NoCheck:- 1.3.6.1.5.5.7.48.1.5
    Critical:no
  Identifier:Extended Key Usage:- 2.5.29.37
    Critical:no
    Extended Key Usage:
      OCSPSigning
!

  Identifier:CRL Distribution Points - 2.5.29.31
    Critical:no
    Number of Points:1
    Point 0
      Distribution Point:
[URIName:ldap://CA-server/CN=CA server,OU=PKI,O=Cisco Systems]
  Signature:
    Algorithm:SHAwithRSA - 1.2.840.113549.1.1.4
  Signature:
    <snip>

```

The following example shows an excerpt of the running configuration output when adding a **match certificate override ocs** command to the beginning of an existing sequence:

```

match certificate map3 override ocs 5 url http://192.0.2.3/
show running-configuration
.
.
.
      match certificate map3 override ocs 5 url http://192.0.2.3/
      match certificate map1 override ocs 10 url http://192.0.2.1/
      match certificate map2 override ocs 15 url http://192.0.2.2/

```

The following example shows an excerpt of the running configuration output when an existing **match certificate override ocs** command is replaced and a trustpoint is specified to use an alternative PKI hierarchy:

```

match certificate map4 override ocs trustpoint tp4 10 url http://192.0.2.4/newvalue
show running-configuration
.
.
.
      match certificate map3 override ocs trustpoint tp3 5 url http://192.0.2.3/
      match certificate map1 override ocs trustpoint tp1 10 url http://192.0.2.1/
      match certificate map4 override ocs trustpoint tp4 10 url
http://192.0.2.4/newvalue
      match certificate map2 override ocs trustpoint tp2 15 url http://192.0.2.2/

```

Troubleshooting Tips

If you ignored revocation check or expired certificates, you should carefully check your configuration. Verify that the certificate map properly matches either the certificate or certificates that should be allowed or the AAA checks that should be skipped. In a controlled environment, try modifying the certificate map and determine what is not working as expected.

Configuring Certificate Chain Validation

Perform this task to configure the processing level for the certificate chain path of your peer certificates.

Before You Begin

- The device must be enrolled in your PKI hierarchy.
- The appropriate key pair must be associated with the certificate.

Note

A trustpoint associated with the root CA cannot be configured to be validated to the next level.

The **chain-validation** command is configured with the **continue** keyword for the trustpoint associated with the root CA, an error message will be displayed and the chain validation will revert to the default **chain-validation** command setting.

	Command	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto pki trustpoint <i>name</i> Example: Router(config)# crypto pki trustpoint ca-sub1	Declares the trustpoint and a given name and enters ca-trustpoint configuration mode.

	Command	Purpose
Step 4	chain-validation [{ stop continue } [<i>parent-trustpoint</i>]] Example: Router(ca-trustpoint)# chain-validation continue ca-sub1	Configures the level to which a certificate chain is processed on all certificates including subordinate CA certificates. Use the stop keyword to specify that the certificate is already trusted. This is the default setting. Use the continue keyword to specify that the subordinate CA certificate associated with the trustpoint must be validated. The <i>parent-trustpoint</i> argument specifies the name of the parent trustpoint the certificate must be validated against.
Step 5	exit Example: Router(ca-trustpoint)# exit	Returns to global configuration mode

Configuring Certificate Servers for High Availability

You can configure certificate servers to synchronize revoke commands and send serial-number commands when new certificates are issued, preparing the standby certificate server to issue certificates and CRLs if it becomes active.

Prerequisites

The following conditions must be met for high availability on certificate servers:

- IPsec-secured SCTP must be configured on both the active and the standby routers.
- For synchronization to work, the redundancy mode on the certificate servers must be set to ACTIVE/STANDBY after you configure SCTP.

This section contains the following subsections:.

Setting Redundancy Mode on Certificate Servers to ACTIVE STANDBY

Perform this task on the active router to enable synchronization by setting the redundancy mode on the certificate servers to ACTIVE/STANDBY.

	Command	Purpose
Step 1	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 2	redundancy inter-device Example: Router(config)# redundancy inter-device	Configures redundancy and enters interdevice configuration mode.
Step 3	scheme standby <i>standby-group-name</i> Example: Router(config-red-interdevice)# scheme standby SB	Defines the redundancy scheme that is to be used. <ul style="list-style-type: none"> The only supported scheme is “standby.” <i>standby-group-name</i> --Must match the standby name specified in the standby name interface configuration command. Also, the standby name must be the same on both routers.
Step 4	exit Example: Router(config-red-interdevice)# exit	Exits interdevice configuration mode and returns to global configuration mode.
Step 5	interface <i>interface-name</i> Example: Router(config) # interface gigabitethernet0/1	Configures an interface type for the router and enters interface configuration mode.
Step 6	ip address <i>ip-address mask</i> Example: Router(config-if) ip address 10.0.0.1 255.255.255.0	Sets the local IP address for the interface.
Step 7	no ip route-cache cef Example: Router(config-if)# no ip route cache cef	Disables Cisco Express Forwarding operation on the interface.
Step 8	no ip route-cache Example: Router(config-if)# no ip route cache	Disables fast switching on the interface.
Step 9	standby ip <i>ip-address</i> Example: Router(config-if)# standby ip 10.0.0.3	Activates the Hot Standby Router Protocol (HSRP), <div>  Note </div> Configure the same address on the active and the standby routers.

	Command	Purpose
Step 10	standby priority <i>priority</i> Example: Router(config-if)# standby priority 50	Sets the HSRP priority to 50. The priority range is from 1 to 255, where 1 denotes the lowest priority and 255 the highest. The router in the HSRP group with the highest priority value becomes the active router.
Step 11	standby name <i>group-name</i> Example: Router(config-if)# standby name SB	Configures the name of the standby group. <ul style="list-style-type: none">The name specifies the HSRP group used. The HSRP group name must be unique on the router.
Step 12	standby delay minimum [<i>min-seconds</i>] reload [<i>reload-seconds</i>] Example: Router(config-if)# standby delay minimum 30 reload 60	Sets a delay for HSRP group initialization as follows: <ul style="list-style-type: none">The minimum delay after the interface comes up before initializing the HSRP groups is 30 seconds.The delay after the router has reloaded is 60 seconds.
Step 13	Repeat Steps 1-12 on the standby router, configuring the interface with a different IP address from that of the interface on the active router (Step 6).	--
Step 14	exit Example: Router(config-if)# exit	Returns to global configuration mode.
Step 15	exit Example: Router(config)# exit	Returns to privileged EXEC mode.
Step 16	show redundancy states Example: Router# show redundancy states	(Optional) Verifies the redundancy states: standby or active.

Configuring SCTP on the Active and Standby Certificate Servers

Perform this task on the active router to configure SCTP on both the active and the standby certificate server.

	Command	Purpose
Step 1	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 2	ipc zone default Example: Switch(config)# ipc zone default	Configures the interdevice communication protocol, Inter-Process Communication (IPC), and enters IPC zone configuration mode. Use this command to initiate the communication link between the active router and the standby router.
Step 3	association association-ID	Configures an association between the two devices and enters IPC association configuration mode.
Step 4	no shutdown Example: Router(config-ipczone-assoc)# no shutdown	Ensures that the server association is in the default (enabled) state.
Step 5	protocol sctp Example: Router(config-ipczone-assoc)# protocol sctp	Configures SCTP as the transport protocol and enters SCTP protocol configuration mode.
Step 6	local-port local-port-number Example: Router(config-ipc-protocol-sctp)# local-port 5000	Defines the local SCTP port number that is used to communicate with the redundant peer and enters IPC transport SCTP local configuration mode. local-port-number --There is not a default value. This argument must be configured for the local port to enable interdevice redundancy. Valid port values: 1 to 65535. The local port numbers should be the same as the remote port number on the peer router.
Step 7	local-ip device-real-ip-address [device-real-ip-address2] Example: Router(config-ipc-local-sctp)# local-ip 10.0.0.1	Defines at least one local IP address that is used to communicate with the redundant peer. The local IP addresses must match the remote IP addresses on the peer router. There can be either one or two IP addresses, which must be in global VPN routing and forwarding (VRF). A virtual IP address cannot be used.
Step 8	exit Example: Router(config-ipc-local-sctp)# exit	Exits IPC transport - SCTP local configuration mode.

	Command	Purpose
Step 9	remote-port <i>remote-port-number</i> Example: Router(config-ipc-protocol-sctp)# remote-port 5000	Defines the remote SCTP port number that is used to communicate with the redundant peer and enters IPC transport SCTP remote configuration mode. Note remote-port-number --There is not a default value. This argument must be configured for the remote port to enable interdevice redundancy. Valid port values: 1 to 65535. The remote port number should be the same as the local port number on the peer router.
Step 10	remote-ip <i>peer-real-ip-address</i> Example: Router(config-ipc-remote-sctp)# remote-ip 10.0.0.2	Defines a remote IP address of the redundant peer that is used to communicate with the local device. All remote IP addresses must refer to the same device. A virtual IP address cannot be used.
Step 11	Repeat Steps 1 through 10 on the standby router, reversing the IP addresses of the local and remote peers specified in Steps 7 and 10.	The virtual IP address (10.0.0.3) will be the same on both routers.

Synchronizing the Active and Standby Certificate Servers

Perform this task to synchronize the active and standby servers.

	Command	Purpose
Step 1	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 2	crypto key generate rsa general-keys redundancy label <i>key-label</i> modulus <i>modulus-size</i> Example: Router (config)# crypto key generate rsa general-keys redundancy label HA modulus 2048	Generates an RSA key pair named HA for the certificate server.  Note Specifying the redundancy keyword means that the keys will be non-exportable.
Step 3	exit Example: Router(config)# exit	Returns to privileged EXEC mode.
Step 4	show crypto key mypubkey rsa Example: Router# show crypto key mypubkey rsa	Verifies that redundancy is enabled.

	Command	Purpose
Step 5	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 6	ip http server Example: Router(config)# ip http server	Enables the HTTP server on your system
Step 7	crypto pki server cs-label Example: Router(config)# crypto pki server HA	Specifies the RSA key pair generated in Step 2 as the label for the certificate server and enters certificate server configuration mode.
Step 8	redundancy Example: Router (cs-server)# redundancy	Ensures that the server is synchronized to the standby server
Step 9	no shutdown Example: Router(cs-server)# no shutdown	Enables the certificate server.

**Note**

If the router interface with the SCTP traffic is not secure, you should ensure that the SCTP traffic between the high-availability devices is secured with IPsec.

Configuration Examples for Setting Up Authorization and Revocation of Certificates

Configuring and Verifying PKI AAA Authorization Examples

This section provides configuration examples of PKI AAA authorizations:

Router Configuration Example

The following **show running-config** command output shows the working configuration of a router that is set up to authorize VPN connections using the PKI Integration with AAA Server feature:

```
Router# show running-config

Debugs of a Failed PKI AAA Authorization Example

The following **show debugging** command output shows that the router is not authorized to connect using VPN. The messages are typical of those that you might see in such a situation.

In this example, the peer username was configured as not authorized, by moving the username to a Cisco Secure ACS group called VPN_Router_Disabled in Cisco Secure ACS. The router, router7200.example.com, has been configured to check with a Cisco Secure ACS AAA server prior to establishing a VPN connection to any peer.

```

Router# show debugging
General OS:

Configuring a Revocation Mechanism Examples

This section contains the following configuration examples that can be used when specifying a revocation mechanism for your PKI:

Configuring an OCSP Server Example

The following example shows how to configure the router to use the OCSP server that is specified in the AIA extension of the certificate:

```
Router(config)# crypto pki trustpoint mytp
Router(ca-trustpoint)# revocation-check ocsp
```

Specifying a CRL and Then an OCSP Server Example

The following example shows how to configure the router to download the CRL from the CDP. If the CRL is unavailable, the OCSP server that is specified in the AIA extension of the certificate will be used. If both options fail, certificate verification will also fail.

```
Router(config)# crypto pki trustpoint mytp
Router(ca-trustpoint)# revocation-check crl ocsp
```

Specifying an OCSP Server Example

The following example shows how to configure your router to use the OCSP server at the HTTP URL “http://myocspserver:81.” If the server is down, the revocation check will be ignored.

```
Router(config)# crypto pki trustpoint mytp
Router(ca-trustpoint)# ocsp url http://myocspserver:81
Router(ca-trustpoint)# revocation-check ocsp none
```

Disabling Nonces in Communications with the OCSP Server Example

The following example shows communications when a nonce, or a unique identifier for the OCSP request, is disabled for communications with the OCSP server:

```
Router(config)# crypto pki trustpoint mytp
Router(ca-trustpoint)# ocsp url http://myocspserver:81
Router(ca-trustpoint)# revocation-check ocsp none
Router(ca-trustpoint)# ocsp disable-nonce
```

Configuring a Hub Router at a Central Site for Certificate Revocation Checks Example

The following example shows a hub router at a central site that is providing connectivity for several branch offices to the central site.

The branch offices are also able to communicate directly with each other using additional IPSec tunnels between the branch offices.

The CA publishes CRLs on an HTTP server at the central site. The central site checks CRLs for each peer when setting up an IPSec tunnel with that peer.

The example does not show the IPSec configuration--only the PKI-related configuration is shown.

Home Office Hub Configuration

```
crypto pki trustpoint VPN-GW
enrollment url http://ca.home-office.com:80/certsrv/mscep/mscep.dll
serial-number none
fqdn none
ip-address none
subject-name o=Home Office Inc,cn=Central VPN Gateway
revocation-check crl
```

Central Site Hub Router

```
Router# show crypto ca certificate
Certificate
Status: Available
Certificate Serial Number: 2F62BE1400000000CA0
Certificate Usage: General Purpose
Issuer:
cn=Central Certificate Authority o=Home Office Inc
Subject:
Name: Central VPN Gateway cn=Central VPN Gateway o=Home Office Inc
CRL Distribution Points:
  http://ca.home-office.com/CertEnroll/home-office.crl Validity Date:
start date: 00:43:26 GMT Sep 26 2003
end date: 00:53:26 GMT Sep 26 2004
  renew date: 00:00:00 GMT Jan 1 1970 Associated Trustpoints: VPN-GW
CACertificate Status: Available
Certificate Serial Number: 1244325DE0369880465F977A18F61CA8 Certificate Usage: Signature
Issuer:
cn=Central Certificate Authority o=Home Office Inc
Subject:
cn=Central Certificate Authority o=Home Office Inc
CRL Distribution Points:
  http://ca.home-office.com/CertEnroll/home-office.crl Validity Date:
start date: 22:19:29 GMT Oct 31 2002
  enddate: 22:27:27 GMT Oct 31 2017 Associated Trustpoints: VPN-GW
```

Trustpoint on the Branch Office Router

```
crypto pki trustpoint home-office
enrollment url http://ca.home-office.com:80/certsrv/mscep/mscep.dll serial-number none
fqdn none

ip-address none
subject-name o=Home Office Inc,cn=Branch 1 revocation-check crl
```

A certificate map is entered on the branch office router.

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
branch1(config)# crypto pki certificate map central-site 10
branch1(ca-certificate-map)#
```

The output from the **show certificate** command on the central site hub router shows that the certificate was issued by the following:

```
cn=Central Certificate Authority
o=Home Office Inc
```

These two lines are combined into one line using a comma (,) to separate them, and the original lines are added as the first criteria for a match.

```
Router (ca-certificate-map)# issuer-name co cn=Central Certificate Authority, ou=Home Office Inc
```

!The above line wrapped but should be shown on one line with the line above it.

The same combination is done for the subject name from the certificate on the central site router (note that the line that begins with ?ame:? is not part of the subject name and must be ignored when creating the certificate map criteria). This is the subject name to be used in the certificate map.

cn=Central VPN Gateway

o=Home Office Inc

```
Router (ca-certificate-map)# subject-name eq cn=central vpn gateway, o=home office inc
```

Now the certificate map is added to the trustpoint that was configured earlier.

```
Router (ca-certificate-map)# crypto pki trustpoint home-office
Router (ca-trustpoint)# match certificate central-site skip revocation-check
Router (ca-trustpoint)# exit
Router (config)# exit
```

The configuration is checked (most of configuration is not shown).

```
Router# write term
!Many lines left out
.
.
.
crypto pki trustpoint home-office
```

```
enrollment url http://ca.home-office.com:80/certsrv/mscep/mscep.dll serial-number none
fqdn none
ip-address none
subject-name o=Home Office Inc,cn=Branch 1 revocation-check crl
match certificate central-site skip revocation-check
!
!
crypto pki certificate map central-site 10
issuer-name co cn = Central Certificate Authority, ou = Home Office Inc subject-name eq cn
= central vpn gateway, o = home office inc
!many lines left out
```

Note that the issuer-name and subject-name lines have been reformatted to make them consistent for later matching with the certificate of the peer.

If the branch office is checking the AAA, the trustpoint will have lines similar to the following:

```
crypto pki trustpoint home-office auth list allow_list
auth user subj commonname
```

After the certificate map has been defined as was done above, the following command is added to the trustpoint to skip AAA checking for the central site hub.

```
match certificate central-site skip authorization-check
```

In both cases, the branch site router has to establish an IPSec tunnel to the central site to check CRLs or to contact the AAA server. However, without the **match certificate** command and **central-site skip authorization-check (argument and keyword)**, the branch office cannot establish the tunnel until it has checked the CRL or the AAA server. (The tunnel will not be established unless the **match certificate** command and **central-site skip authorization-check** argument and keyword are used.)

The **match certificate** command and **allow expired-certificate** keyword would be used at the central site if the router at a branch site had an expired certificate and it had to establish a tunnel to the central site to renew its certificate.

Trustpoint on the Central Site Router

```
crypto pki trustpoint VPN-GW
enrollment url http://ca.home-office.com:80/certsrv/mscep/mscep.dll
serial-number none
fqdn none
ip-address none
subject-name o=Home Office Inc,cn=Central VPN Gateway
revocation-check crl
```

Trustpoint on the Branch 1 Site Router

```
Router# show crypto ca certificate
Certificate
Status: Available
Certificate Serial Number: 2F62BE1400000000CA0 Certificate Usage: General Purpose
Issuer:
cn=Central Certificate Authority o=Home Office Inc
Subject:
Name: Branch 1 Site cn=Branch 1 Site o=Home Office Inc
CRL Distribution Points:
  http://ca.home-office.com/CertEnroll/home-office.crl Validity Date:
start date: 00:43:26 GMT Sep 26 2003
end date: 00:53:26 GMT Oct 3 2003
renew date: 00:00:00 GMT Jan 1 1970
Associated Trustpoints: home-office
CA Certificate
Status: Available
Certificate Serial Number: 1244325DE0369880465F977A18F61CA8
Certificate Usage: Signature
Issuer:
cn=Central Certificate Authority o=Home Office Inc
Subject:
cn=Central Certificate Authority o=Home Office Inc
CRL Distribution Points:
  http://ca.home-office.com/CertEnroll/home-office.crl
Validity Date:
start date: 22:19:29 GMT Oct 31 2002
end date: 22:27:27 GMT Oct 31 2017
Associated Trustpoints: home-office
A certificate map is entered on the central site router.
```

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router (config)# crypto pki certificate map branch1 10
Router (ca-certificate-map)# issuer-name co cn=Central Certificate Authority, ou=Home
Office Inc
```

!The above line wrapped but should be part of the line above it.
 Router (ca-certificate-map)# **subject-name eq cn=Brahcn 1 Site,o=home office inc**
 The certificate map is added to the trustpoint.

```
Router (ca-certificate-map)# crypto pki trustpoint VPN-GW
Router (ca-trustpoint)# match certificate branch1 allow expired-certificate
Router (ca-trustpoint)# exit
Router (config)# exit
```

The configuration should be checked (most of the configuration is not shown).

```
Router# write term
!many lines left out
crypto pki trustpoint VPN-GW
enrollment url http://ca.home-office.com:80/certsrv/mscep/mscep.dll serial-number none
fqdn none
ip-address none
subject-name o=Home Office Inc,cn=Central VPN Gateway revocation-check crl
match certificate branch1 allow expired-certificate
!
!
crypto pki certificate map central-site 10
issuer-name co cn = Central Certificate Authority, ou = Home Office Inc
subject-name eq cn = central vpn gateway, o = home office inc
! many lines left out
```

The **match certificate** command and **branch1 allow expired-certificate** (argument and keyword) and the certificate map should be removed as soon as the branch router has a new certificate.

Configuring Certificate Authorization and Revocation Settings Examples

This section contains the following configuration examples that can be used when specifying a CRL cache control setting or certificate serial number session control:

Configuring Certificate Authorization and Revocation Settings Examples

This section contains the following configuration examples that can be used when specifying a CRL cache control setting or certificate serial number session control:

Configuring CRL Cache Control

The following example shows how to disable CRL caching for all CRLs associated with the CA1 trustpoint:

```
crypto pki trustpoint CA1 enrollment url http://CA1:80 ip-address FastEthernet0/0 crl
query ldap://ldap_CA1 revocation-check crl
crl-cache none
The current CRL is still cached immediately after executing the example configuration
shown above:
Router# show crypto pki crls
CRL Issuer Name:
cn=name Cert Manager,ou=pki,o=example.com,c=US
```

```
LastUpdate: 18:57:42 GMT Nov 26 2005
NextUpdate: 22:57:42 GMT Nov 26 2005
Retrieved from CRL Distribution Point:
ldap://ldap.example.com/CN=name Cert Manager,O=example.com
```

When the current CRL expires, a new CRL is then downloaded to the router at the next update. The **crl-cache none** command takes effect and all CRLs for the trustpoint are no longer cached; caching is disabled. You can verify that no CRL is cached by executing the **show crypto pki crls** command. No output will be shown because there are no CRLs cached.

The following example shows how to configure the maximum lifetime of 2 minutes for all CRLs associated with the CA1 trustpoint:

```
crypto pki trustpoint CA1
enrollment url http://CA1:80
ip-address FastEthernet0/0
crl query ldap://ldap_CA1
revocation-check crl
crl-cache delete-after 2
```

The current CRL is still cached immediately after executing the example configuration above for setting the maximum lifetime of a CRL:

```
Router# show crypto pki crls
CRL Issuer Name:
cn=name Cert Manager,ou=pki,o=example.com,c=US
LastUpdate: 18:57:42 GMT Nov 26 2005
NextUpdate: 22:57:42 GMT Nov 26 2005
Retrieved from CRL Distribution Point:
ldap://ldap.example.com/CN=name Cert Manager,O=example.com
When the current CRL expires, a new CRL is downloaded to the router at the next update and
the crl-cache delete-after command takes effect. This newly cached CRL and all subsequent
CRLs will be deleted after a maximum lifetime of 2 minutes.
You can verify that the CRL will be cached for 2 minutes by executing the show crypto pki
crls
command. Note that the NextUpdate time is 2 minutes after the LastUpdate time.
Router# show crypto pki crls
```

```
CRL Issuer Name:
cn=name Cert Manager,ou=pki,o=example.com,c=US
LastUpdate: 22:57:42 GMT Nov 26 2005
NextUpdate: 22:59:42 GMT Nov 26 2005 Retrieved from CRL Distribution Point:
ldap://ldap.example.com/CN=name Cert Manager,O=example.com
```

Configuring Certificate Serial Number Session Control

The following example shows the configuration of certificate serial number session control using a certificate map for the CA1 trustpoint:

```
crypto pki trustpoint CA1 enrollment url http://CA1 chain-validation stop
crl query ldap://ldap_server revocation-check crl
match certificate crl
!
crypto pki certificate map crl 10 serial-number co 279d
```

Note

If the match-criteria value is set to **eq** (equal) instead of **co** (contains), the serial number must match the certificate map serial number exactly, including any spaces.

The following example shows the configuration of certificate serial number session control using AAA attributes. In this case, all valid certificates will be accepted if the certificate does not have the serial number “4ACA.”

```
crypto pki trustpoint CA1
enrollment url http://CA1 ip-address FastEthernet0/0
crl query ldap://ldap_CA1
revocation-check crl
aaa new-model
!
aaa attribute list crl
attribute-type aaa-cert-serial-not 4ACA
```

The server log shows that the certificate with the serial number ?ACA?was rejected. The certificate rejection is shown using exclamation points.

```
...

Configuring Certificate Chain Validation Examples

This section contains the following configuration examples that can be used to specify the level of certificate chain processing for your device certificates:

Configuring Certificate Chain Validation from Peer to Root CA

In the following configuration example, all of the certificates will be validated--the peer, SubCA11, SubCA1, and RootCA certificates.

```
crypto pki trustpoint RootCA enrollment terminal
chain-validation stop revocation-check none rsakeypair RootCA
crypto pki trustpoint SubCA1 enrollment terminal
chain-validation continue RootCA revocation-check none
rsakeypair SubCA1
crypto pki trustpoint SubCA11 enrollment terminal
chain-validation continue SubCA1 revocation-check none
rsakeypair SubCA11
```

Configuring Certificate Chain Validation from Peer to Subordinate CA

In the following configuration example, the following certificates will be validated--the peer and SubCA1 certificates.

```
crypto pki trustpoint RootCA
enrollment terminal
chain-validation stop
revocation-check none
rsakeypair RootCA
crypto pki trustpoint SubCA1
enrollment terminal
chain-validation continue RootCA
revocation-check none
rsakeypair SubCA1
crypto pki trustpoint SubCA11
enrollment terminal
chain-validation continue SubCA1 r
evocation-check none
rsakeypair SubCA11
```

Configuring Certificate Chain Validation Through a Gap

In the following configuration example, SubCA1 is not in the configured Cisco IOS hierarchy but is expected to have been supplied in the certificate chain presented by the peer.

If the peer supplies the SubCA1 certificate in the presented certificate chain, the following certificates will be validated--the peer, SubCA11, and SubCA1 certificates.

If the peer does not supply the SubCA1 certificate in the presented certificate chain, the chain validation will fail.

```
crypto pki trustpoint RootCA
enrollment terminal
chain-validation stop
revocation-check none
rsakeypair RootCA
crypto pki trustpoint SubCA11
enrollment terminal
chain-validation continue RootCA
revocation-check none
rsakeypair SubCA11
```

Support for IPv6

This chapter lists the IP version 6 (IPv6) features supported on the switch.

The IPv6 for Cisco IOS software feature documentation provides implementation and command reference information for IPv6 features supported in the Cisco IOS software. Not all IPv6 features are supported. We recommend that you read this entire chapter before reading the other IPv6 for Cisco IOS software feature documentation.

This chapter consists of these sections:

- [Finding Feature Information, page 64-1](#)
- [About IPv6, page 64-1](#)
- [IPv6 Default States, page 64-7](#)

Note

For Cisco IOS IPv6 Configuration Guides, see:

- [IPv6 Configuration Library, Cisco IOS Release 15E](#)
- [IPv6 Configuration Guide Library, Cisco IOS XE Release 3E](#)

For complete syntax and usage information for the switch commands used in this chapter, see:

- The [Cisco IOS IPv6 Command Reference](#)
 - The [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).
-

Finding Feature Information

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://tools.cisco.com/ITDIT/CFN/>. An account on Cisco.com is not required.

About IPv6

IPv6 provides services such as end-to-end security, quality of service (QoS), and globally unique addresses. The IPv6 address space reduces the need for private addresses and Network Address Translation (NAT) processing by border routers at network edges.

For information about how Cisco Systems implements IPv6, go to this URL:

http://www.cisco.com/en/US/products/ps6553/products_ios_technology_home.html

This section describes the features that are supported for IPv6:

- [IPv6 Addressing and Basic Connectivity, page 65-1](#)
- [DHCP, page 64-2](#)
- [Security, page 64-2](#)
- [First-Hop Security, page 64-3](#)
- [QoS, page 64-3](#)
- [Management, page 64-3](#)
- [Multicast, page 64-4](#)
- [Static Routes, page 64-4](#)
- [First-Hop Redundancy Protocols, page 64-5](#)
- [Unicast Routing, page 64-5](#)
- [Tunneling, page 64-7](#)

DHCP

The following DHCP features are supported for IPv6 on the Catalyst 4500 series switch:

- Relay agent
- Relay agent notification for prefix delegation
- Reload persistent interface ID option
- Ethernet remote ID option
- Stateless auto-configuration

You can find information about these features at this location:

[IP Addressing: DHCP Configuration Guide, Cisco IOS Release 15E](#)

[IP Addressing: DHCP Configuration Guide, Cisco IOS XE Release 3E](#)

Security

The following security features are supported for IPv6 on the Catalyst 4500 series switch:

- Secure Shell (SSH) support over IPv6
- Traffic filters
- standard access control lists (ACL)
- extended access control lists
- ACL accounting
- ACL addressing
- ACL DSCP
- ACL flags

- ACL flows
- ACL fragments
- ACL ICMP codes
- ACL logging
- ACL protocols

You can find information about these features at this location:

[Security Configuration Guide: Access Control Lists, Cisco IOS Release 15E](#)

[Security Configuration Guide: Access Control Lists, Cisco IOS XE Release 3E](#)

First-Hop Security

The following First-Hop Security (FHS) features are supported for IPv6 on the Catalyst 4500-E and -X series switch:

- SISF-Based Device Tracking
- IPv6 RA Guard
- IPv6 Source Guard and Prefix Guard
- IPv6 Snooping
- DHCPv6 Guard
- IPv6 Neighbor Discovery Multicast Suppress
- IPv6 Destination Guard
- IPv6 RFCs

You can find information about these features at this location:

[IPv6 First-Hop Security Configuration Guide, Cisco IOS Release 15E](#)

[IPv6 First-Hop Security Configuration Guide, Cisco IOS Release XE 3E](#)

QoS

The following QoS features are supported for IPv6 on the Catalyst 4500 series switch:

- MQC packet classification
- MQC traffic shaping
- MQC traffic policing
- MQC packet marking and remarking
- Queueing

You can find information about these features at this location:

[QoS: Classification Configuration Guide, Cisco IOS XE Release 3S](#)

Management

The following management features are supported for IPv6 on the Catalyst 4500 series switch:

- Ping
- Syslog
- Netconf support
- SNMP
- SOAP
- HTTP(s)

You can find information about these features at this location:

[Network Management Configuration Guide Library, Cisco IOS Release 15E](#)

[Network Management Configuration Guide Library, Cisco IOS XE Release 3E](#)

Multicast

Traditional IP communication allows a host to send packets to a single host (unicast transmission) or to all hosts (broadcast transmission). IPv6 multicast, allows a host to send a single data stream to a subset of all hosts (group transmission) simultaneously.

The following multicast features are supported for IPv6 on the Catalyst 4500 series switch:

- Multicast Listener Discovery (MLD) protocol, versions 1 and 2

You can find information about IPv6 MLD Snooping at this location:

<http://www.cisco.com/en/US/docs/switches/lan/catalyst4500/12.2/53SG/configuration/mldsnoop.html>

- MLD access group
- MLD snooping
- Scope boundaries
- Protocol Independent Multicast (PIM) features:

A switch running the LAN Base license level supports PIM for IPv6. VRF support is not available at the LAN Base level.

- PIM embedded Rendezvous Point (RP) support
 - PIM Sparse Mode (PIM-SM)
 - PIM Source Specific Multicast (PIM-SSM)
- Static multicast routing (mroute)
- Explicit tracking of receivers
- Bootstrap routers (BSR)

You can find information about these features at this location:

[IP Multicast Configuration Guide Library, Cisco IOS XE Release 3E](#)

Static Routes

Networking devices forward packets using route information that is either manually configured or dynamically learned using a routing protocol. Static routes are manually configured and define an explicit path between two networking devices. Unlike a dynamic routing protocol, static routes are not

automatically updated and must be manually reconfigured if the network topology changes. The benefits of using static routes include security and resource efficiency. Static routes use less bandwidth than dynamic routing protocols and no CPU cycles are used to calculate and communicate routes. The main disadvantage to using static routes is the lack of automatic reconfiguration if the network topology changes.

Static routes can be redistributed into dynamic routing protocols but routes generated by dynamic routing protocols cannot be redistributed into the static routing table. No algorithm exists to prevent the configuration of routing loops that use static routes.

Static routes are useful for smaller networks with only one path to an outside network and to provide security for a larger network for certain types of traffic or links to other networks that need more control. In general, most networks use dynamic routing protocols to communicate between networking devices but may have one or two static routes configured for special cases.

You can find more information regarding static routes at:

[IP Routing: Protocol-Independent Configuration Guide, Cisco IOS Release 15E](#)

[IP Routing: Protocol-Independent Configuration Guide, Cisco IOS XE Release 3E](#)

[IP Routing: Protocol-Independent Configuration Guide, Cisco IOS XE Release 3S](#)

First-Hop Redundancy Protocols

IPv6 routing protocols ensure router-to-router resilience and failover. However, in situations in which the path between a host and the first-hop router fails, or the first-hop router itself fails, First-Hop Redundancy Protocols (FHRPs) ensure host-to-router resilience and failover.

The Hot Standby Router Protocol (HSRP) protects data traffic in case of a gateway failure.

You can find more information about First-Hop Redundancy Protocols at:

[First Hop Redundancy Protocols Configuration Guide, Cisco IOS Release 15E](#)

[First Hop Redundancy Protocols Configuration Guide, Cisco IOS XE Release 3E](#)

Unicast Routing

These sections describe the IPv6 unicast routing protocol features supported by the switch:

- [RIP, page 64-5](#)
- [OSPF, page 64-6](#)
- [EIGRP, page 64-6](#)
- [IS-IS, page 64-6](#)
- [Multiprotocol BGP, page 64-6](#)

RIP

A switch running the LAN Base license level supports the Routing Information Protocol (RIP) for IPv6. VRF support is not available at the LAN Base level.

RIP is a distance-vector protocol that uses hop count as a routing metric. It includes support for IPv6 addresses and prefixes and the all-RIP routers multicast group address FF02::9 as the destination address for RIP update messages.

You can find more about RIP at this location:

[IP Routing: RIP Configuration Guide, Cisco IOS XE Release 3E](#)

OSPF

A switch running the LAN Base license level supports the Open Shortest Path First (OSPF) for IPv6. VRF support is not available at the LAN Base level

OSPF is a link-state protocol for IP.

You can find more information about OSPF at this location:

[IP Routing: OSPF Configuration Guide, Cisco IOS Release 15E](#)

[IP Routing: OSPF Configuration Guide, Cisco IOS XE Release 3E](#)

EIGRP

The switch running the IP-services feature set supports Enhanced Interior Gateway Routing Protocol (EIGRP) for IPv6. It is configured on the interfaces on which it runs and does not require a global IPv6 address.

Before running, an instance of EIGRP IPv6 requires an implicit or explicit router ID. An implicit router ID is derived from a local IPv4 address, so any IPv4 node always has an available router ID. However, EIGRP IPv6 might be running in a network with only IPv6 nodes and therefore might not have an available IPv4 router ID.

You can find more information about EIGRP at this location:

[IP Routing: EIGRP Configuration Guide, Cisco IOS Release 15E](#)

[IP Routing: EIGRP Configuration Guide, Cisco IOS XE Release 3E](#)

IS-IS

Intermediate System-to-Intermediate System (IS-IS) is an Interior Gateway Protocol (IGP) that advertises link-state information throughout the network to create a picture of the network topology. IS-IS is an Open Systems Interconnection (OSI) hierarchical routing protocol that designates an intermediate system as a Level 1 or Level 2 device. Level 2 devices route between Level 1 areas to create an intradomain routing backbone. Integrated IS-IS uses a single routing algorithm to support several network address families, such as IPv6, IPv4, and OSI.

You can find more information about Is-IS at this location:

[IP Routing: ISIS Configuration Guide, Cisco IOS XE Release 3E](#)

Multiprotocol BGP

Multiprotocol Border Gateway Protocol (BGP) is an Exterior Gateway Protocol (EGP) used mainly to connect separate routing domains that contain independent routing policies (autonomous systems). Connecting to a service provider for access to the Internet is a common use for BGP. BGP can also be used within an autonomous system, which is referred to as internal BGP (iBGP). Multiprotocol BGP is an enhanced BGP that carries routing information for multiple network layer protocol address families, for example, IPv6 address family and for IP multicast routes. All BGP commands and routing policy capabilities can be used with multiprotocol BGP.

You can find more information about multiprotocol BGP at this location:

IP Routing: [BGP Configuration Guide, Cisco IOS Release 15E](#)

IP Routing: [BGP Configuration Guide, Cisco IOS XE Release 3E](#)

Tunneling

The following tunneling features are supported for IPv6 on the Catalyst 4500 series switch:

- Automatic 6to4
- ISATAP
- Configured tunnels

**Note**

Tunneling is not supported in hardware but is supported in software.

You can find information about these features at this location:

IPv6 Implementation Guide, Cisco IOS XE Release 3S > [Implementing Tunneling for IPv6](#)

IPv6 Default States

[Table 64-1](#) shows the default states of IPv6 configuration.

Table 64-1 **Default IPv6 Configuration**

Feature	Default Setting
IPv6 routing	Disabled globally and on all interfaces
CEFv6 or dCEFv6	Disabled (IPv4 CEF and dCEF are enabled by default) Note When IPv6 routing is enabled, CEFv6 and dCEF6 are automatically enabled.
IPv6 addresses	None configured

IPv6 Addressing and Basic Connectivity

Internet Protocol version 6 (IPv6) expands the number of network address bits from 32 bits (in IPv4) to 128 bits, which provides more than enough globally unique IP addresses for every networked device on the planet. The unlimited address space provided by IPv6 allows Cisco to deliver more and newer applications and services with reliability, improved user experience, and increased security.

Implementing basic IPv6 connectivity in the Cisco software consists of assigning IPv6 addresses to individual device interfaces. IPv6 traffic forwarding can be enabled globally, and Cisco Express Forwarding switching for IPv6 can also be enabled. The user can enhance basic connectivity functionality by configuring support for AAAA record types in the Domain Name System (DNS) name-to-address and address-to-name lookup processes, and by managing IPv6 neighbor discovery.

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Note

The switch supports the following features:

IPv6 address types: Anycast, IPv6 default router preferences, IPv6 MTU path discovery, Neighbor discovery duplicate address detection, Cisco Discovery Protocol — IPv6 address family support for neighbor information, ICMPv6 redirect, ICMP rate limiting, DNS lookups over an IPv6 transport, uRPF, ICMPv6

IPv6 for Cisco Software

IPv6, formerly named IPng (next generation), is the latest version of the Internet Protocol (IP). IP is a packet-based protocol used to exchange data, voice, and video traffic over digital networks. IPv6 was proposed when it became clear that the 32-bit addressing scheme of IP version 4 (IPv4) was inadequate to meet the demands of Internet growth. After extensive discussion it was decided to base IPng on IP but add a much larger address space and improvements such as a simplified main header and extension headers. IPv6 is described initially in RFC 2460, Internet Protocol, Version 6 (IPv6) Specification, issued by the Internet Engineering Task Force (IETF). Further RFCs describe the architecture and services supported by IPv6.

The architecture of IPv6 has been designed to allow existing IPv4 users to transition easily to IPv6 while providing services such as end-to-end security, quality of service (QoS), and globally unique addresses. The larger IPv6 address space allows networks to scale and provide global reachability. The simplified IPv6 packet header format handles packets more efficiently. IPv6 prefix aggregation, simplified network renumbering, and IPv6 site multihoming capabilities provide an IPv6 addressing hierarchy that allows for more efficient routing. IPv6 supports widely deployed routing protocols such as Integrated Intermediate System-to-Intermediate System (IS-IS), Open Shortest Path First (OSPF) for IPv6, and multiprotocol Border Gateway Protocol (BGP). Other available features include stateless autoconfiguration and an increased number of multicast addresses.

Large IPv6 Address Space for Unique Addresses

The primary motivation for IPv6 is the need to meet the demand for globally unique IP addresses. IPv6 quadruples the number of network address bits from 32 bits (in IPv4) to 128 bits, which provides more than enough globally unique IP addresses for every networked device on the planet. By being globally unique, IPv6 addresses inherently enable global reachability and end-to-end security for networked devices, functionality that is crucial to the applications and services that are driving the demand for the addresses. Additionally, the flexibility of the IPv6 address space reduces the need for private addresses; therefore, IPv6 enables new application protocols that do not require special processing by border devices at the edge of networks.

IPv6 Address Formats

IPv6 addresses are represented as a series of 16-bit hexadecimal fields separated by colons (:) in the format: x:x:x:x:x:x:x. Following are two examples of IPv6 addresses:

```
2001:DB8:7654:3210:FEDC:BA98:7654:3210
```

```
2001:DB8:0:0:8:800:200C:417A
```

IPv6 addresses commonly contain successive hexadecimal fields of zeros. Two colons (::) may be used to compress successive hexadecimal fields of zeros at the beginning, middle, or end of an IPv6 address (the colons represent successive hexadecimal fields of zeros). The table below lists compressed IPv6 address formats.

A double colon may be used as part of the ipv6-address argument when consecutive 16-bit values are denoted as zero. You can configure multiple IPv6 addresses per interfaces, but only one link-local address.

Note Two colons (::) can be used only once in an IPv6 address to represent the longest successive hexadecimal fields of zeros. The hexadecimal letters in IPv6 addresses are not case-sensitive.

Table 65-1 Compressed IPv6 Address Formats

IPv6 Address Type	Preferred Format	Compressed Format
Unicast	2001:0:0:0:DB8:800:200C:417A	2001::DB8:800:200C:417A
Multicast	FF01:0:0:0:0:0:101	FF01::101
Loopback	0:0:0:0:0:0:1	::1
Unspecified	0:0:0:0:0:0:0	::

The loopback address listed in the table above may be used by a node to send an IPv6 packet to itself. The loopback address in IPv6 functions the same as the loopback address in IPv4 (127.0.0.1).

Note The IPv6 loopback address cannot be assigned to a physical interface. A packet that has the IPv6 loopback address as its source or destination address must remain within the node that created the packet. IPv6 devices do not forward packets that have the IPv6 loopback address as their source or destination address.

The unspecified address listed in the table above indicates the absence of an IPv6 address. For example, a newly initialized node on an IPv6 network may use the unspecified address as the source address in its packets until it receives its IPv6 address.

Note The IPv6 unspecified address cannot be assigned to an interface. The unspecified IPv6 addresses must not be used as destination addresses in IPv6 packets or the IPv6 routing header.

An IPv6 address prefix, in the format ipv6-prefix/prefix-length, can be used to represent bit-wise contiguous blocks of the entire address space. The ipv6-prefix must be in the form documented in RFC 2373 where the address is specified in hexadecimal using 16-bit values between colons. The prefix length is a decimal value that indicates how many of the high-order contiguous bits of the address comprise the prefix (the network portion of the address). For example, 2001:DB8:8086:6502::/32 is a valid IPv6 prefix.

IPv6 Address Output Display

When IPv6 or IPv4 command output displays an IPv6 address, a long IPv6 address can overflow into neighboring fields, causing the output to be difficult to read. The output fields were designed to work with the longest possible IPv4 address, which has 15 characters; IPv6 addresses can be up to 39 characters long. The following scheme has been adopted in IPv4 and IPv6 commands to allow the appropriate length of IPv6 address to be displayed and move the following fields to the next line, if necessary. The fields that are moved are kept in alignment with the header row.

The following example displays eight connections. The first six connections feature IPv6 addresses; the last two connections feature IPv4 addresses.

Switch#	where					
Conn	Host	Address	Byte	Idle	Conn	Name
1	test5	2001:DB8:3333:4::5	6	24		test5
2	test4	2001:DB8:3333:44::5				
			6	24		test4
3	2001:DB8:3333:4::5	2001:DB8:3333:4::5	6	24		2001:DB8:3333:4::5
4	2001:DB8:3333:44::5					
		2001:DB8:3333:44::5				
			6	23		2001:DB8:3333:44::5
5	2001:DB8:3000:4000:5000:6000:7000:8001					
		2001:DB8:3000:4000:5000:6000:7000:8001				
			6	20		2001:DB8:3000:4000:5000:6000:
6	2001:DB8:1::1	2001:DB8:1::1	0	1		2001:DB8:1::1
7	10.1.9.1	10.1.9.1	0	0		10.1.9.1
8	10.222.111.222	10.222.111.222	0	0		10.222.111.222

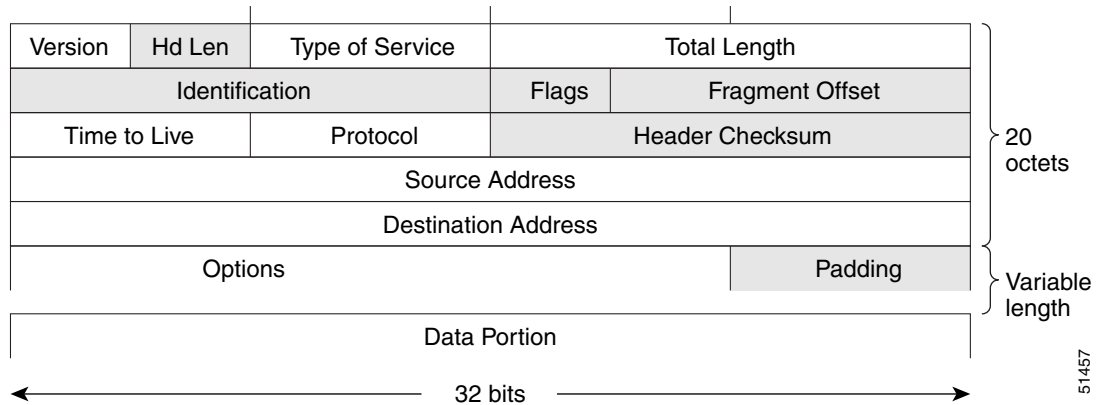

Connection 1 contains an IPv6 address that uses the maximum address length in the address field. Connection 2 shows the IPv6 address overflowing the address field and the following fields moved to the next line, but in alignment with the appropriate headers. Connection 3 contains an IPv6 address that fills the maximum length of the hostname and address fields without wrapping any lines. Connection 4 shows the effect of both the hostname and address fields containing a long IPv6 address. The output is shown over three lines keeping the correct heading alignment. Connection 5 displays a similar effect as connection 4 with a very long IPv6 address in the hostname and address fields. Note that the connection name field is actually truncated. Connection 6 displays a very short IPv6 address that does not require any change in the display. Connections 7 and 8 display short and long IPv4 addresses.

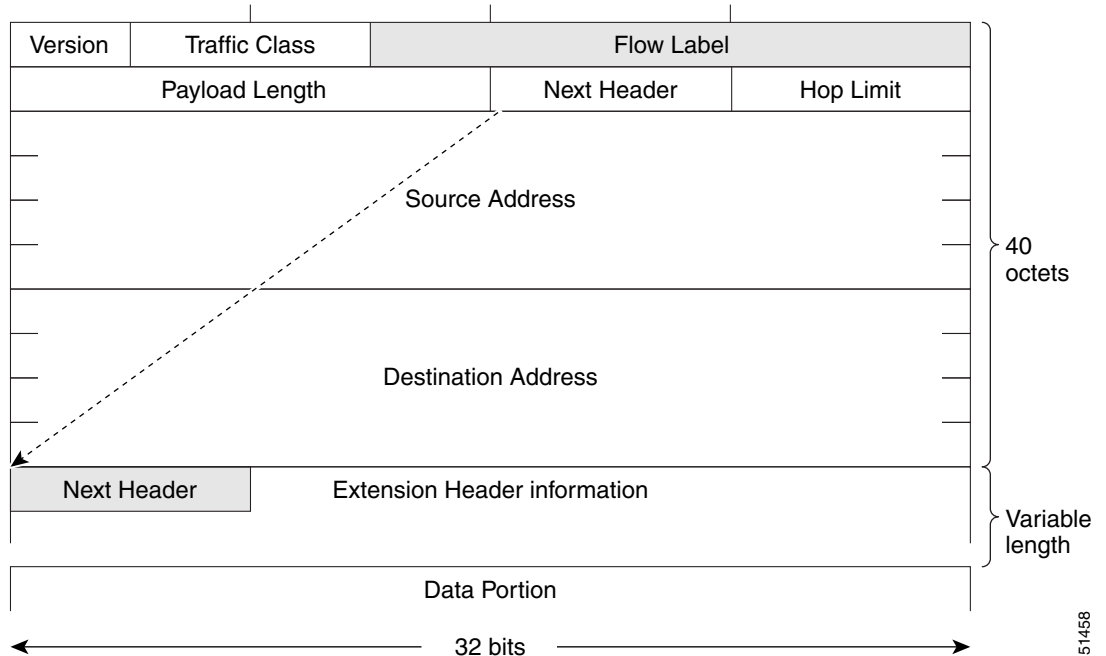

Note The IPv6 address output display applies to all commands that display IPv6 addresses.

Simplified IPv6 Packet Header

The basic IPv4 packet header has 12 fields with a total size of 20 octets (160 bits) (see the figure below). The 12 fields may be followed by an Options field, which is followed by a data portion that is usually the transport-layer packet. The variable length of the Options field adds to the total size of the IPv4 packet header. The shaded fields of the IPv4 packet header shown in the figure below are not included in the IPv6 packet header.

Figure 65-1 IPv4 Packet Header Format

The basic IPv6 packet header has 8 fields with a total size of 40 octets (320 bits) (see the figure below). Fields were removed from the IPv6 header because, in IPv6, fragmentation is not handled by devices and checksums at the network layer are not used. Instead, fragmentation in IPv6 is handled by the source of a packet and checksums at the data link layer and transport layer are used. (In IPv4, the UDP transport layer uses an optional checksum. In IPv6, use of the UDP checksum is required to check the integrity of the inner packet.) Additionally, the basic IPv6 packet header and Options field are aligned to 64 bits, which can facilitate the processing of IPv6 packets.

Figure 65-2 IPv6 Packet Header Format

The table below lists the fields in the basic IPv6 packet header.

Table 65-1 Basic IPv6 Packet Header Fields

Field	Description
Version	Similar to the Version field in the IPv4 packet header, except that the field lists number 6 for IPv6 instead of number 4 for IPv4.
Traffic Class	Similar to the Type of Service field in the IPv4 packet header. The Traffic Class field tags packets with a traffic class that is used in differentiated services.
Flow Label	A new field in the IPv6 packet header. The Flow Label field tags packets with a specific flow that differentiates the packets at the network layer.
Payload Length	Similar to the Total Length field in the IPv4 packet header. The Payload Length field indicates the total length of the data portion of the packet.
Next Header	Similar to the Protocol field in the IPv4 packet header. The value of the Next Header field determines the type of information following the basic IPv6 header. The type of information following the basic IPv6 header can be a transport-layer packet, for example, a TCP or UDP packet, or an Extension Header, as shown in the figure immediately above.
Hop Limit	Similar to the Time to Live field in the IPv4 packet header. The value of the Hop Limit field specifies the maximum number of devices that an IPv6 packet can pass through before the packet is considered invalid. Each device decrements the value by one. Because no checksum is in the IPv6 header, the device can decrement the value without needing to recalculate the checksum, which saves processing resources.
Source Address	Similar to the Source Address field in the IPv4 packet header, except that the field contains a 128-bit source address for IPv6 instead of a 32-bit source address for IPv4.
Destination Address	Similar to the Destination Address field in the IPv4 packet header, except that the field contains a 128-bit destination address for IPv6 instead of a 32-bit destination address for IPv4.

Following the eight fields of the basic IPv6 packet header are optional extension headers and the data portion of the packet. If present, each extension header is aligned to 64 bits. There is no fixed number of extension headers in an IPv6 packet. The extension headers form a chain of headers. Each extension header is identified by the Next Header field of the previous header. Typically, the final extension header has a Next Header field of a transport-layer protocol, such as TCP or UDP. The figure below shows the IPv6 extension header format.

Figure 65-3 IPv6 Extension Header Format

The table below lists the extension header types and their Next Header field values.

Table 65-2 IPv6 Extension Header Types

Header Type	Next Header Value	Description
Hop-by-hop options header	0	This header is processed by all hops in the path of a packet. When present, the hop-by-hop options header always follows immediately after the basic IPv6 packet header.
Destination options header	60	The destination options header can follow any hop-by-hop options header, in which case the destination options header is processed at the final destination and also at each visited address specified by a routing header. Alternatively, the destination options header can follow any Encapsulating Security Payload (ESP) header, in which case the destination options header is processed only at the final destination.
Routing header	43	The routing header is used for source routing.
Fragment header	44	The fragment header is used when a source must fragment a packet that is larger than the maximum transmission unit (MTU) for the path between itself and a destination. The Fragment header is used in each fragmented packet.
Authentication header and ESP header	51 50	The Authentication header and the ESP header are used within IP Security Protocol (IPsec) to provide authentication, integrity, and confidentiality of a packet. These headers are identical for both IPv4 and IPv6.

Table 65-2 IPv6 Extension Header Types

Upper-layer headers	6 (TCP) 17 (UDP)	The upper-layer (transport) headers are the typical headers used inside a packet to transport the data. The two main transport protocols are TCP and UDP.
Mobility headers	135	Extension headers used by mobile nodes, correspondent nodes, and home agents in all messaging related to the creation and management of bindings.

Path MTU Discovery for IPv6

As in IPv4, you can use path MTU discovery in IPv6 to allow a host to dynamically discover and adjust to differences in the MTU size of every link along a data path. In IPv6, however, fragmentation is handled by the source of a packet when the path MTU of one link along a given data path is not large enough to accommodate the size of the packets. Having IPv6 hosts handle packet fragmentation saves IPv6 router processing resources and helps IPv6 networks run more efficiently. Once the path MTU is reduced by the arrival of an ICMP Too Big message, Cisco NX-OS retains the lower value. The connection does not increase the segment size to gauge the throughput.

Note

In IPv6, the minimum link MTU is 1280 octets. We recommend that you use an MTU value of 1500 octets for IPv6 links.

IPv6 Prefix Aggregation

The aggregatable nature of the IPv6 address space enables an IPv6 addressing hierarchy. For example, an enterprise can subdivide a single IPv6 prefix from a service provider into multiple, longer prefixes for use within its internal network. Conversely, a service provider can aggregate all of the prefixes of its customers into a single, shorter prefix that the service provider can then advertise over the IPv6 internet (see the figure below).

Figure 65-4 IPv6 Prefix Aggregation

IPv6 Site Multihoming

Multiple IPv6 prefixes can be assigned to networks and hosts. Having multiple prefixes assigned to a network allows that network to connect easily to multiple ISPs without breaking the global routing table (see the figure below).

Figure 65-5 IPv6 Site Multihoming

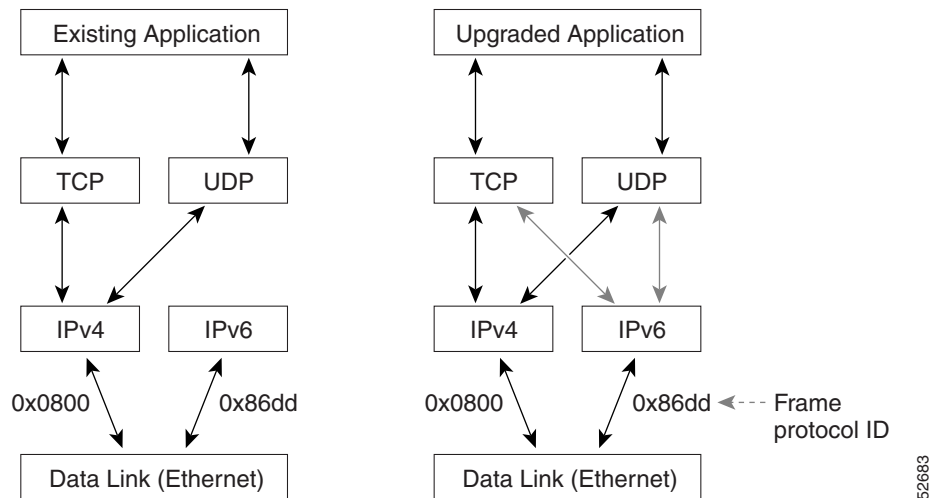

IPv6 Data Links

In IPv6 networks, a data link is a network sharing a particular link-local prefix. Data links are networks arbitrarily segmented by a network administrator in order to provide a multilevel, hierarchical routing structure while shielding the subnetwork from the addressing complexity of attached networks. The function of a subnetwork in IPv6 is similar to a subnetwork in IPv4. A subnetwork prefix is associated with one data link; multiple subnetwork prefixes may be assigned to the same data link.

The following data links are supported for IPv6: FDDI, Frame Relay PVC, Cisco High-Level Data Link Control (HDLC), PPP over Packet over SONET, ISDN, and serial interfaces.

Dual IPv4 and IPv6 Protocol Stacks

The dual IPv4 and IPv6 protocol stack technique can be used to transition to IPv6. It enables gradual, one-by-one upgrades to applications running on nodes. Applications running on nodes are upgraded to make use of the IPv6 protocol stack. Applications that are not upgraded (for example, they support only the IPv4 protocol stack) can coexist with upgraded applications on a node. New and upgraded applications make use of both the IPv4 and IPv6 protocol stacks (see the figure below).

Figure 65-6 Dual IPv4 and IPv6 Protocol Stack Technique

One application program interface (API) supports both IPv4 and IPv6 addresses and DNS requests. An application can be upgraded to the new API and still use only the IPv4 protocol stack. The Cisco software supports the dual IPv4 and IPv6 protocol stack technique. When an interface is configured with both an IPv4 and an IPv6 address, the interface will forward both IPv4 and IPv6 traffic.

In the figure below, an application that supports dual IPv4 and IPv6 protocol stacks requests all available addresses for the destination hostname `www.example.com` from a DNS server. The DNS server replies with all available addresses (both IPv4 and IPv6 addresses) for `www.example.com`. The application chooses an address (in most cases, IPv6 addresses are the default choice), and connects the source node to the destination using the IPv6 protocol stack.

Figure 65-7 Dual IPv4 and IPv6 Protocol Stack Applications

Cisco Discovery Protocol IPv6 Address Support

The Cisco Discovery Protocol IPv6 address support for neighbor information feature adds the ability to transfer IPv6 addressing information between two Cisco devices. Cisco Discovery Protocol support for IPv6 addresses provides IPv6 information to network management products and troubleshooting tools.

ICMP for IPv6

You can use ICMP in IPv6 to provide information about the health of the network. ICMPv6, the version that works with IPv6, reports errors if packets cannot be processed correctly and sends informational messages about the status of the network. For example, if a router cannot forward a packet because it is too large to be sent out on another network, the router sends out an ICMPv6 message to the originating host. Additionally, ICMP packets in IPv6 are used in IPv6 neighbor discovery and path MTU discovery. The path MTU discovery process ensures that a packet is sent using the largest possible size that is supported on a specific route.

A value of 58 in the Next Header field of the base IPv6 packet header identifies an IPv6 ICMP packet. The ICMP packet follows all the extension headers and is the last piece of information in the IPv6 packet. Within the IPv6 ICMP packets, the ICMPv6 Type and ICMPv6 Code fields identify IPv6 ICMP packet specifics, such as the ICMP message type. The value in the Checksum field is computed by the sender and checked by the receiver from the fields in the IPv6 ICMP packet and the IPv6 pseudo header.

**Note**

The IPv6 header does not have a checksum. But a checksum on the transport layer can determine if packets have not been delivered correctly. All checksum calculations that include the IP address in the calculation must be modified for IPv6 to accommodate the new 128-bit address. A checksum is generated using a pseudo header.

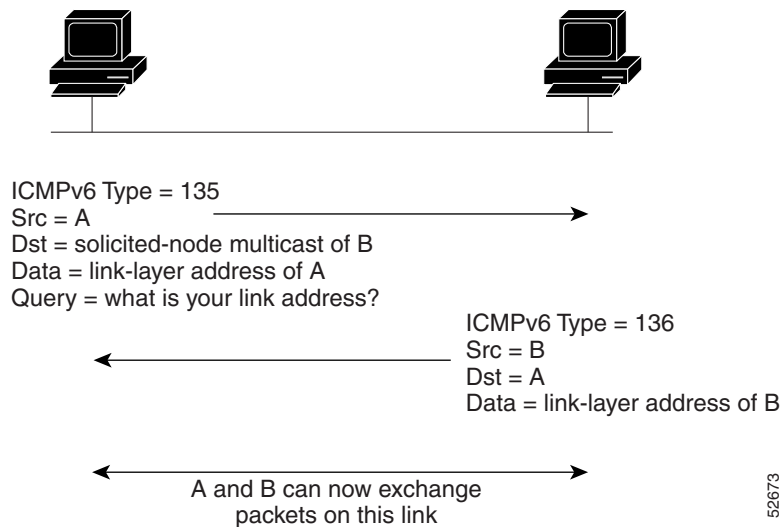

The ICMPv6 Payload field contains error or diagnostic information that relates to IP packet processing.

IPv6 Neighbor Discovery

You can use the IPv6 Neighbor Discovery Protocol (NDP) to determine whether a neighboring router is reachable. IPv6 nodes use neighbor discovery to determine the addresses of nodes on the same network (local link), to find neighboring routers that can forward their packets, to verify whether neighboring routers are reachable or not, and to detect changes to link-layer addresses. NDP uses ICMP messages to detect whether packets are sent to neighboring routers that are unreachable.

IPv6 Neighbor Solicitation Message

A node sends a neighbor solicitation message, which has a value of 135 in the Type field of the ICMP packet header, on the local link when it wants to determine the link-layer address of another node on the same local link. The source address is the IPv6 address of the node that sends the neighbor solicitation message. The destination address is the solicited-node multicast address that corresponds to the IPv6 address of the destination node. The neighbor solicitation message also includes the link-layer address of the source node.

Figure 65-8 IPv6 Neighbor Discovery-Neighbor Solicitation Message

After receiving the neighbor solicitation message, the destination node replies by sending a neighbor advertisement message, which has a value of 136 in the Type field of the ICMP packet header, on the local link. The source address is the IPv6 address of the node (the IPv6 address of the node interface that sends the neighbor advertisement message). The destination address is the IPv6 address of the node that sends the neighbor solicitation message. The data portion includes the link-layer address of the node that sends the neighbor advertisement message.

After the source node receives the neighbor advertisement, the source node and destination node can communicate.

Neighbor solicitation messages can verify the reachability of a neighbor after a node identifies the link-layer address of a neighbor. When a node wants to verify the reachability of a neighbor, it uses the destination address in a neighbor solicitation message as the unicast address of the neighbor.

Neighbor advertisement messages are also sent when there is a change in the link-layer address of a node on a local link. When there is a change, the destination address for the neighbor advertisement is the all-nodes multicast address.

Neighbor unreachability detection identifies the failure of a neighbor or the failure of the forward path to the neighbor and is used for all paths between hosts and neighboring nodes (hosts or routers).

Neighbor unreachability detection is performed for neighbors to which only unicast packets are being sent and is not performed for neighbors to which multicast packets are being sent.

A neighbor is considered reachable when a positive acknowledgment is returned from the neighbor (indicating that packets previously sent to the neighbor have been received and processed). A positive acknowledgment—from an upper-layer protocol (such as TCP)—indicates that a connection is making forward progress (reaching its destination). If packets are reaching the peer, they are also reaching the next-hop neighbor of the source. Forward progress is also a confirmation that the next-hop neighbor is reachable.

For destinations that are not on the local link, forward progress implies that the first-hop router is reachable. When acknowledgments from an upper-layer protocol are not available, a node probes the neighbor using unicast neighbor solicitation messages to verify that the forward path is still working. The return of a solicited neighbor advertisement message from the neighbor is a positive acknowledgment that the forward path is still working (neighbor advertisement messages that have the solicited flag set to a value of 1 are sent only in response to a neighbor solicitation message). Unsolicited messages confirm only the one-way path from the source to the destination node; solicited neighbor advertisement messages indicate that a path is working in both directions.

**Note**

A neighbor advertisement message that has the solicited flag set to a value of 0 is not considered as a positive acknowledgment that the forward path is still working.

Neighbor solicitation messages are also used in the stateless autoconfiguration process to verify the uniqueness of unicast IPv6 addresses before the addresses are assigned to an interface. Duplicate address detection is performed first on a new, link-local IPv6 address before the address is assigned to an interface (the new address remains in a tentative state while duplicate address detection is performed). A node sends a neighbor solicitation message with an unspecified source address and a tentative link-local address in the body of the message. If another node is already using that address, the node returns a neighbor advertisement message that contains the tentative link-local address. If another node is simultaneously verifying the uniqueness of the same address, that node also returns a neighbor solicitation message. If no neighbor advertisement messages are received in response to the neighbor solicitation message and no neighbor solicitation messages are received from other nodes that are attempting to verify the same tentative address, the node that sent the original neighbor solicitation message considers the tentative link-local address to be unique and assigns the address to the interface.

Configuring IPv6 Addressing and Basic Connectivity

- [Guidelines for Implementing IPv6 Addressing and Basic Connectivity, page 65-13](#)
- [Configuring IPv6 Addressing and Enabling IPv6 Routing, page 65-14](#)
- [Mapping Hostnames to IPv6 Addresses, page 65-15](#)
- [Configuration Examples for IPv6 Addressing and Basic Connectivity, page 65-16](#)

Guidelines for Implementing IPv6 Addressing and Basic Connectivity

- The switch supports only IPv6 unicast addresses. It does not support site-local unicast addresses or multicast addresses.
- The IPv6 128-bit addresses are represented as a series of eight 16-bit hexadecimal fields separated by colons in the format: *n:n:n:n:n:n:n:n*. It is an example of an IPv6 address:
2031:0000:130F:0000:0000:09C0:080F:130B
- The leading zeros in each field are optional, implementation is easier without them. It is the same address without leading zeros:
2031:0:130F:0:0:9C0:80F:130B
- You can also use two colons (::) to represent successive hexadecimal fields of zeros, but you can use this short version only once in each address:
2031:0:130F::09C0:080F:130B
- Multiple IPv6 global addresses within the same prefix can be configured on an interface; however, multiple IPv6 link-local addresses on an interface are not supported.

Configuring IPv6 Addressing and Enabling IPv6 Routing

Perform this task to assign IPv6 addresses to individual device interfaces and enable IPv6 traffic forwarding globally on the device. By default, IPv6 addresses are not configured and IPv6 routing is disabled.

Multiple IPv6 link-local addresses on an interface are not supported.

	Command	Purpose
Step 1	configure terminal Example: Switch# configure terminal	Enters global configuration mode.
Step 2	interface type number Example: Switch(config)# ip name-server 192.0.2.1 192.0.2.2	Specifies an interface type and number, and places the device in interface configuration mode.
Step 3	ipv6 address ipv6-prefix prefix-length eui-64 OR ipv6 address ipv6-prefix prefix-length link-local OR ipv6 enable Example: Switch(config-if)# ipv6 address 2001:DB8:0:1::/64 eui-64 OR Switch(config-if)# ipv6 address FE80::260:3EFF:FE11:6770 link-local OR Switch(config-if)# ipv6 enable	Specifies an IPv6 network assigned to the interface and enables IPv6 processing on the interface. or Specifies an IPv6 address assigned to the interface and enables IPv6 processing on the interface. or Automatically configures an IPv6 link-local address on the interface while also enabling the interface for IPv6 processing. The link-local address can be used only to communicate with nodes on the same link. Specifying the ipv6 address eui-64 command configures global IPv6 addresses with an interface identifier (ID) in the low-order 64 bits of the IPv6 address. Only the 64-bit network prefix for the address needs to be specified; the last 64 bits are automatically computed from the interface ID. Specifying the ipv6 address link-local command configures a link-local address on the interface that is used instead of the link-local address that is automatically configured when IPv6 is enabled on the interface.
Step 4	exit Example: Switch(config-if)# exit	Exits interface configuration mode, and returns the device to global configuration mode.
Step 5	ipv6 unicast-routing Example: Switch(config)# ipv6 unicast-routing	Enables the forwarding of IPv6 unicast datagrams.

Mapping Hostnames to IPv6 Addresses

A name server is used to track information associated with domain names. A name server can maintain a database of hostname-to-address mappings. Each name can map to one or more IPv4 addresses, IPv6 addresses, or both address types. In order to use this service to map domain names to IPv6 addresses, you must specify a name server and enable the DNS, which is the global naming scheme of the Internet that uniquely identifies network devices.

Cisco software maintains a cache of hostname-to-address mappings for use by the connect, telnet, and ping commands, related Telnet support operations, and many other commands that generate command output. This cache speeds the conversion of names to addresses.

Similar to IPv4, IPv6 uses a naming scheme that allows a network device to be identified by its location within a hierarchical name space that provides for domains. Domain names are joined with periods (.) as the delimiting characters. For example, Cisco is a commercial organization that is identified by a com domain name, so its domain name is cisco.com. A specific device in this domain, the FTP server, for example, is identified as ftp.cisco.com.

	Command	Purpose
Step 1	configure terminal Example: Switch# configure terminal	Enters global configuration mode.
Step 2	ip host name ipv6-address1 [ipv6-address2...ipv6-address4] Example: Switch(config)# ip host cisco0-sj 2001:DB8:20:1::12	Defines a static hostname-to-address mapping in the hostname cache. Typically, it is easier to refer to network devices by symbolic names rather than numerical addresses (services such as Telnet can use hostnames or addresses). Hostnames and IPv6 addresses can be associated with one another through static or dynamic means. Manually assigning hostnames to addresses is useful when dynamic mapping is not available.
Step 3	ip domain name [vrf vrf-name] name OR ip domain list [vrf vrf-name] name Example: Switch(config)# ip domain-name example1.com Switch(config)# ip domain list example2.com	(Optional) ip domain name —Defines a default domain name that Cisco software will use to complete unqualified hostnames. or (Optional) ip domain list —Defines a list of default domain names to complete unqualified hostnames. You can specify a default domain name that Cisco software will use to complete domain name requests. You can specify either a single domain name or a list of domain names. Any hostname that does not contain a complete domain name will have the default domain name you specify appended to it before the name is looked up. Note The ip domain name and ip domain list commands are used to specify default domain names that can be used by both IPv4 and IPv6.

	Command	Purpose
Step 4	ip name-server [vrf vrf-name] <i>server-address1</i> [<i>server-address2...server-address6</i>] Example: Switch(config)# ip name-server 2001:DB8::250:8bff:fee8:f800 2001:DB8:0:f004::1	Specifies one or more hosts that supply name information. Specifies one or more hosts (up to six) that can function as a name server to supply name information for DNS. Note The server-address argument can be either an IPv4 or IPv6 address.
Step 5	ip domain-lookup Example: Switch(config)# ip domain-lookup	Enables DNS-based address translation. DNS is enabled by default.

Displaying IPv6 Redirect Messages

Enter the following commands in the privileged EXEC mode:

Table 65-3 Displaying IPv6 Redirect Messages

Command or Action	Purpose
show ipv6 interface [brief] [<i>type number</i>] [<i>prefix</i>]	Displays the usability status of interfaces configured for IPv6.
show ipv6 route [<i>ipv6-address ipv6-prefix/prefix-length protocol interface-type interface-number</i>]	Displays the current contents of the IPv6 routing table.
show ipv6 traffic	Displays statistics about IPv6 traffic.
show hosts [vrf vrf-name all hostname summary]	Displays the default domain name, the style of name lookup service, a list of name server hosts, and the cached list of hostnames and addresses.
show running-config	Displays the current configuration running on the device.

Configuration Examples for IPv6 Addressing and Basic Connectivity

Example: IPv6 Addressing and IPv6 Routing Configuration

In the following example, IPv6 is enabled on the device with both a link-local address and a global address based on the IPv6 prefix 2001:DB8:c18:1::/64. The EUI-64 interface ID is used in the low-order 64 bits of both addresses. Output from the show ipv6 interface command is included to show how the interface ID (260:3EFF:FE47:1530) is appended to the link-local prefix FE80::/64 of Gigabit Ethernet interface 0/0/0.

```
ipv6 unicast-routing
```

```
interface gigabitethernet 0/0/0
  ipv6 address 2001:DB8:c18:1::/64 eui-64
Device# show ipv6 interface gigabitethernet 0/0/0
Gigabitethernet0/0/0 is up, line protocol is up
IPv6 is enabled, link-local address is FE80::260:3EFF:FE47:1530
Global unicast address(es):
  2001:DB8:C18:1:260:3EFF:FE47:1530, subnet is 2001:DB8:C18:1::/64
Joined group address(es):
  FE02::1
  FE02::2
  FE02::1:FE47:1530
  FE02::9
MTU is 1500 bytes
ICMP error messages limited to one every 500 milliseconds
ND reachable time is 30000 milliseconds
ND advertised reachable time is 0 milliseconds
ND advertised retransmit interval is 0 milliseconds
ND router advertisements are sent every 200 seconds
ND router advertisements live for 1800 seconds
Hosts use stateless autoconfig for addresses.
```

Example: Dual-Protocol Stacks Configuration

The following example enables the forwarding of IPv6 unicast datagrams globally on the device and configures Gigabit Ethernet interface 0/0/0 with both an IPv4 address and an IPv6 address:

```
ipv6 unicast-routing
interface gigabitethernet0/0/0
  ip address 192.168.99.1 255.255.255.0
  ipv6 address 2001:DB8:c18:1::3/64
```

Example: Hostname-to-Address Mappings Configuration

The following example defines two static hostname-to-address mappings in the hostname cache, establishes a domain list with several alternate domain names to complete unqualified hostnames, specifies host 2001:DB8::250:8bff:fee8:f800 and host 2001:DB8:0:f004::1 as the name servers, and reenables the DNS service:

```
ip host cisco-sj 2001:DB8:700:20:1::12
ip host cisco-hq 2001:DB8:768::1 2001:DB8:20:1::22
ip domain list domain1-list.com
ip domain list serviceprovider2-name.com
ip domain list college2-name.edu
ip name-server 2001:DB8::250:8bff:fee8:f800 2001:DB8:0:f004::1
ip domain-lookup
```

Configuring SISF-Based Device Tracking

The Switch Integrated Security Features based (SISF-based) device tracking is part of the suite of first-hop security features. Starting from Cisco IOS XE Release 3.10.1E, this feature is available on Catalyst 4500E Series Switches with Supervisor Engines 9-E, 8-E, 8L-E, 7-E, 7L-E, and Catalyst 4500-X Series Switches.

This chapter describes how to enable and configure the feature. It consists of the following major sections:

- [About SISF-Based Device Tracking, page 66-1](#)
- [Guidelines for Enabling SISF-Based Device Tracking, page 66-2](#)
- [Migrating from Legacy Commands to SISF-Based Device Tracking, page 66-3](#)
- [Manually Enabling SISF-Based Device Tracking, page 66-4](#)
- [Programmatically Enabling SISF-Based Device Tracking, page 66-10](#)
- [Configuration Examples for SISF-Based Device Tracking, page 66-12](#)

About SISF-Based Device Tracking

The main purpose of the feature is to track the presence, location, and movement of end-nodes in the network. SISF snoops traffic received by the switch, extracts device identity (MAC and IP address), and stores them in a binding table. Many other features, such as, IEEE 802.1X, web authentication, IP Source Guard (IPSG), Cisco TrustSec and Cisco Locator/ID Separation Protocol (LISP) etc., depend on the accuracy of this information to operate properly.

SISF-based device tracking supports both IPv4 and IPv6.

If you are using the legacy IPv6 Snooping commands, we recommend that you migrate to SISF-based device tracking. See [Migrating from Legacy Commands to SISF-Based Device Tracking, page 66-3](#).

Note

Even if there is no existing IP device tracking (IPDT) or IPv6 Snooping configuration, you still have to enter the **device-tracking upgrade-cli** command in global configuration mode, before you can start using SISF-based device tracking.

After you migrate to SISF-based device tracking, the IPv6 Snooping commands will no longer be available; the IPDT commands continue to be supported and are required, to create IPv4 device tracking policies.

Guidelines for Enabling SISF-Based Device Tracking

SISF-Based device tracking is disabled by default.

You can enable the feature by manually creating the required policy, or it can be enabled programmatically. Review all the available options and choose the method that best suits your requirements.

This section includes the following major subsections:

- [Manually Enabling SISF-Based Device Tracking, page 66-4](#)
- [Programmatically Enabling SISF-Based Device Tracking, page 66-10](#)

Manually Enabling the Device Tracking

You can manually enable the feature by defining a device tracking policy and attaching the policy to a specific target. The target can be an interface or a VLAN. However, the steps you have to follow for IPv4 and IPv6 are different:

Tip

Use this method only if the programmatic policy's settings do not meet your requirements.

For IPv4, Use IPDT Commands

Enter the **ip device tracking maximum *n*** command in interface configuration mode; the system creates and attaches the IPDT-MAX-N policy to the interface. Note these guidelines and limitations:

- To attach a policy to a VLAN, configure the **ip device tracking maximum *n*** command on a switched virtual interface (SVI). See [Attaching a Device Tracking Policy to a VLAN, page 66-9](#).
- You cannot create a custom policy by specifying a name; The policy name can only be IPDT-MAX-N.

For IPv6, Use SISF-Based Device Tracking Commands

- If you enter the **device-tracking** command in the interface configuration mode or in the VLAN configuration mode, the system attaches a policy called **default**, to the interface or VLAN.
The **default** policy is a built-in policy with default settings; you cannot change any of the attributes of this policy.
- If you enter the **device-tracking policy** command in global configuration mode, you can specify a policy name; the system creates a policy with the name you specify. You can then configure the available settings, in the device tracking configuration mode (config-device-tracking) and attach the policy to a target.

For a Policy that Supports IPv4 and IPv6

Note

Create a policy for IPv4 and IPv6 separately and then attach it to the same interface or VLAN; the system merges the two policies and attaches it to the specified target. See example: [Example: Applying a Merged \(IPv4 and IPv6\) Device Tracking Policy to the Same Target, page 66-12](#).

Programmatically Enabling Device Tracking

Some features rely on device tracking and utilize the trusted database of binding entries that SISF-based device tracking builds and maintains. These features, also called device tracking clients, enable device tracking programmatically (create and attach the device tracking policy).

- The IEEE 802.1X, web authentication, IPSG, Cisco TrustSec features programmatically enable SISF-Based Device Tracking; the IPDT-DEFAULT policy is created and attached to the interface. The IPDT-DEFAULT policy supports only IPv4.
- When the LISP feature programmatically enables SISF-Based Device Tracking, the DT-PROGRAMMATIC policy is created and attached to the VLAN. The DT-PROGRAMMATIC policy supports both IPv4 and IPv6.

Tip

The IPDT-DEFAULT settings cannot be changed; DT-PROGRAMMATIC policy settings can.

Migrating from Legacy Commands to SISF-Based Device Tracking

You can migrate to SISF-based device tracking by entering the **device-tracking upgrade-cli** command in global configuration mode. Consider the following existing configuration scenarios and the corresponding migration results, before you migrate.

This section covers the following scenarios:

- [No IPDT and No IPv6 Snooping Configuration Exists, page 66-3](#)
- [Only IPDT Configuration Exists, page 66-3](#)
- [Only IPv6 Snooping Configuration Exists, page 66-4](#)
- [Both IPDT and IPv6 Snooping Configurations Exist, page 66-4](#)

No IPDT and No IPv6 Snooping Configuration Exists

Enter the **device-tracking upgrade-cli** command in global configuration mode. After this:

- SISF-based device tracking commands are available.
- IPDT commands continue to be available. Continue to use the IPDT commands to manually create a device tracking policy for IPv4.
- IPv6 snooping commands are not available.

Only IPDT Configuration Exists

After migration:

- SISF-based device tracking commands are available.
- IPDT commands continue to be available. Continue to use the IPDT commands to manually create a device tracking policy for IPv4.

- Entering the **[no] ip device tracking probe interval** command in interface configuration mode causes running configuration to display **ip device tracking probe interval** configuration and **device-tracking binding reachable-lifetime** command configurations. But if you configure **device-tracking binding reachable-lifetime** the system does not generate the **ip device tracking probe interval** command.
- IPv6 snooping commands are not available.

**Note**

Starting from Cisco IOS XE Release 3.10.1E, irrespective of whether you migrate to SISF-Based device tracking or not, the following IPDT commands are deprecated; there are no replacement commands:

- **[no] ip device tracking probe count**
- **[no] ip device tracking probe delay**

Only IPv6 Snooping Configuration Exists

After migration:

- SISF-based device-tracking commands are available.
- IPv6 snooping commands are not available.
- IPDT commands continue to be available. Continue to use the IPDT commands if you manually create a device tracking policy for IPv4.

Both IPDT and IPv6 Snooping Configurations Exist

After migration:

- SISF-based device-tracking commands are available.
- IPv6 snooping commands are not available.
- IPDT commands continue to be available. Continue to use the IPDT commands when you manually create a device tracking policy for IPv4.

Manually Enabling SISF-Based Device Tracking

This section includes the following major subsections:

- [Applying the Default Device Tracking Policy to a Target, page 66-5](#)
- [Creating a Custom Device Tracking Policy with Custom Settings, page 66-6](#)
- [Attaching a Device Tracking Policy to an Interface, page 66-9](#)
- [Attaching a Device Tracking Policy to a VLAN, page 66-9](#)
- [Attaching a Device Tracking Policy to a VLAN, page 66-9](#)

Applying the Default Device Tracking Policy to a Target

Beginning in privileged EXEC mode, follow these steps to apply the default device tracking policy to an interface or VLAN:

Note This procedure applies only to IPv6.

	Command or Action	Purpose
Step 1	configure terminal Example: Switch# configure terminal	Enters global configuration mode.
Step 2	interface <i>type/id</i> or vlan configuration <i>vlan_list</i> Example: Switch# interface gigabitethernet 1/1/4 or Switch# vlan configuration 333	<ul style="list-style-type: none"> • interface <i>type/id</i>—Specifies the interface and enters the interface configuration mode. The device tracking policy is attached to the specified interface. • vlan configuration <i>vlan_list</i>—Specifies the VLANs and enters the VLAN feature configuration mode. The device tracking policy is attached to the specified VLAN.
Step 3	device-tracking Example: Switch(config-if)# device-tracking or Switch(config-vlan-config)# device-tracking	<p>Enables SISF-based device tracking and attaches the default policy it to the interface or VLAN.</p> <p>The default policy is a built-in policy with default settings; none of the attributes of the default policy can be changed.</p>
Step 4	exit Example: Switch(config-if)# exit or Switch(config-vlan-config)# exit	Exits configuration mode.
Step 5	show device-tracking policy <i>policy-name</i> Example: Switch# show device-tracking policy default	Displays device-tracking policy configuration, and all the targets it is applied to.

Creating a Custom Device Tracking Policy with Custom Settings

Beginning in privileged EXEC mode, follow these steps to create and configure a device tracking policy:

Note

This procedure applies only to IPv6

	Command or Action	Purpose
Step 1	configure terminal Example: Switch# configure terminal	Enters global configuration mode.
Step 2	[no] device-tracking policy <i>policy-name</i> Example: Switch(config)# device-tracking policy example_policy	Creates the policy and enters the device-tracking configuration mode.

	Command or Action	Purpose
Step 3	<p>[data-glean default destination-glean device-role distribution-switch exit limit no prefix-glean protocol security-level tracking trusted-port vpc]</p> <p>Example:</p> <pre>Switch (config-device-tracking) # destination-glean log-only</pre>	<p>Enter the question mark (?) at the system prompt to obtain a list of available options in this mode. You can configure the following for IPv6:</p> <ul style="list-style-type: none"> (Optional) data-glean—Enables learning of addresses from a data packet snooped from a source inside the network and populates the binding table with the data traffic source address. Enter one of these options: <ul style="list-style-type: none"> log-only—Generates a system log message upon data packet notification. recovery—Uses a protocol to enable binding table recovery. Enter NDP or DHCP. (Optional) default—Sets the policy attribute to its default value. You can set these policy attributes to their default values: data-glean, destination-glean, device-role, limit, prefix-glean, protocol, security-level, tracking, trusted-port. (Optional) destination-glean—Populates the binding table by gleaning data traffic destination address. Enter one of these options: <ul style="list-style-type: none"> log-only—Generates a system log message upon data packet notification. recovery—Uses a protocol to enable binding table recovery. Enter DHCP. (Optional) device-role—Sets the role of the device attached to the port. It can be a node or a switch. Enter one of these options: <ul style="list-style-type: none"> node—Configures the attached device as a node. This is the default option. switch—Configures the attached device as a switch. (Optional) distribution-switch—Although visible on the CLI, this option is not supported. Any configuration settings you make will not take effect. (Optional) exit—Exits the device-tracking policy configuration mode. (Optional) limit address-count—Specifies an address count limit per port. The range is 1 to 32000. (Optional) no—Negates the command or sets it to defaults. (Optional) prefix-glean—Enables learning of prefixes from either IPv6 Router Advertisements or from DHCP-PD. You have the following option: <ul style="list-style-type: none"> (Optional) only—Gleans only prefixes and not host addresses. (Optional) protocol—Sets the protocol to glean; by default, all are gleaned. Enter one of these options:

Step 3
continued

Command or Action	Purpose
	<ul style="list-style-type: none"> – arp [<i>prefix-list name</i>] —Gleans addresses in ARP packets. Optionally, enter the name of prefix-list that is to be matched. – dhcp4 [<i>prefix-list name</i>] —Glean addresses in DHCPv4 packets. Optionally, enter the name of prefix-list that is to be matched. – dhcp6 [<i>prefix-list name</i>] —Glean addresses in DHCPv6 packets. Optionally, enter the name of prefix-list that is to be matched. – ndp [<i>prefix-list name</i>] —Glean addresses in NDP packets. Optionally, enter the name of prefix-list that is to be matched. – udp [<i>prefix-list name</i>] —Although visible on the CLI, this option is not supported. Any configuration settings you make will not take effect. • (Optional) security-level —Specifies the level of security enforced by the feature. Enter one of these options: <ul style="list-style-type: none"> – glean —Gleans addresses passively. – guard —Inspects and drops un-authorized messages. This is the default. – inspect —Gleans and validates messages. • (Optional) tracking —Specifies a tracking option. Enter one of these options: <ul style="list-style-type: none"> – disable [stale-lifetime [1-86400-seconds infinite]] —Turns off device-tracking. Optionally, you can enter the duration for which the entry is kept inactive before deletion, or keep it permanently inactive. – enable [reachable-lifetime [1-86400-seconds infinite]] —Turns on device-tracking. Optionally, you can enter the duration for which the entry is kept reachable, or keep it permanently reachable. • (Optional) trusted-port —Sets up a trusted port. Disables the guard on applicable targets. Bindings learned through a trusted port have preference over bindings learned through any other port. A trusted port is given preference in case of a collision while making an entry in the table. • (Optional) vpc —Although visible on the CLI, this option is not supported. Any configuration settings you make will not take effect.

	Command or Action	Purpose
Step 4	exit Example: Switch(config-if)# exit or Switch(config-vlan-config)# exit	Exits configuration mode.
Step 5	show device-tracking policy <i>policy-name</i> Example: Switch# show device-tracking policy default	Displays device-tracking policy configuration, and all the targets it is applied to.

Attaching a Device Tracking Policy to an Interface

Beginning in privileged EXEC mode, follow these steps to attach a device tracking policy to an interface:

	Command or Action	Purpose
Step 1	configure terminal Example: Switch# configure terminal	Enters global configuration mode.
Step 2	interface <i>type/id</i> Example: Switch# interface gigabitethernet 1/1/4	Specifies the interface and enters the interface configuration mode. The device tracking policy is attached to the specified interface.
Step 3	[no] device-tracking attach-policy <i>policy-name</i> Example: Switch(config-if)# device-tracking attach-policy example_policy	Attaches the device tracking policy to the interface. Device tracking is also supported on EtherChannels Note SISF based device-tracking policies can be detached only if they are custom policies. Programmatically created policies can be removed only if the corresponding device-tracking client feature configuration is removed.
Step 4	show device-tracking policies [interface <i>type/id</i>] Example: Switch# show device-tracking policies interface gigabitethernet 1/1/4	Displays policies that match the specified interface type and number.

Attaching a Device Tracking Policy to a VLAN

Beginning in privileged EXEC mode, follow these steps to attach a device-tracking policy to VLANs across multiple interfaces:

	Command or Action	Purpose
Step 1	configure terminal Example: Switch# configure terminal	Enters global configuration mode.
Step 2	vlan configuration <i>vlan_list</i> Example: Switch# vlan configuration 333	Specifies the VLANs to which the device tracking policy will be attached; enters the VLAN interface configuration mode.
Step 3	[no] device-tracking attach-policy <i>policy-name</i> Example: Switch (config-vlan-config)# device-tracking attach-policy example_policy	Attaches the device tracking policy to the specified VLANs across all switch interfaces. Note SISF based device-tracking policies can be detached only if they are custom policies. Programmatically created policies can be removed only if the corresponding device-tracking client feature configuration is removed.
Step 4	end Example: Switch(config-if)# end	Returns to the privileged EXEC mode.
Step 5	do show device-tracking policies vlan <i>vlan-ID</i> Example: Switch(config-vlan-config)# do show device-tracking policies vlan 333	Verifies that the policy is attached to the specified VLAN, without exiting the VLAN interface configuration mode.

Programmatically Enabling SISF-Based Device Tracking

Device tracking client features that enable SISF-based device tracking	These features can programmatically enable SISF-based device tracking: <ul style="list-style-type: none"> • IEEE 802.1X, web authentication, Cisco TrustSec, and IPSG. • Cisco LISP.
--	--

Policy Name	<p>For IEEE 802.1X, web authentication, IPSG, and Cisco TrustSec, the IPDT-DEFAULT policy is created and attached to the interface.</p> <p>For LISP, the DT-PROGRAMMATIC policy is created and attached to the VLAN.</p>
User Options	<ul style="list-style-type: none"> • The policy cannot be replaced by another policy. • The policy cannot be removed unless the device tracking client feature configuration is removed. • Only one policy can be attached to the same interface or VLAN. <p>If you create an IPv4 and an IPv6 policy, the system merges it and applies the merged policy to the interface or VLAN.</p> <ul style="list-style-type: none"> • You cannot change the settings of a merged policy. <p>You can change the settings of the IPv6 policy separately. Changing the settings of such a custom IPv6 policy (which is part of a merged policy) will cause the settings to also be applied to the IPv4 policy which is part of the merged policy.</p> <ul style="list-style-type: none"> • You cannot change the settings of any IPv4 policy. • You can change the settings of <ul style="list-style-type: none"> – a DT-PROGRMMATC policy; IPv4 and IPv6 settings are changed – a custom IPv6 policy <p>In case of DT-PROGRMMATC and a custom IPv6 policy, these are the settings you can change: (device-tracking policy command, in the device tracking configuration mode (config-device-tracking))</p> <ul style="list-style-type: none"> – data-glean – default – device-role – destination-glean – exit – limit – no – prefix-glean – protocol – security-level – tracking – trusted-port – The distribution-switch and vpc options are visible on the CLI, but any configuration changes are not effective. <p>The address count limit per MAC setting cannot be changed (This refers to the limit address-count for IPv4 per mac and limit address-count for IPv6 per mac commands), but the address count limit per port or interface can be changed.</p> <p>When a device-tracking policy is attached to an interface under a VLAN, the policy settings on the interface take precedence over those on its VLAN; exceptions here are the values for limit address-count for IPv4 per mac and limit address-count for IPv6 per mac, which are aggregated from the policy on both the interface and VLAN.</p>

Configuration Examples for SISF-Based Device Tracking

This section provides examples for the following scenarios:

- [Example: Configuring a Multi-Switch Network to Stop Creating Binding Entries from a Trunk Port, page 66-12](#)
- [Example: Applying a Merged \(IPv4 and IPv6\) Device Tracking Policy to the Same Target, page 66-12](#)
- [Example: Manually Attaching an IPv4 Device Tracking Policy to a VLAN, page 66-14](#)
- [Example: Disabling IPv6 Device Tracking, page 66-15](#)
- [Example: Enabling IPv6 for SVI on VLAN \(To Mitigate the Duplicate Address Problem\), page 66-15](#)
- [Example: Mitigating the IPv4 Duplicate Address Problem, page 66-15](#)
- [Example: Avoiding a Short Device-Tracking Binding Reachable Time, page 66-17](#)

Example: Configuring a Multi-Switch Network to Stop Creating Binding Entries from a Trunk Port

In a multi-switch network, SISF-based device tracking provides the capability to distribute binding table entries between switches running the feature. Binding entries are only created on the switches where the host appears on an access port. No entry is created for a host that appears over a trunk port. This is achieved by configuring a custom policy with the **trusted-port** and **device-role switch** options, and attaching it to the trunk port. The following example shows you how:

Note

Both, the **trusted-port**, and **device-role switch** options, must be configured in the policy. Further, we recommended that you apply such a policy on a port facing a device, which also has SISF-based device tracking enabled.

```
Switch# configure terminal
Switch(config)# device-tracking policy example_trusted_policy
Switch(config-device-tracking)# device-role switch
Switch(config-device-tracking)# trusted-port
Switch(config-device-tracking)# end
Switch(config)# interface gigabitethernet 1/0/25
Switch(config-if)# device-tracking attach-policy example_trusted_policy
```

Example: Applying a Merged (IPv4 and IPv6) Device Tracking Policy to the Same Target

This example shows you how to create IPv4 and IPv6 policies separately and then attach them to the same interface or VLAN:

Create an IPv4 policy using the IPDT command, and use the **show** command to display settings and verify that it is attached to the target:

```
Switch# configure terminal
Switch(config)# interface gigabitethernet2/47
Switch(config-if)# ip device tracking max 10
Switch(config-if)# end
```

```
Switch# show device-tracking policy IPDT-MAX-10
Policy IPDT-MAX-10 configuration:
  security-level guard
  device-role node
  NOT glean from Neighbor Discovery
  NOT glean from DHCP
  glean from ARP
  glean from DHCP4
  NOT glean from protocol unkn
  limit address-count for IPv4 per mac 1
  limit address-count for IPv4 per target 10
  tracking enable
Policy IPDT-MAX-10 is applied on the following targets:
Target          Type Policy          Feature    Target range
Gi2/47          PORT IPDT-MAX-10    Snooping   vlan all
```

Create a custom IPv6 policy and use the **show** command to display its settings. Note that this policy has not been attached to a target yet:

```
Switch# configure terminal
Switch(config)# device-tracking policy eg_cust_v6
Switch(config-device-tracking)# end

Switch# show device-tracking policy eg_cust_v6
Policy eg_cust_v6 configuration:
  security-level guard
  device-role node
  glean from Neighbor Discovery
  glean from DHCP
  NOT glean from ARP
  NOT glean from DHCP4
  NOT glean from protocol unkn
Policy eg_cust_v6 is applied on the following targets:
Target          Type Policy          Feature    Target range
eg_cust_v6
```

Attach the custom IPv6 policy to the same target as the IPv4 policy, that is, interface GigabitEthernet 2/47:

```
Switch# configure terminal
Switch(config)# interface gigabitethernet2/47
Switch(config-if)# device-tracking attach-policy eg_cust_v6
Switch(config-if)# end
```

Enter the **show** command to display the merged policy that is now attached to interface GigabitEthernet 2/47:

Note You cannot change the settings of the merged **IPDT-MAX-10+_eg_cust_v6** policy. You can however change the settings of **eg_cust_v6**. Changes made to **eg_cust_v6**, are applied to **IPDT-MAX-10** as well.

```
Switch# show device-tracking policy IPDT-MAX-10+_eg_cust_v6
Policy IPDT-MAX-10+_eg_cust_v6 configuration:
  security-level guard
  device-role node
  glean from Neighbor Discovery
  glean from DHCP
  glean from ARP
  glean from DHCP4
  NOT glean from protocol unkn
  limit address-count for IPv4 per mac 1
  limit address-count for IPv4 per target 10
```

```

tracking enable
Policy IPDT-MAX-10+_eg_cust_v6 is applied on the following targets:
Target  Type  Policy                      Feature      Target range
Gi2/47  PORT   IPDT-MAX-10+_eg_cust_v6 Snooping     vlan all

```

Example: Manually Attaching an IPv4 Device Tracking Policy to a VLAN

This example shows how to attach an IPv4 device tracking policy to a VLAN:

```

Switch# configure terminal
Switch(config)# interface
Switch(config)# interface vlan 300
Switch(config-if)# ip device tracking maximum 10
Switch(config-if)# end

Switch# show device-tracking policies
Target      Type  Policy      Feature      Target range
vlan 300    VLAN  IPDT-MAX-10 Snooping     vlan all

```

Note The value you specify for **ip device tracking maximum *n*** refers to the maximum number of entries that are permitted for the specified VLAN. The permitted value range is 0 to 65535; entering 0 means entries are not learned.

Example: Programmatically Enabling SISF-Based Device Tracking

This example show you the settings of a programmatic policy that is created when you configure LISP on the switch.

Device tracking client: LISP (The LISP configuration here is only meant to serve as an example).

After you configure LISP, enter the **show device-tracking policy** command in privileged EXEC mode, to display the DT-PROGRAMMATIC policy that is created and the corresponding settings:

```

Switch(config)# router lisp
<output truncated>
Switch(config-router-lisp)# instance-id 3
Switch(config-router-lisp-instance)# service ethernet
Switch(config-router-lisp-instance-service)# eid-table vlan 10
Switch(config-router-lisp-instance-dynamic-eid)# database-mapping 10.1.1.0/24
locator-set set1
Switch(config-router-lisp-instance-service)# exit-service-ethernet
Switch(config-router-lisp-instance)# exit-instance-id
Switch(config-router-lisp)# exit-router-lisp

Switch# show device-tracking policy DT-PROGRAMMATIC
Policy DT-PROGRAMMATIC configuration:
  security-level guard (*)
  device-role node
  gleaning from Neighbor Discovery
  gleaning from DHCP
  gleaning from ARP
  gleaning from DHCP4
  NOT gleaning from protocol unkn
  limit address-count for IPv4 per mac 1 (*)
  limit address-count for IPv6 per mac 8 (*)
  tracking enable
Policy DT-PROGRAMMATIC is applied on the following targets:

```

Target	Type	Policy	Feature	Target range
vlan 10	VLAN	DT-PROGRAMMATIC	Device-tracking	vlan all

note:
 Binding entry Down timer: 10 minutes (*)
 Binding entry Stale timer: 30 minutes (*)

Example: Disabling IPv6 Device Tracking

If SISF-based device tracking is enabled by a custom policy, detach the policy from the target by entering the **no device-tracking attach-policy *policy-name*** command in interface configuration mode. For example, to detach custom policy `example_policy` from interface GigabitEthernet 1/1/4:

```
Switch# configure terminal
Switch(config)# interface gigabitethernet 1/1/4
Switch(config-if)# no device-tracking attach-policy example_policy
Switch# end
```

If SISF-based device tracking is programmatically enabled, by configuring LISP, enter the following commands to change the programmatic policy and thus disable SISF-based device tracking:

```
Switch(config)# device-tracking policy DT-PROGRAMMATIC
Switch(config-device-tracking)# no protocol ndp
Switch(config-device-tracking)# no protocol dhcp6
Switch(config-device-tracking)# end
```

Example: Enabling IPv6 for SVI on VLAN (To Mitigate the Duplicate Address Problem)

For an IPv6 device-tracking entry, its reachability is verified by sending an SISF probe to its end-node, which is a neighbor solicitation message. Selection of the source IP address for this neighbor solicitation probe follows these rules:

- If an SVI is configured on the VLAN, the link-local IPv6 address of the SVI is selected. Please ensure that the SVI IP address is unique in the subnet.
- Otherwise, an address with all zeros (0:0:0:0:0:0:0:0) is selected.

When IPv6 is enabled in the network and a switched virtual interface (SVI) is configured on a VLAN, we recommend that you add the following to the SVI configuration. This enables the SVI to acquire a link-local address automatically; this address is used as the source IP address of the SISF probe, thus preventing the duplicate IP address issue.

```
Switch(config)# interface vlan 10
Switch(config-if)# ipv6 enable
Switch(config-if)# end
```

Example: Mitigating the IPv4 Duplicate Address Problem

For an IPv4 device-tracking entry, its reachability is verified by sending an SISF probe to its end-node, which is an ARP request message. Selection of the source IP address for this ARP probe follows these rules:

- If an SVI is configured on the VLAN, the IPv4 address of the SVI is selected. Please ensure that the SVI IP address is unique in the subnet.
- If SVI does not exist and the **device-tracking tracking auto-source [fallback host-ip mask] [override]** command is configured, source IP is selected according to the table below.
- Otherwise, an address with all zeros (0.0.0.0) is selected.

This example shows how you can tackle the Duplicate IP Address 0.0.0.0 error message problem encountered by clients that run Microsoft Windows:

Configure the **ip device tracking probe auto-source** command in global configuration mode. This command determines the source IP and MAC address used in the Address Resolution Packet (ARP) request sent by the switch to probe a client, in order to maintain its entry in the device-tracking table. The purpose, is to avoid using 0.0.0.0 as source IP address.

Note Configure the **ip device tracking probe auto-source** command only when a switch virtual interface (SVI) is not configured. You do not have to configure it when a SVI is configured with an IPv4 address on the VLAN.

Command	Required Action (In order to select source IP and MAC address for device tracking ARP probe)	Notes
ip device tracking probe auto-source	Set source to VLAN SVI if present. Look for IP and MAC binding in device-tracking table from same subnet. Use 0.0.0.0	We recommend that you disable device-tracking on all trunk ports to avoid MAC flapping.
ip device tracking probe auto-source override	Set source to VLAN SVI if present Use 0.0.0.0	Not recommended when there is no SVI.
ip device tracking probe auto-source fallback 0.0.0.X 255.255.255.0	Set source to VLAN SVI if present. Look for IP and MAC binding in device-tracking table from same subnet. Compute source IP from client IP using host bit and mask provided. Source MAC is taken from the MAC address of the switchport facing the client ¹ .	We recommend that you disable device-tracking on all trunk ports to avoid MAC flapping. The computed IPv4 address must not be assigned to any client or network device.
ip device tracking probe auto-source fallback 0.0.0.X 255.255.255.0 override	Set source to VLAN SVI if present. Compute source IP from client IP using host bit and mask provided ¹ . Source MAC is taken from the MAC address of the switchport facing the client ¹ .	-

1. Depending on the client IP address, an IPv4 address has to be reserved for the source IP.

A reserved source IPv4 address = (client-ip and mask) | host-ip

Client IP = 192.0.2.25

Source IP = (192.0.2.25 and 255.255.255.0) | (0.0.0.1) = 192.0.2.1

IP address 192.0.2.1 should not be assigned to any client or network device.

Example: Avoiding a Short Device-Tracking Binding Reachable Time

When migrating from an older release, the following configuration may be present:

device-tracking binding reachable-time 10

Remove this by entering the **no** version of the command.

Port Unicast and Multicast Flood Blocking

This chapter describes how to configure multicast and unicast flood blocking on the Catalyst 4500 series switch. This chapter contains these topics:

- [About Flood Blocking, page 67-1](#)
- [Configuring Port Blocking, page 67-1](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Flood Blocking

Occasionally, unknown unicast or multicast traffic is flooded to a switch port because a MAC address has timed out or has not been learned by the switch. (This condition is especially undesirable for a private VLAN isolated port.) To guarantee that no unicast and multicast traffic is flooded to the port, use the **switchport block unicast** and **switchport block multicast** commands to enable flood blocking on the switch.

Note

The flood blocking feature is supported on all switched ports (including PVLAN ports) and is applied to all VLANs on which the port is forwarding.

Configuring Port Blocking

By default, a switch floods packets with unknown destination MAC addresses to all ports. If unknown unicast and multicast traffic is forwarded to a switch port, there might be security issues. To prevent forwarding such traffic, you can configure a port to block unknown unicast or multicast packets.

Note

Blocking of unicast or multicast traffic is not automatically enabled on a switch port; you must explicitly configure it.

Blocking Flooded Traffic on an Interface

Note The interface can be a physical interface (for example, GigabitEthernet 1/1) or an EtherChannel group (such as port-channel 5). When you block multicast or unicast traffic for a port channel, it is blocked on all ports in the port channel group.

Note Starting with Cisco IOS Release 12.2(52)SG, only IPV4 and IPv6 unknown multicast traffic flooding is blocked; Layer 2 unknown multicast flooding is not. This behavior stems from a fix for the following problem: when you configure blocking of unknown multicast flooding on a port, broadcast traffic to the port is also blocked.

To disable the flooding of multicast and unicast packets to an interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode and enter the type and number of the switch port interface (for example, GigabitEthernet 1/1).
Step 3	Switch(config-if)# switchport block multicast	Blocks unknown multicast forwarding to the port.
Step 4	Switch(config-if)# switchport block unicast	Blocks unknown unicast forwarding to the port.
Step 5	Switch(config)# end	Returns to privileged EXEC mode.
Step 6	Switch# show interface <i>interface-id</i> switchport	Verifies your entry.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to block unicast and multicast flooding on a GigabitEthernet interface1/1 and how to verify the configuration:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# switchport block multicast
Switch(config-if)# switchport block unicast
Switch(config-if)# end
Switch# show interface gigabitethernet1/1 switchport
Name: Gi1/3
Switchport: Enabled

<output truncated>

Port Protected: On
Unknown Unicast Traffic: Not Allowed
Unknown Multicast Traffic: Not Allowed

Broadcast Suppression Level: 100
Multicast Suppression Level: 100
Unicast Suppression Level: 100
```

Resuming Normal Forwarding on a Port

To resume normal forwarding on a port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode and enter the type and number of the switch port interface (GigabitEthernet1/1).
Step 3	Switch(config-if)# no switchport block multicast	Enables unknown multicast flooding to the port.
Step 4	Switch(config-if)# no switchport block unicast	Enables unknown unicast flooding to the port.
Step 5	Switch(config)# end	Returns to privileged EXEC mode.
Step 6	Switch# show interface <i>interface-id</i> switchport	Verifies your entry.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring Storm Control

This chapter describes how to configure port-based traffic control on a switch and consists of these sections:

- [About Storm Control, page 68-1](#)
- [Enabling Broadcast Storm Control, page 68-3](#)
- [Enabling Multicast Storm Control, page 68-4](#)
- [Disabling Broadcast Storm Control, page 68-5](#)
- [Disabling Multicast Storm Control, page 68-6](#)
- [Displaying Storm Control, page 68-6](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Storm Control

This section contains the following subsections:

- [Hardware-Based Storm Control Implementation, page 68-1](#)
- [Software-Based Storm Control Implementation, page 68-2](#)

Storm control prevents LAN interfaces from being disrupted by a broadcast storm. A broadcast storm occurs when broadcast packets flood the subnet, creating excessive traffic and degrading network performance. Errors in the protocol-stack implementation or in the network configuration can cause a broadcast storm.

Hardware-Based Storm Control Implementation

Broadcast suppression uses filtering that measures broadcast activity in a subnet over a one-second interval and compares the measurement with a predefined threshold. If the threshold is reached, further broadcast activity is suppressed for the duration of the interval. Broadcast suppression is disabled by default.

Figure 68-1 shows the broadcast traffic patterns on a LAN interface over a given interval. In this example, broadcast suppression occurs between times T1 and T2 and between T4 and T5. During those intervals, the amount of broadcast traffic exceeded the configured threshold.

Figure 68-1 Storm Control Example—Hardware-based Implementation

The broadcast suppression threshold numbers and the time interval combination make the broadcast suppression algorithm work with different levels of granularity. A higher threshold allows more broadcast packets to pass through.

Broadcast suppression on the Catalyst 4500 series switches is implemented in hardware. The suppression circuitry monitors packets passing from a LAN interface to the switching bus. If the packet destination address is broadcast, then the broadcast suppression circuitry tracks the current count of broadcasts within the one-second interval, and when a threshold is reached, it filters out subsequent broadcast packets.

Because hardware broadcast suppression uses a bandwidth-based method to measure broadcast activity, the most significant implementation factor is setting the percentage of total available bandwidth that can be used by broadcast traffic. Because packets do not arrive at uniform intervals, the one-second interval during which broadcast activity is measured can affect the behavior of broadcast suppression.

Software-Based Storm Control Implementation

When storm control is enabled on an interface, the switch monitors packets received on the interface and determines whether the packets are broadcast. The switch monitors the number of broadcast packets received within a one-second time interval. When the interface threshold is met, all incoming data traffic on the interface is dropped. This threshold is specified as a percentage of total available bandwidth that can be used by broadcast traffic. If the lower threshold is specified, all data traffic is forwarded as soon as the incoming traffic falls below that threshold.

Note

A Cisco Catalyst 4500-X series switch checks for a broadcast storm in real-time, too. When a broadcast storm occurs on a Cisco Catalyst 4500-X series switch and the threshold is reached within a fraction of a second, the broadcast is suppressed. This behavior on Cisco Catalyst 4500-X series switches is in addition to the hardware-based storm control and software-based storm control described earlier.

Enabling Broadcast Storm Control

To enable storm control, perform this task:

	Command or Action	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode and enters the port to configure.
Step 3	Switch(config-if)# storm-control broadcast level { <i>high-level</i> bps <i>bps</i> [k m g] pps <i>pps</i> [k m g]}	<p>Configures broadcast storm control. The keywords and arguments are described here.</p> <ul style="list-style-type: none"> <i>high-level</i>—Specifies the upper threshold levels for broadcast traffic as a percentage (up to two decimal places) of the bandwidth. The port blocks traffic that exceeds this level. The range is from 0 to 100. <p> Note For the Catalyst 4500-X Series Switch, on ports operating at 1Gigabit, thresholds less than 0.02% are not supported.</p> <ul style="list-style-type: none"> bps <i>bps</i>—Specifies the threshold level for broadcast traffic in bits per second (bps) (up to one decimal place). The port blocks only the traffic that exceeds this level. The range is 0.0 to 10000000000.0. pps <i>pps</i>—Specifies the threshold level for broadcast traffic in packets per second (pps) (up to one decimal place). The port blocks all traffic when traffic utilization exceeds this level. The range is 0.0 to 10000000000.0. (Optional) [k m g]—Specifies the metric suffixes for large number thresholds, in bps and pps settings.
Step 4	Switch(config-if)# storm-control action { shutdown trap }	<p>Specifies the action to be taken when a storm is detected.</p> <p>The default is to filter out the broadcast traffic and not to send out traps.</p> <p>The shutdown keyword sets the port to the error-disable state during a storm. If the recover interval is not set, the port remains in shutdown state.</p>
Step 5	Switch(config-if)# exit	Returns to configuration mode.
Step 6	Switch(config)# end	Returns to privileged EXEC mode.
Step 7	Switch# show storm-control [<i>interface</i>] broadcast	Displays the number of packets suppressed.
Step 8	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to enable storm control on an interface and verify configuration:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet 2/1
Switch(config-if)# storm-control broadcast level bps 100k
```

```

Switch(config-if)# end

Switch# show storm-control gigabitethernet 2/1
Interface  Filter State    Broadcast Multicast Level
-----
Gi2/1      Link Down    Enabled   Disabled   100k bps

Switch# show interfaces counters storm-control

```

Enabling Multicast Storm Control

Per-interface multicast suppression, which allows you to subject incoming multicast and broadcast traffic to interface-level suppression.

Note

Multicast and broadcast suppression share a common threshold per interface. Multicast suppression takes effect *only* if broadcast suppression is enabled. Disabling broadcast suppression on an interface also disables multicast suppression.

To enable multicast suppression, perform this task:

	Command or Action	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode and specifies the port to be configured.

	Command or Action	Purpose
Step 3	Switch(config-if)# storm-control broadcast include multicast	Enables multicast suppression.
Step 4	Switch(config-if)# exit	Returns to configuration mode.
Step 5	Switch(config)# end	Returns to privileged EXEC mode.
Step 6	Switch# show storm-control [interface] multicast	Verifies the configuration.

This example shows how to enable multicast suppression on ports that already have broadcast suppression enabled:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet 2/1
Switch(config-if)# storm-control broadcast include multicast
Switch(config-if)# end
```

```
Switch# show storm-control gigabitethernet 2/1
Interface  Filter State  Broadcast Multicast Level
-----  -
Gi2/1      Forwarding  Enabled   Enabled   50.00%
```

```
Switch# show interface counters storm-control
Port          Broadcast  Multicast  Level  TotalSuppressedPackets
Gi2/1         Enabled    Enabled    50.00% 0
```

Disabling Broadcast Storm Control

To disable storm control, perform this task:

	Command or Action	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface interface-id	Enters interface configuration mode and specifies the port to be configured.
Step 3	Switch(config-if)# no storm-control broadcast level	Disables port storm control.
Step 4	Switch(config-if)# no storm-control action {shutdown trap}	Disables the specified storm control action and returns to default filter action.
Step 5	Switch(config-if)# exit	Returns to configuration mode.
Step 6	Switch(config)# end	Returns to privileged EXEC mode.
Step 7	Switch# show storm-control broadcast	Verifies your entries.
Step 8	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to enable multicast suppression on ports that already have broadcast suppression enabled:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet 2/1
```

```

Switch(config-if)# storm-control broadcast include multicast
Switch(config-if)# end

Switch# show storm-control gigabitethernet 2/1
Interface  Filter State    Broadcast Multicast Level
-----
Gi2/1      Forwarding    Enabled   Enabled   50.00%

Switch# show interface counters storm-control
Port          Broadcast  Multicast    Level    TotalSuppressedPackets
Gi2/1         Enabled   Enabled      50.00%      0

```

Disabling Multicast Storm Control

To disable multicast suppression, perform this task:

	Command or Action	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# [no] storm-control broadcast include multicast	Enables and disables multicast suppression.
Step 3	Switch(config-if)# no storm-control broadcast level	Disables port storm control (broadcast and multicast).
Step 4	Switch(config-if)# exit	Returns to configuration mode.
Step 5	Switch(config)# end	Returns to privileged EXEC mode.

Displaying Storm Control

Use the **show interface capabilities** command to determine the mode in which storm control is supported in an interface.

This example shows how an interface that supports broadcast suppression in software:

```

Switch# show interface gigabitethernet 2/1 capabilities
GigabitEthernet2/1
  Model: WS-X4648-RJ45V-E-RJ-45
  Type: 10/100/1000-TX
  Speed: 10,100,1000,auto
  Duplex: half,full,auto
  Auto-MDIX: yes
  EEE: no
  Trunk encap. type: 802.1Q
  Trunk mode: on,off,desirable,nonegotiate
  Channel: yes
  Broadcast suppression: percentage(0-100), hw
  Multicast suppression: percentage(0-100), hw
  Flowcontrol: rx-(off,on,desired),tx-(off,on,desired)
  VLAN Membership: static, dynamic
  Fast Start: yes
  CoS rewrite: yes
  ToS rewrite: yes
  Inline power: yes (Cisco Voice Protocol/IEEE Protocol 802.3af)
  SPAN: source/destination
  UDLD: yes

```

```

Link Debounce:          no
Link Debounce Time:     no
Port Security:          yes
Dot1x:                  yes
Maximum MTU:            9198 bytes (Jumbo Frames)
Multiple Media Types:    no
Diagnostic Monitoring:   N/A

```

Use the **show interfaces counters storm-control** command to display a count of discarded packets.

```
Switch# show interfaces counters storm-control
```

Port	Broadcast	Multicast	Level	TotalSuppressedPackets
Fa3/1	Enabled	Disabled	10.00%	46516510
Gi2/1	Enabled	Enabled	50.00%	0

```
Switch# show storm-control
```

Interface	Filter State	Broadcast	Multicast	Level
Fa3/1	Blocking	Enabled	Disabled	10.00%
Gi2/1	Link Down	Enabled	Enabled	50.00%

Configuring SPAN and RSPAN

This chapter describes how to configure the Switched Port Analyzer (SPAN) and Remote SPAN (RSPAN) on the Catalyst 4500 series switches. SPAN selects network traffic for analysis by a network analyzer, such as a SwitchProbe device or other Remote Monitoring (RMON) probe.

This chapter consists of the following sections:

- [About SPAN and RSPAN, page 69-1](#)
- [Configuring SPAN, page 69-7](#)
- [CPU Port Sniffing, page 69-10](#)
- [Encapsulation Configuration, page 69-11](#)
- [Ingress Packets, page 69-12](#)
- [Access List Filtering, page 69-13](#)
- [Packet Type Filtering, page 69-14](#)
- [Configuration Example, page 69-15](#)
- [Configuring RSPAN, page 69-16](#)
- [Displaying SPAN and RSPAN Status, page 69-24](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About SPAN and RSPAN

This sections includes the following subsections:

- [SPAN and RSPAN Concepts and Terminology, page 69-3](#)
- [SPAN and RSPAN Session Limits, page 69-6](#)
- [Default SPAN and RSPAN Configuration, page 69-6](#)

SPAN mirrors traffic from one or more source interfaces on any VLAN or from one or more VLANs to a destination interface for analysis. In [Figure 69-1](#), all traffic on Ethernet interface 5 (the source interface) is mirrored to Ethernet interface 10. A network analyzer on Ethernet interface 10 receives all network traffic from Ethernet interface 5 without being physically attached to it.

For SPAN configuration, the source interfaces and the destination interface must be on the same switch.

SPAN does not affect the switching of network traffic on source interfaces; copies of the packets received or transmitted by the source interfaces are sent to the destination interface.

Figure 69-1 Example SPAN Configuration

RSPAN extends SPAN by enabling remote monitoring of multiple switches across your network. The traffic for each RSPAN session is carried over a user-specified RSPAN VLAN that is dedicated for that RSPAN session in all participating switches. The SPAN traffic from the sources is copied onto the RSPAN VLAN and then forwarded over trunk ports that are carrying the RSPAN VLAN to any RSPAN destination sessions monitoring the RSPAN VLAN, as shown in [Figure 69-2](#).

Figure 69-2 Example of RSPAN Configuration

SPAN and RSPAN do not affect the switching of network traffic on source ports or source VLANs; a copy of the packets received or sent by the sources is sent to the destination. Except for traffic that is required for the SPAN or RSPAN session, by default, destination ports do not receive or forward traffic.

You can use the SPAN or RSPAN destination port to forward transmitted traffic from a network security device. For example, if you connect a Cisco Intrusion Detection System (IDS) sensor appliance to a destination port, the IDS device can send TCP reset packets to close down the TCP session of a suspected attacker.

SPAN and RSPAN Concepts and Terminology

This section describes concepts and terminology associated with SPAN and RSPAN configuration and includes the following subsections:

- [SPAN Session, page 69-3](#)
- [Traffic Types, page 69-3](#)
- [Source Port, page 69-4](#)
- [Destination Port, page 69-5](#)
- [VLAN-Based SPAN, page 69-5](#)
- [SPAN Traffic, page 69-6](#)

SPAN Session

A local SPAN session associates a destination port with source ports. You can monitor incoming or outgoing traffic on a series or range of ports and source VLANs. An RSPAN session associates source ports and source VLANs across your network with an RSPAN VLAN. The destination source is the RSPAN VLAN.

You configure SPAN sessions by using parameters that specify the source of network traffic to monitor.

You can configure multiple SPAN or RSPAN sessions with separate or overlapping sets of SPAN sources. Both switched and routed ports can be configured as SPAN sources or destination ports.

An RSPAN source session associates SPAN source ports or VLANs with a destination RSPAN VLAN. An RSPAN destination session associates an RSPAN VLAN with a destination port.

SPAN sessions do not interfere with the normal operation of the switch; however, an oversubscribed SPAN destination (for example, a 10-Mbps port monitoring a 100-Mbps port) results in dropped or lost packets.

You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.

A SPAN session remains inactive after system startup until the destination port is operational.

Traffic Types

SPAN sessions include these traffic types:

- **Receive (Rx) SPAN**—The goal of receive (or ingress) SPAN is to monitor as much as possible all packets received by the source interface or VLAN before any modification or processing is performed by the switch. A copy of each packet received by the source is sent to the destination port for that SPAN session. You can monitor a series or range of ingress ports or VLANs in a SPAN session.

On tagged packets (Inter-Switch Link IEEE 802.1Q), the tagging is removed at the ingress port. At the destination port, if tagging is enabled, the packets appear with 802.1Q headers. If no tagging is specified, packets appear in the native format.

Packets that are modified because of routing are copied without modification for Rx SPAN; that is, the original packet is copied. Packets that are modified because of quality of service (QoS)—for example, modified Differentiated Services Code Point (DSCP)—are copied without modification for Rx SPAN.

Some features that can cause a packet to be dropped during receive processing have no effect on SPAN; the destination port receives a copy of the packet even if the actual incoming packet is dropped. These features include IP standard and extended input access control lists (ACLs), IP standard and extended output ACLs for unicast and ingress QoS policing, VLAN maps, ingress QoS policing, and policy-based routing. Switch congestion that causes packets to be dropped also has no effect on SPAN.

- **Transmit (Tx) SPAN**—The goal of transmit (or egress) SPAN is to monitor as much as possible all packets sent by the source interface after the switch performs all modification and processing. After the packet is modified, the source sends a copy of each packet to the destination port for that SPAN session. You can monitor a range of egress ports in a SPAN session.

Packets that are modified because of routing—for example, with a time-to-live (TTL) or MAC-address modification—are duplicated at the destination port. On packets that are modified because of QoS, the modified packet might not have the same DSCP (IP packet) or CoS (non-IP packet) as the SPAN source.

Some features that can cause a packet to be dropped during transmit processing might also affect the duplicated copy for SPAN. These features include VLAN maps, IP standard and extended output ACLs on multicast packets, and egress QoS policing. In the case of output ACLs, if the SPAN source drops the packet, the SPAN destination would also drop the packet. In the case of egress QoS policing, if the SPAN source drops the packet, the SPAN destination might not drop it. If the source port is oversubscribed, the destination ports have different dropping behavior.

- **Both**—In a SPAN session, you can monitor a single port series or a range of ports for both received and sent packets.

Source Port

A source port (also called a *monitored port*) is a switched or routed port that you monitor for network traffic analysis. In a single local SPAN session or RSPAN source session, you can monitor source port traffic, such as received (Rx), transmitted (Tx), or bidirectional (both). The switch supports any number of source ports (up to the maximum number of available ports on the switch) and any number of source VLANs.

A source port has these characteristics:

- It can be any port type (for example, EtherChannel, Fast Ethernet, Gigabit Ethernet, and so forth).
- It can be monitored in multiple SPAN sessions.
- It cannot be a destination port.
- Each source port can be configured with a direction (ingress, egress, or both) to monitor. For EtherChannel sources, the monitored direction would apply to all physical ports in the group.
- Source ports can be in the same or different VLANs.
- For VLAN SPAN sources, all active ports in the source VLAN are included as source ports.

You can configure a trunk port as a source port. By default, all VLANs active on the trunk are monitored. You can limit SPAN traffic monitoring on trunk source ports to specific VLANs by using VLAN filtering. Only switched traffic in the selected VLANs is sent to the destination port. This feature affects only traffic forwarded to the destination SPAN port and does not affect the switching of normal traffic. This feature is not allowed in sessions with VLAN sources.

Destination Port

Each local SPAN session or RSPAN destination session must have a destination port (also called a *monitoring port*) that receives a copy of traffic from the source ports and VLANs.

A destination port has these characteristics:

- A destination port must reside on the same switch as the source port (for a local SPAN session).
- A destination port can be any Ethernet physical port.
- A destination port can participate in only one SPAN session at a time. (A destination port in one SPAN session cannot be a destination port for a second SPAN session.)
- A destination port cannot be a source port.
- A destination port cannot be an EtherChannel group.
- A destination port can be a physical port that is assigned to an EtherChannel group, even if the EtherChannel group has been specified as a SPAN source. The port is removed from the group while it is configured as a SPAN destination port.
- The port does not transmit any traffic except that traffic required for the SPAN session unless learning is enabled. If learning is enabled, the port also transmits traffic directed to hosts that have been learned on the destination port.
- If ingress traffic forwarding is enabled for a network security device, the destination port forwards traffic at Layer 2.
- A destination port does not participate in spanning tree while the SPAN session is active.
- When it is a destination port, it does not participate in any of the Layer 2 protocols (STP, VTP, CDP, DTP, PagP).
- A destination port that belongs to a source VLAN of any SPAN session is excluded from the source list and is not monitored.
- A destination port receives copies of sent and received traffic for all monitored source ports. If a destination port is oversubscribed, it could become congested and result in packet drops at the destination port. This congestion does not affect traffic forwarding on the source ports.

VLAN-Based SPAN

VLAN-based SPAN (VSPAN) is the monitoring of the network traffic in one or more VLANs.

Use these guidelines for VSPAN sessions:

- Traffic on RSPAN VLANs is not monitored by VLAN-based SPAN sessions.
- Only traffic on the monitored VLAN is sent to the destination port.
- If a destination port belongs to a source VLAN, it is excluded from the source list and is not monitored.
- If ports are added to or removed from the source VLANs, the traffic on the source VLAN received by those ports is added to or removed from the sources being monitored.
- VLAN pruning and the VLAN allowed list have no effect on SPAN monitoring.

- VSPAN monitors only traffic that enters the switch, not traffic that is routed between VLANs. For example, if a VLAN is being Rx-monitored, and the multilayer switch routes traffic from another VLAN to the monitored VLAN, that traffic is not monitored and is not received on the SPAN destination port.
- You cannot use filter VLANs in the same session with VLAN sources.
- You can monitor only Ethernet VLANs.

SPAN Traffic

You can use local SPAN to monitor all network traffic, including multicast and bridge protocol data unit (BPDU) packets, Cisco Discovery Protocol (CDP), VLAN Trunk Protocol (VTP), Dynamic Trunking Protocol (DTP), Spanning Tree Protocol (STP), and Port Aggregation Protocol (PAgP) packets. You cannot use RSPAN to monitor Layer 2 protocols. See the [“RSPAN Configuration Guidelines” section on page 69-16](#) for more information.)

In some SPAN configurations, multiple copies of the same source packet are sent to the SPAN destination port. For example, a bidirectional (both Rx and Tx) SPAN session is configured for the sources a1 Rx monitor and the a2 Rx and Tx monitor to destination port d1. If a packet enters the switch through a1 and is switched to a2, both incoming and outgoing packets are sent to destination port d1. Both packets are the same (unless a Layer-3 rewrite occurs, in which case the packets are different because of the added Layer 3 information).

SPAN and RSPAN Session Limits

You can configure a maximum of sixteen SPAN/RSPAN sessions (eight concurrent sessions with ingress-only sources and eight concurrent sessions with egress-only sources). Bidirectional sources count as both ingress and egress. RSPAN destination sessions count as a session containing an ingress source.

Default SPAN and RSPAN Configuration

[Table 69-1](#) shows the default SPAN and RSPAN configuration.

Table 69-1 *Default SPAN and RSPAN Configuration*

Feature	Default Setting
SPAN state	Disabled.
Source port traffic to monitor	Both received and sent traffic (both).
Filters	All VLANs, all packet types, all address types.
Encapsulation type (destination port)	Native form (no encapsulation type header).
Ingress forwarding (destination port)	Disabled.
Host learning (destination port)	Disabled.

Configuring SPAN

The following sections describe how to configure SPAN:

- [SPAN Configuration Guidelines and Restrictions, page 69-7](#)
- [Configuring SPAN Sources, page 69-8](#)
- [Configuring SPAN Destinations, page 69-9](#)
- [Monitoring Source VLANs on a Trunk Interface, page 69-9](#)
- [Configuration Scenario, page 69-10](#)
- [Verifying a SPAN Configuration, page 69-10](#)

**Note**

Entering SPAN configuration commands does not clear previously configured SPAN parameters. You must enter the **no monitor session** command to clear configured SPAN parameters.

SPAN Configuration Guidelines and Restrictions

Follow these guidelines and restrictions when configuring SPAN:

- You must use a network analyzer to monitor interfaces.
- You cannot mix source VLANs and filter VLANs within a SPAN session. You can have source VLANs or filter VLANs, but not both at the same time.
- EtherChannel interfaces can be SPAN source interfaces; they cannot be SPAN destination interfaces.
- When you specify source interfaces and do not specify a traffic type (Tx, Rx, or both), “both” is used by default. To change from both to either “tx” or “rx,” unconfigure the corresponding other type “rx” or “tx” with the **no monitor session {session_number} {source {interface interface_list | {vlan vlan_ids | cpu [queue queue_ids] } {rx | tx}}** command.
- If you specify multiple SPAN source interfaces, the interfaces can belong to different VLANs.
- You must enter the **no monitor session number** command with no other parameters to clear the SPAN session *number*.
- The **no monitor** command clears all SPAN sessions.
- SPAN destinations never participate in any spanning tree instance. SPAN includes BPDUs in the monitored traffic, so any BPDUs seen on the SPAN destination are from the SPAN source.
- SPAN is limited to one destination port per session.
- When you create a SPAN session, it sets the packet filter to **good** automatically (default) and hence you will see another configuration line:

monitor session 1 filter packet-type good rx

To remove or change this filter, first enter the **no monitor session 1 filter packet-type good rx** and then configure the kind of span filter you want to. But do not reload the switch after this. Reloading the switches automatically re-creates the default configuration, and does not delete user-configuration. Having both **good** and **bad** packet types configured, disables the filtering function.

Configuring SPAN Sources

To configure the source for a SPAN session, perform this task:

Command	Purpose
<pre>Switch(config)# [no] monitor session {session_number} {source {interface interface_list {vlan vlan_IDs cpu [queue queue_ids] } [rx tx both]}</pre>	<p>Specifies the SPAN session number (1 through 6), the source interfaces (FastEthernet or GigabitEthernet), VLANs (1 through 4094), whether traffic received or sent from the CPU is copied to the session destination, and the traffic direction to be monitored.</p> <p>For <i>session_number</i>, specifies the session number identified with this RSPAN session (1 through 6).</p> <p>For <i>interface-list</i>, specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (port-channel <i>port-channel-number</i>).</p> <p>For <i>vlan_IDs</i>, specifies the source VLAN.</p> <p>For <i>queue_ids</i>, specifies the queue(s) involved.</p> <p>(Optional) [, l -] Specifies a series or range of interfaces. Enter a space after the comma; enter a space before and after the hyphen.</p> <p>(Optional) Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both transmitted (Tx) and received (Rx) traffic. Only received traffic can be monitored on additional source ports.</p> <ul style="list-style-type: none"> • Rx—Monitor received traffic. • Tx—Monitor transmitted traffic. • both—Monitor both received and transmitted traffic (bidirectional). <p>Queues may be identified either by number or by name. Queue names may subsume multiple numbered queues for convenience.</p> <p>Use the no keyword to restore the defaults.</p>

This example shows how to configure SPAN session 1 to monitor bidirectional traffic from source interface Fast Ethernet 5/1:

```
Switch(config)# monitor session 1 source interface fastethernet 5/1
```

This example shows how to configure sources with differing directions within a SPAN session:

```
Switch(config)# monitor session 1 source interface fa2/3 rx
Switch(config)# monitor session 1 source interface fa2/2 tx
Switch(config)#
```

Configuring SPAN Destinations

To configure the destination for a SPAN session, perform this task:

Command	Purpose
Switch(config)# [no] monitor session <session_number> destination interface <interface> [encapsulation {dot1q}] [ingress [vlan vlan_IDs] [learning]]	Specifies the SPAN session number (1 through 6) and the destination interfaces or VLANs. For <i>session_number</i> , specifies the session number identified with this RSPAN session (1 through 6). For <i>interface</i> , specifies the destination interface. For <i>vlan_IDs</i> , specifies the destination VLAN. Use the no keyword to restore the defaults.

Note

SPAN is limited to one destination port per session.

This example shows how to configure interface Fast Ethernet 5/48 as the destination for SPAN session 1:

```
Switch(config)# monitor session 1 destination interface fastethernet 5/48
```

Monitoring Source VLANs on a Trunk Interface

To monitor specific VLANs when the SPAN source is a trunk interface, perform this task:

Command	Purpose
Switch(config)# [no] monitor session {session_number} filter {vlan vlan_IDs [, -]} {packet-type {good bad}} {address-type {unicast multicast broadcast} [rx tx both]}	Monitors specific VLANs when the SPAN source is a trunk interface. The filter keyword restricts monitoring to traffic that is on the specified VLANs; it is typically used when monitoring a trunk interface. For <i>session_number</i> , specifies the session number identified with this RSPAN session (1 through 6). For <i>vlan_IDs</i> , specifies the VLAN. Monitoring is established through all the ports in the specified VLANs Use the no keyword to restore the defaults.

This example shows how to monitor VLANs 1 through 5 and VLAN 9 when the SPAN source is a trunk interface:

```
Switch(config)# monitor session 2 filter vlan 1 - 5 , 9
```

Configuration Scenario

This example shows how to use the commands described in this chapter to completely configure and unconfigure a span session. Assume that you want to monitor bidirectional traffic from source interfaces Fast Ethernet 4/10, 4/11 and 4/12, Interface 4/10 is configured as a trunk interface carrying VLANs 1 through 4094. Interface Fast Ethernet 4/11 is configured as an access port in VLAN 57 and interface Fast Ethernet 4/12 is configured as an access port in VLAN 58. You want to monitor only traffic in VLAN 57 in that session. Using Fast Ethernet 4/15 as your destination interface, you would enter the following commands:

```
Switch(config)# monitor session 1 source interface fastethernet 4/10 - 12
Switch(config)# monitor session 1 filter vlan 57
Switch(config)# monitor session 1 destination interface fastethernet 4/15
```

You are now monitoring traffic from interface Fast Ethernet 4/10 that is on VLAN 57 out of interface FastEthernet 4/15. To disable the span session enter the following command:

```
Switch(config)# no monitor session 1
```

Verifying a SPAN Configuration

This example shows how to verify the configuration of SPAN session 2:

```
Switch# show monitor session 2
Session 2
-----
Source Ports:
  RX Only:      Fa5/12
  TX Only:      None
  Both:         None
Source VLANs:
  RX Only:      None
  TX Only:      None
  Both:         None
Destination Ports: Fa5/45
Filter VLANs:    1-5,9
Switch#
```

CPU Port Sniffing

When configuring a SPAN session, you can specify the CPU (or a subset of CPU queues) as a SPAN source. Queues may be specified either by number or by name. When such a source is specified, traffic going to the CPU through one of the specified queues is mirrored and sent out of the SPAN destination port in the session. This traffic includes both control packets and regular data packets that are sent to or from the CPU (due to software forwarding).

You can mix the CPU source with either regular port sources or VLAN sources.

To configure CPU source sniffing, perform this task:

Command	Purpose
<pre>Switch(config)# [no] monitor session {session_number} {source {interface interface_list {vlan vlan_ids cpu [queue queue_ids] } [rx tx both]}</pre>	<p>Specifies that the CPU causes traffic received by or sent from the CPU to be copied to the destination of the session. The queue identifier optionally allows sniffing-only traffic (received) on the specified CPU queue(s).</p> <p>For <i>session_number</i>, specifies the session number identified with this SPAN session (1 through 6).</p> <p>For <i>interface-list</i>, specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (port-channel <i>port-channel-number</i>).</p> <p>For <i>vlan_ids</i>, specifies the source VLAN.</p> <p>For <i>queue_ids</i>, specifies the queue(s) involved.</p> <p>(Optional) [, -] Specifies a series or range of interfaces. Enter a space after the comma; enter a space before and after the hyphen.</p> <p>(Optional) Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both transmitted (Tx) and received (Rx) traffic. Only received traffic can be monitored on additional source ports.</p> <ul style="list-style-type: none"> • Rx—Monitor received traffic. • Tx—Monitor transmitted traffic. • both—Monitor both received and transmitted traffic (bidirectional). <p>Queues may be identified either by number or by name. Queue names may subsume multiple numbered queues for convenience.</p> <p>Use the no keyword to restore the defaults.</p>

This example shows how to configure a CPU source to sniff all packets received by the CPU:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# monitor session 1 source cpu rx
```

Encapsulation Configuration

When configuring a SPAN destination port, you can explicitly specify the encapsulation type used by the port. Packets sent out the port are tagged in accordance with the specified mode. (The encapsulation mode also controls how tagged packets are handled when the ingress packet option is enabled.) The Catalyst 4500 series switch supervisor engines support 802.1q encapsulation and untagged packets.

**Note**

Only 802.1q encapsulation is supported.

The “replicate” encapsulation type (in which packets are transmitted from the destination port using whatever encapsulation applied to the original packet) is not supported. If no encapsulation mode is specified, the port default is untagged.

Ingress Packets

When ingress is enabled, the SPAN destination port accepts incoming packets (potentially tagged depending on the specified encapsulation mode) and switches them normally. When configuring a SPAN destination port, you can specify whether the ingress feature is enabled and what VLAN to use to switch untagged ingress packets. Although the port is STP forwarding, it does not participate in the STP, so use caution when configuring this feature lest a spanning-tree loop be introduced in the network. When both ingress and a trunk encapsulation are specified on a SPAN destination port, the port goes forwarding in all active VLANs. Configuring a non-existent VLAN as an ingress VLAN is not allowed.

By default, host learning is disabled on SPAN destination ports with ingress enabled. The port is also removed from VLAN floodsets, so regular traffic is not switched out of the destination port. If learning is enabled, then traffic for hosts learned on the destination port is switched out the destination port. A host connected to the SPAN destination port will not receive broadcast ARP requests and will not respond. You can also configure static host entries (including a static ARP entry and a static entry in the MAC-address table) on SPAN destination ports.

**Note**

This configuration does not work if the SPAN session does not have a source configured; the session is half configured with only the SPAN destination port.

To configure ingress packets and encapsulation, perform this task:

Command	Purpose
Switch(config)# [no] monitor session <i>session_number</i> destination interface <i>interface</i> [encapsulation {dot1q}] [ingress [vlan <i>vlan_IDs] [learning]</i>	Specifies the configuration of the ingress packet and the encapsulation type of the destination port. For <i>session_number</i> , specifies the session number identified with this SPAN session (1 through 6). For <i>interface</i> , specifies the destination interface. For <i>vlan_IDs</i> , specifies the destination VLAN. Use the no keyword to restore the defaults.

This example shows how to configure a destination port with 802.1q encapsulation and ingress packets using native VLAN 7:

```
Switch(config)# monitor session 1 destination interface fastethernet 5/48
encapsulation dot1q ingress vlan 7
```

With this configuration, traffic from SPAN sources associated with session 1 would be copied out of interface Fast Ethernet 5/48, with 802.1q encapsulation. Incoming traffic would be accepted and switched, with untagged packets being classified into VLAN 7.

Access List Filtering

When configuring a SPAN session, you can apply access list filtering. Access list filtering applies to all packets passing through a SPAN destination port that might be sniffed in the egress or ingress direction. Access list filters are allowed on local SPAN sessions only. If the SPAN destination is an RSPAN VLAN, the access list filter is rejected.

Note

Access list filtering is available in Cisco IOS Release 12.2(20)EW and later releases.

ACL Configuration Guidelines

You can configure ACLs on a SPAN session. Use these guidelines for ACL/SPAN sessions:

- If an ACL is associated with a SPAN session, the rules associated with that ACL are applied against all packets exiting the SPAN destination interface. Rules pertaining to other VACLs or RACLs previously associated with the SPAN destination interface are not applied.
- Only one IP named ACL and one IPv6 ACL can be associated with a SPAN session.
- When no ACLs are applied to packets exiting a SPAN destination interface, all traffic is permitted regardless of the PACLs, VACLs, or RACLs that have been previously applied to the destination interface or VLAN to which the SPAN destination interface belongs.
- If an ACL is removed from a SPAN session, all traffic is permitted once again.
- If SPAN configuration is removed from the SPAN session, all rules associated with the SPAN destination interface are applied once again.
- If a SPAN destination port is configured as a trunk port and the VLANs to which it belongs have ACLs associated with them, the traffic is not subjected to the VACLs.
- ACL configuration applies normally to the RSPAN VLAN and to trunk ports carrying the RSPAN VLAN. This configuration enables you to apply VACLs on RSPAN VLANs. If a user attempts to configure an ACL on a SPAN session with the destination port as an RSPAN VLAN, the configuration is rejected.
- If CAM resources are exhausted and packets are passed to the CPU for lookup, any output port ACLs associated with a SPAN session are not applied.
- If a named IP ACL or IPv6 ACL is configured on a SPAN session before an ACL is created, the configuration is accepted, and the software creates an empty ACL with no ACEs. (An empty ACL permits all packets.) Subsequently, the rules can be added to the ACL.
- The ACLs associated with a SPAN session are applied on the destination interface on output.
- No policing is allowed on traffic exiting SPAN ports.
- IP and IPv6 ACLs are supported on SPAN sessions.

Configuring Access List Filtering

To configure access list filtering, perform this task:

Command	Purpose
Switch(config)# [no] monitor session { <i>session_number</i> } filter { ip ipv6 } access-group [<i>name</i> <i>id</i>] [{ vlan <i>vlan_IDs</i> [, -]}] [{ packet-type { good bad }} { address-type { unicast multicast broadcast } [rx tx both }]	Specifies filter sniffing based on the access list. For <i>session_number</i> , specify the session number identified with this SPAN session (1 through 6). You can specify either a name or a numeric ID for the access list. For <i>name</i> , specify the IP access list name. For <i>id</i> , specify a standard (1 to 199) or extended (1300-2699) IP access list.

Note

IP and IPv6 access lists must be created in configuration mode as described in the chapter “Configuring Network Security with ACLs.”

This example shows how to configure IP access group 10 on a SPAN session and verify that an access list has been configured:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# monitor session 1 source interface fa6/1 both
Switch(config)# monitor session 1 destination interface fa6/2
Switch(config)# monitor session 1 filter vlan 1
Switch(config)# monitor session 1 filter ip access-group 10
Switch(config)# exit
Switch# show monitor
```

```
Session 1
-----
Type                : Local Session
Source Ports        :
    Both            : Fa6/1
Destination Ports   : Fa6/2
    Encapsulation   : Native
    Ingress         : Disabled
    Learning        : Disabled
Filter VLANs        : 1
IP Access-group     : 10
```

Packet Type Filtering

When configuring a SPAN session, you can specify packet filter parameters similar to VLAN filters. When specified, the packet filters indicate types of packets that may be sniffed. If no packet filters are specified, packets of all types may be sniffed. Different types of packet filters may be specified for ingress and egress traffic.

The two categories of packet filtering are packet-based (good, error) or address-based (unicast/multicast/broadcast). Packet-based filters can only be applied in the ingress direction. Packets are classified as broadcast, multicast, or unicast by the hardware based on the destination address.

**Note**

When filters of both types are configured, only packets that pass both filters are spanned. For example, if you set both “error” and “multicast,” only multicast packets with errors are spanned.

To configure packet type filtering, perform this task:

Command	Purpose
Switch(config)# [no] monitor session { <i>session_number</i> } filter { vlan <i>vlan_IDs</i> [, -] } { packet-type { good bad } { address-type { unicast multicast broadcast } [rx tx both]}	Specifies filter sniffing of the specified packet types in the specified directions. For <i>session_number</i> , specifies the session number identified with this SPAN session (1 through 6). For <i>vlan_IDs</i> , specifies the VLAN. You can specify both Rx and Tx type filters, as well as specify multiple type filters at the same time (such as good and unicast to only sniff non-error unicast frames). As with VLAN filters, if no type or filter is specified, then the session sniffs all packet types. Use the no keyword to restore the defaults.

This example shows how to configure a session to accept only unicast packets in the ingress direction:

```
Switch(config)# monitor session 1 filter address-type unicast rx
```

Configuration Example

The following is an example of SPAN configuration using some of the SPAN enhancements.

In this example, you configure a session to sniff unicast traffic arriving on interface Gi1/1.

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# monitor session 1 source interface gi1/1 rx
Switch(config)# monitor session 1 destination interface gi1/2 encapsulation dot1q ingress
Switch(config)# monitor session 1 filter address-type unicast rx
Switch(config)# exit
Switch# show monitor

Session 1
-----
Type                : Local Session
Source Ports        :
    RX Only         : Gi1/1
Destination Ports   : Gi1/2
    Encapsulation   : DOT1Q
    Ingress         : Enabled
    Learning        : Disabled
Filter Addr Type    :
    RX Only         : Unicast
```

Configuring RSPAN

This section describes how to configure RSPAN on your switch and it contains this configuration information:

- [RSPAN Configuration Guidelines, page 69-16](#)
- [Creating an RSPAN Session, page 69-17](#)
- [Creating an RSPAN Destination Session, page 69-18](#)
- [Creating an RSPAN Destination Session and Enabling Ingress Traffic, page 69-19](#)
- [Removing Ports from an RSPAN Session, page 69-20](#)
- [Specifying VLANs to Monitor, page 69-21](#)
- [Specifying VLANs to Filter, page 69-23](#)

RSPAN Configuration Guidelines

Follow these guidelines when configuring RSPAN:

**Note**

Since RSPAN VLANs have special properties, you should reserve a few VLANs across your network for use as RSPAN VLANs; do not assign access ports to these VLANs.

**Note**

You can apply an output access control list (ACL) to RSPAN traffic to selectively filter or monitor specific packets. Specify these ACLs on the RSPAN VLAN in the RSPAN source switches.

- RSPAN sessions can coexist with SPAN sessions within the limits described in the “[SPAN and RSPAN Session Limits](#)” section on page 69-6.
- For RSPAN configuration, you can distribute the source ports and the destination ports across multiple switches in your network.
- RSPAN does not support BPDU packet monitoring or other Layer 2 switch protocols.
- The RSPAN VLAN is configured only on trunk ports and not on access ports. To avoid unwanted traffic in RSPAN VLANs, make sure that all participating switches support the VLAN remote-span feature. Access ports on the RSPAN VLAN are silently disabled.
- You should create an RSPAN VLAN before configuring an RSPAN source or destination session.
- If you enable VTP and VTP pruning, RSPAN traffic is pruned in the trunks to prevent the unwanted flooding of RSPAN traffic across the network for VLAN-IDs that are lower than 1005.
- Because RSPAN traffic is carried across a network on an RSPAN VLAN, the original VLAN association of the mirrored packets is lost. RSPAN can only support forwarding of traffic from an IDS device onto a single user-specified VLAN.

Creating an RSPAN Session

First create an RSPAN VLAN that *does not* exist for the RSPAN session in any of the switches that participate in RSPAN. With VTP enabled in the network, you can create the RSPAN VLAN in one switch, and then VTP propagates it to the other switches in the VTP domain for VLAN-IDs that are lower than 1005.

Use VTP pruning to get efficient flow of RSPAN traffic, or manually delete the RSPAN VLAN from all trunks that do not need to carry the RSPAN traffic.

To start an RSPAN source session and to specify the source (monitored) ports and the destination RSPAN VLAN, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# no monitor session { <i>session_number</i> all local remote }	Clears any existing RSPAN configuration for the session. For <i>session_number</i> , specifies the session number identified with this RSPAN session (1 through 6). Specifies all to remove all RSPAN sessions, local to remove all local sessions, or remote to remove all remote SPAN sessions.
Step 3	Switch(config)# vlan { <i>remote_vlan_ID</i> }	Specifies a remote VLAN ID. Ensure that the VLAN ID is not being used for any user traffic.
Step 4	Switch(config-vlan)# remote-span	Converts the VLAN ID to a remote VLAN ID.
Step 5	Switch(config-vlan)# exit	Returns to global configuration mode.
Step 6	Switch(config)# [no] monitor session { <i>session_number</i> } { source { interface <i>interface_list</i> { vlan <i>vlan_IDs</i> cpu [<i>queue queue_ids</i>]}} [rx tx both]	Specifies the RSPAN session and the source port (monitored port). For <i>session_number</i> , specifies the session number identified with this RSPAN session (1 through 6). For <i>interface-list</i> , specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (port-channel <i>port-channel-number</i>). For <i>vlan-IDs</i> , specifies the source VLAN or VLANs to monitor. Valid VLANs are in the range from 1 to 4094. For <i>queue_ids</i> , specifies either a set of CPU queue numerical identifiers from 1 to 32, or a named queue. (Optional) [, -] Specifies a series or range of interfaces. Enter a space after the comma; enter a space before and after the hyphen. (Optional) Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both transmitted (Tx) and received (Rx) traffic. Only received traffic can be monitored on additional source ports. <ul style="list-style-type: none"> • Rx—Monitor received traffic. • Tx—Monitor transmitted traffic. • both—Monitor both received and transmitted traffic (bidirectional).

	Command	Purpose
Step 7	Switch(config)# monitor session <i>session_number</i> destination remote vlan <i>vlan-ID</i>	Specifies the RSPAN session and the destination remote VLAN. For <i>session_number</i> , specifies the session number identified with this RSPAN session (1 through 6). For <i>vlan-ID</i> , specifies the RSPAN VLAN to carry the monitored traffic to the destination port.
Step 8	Switch(config)# end	Returns to privileged EXEC mode.
Step 9	Switch# show monitor [session <i>session_number</i>]	Verifies your entries.
Step 10	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to clear any existing RSPAN configuration for session 1, configure RSPAN session 1 to monitor multiple source interfaces, and configure the destination RSPAN VLAN.

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# no monitor session 1
Switch(config)# monitor session 1 source interface fastEthernet3/10 tx
Switch(config)# monitor session 1 source interface fastEthernet3/2 rx
Switch(config)# monitor session 1 source interface fastEthernet3/3 rx
Switch(config)# monitor session 1 source interface port-channel 102 rx
Switch(config)# monitor session 1 destination remote vlan 901
Switch(config)# end
```

Creating an RSPAN Destination Session

To create an RSPAN destination session and to specify the source RSPAN VLAN and the destination port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# monitor session <i>session_number</i> source remote vlan <i>vlan-ID</i>	Specifies the RSPAN session and the source RSPAN VLAN. For <i>session_number</i> , specifies the session number identified with this RSPAN session (1 through 6). For <i>vlan-ID</i> , specifies the source RSPAN VLAN to monitor.

	Command	Purpose
Step 3	Switch(config)# [no] monitor session <i>session_number</i> destination interface <i>interface</i> [encapsulation {dot1q}] [ingress [vlan <i>vlan_IDs</i>] [learning]]	Specifies the RSPAN session and the destination interface. For <i>session_number</i> , specifies the session number identified with this RSPAN session (1 through 6). For <i>interface</i> , specifies the destination interface. For <i>vlan_IDs</i> , specifies the ingress VLAN, if necessary. (Optional) [, -] Specifies a series or range of interfaces. Enter a space after the comma; enter a space before and after the hyphen. (Optional) Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both sent and received traffic. Only received (rx) traffic can be monitored on additional source ports. <ul style="list-style-type: none"> dot1q—Use 802.1Q encapsulation.
Step 4	Switch(config)# end	Returns to privileged EXEC mode.
Step 5	Switch# show monitor [session <i>session_number</i>]	Verifies your entries.
Step 6	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to configure VLAN 901 as the source remote VLAN and port 5 as the destination interface:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# monitor session 1 source remote vlan 901
Switch(config)# monitor session 1 destination interface gigabitEthernet1/2
Switch(config)# end
```

Creating an RSPAN Destination Session and Enabling Ingress Traffic

To create an RSPAN destination session, to specify the source RSPAN VLAN, and to enable ingress traffic on the destination port for a network security device (such as a Cisco IDS [Intrusion Detection System] sensor appliance), perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# monitor session { <i>session_number</i> } source vlan <i>vlan_IDs</i>	Specifies the RSPAN session and the source RSPAN VLAN. For <i>session_number</i> , specifies the session number identified with this RSPAN session (1 through 6). For <i>vlan_IDs</i> , specifies the source VLAN or VLANs to monitor. Valid VLANs are in the range from 1 to 4094.

	Command	Purpose
Step 3	Switch(config)# monitor session <i>session_number</i> destination interface <i>interface-id</i> [encapsulation { dot1q ingress vlan <i>vlan id</i> } ingress vlan <i>vlan id</i>] [learning]	<p>Specifies the RSPAN session, the destination port, the packet encapsulation, and the ingress VLAN.</p> <p>For <i>session_number</i>, specifies the session number identified with this RSPAN session (1 through 6).</p> <p>For <i>interface-id</i>, specifies the destination port. Valid interfaces include physical interfaces.</p> <p>(Optional) Specifies the encapsulation of the packets transmitted on the RSPAN destination port. If no encapsulation is specified, all transmitted packets are sent in native format (untagged).</p> <ul style="list-style-type: none"> Enter encapsulation dot1q to send native VLAN packets untagged, and all other VLAN tx packets tagged dot1q. <p>(Optional) Specifies whether forwarding is enabled for ingress traffic on the RSPAN destination port.</p> <ul style="list-style-type: none"> For native (untagged) and dot1q encapsulation, specify ingress vlan <i>vlan id</i> to enable ingress forwarding with <i>vlan id</i> as the native VLAN; <i>vlan id</i> is also used as the native VLAN for transmitted packets. Specify learning to enable learning when ingress is enabled.
Step 4	Switch(config)# end	Returns to privileged EXEC mode.
Step 5	Switch# show monitor [session <i>session_number</i>]	Verifies your entries.
Step 6	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to configure VLAN 901 as the source remote VLAN and how to configure the destination port for ingress traffic on VLAN 5 by using a security device that supports 802.1Q encapsulation:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# monitor session 1 source remote vlan 901
Switch(config)# monitor session 1 destination interface gigabitEthernet1/2 ingress vlan 5
Switch(config)# end
```

Removing Ports from an RSPAN Session

To remove a port as an RSPAN source for a session, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# [no] monitor session {session_number} {source {interface interface_list {vlan vlan_ids cpu [queue queue_ids]} [rx tx both]	Specifies the characteristics of the RSPAN source port (monitored port) to remove. For <i>session_number</i> , specifies the session number identified with this RSPAN session (1 through 6). For <i>interface-list</i> , specifies the source port to no longer monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (port-channel <i>port-channel-number</i>). For <i>vlan_ids</i> , specifies the source vlan or vlans to monitor. Valid VLANs are in the range from 1 to 4094. For <i>queue_ids</i> , specifies either a set of CPU queue numerical identifiers from 1 to 32, or a named queue. (Optional) [, -] Specifies a series or range of interfaces. Enter a space after the comma; enter a space before and after the hyphen. (Optional) Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both transmitted (Tx) and received (Rx) traffic. Only received traffic can be monitored on additional source ports. <ul style="list-style-type: none"> • Rx—Monitor received traffic. • Tx—Monitor transmitted traffic. • both—Monitor both received and transmitted traffic (bidirectional).
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show monitor [session session_number]	Verifies your entries.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to remove port 1 as an RSPAN source for RSPAN session 1:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# no monitor session 1 source interface gigabitEthernet1/1
Switch(config)# end
```

This example shows how to disable received traffic monitoring on port 1, which was configured for bidirectional monitoring:

```
Switch(config)# no monitor session 1 source interface gigabitEthernet1/1 rx
```

The monitoring of traffic received on port 1 is disabled, but traffic transmitted from this port continues to be monitored.

Specifying VLANs to Monitor

VLAN monitoring is similar to port monitoring. To specify VLANs to monitor, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# no monitor session { <i>session_number</i> all local remote }	<p>Clears any existing SPAN configuration for the session.</p> <p>For <i>session_number</i>, specifies the session number identified with this RSPAN session (1 through 6).</p> <p>Specify all to remove all SPAN sessions, local to remove all local sessions, or remote to remove all remote SPAN sessions.</p>
Step 3	Switch(config)# [no] monitor session { <i>session_number</i> } { source { interface <i>interface_list</i> { vlan <i>vlan_ids</i> cpu [<i>queue queue_ids</i>]}} [rx tx both]	<p>Specifies the RSPAN session and the source VLANs (monitored VLANs). You can monitor only received (rx) traffic on VLANs.</p> <p>For <i>session_number</i>, specifies the session number identified with this RSPAN session (1 through 6).</p> <p>For <i>interface-list</i>, specifies the source port to no longer monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (port-channel <i>port-channel-number</i>).</p> <p>For <i>vlan-ids</i>, the range is 1 to 4094; do not enter leading zeros.</p> <p>For <i>queue_ids</i>, specifies the source queue.</p> <p>(Optional) [rx tx both] Specifies a series or range of interfaces. Enter a space after the comma; enter a space before and after the hyphen.</p> <p>(Optional) Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both transmitted (Tx) and received (Rx) traffic. Only received traffic can be monitored on additional source ports.</p> <ul style="list-style-type: none"> • Rx—Monitor received traffic. • Tx—Monitor transmitted traffic. • both—Monitor both received and transmitted traffic (bidirectional).
Step 4	Switch(config)# monitor session <i>session_number</i> destination remote vlan <i>vlan-id</i>	<p>Specifies the RSPAN session, the destination remote VLAN.</p> <p>For <i>session_number</i>, specifies the session number identified with this RSPAN session (1 through 6).</p> <p>For <i>vlan-id</i>, specifies the RSPAN VLAN to carry the monitored traffic to the destination port.</p>
Step 5	Switch(config)# end	Returns to privileged EXEC mode.
Step 6	Switch# show monitor [session <i>session_number</i>]	Verifies your entries.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To remove one or more source VLANs from the RSPAN session, use the **no monitor session session_number source vlan vlan-id rx** global configuration command.

This example shows how to clear any existing configuration on RSPAN session 2, configure RSPAN session 2 to monitor received traffic on all ports belonging to VLANs 1 through 3, and send it to destination remote VLAN 902. The configuration is then modified to also monitor received traffic on all ports belonging to VLAN 10.

```

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# no monitor session 2
Switch(config)# monitor session 2 source vlan 1 - 3 rx
Switch(config)# monitor session 2 destination remote vlan 902
Switch(config)# monitor session 2 source vlan 10 rx
Switch(config)# end

```

Specifying VLANs to Filter

To limit RSPAN source traffic to specific VLANs, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# no monitor session { <i>session_number</i> all local remote }	<p>Clears any existing SPAN configuration for the session.</p> <p>For <i>session_number</i>, specifies the session number identified with this RSPAN session (1 through 6).</p> <p>Specify all to remove all SPAN sessions, local to remove all local sessions, or remote to remove all remote SPAN sessions.</p>
Step 3	Switch(config)# [no] monitor session { <i>session_number</i> } { source { interface <i>interface_list</i> { vlan <i>vlan_IDs</i> cpu [<i>queue</i> <i>queue_ids</i>]}} [rx tx both]	<p>Specifies the characteristics of the source port (monitored port) and RSPAN session.</p> <p>For <i>session_number</i>, specifies the session number identified with this RSPAN session (1 through 6).</p> <p>For <i>interface-list</i>, specifies the source port to monitor. The interface specified must already be configured as a trunk port.</p> <p>For <i>vlan-IDs</i>, the range is 1 to 4094; do not enter leading zeros.</p> <p>For <i>queue_ids</i>, specifies the source queue.</p> <p>(Optional) [, -] Specifies a series or range of interfaces. Enter a space after the comma; enter a space before and after the hyphen.</p> <p>(Optional) Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both transmitted (Tx) and received (Rx) traffic. Only received traffic can be monitored on additional source ports.</p> <ul style="list-style-type: none"> • Rx—Monitor received traffic. • Tx—Monitor transmitted traffic. • both—Monitor both received and transmitted traffic (bidirectional).
Step 4	Switch(config)# monitor session <i>session_number</i> filter vlan <i>vlan-id</i> [, -]	<p>Limits the RSPAN source traffic to specific VLANs.</p> <p>For <i>session_number</i>, specifies the session number identified with this RSPAN session (1 through 6).</p> <p>For <i>vlan-id</i>, the range is 1 to 4094; do not enter leading zeros.</p> <p>(Optional) Use a comma (,) to specify a series of VLANs or use a hyphen (-) to specify a range of VLANs. Enter a space after the comma; enter a space before and after the hyphen.</p>

	Command	Purpose
Step 5	Switch(config)# monitor session <i>session_number</i> destination remote vlan <i>vlan-id</i>	Specifies the RSPAN session, the destination remote VLAN. For <i>session_number</i> , specifies the session number identified with this RSPAN session (1 through 6). For <i>vlan-id</i> , specifies the RSPAN VLAN to carry the monitored traffic to the destination port.
Step 6	Switch(config)# end	Returns to privileged EXEC mode.
Step 7	Switch# show monitor [session <i>session_number</i>]	Verifies your entries.
Step 8	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To monitor all VLANs on the trunk port, use the **no monitor session** *session_number* **filter vlan** global configuration command.

This example shows how to clear any existing configuration on RSPAN session 2, configure RSPAN session 2 to monitor traffic received on trunk port 4, and send traffic for only VLANs 1 through 5 and 9 to destination remote VLAN 902.

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# no monitor session 2
Switch(config)# monitor session 2 source interface gigabitethernet1/1 rx
Switch(config)# monitor session 2 filter vlan 1 - 5 , 9
Switch(config)# monitor session 2 destination remote vlan 902
Switch(config)# end
```

Displaying SPAN and RSPAN Status

To display the status of the current SPAN or RSPAN configuration, use the **show monitor** privileged EXEC command.

This example displays the output for the **show monitor** command for SPAN source session 1:

```
Switch# show monitor session 1
Session 1
-----
Type: Local Source Session
Source Ports:
    RX Only: Fa3/13
    TX Only:   None
    Both:      None

Source VLANs:
    RX Only:   None
    TX Only:   None
    Both:      None
Source RSPAN VLAN: None
Destination Ports: None
    Encapsulation: DOT1Q
    Ingress:Enabled, default VLAN=5
Filter VLANs:   None
Dest RSPAN VLAN: None
Ingress : Enabled, default VLAN=2
Learning : Disabled
```

Configuring ERSPAN

This module describes how to configure Encapsulated Remote Switched Port Analyzer (ERSPAN). The Cisco ERSPAN feature allows you to monitor traffic on ports or VLANs and send the monitored traffic to destination ports.

Note

The ERSPAN feature is not supported on Layer 2 switching interfaces.

This module describes the feature and consists of these sections:

- [Information About ERSPAN, page 70-2](#)
- [How to Configure ERSPAN, page 70-5](#)
- [Configuration Examples for ERSPAN, page 70-6](#)
- [Verifying ERSPAN, page 70-6](#)
- [Additional References for Configuring ERSPAN, page 70-8](#)
- [Feature Information for ERSPAN, page 70-9](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Prerequisites for ERSPAN

- Only IPv4 delivery/transport header is supported.
- Access control list (ACL) filter is applied before sending the monitored traffic on to the tunnel.
- Only supports Type-II ERSPAN header.
- The extended VLAN ID that is reserved for each ERSPAN session cannot be used for any other purpose, until the ERSPAN source session is present in the configuration. Use the **show vlan internal usage** command to display the extended VLAN ID.
- This feature is supported on Cisco Catalyst 4500E Series Switches with Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E, and 4500-X Series Switches.

Restrictions for ERSPAN

The following restrictions apply for this feature:

- The maximum number of available ports for each ERSPAN session is 128.
- A maximum of 8 ingress and 8 egress ERSPAN sessions (a total of 16 sessions) are supported.
- You can configure either a list of ports or a list of VLANs as a source, but cannot configure both for a given session.
- When a session is configured through the ERSPAN CLI, the session ID and the session type cannot be changed. To change them, you must use the **no** form of the configuration commands to remove the session and then reconfigure the session.
- ERSPAN source sessions do not copy locally-sourced Remote SPAN (RSPAN) VLAN traffic from source trunk ports that carry RSPAN VLANs.
- ERSPAN source sessions do not copy locally-sourced ERSPAN GRE-encapsulated traffic from source ports.

The Catalyst 4500 series switches do not support the following for this feature:

- ERSPAN destination type.
- Timestamp indication in the ERSPAN header.
- Bad/Short/Oversized (BSO) packet indication in the ERSPAN header.
- The original VLAN ID or Class of Service (COS) in the ERSPAN header.
- Generic routing encapsulation (GRE) header flags.
- GRE header sequence number or key.
- Maximum transmission unit (MTU) checking and fragmentation. Hence, traffic exceeding the configured MTU size (as determined by Layer 3 protocols) is dropped.
- Truncation of the original packet; because of which the T-bit in the ERSPAN header is always zero.
- Setting of the Differentiated Services Code Point (DSCP)/Time to Live (TTL) field for IP encapsulation differently for various ERSPAN source sessions. Use the **erspan {ttl | tos}** command to set these values. The configured values are used in all ERSPAN source sessions originating from the device.
- Simple Network Management Protocol (SNMP).

Information About ERSPAN

- [ERSPAN Overview, page 70-2](#)
- [ERSAN Sources, page 70-4](#)

ERSPAN Overview

The Cisco ERSPAN feature allows you to monitor traffic on ports or VLANs, and send the monitored traffic to destination ports. ERSPAN sends traffic to a network analyzer, such as a Switch Probe device or a Remote Monitoring (RMON) probe. ERSPAN supports source ports, source VLANs, and destination ports on different devices, which helps remote monitoring of multiple devices across a network.

ERSPAN supports encapsulated packets of up to 9180 bytes. ERSPAN consists of an ERSPAN source session, routable ERSPAN GRE-encapsulated traffic, and an ERSPAN destination session.

ERSPAN consists of an ERSPAN source session, routable ERSPAN GRE-encapsulated traffic, and an ERSPAN destination session. You can configure an ERSPAN source session, an ERSPAN destination session, or both on a device. A device on which only an ERSPAN source session is configured is called an ERSPAN source device, and a device on which only an ERSPAN destination session is configured is called an ERSPAN termination device. A device can act as both; an ERSPAN source device and a termination device.

**Note**

Catalyst 4500 series switches do not support ERSPAN destination type/session.

For a source port or a source VLAN, the ERSPAN can monitor the ingress, egress, or both ingress and egress traffic. By default, ERSPAN monitors all traffic, including multicast, and Bridge Protocol Data Unit (BPDU) frames.

An ERSPAN source session is defined by the following parameters:

- A session ID
- List of source ports or source VLANs to be monitored by the session
- The destination and origin IP addresses, which are used as the destination and source IP addresses of the GRE envelope for the captured traffic, respectively
- ERSPAN flow ID
- Optional attributes, such as, IP type of service (TOS) and IP Time to Live (TTL), related to the GRE envelope

**Note**

ERSPAN source sessions do not copy ERSPAN GRE-encapsulated traffic from source ports. Each ERSPAN source session can have either ports or VLANs as sources, but not both.

An ERSPAN destination session is defined by the following parameters:

- Session ID
- Destination ports
- Source IP address, which is the same as the destination IP address of the corresponding source session
- ERSPAN flow ID, which is used to match the destination session with the source session
- The ERSPAN source sessions copy traffic from the source ports or source VLANs and forwards the traffic using routable GRE-encapsulated packets to the ERSPAN destination session. The ERSPAN destination session switches the traffic to the destination ports

**Note**

Because encapsulation is performed in the hardware, the CPU performance is not impacted.

Figure 70-1 ERSPAN Configuration

120377

ERSAN Sources

The Cisco ERSPAN feature supports the following sources:

- Source ports—A source port that is monitored for traffic analysis. Source ports in any VLAN can be configured and trunk ports can be configured as source ports along with nontrunk source ports.
- Source VLANs—A VLAN that is monitored for traffic analysis.

The following tunnel interfaces are supported as source ports for a source session:

- GRE
- IPv6
- IPv6-over-IP tunnel
- Multipoint GRE (mGRE)

How to Configure ERSPAN

- [Configuring an ERSPAN Source Session, page 70-5](#)

Configuring an ERSPAN Source Session

The ERSPAN source session defines the session configuration parameters and the ports or VLANs to be monitored.

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# monitor session <i>span-session-number</i> type erspan-source	Defines an ERSPAN source session using the session ID and the session type, and enters ERSPAN monitor source session configuration mode. <ul style="list-style-type: none"> • Session IDs for source sessions or destination sessions are in the same global ID space, so each session ID is globally unique for both session types. • The <i>span-session-number</i> and the session type (configured by the erspan-source keyword) cannot be changed once configured. Use the no form of this command to remove the session and then re-create the session with a new session ID or a new session type.
Step 4	Switch(config-mon-erspan-src)# description <i>description</i>	Describes the ERSPAN source session.
Step 5	Switch(config-mon-erspan-src)# source { interface <i>type number</i> vlan <i>vlan-ID</i> } [, - <i>both</i> <i>rx</i> <i>tx</i>]	Configures the source interface or the VLAN, and the traffic direction to be monitored.
Step 6	Switch(config-mon-erspan-src)# filter { ip { <i>standard-access-list</i> <i>expanded-access-list</i> <i>acl-name</i> } ipv6 { access-group <i>acl-name</i> } vlan <i>vlan-ID</i> }	(Optional) Configures source VLAN filtering when the ERSPAN source is a trunk port. <div>  <p>Note You cannot include source VLANs and filter VLANs in the same session.</p> </div>
Step 7	Switch(config-mon-erspan-src)# no shutdown	Disables the shutting down of the configured session.
Step 8	Switch(config-mon-erspan-src)# destination	Defines an ERSPAN destination session and enters ERSPAN monitor destination session configuration mode.
Step 9	Switch(config-mon-erspan-src-dst)# ip address <i>ip-address</i>	Configures an IP address for the ERSPAN destination session.
Step 10	Switch(config-mon-erspan-src-dst)# erspan-id <i>erspan-ID</i>	Configures the ID used by the destination session to identify the ERSPAN traffic.
Step 11	Switch(config-mon-erspan-src-dst)# origin ip address <i>ip-address</i>	Configures the IP address used as the source for the ERSPAN traffic.

	Command or Action	Purpose
Step 12	Switch(config-mon-erspan-src-dst)# vrf vrf-ID	(Optional) Configures the VRF name to use instead of the global routing table.
Step 13	Switch(config-mon-erspan-src-dst)# exit	Exits ERSPAN monitor destination session configuration mode and returns to ERSPAN monitor source session configuration mode.
Step 14	Switch(config-mon-erspan-src)# exit	Exits ERSPAN monitor source session configuration mode and returns to privileged EXEC mode.
Step 15	Switch(config)# erspan {tos tos-value ttl ttl-value}	Configures type of service (ToS) and Time to Live (TTL) values for packets in the ERSPAN traffic.
		 Note The configured ToS and TTL values apply to all configured ERSPAN sessions. The ToS and TTL values for ERSPAN are configured in global configuration mode.
Step 16	Switch(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

Configuration Examples for ERSPAN

- [Example: Configuring an ERSPAN Source Session, page 70-6](#)

Example: Configuring an ERSPAN Source Session

```
Switch> enable
Switch# configure terminal
Switch(config)# monitor session 1 type erspan-source
Switch(config-mon-erspan-src)# description source1
Switch(config-mon-erspan-src)# source interface fastethernet 0/1 rx
Switch(config-mon-erspan-src)# filter vlan 3
Switch(config-mon-erspan-src)# no shutdown
Switch(config-mon-erspan-src)# destination
Switch(config-mon-erspan-src-dst)# ip address 192.0.2.9
Switch(config-mon-erspan-src-dst)# erspan-id 2
Switch(config-mon-erspan-src-dst)# origin ip address 203.0.113.2
Switch(config-mon-erspan-src-dst)# vrf 1
Switch(config-mon-erspan-src)# exit
Switch(config)# erspan ttl 32
Switch(config)# end
Switch#
```

Verifying ERSPAN

To verify the ERSPAN configuration, use the following commands:

The following is sample output from the **show monitor session erspan-source** command:

```
Switch# show monitor session erspan-source session
```

```
Type : ERSPAN Source Session
```

```
Status : Admin Enabled
Source Ports :
RX Only : Gi1/4/33
Destination IP Address : 20.20.163.20
Destination ERSPAN ID : 110
Origin IP Address : 10.10.10.216
IPv6 Flow Label : None
```

The following is sample output from the **show monitor session erspan-source detail** command:

```
Switch# show monitor session erspan-source detail
```

```
Type : ERSPAN Source Session
Status : Admin Enabled
Description : -
Source Ports :
RX Only : Gi1/4/33
TX Only : None
Both : None
Source VLANs :
RX Only : None
TX Only : None
Both : None
Source RSPAN VLAN : None
Destination Ports : None
Filter VLANs : None
Filter Addr Type :
RX Only : None
TX Only : None
Both : None
Filter Pkt Type :
RX Only : None
Dest RSPAN VLAN : None
IP Access-group : None
IPv6 Access-group : None
Destination IP Address : 20.20.163.20
Destination IPv6 Address : None
Destination IP VRF : None
Destination ERSPAN ID : 110
Origin IP Address : 10.10.10.216
Origin IPv6 Address : None
IP QOS PREC : 0
IPv6 Flow Label : None
IP TTL : 255
```

The following output from the **show capability feature monitor erspan-source** command displays information about the configured ERSPAN source sessions:

```
Switch# show capability feature monitor erspan-source
```

```
ERSPAN Source Session Supported: true
No of Rx ERSPAN source session: 8
No of Tx ERSPAN source session: 8
ERSPAN Header Type supported: II
ACL filter Supported: true
Fragmentation Supported: false
Truncation Supported: false
Sequence number Supported: false
QOS Supported: true
```

The following output from the **show capability feature monitor erspan-destination** command displays all the configured global built-in templates:

```
Switch# show capability feature monitor erspan-destination
```

```
ERSPAN Destination Session Supported: false
```

Feature Information for ERSPAN

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

**Note**

Table 1 lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Table 1 Feature Information for ERSPAN

Feature Name	Releases	Feature Information
ERSPAN	Cisco IOS Release 15.2(4)E1	This module describes how to configure Encapsulated Remote Switched Port Analyzer (ERSPAN). The Cisco ERSPAN feature allows you to monitor traffic on ports or VLANs and send the monitored traffic to destination ports over a generic routing encapsulation (GRE) tunnel in any VRF. The following commands were introduced or modified: destination (ERSPAN) , erspan , filter (ERSPAN) , and show capability feature monitor .

Configuring Wireshark

Beginning with Cisco IOS Release XE 3.3.0SG in the IP Base and Enterprise Services feature sets, the Catalyst 4500 series switch supports Wireshark.

Note

Wireshark is only supported on Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E, Catalyst 4500X-16, and Catalyst 4500X-32.

Note

Wireshark is supported on VSS and the functionality is the same as a standalone switch as detailed in the [“Configuring Wireshark on VSS” section on page 71-14](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to

<http://www.cisco.com/go/cfn>

An account on Cisco.com is not required.

Prerequisites for Wireshark

For general packet filtering, you will require Wireshark display filters. Refer to

<http://wiki.wireshark.org/DisplayFilters>

Guidelines for Wireshark

- During Wireshark packet capture, hardware forwarding happens concurrently.
- Before starting a Wireshark capture process, ensure that CPU usage is moderate and that sufficient memory (at least 200 MB) is available.
- If you plan to store packets to a storage file, ensure that sufficient space is available before beginning a Wireshark capture process.
- The CPU usage during Wireshark capture depends on how many packets match the specified conditions and on the intended actions for the matched packets (store, decode and display, or both).
- Where possible, keep the capture to the minimum (limit by packets, duration) to avoid high CPU usage and other undesirable conditions.
- Because packet forwarding typically occurs in hardware, packets are not copied to the CPU for software processing. For Wireshark packet capture, packets are copied and delivered to the CPU, which causes an increase in CPU usage.

To avoid high CPU, do the following:

- Attach only relevant ports.
- Use a class map, and secondarily, an access list to express match conditions. If neither is viable, use an explicit, in-line filter.
- Adhere closely to the filter rules. Restrict the traffic type (such as, IPv4 only) with a restrictive, rather than relaxed ACL, which elicits unwanted traffic.
- Always limit packet capture to either a shorter duration or a smaller packet number. The parameters of the **capture** command enable you to specify the following:
 - Capture duration
 - Number of packets captured
 - File size
 - Packet segment size
- Run a capture session without limits if you know that very little traffic matches the core filter.
- You might experience high CPU (or memory usage) if:
 - You leave a capture session enabled and unattended for a long period of time, resulting in unanticipated bursts of traffic.

- You launch a capture session with ring files or capture buffer and leave it unattended for a long time, resulting in performance or system health issues.
- During a capture session, watch for high CPU usage and memory consumption due to Wireshark that may impact switch performance or health. If these situations arise, stop the Wireshark session immediately.
- Avoid decoding and displaying packets from a .pcap file for a large file. Instead, transfer the .pcap file to a PC and run Wireshark on the PC.
- Limit the number of Wireshark instances to two or less to avoid CPU or memory resource drain.
You can use up to eight Wireshark instances. An active **show** command that decodes and displays packets from a .pcap file or capture buffer counts as one instance.
- Whenever an ACL is installed or modified on a switch in the ingress direction, for the first 15 seconds, the software ignores packet classification details sent by the hardware. Instead, it uses software-based classification for the packets received by CPU. So, during this period, the system can only capture fewer packets (compared to the time after the first 15 seconds) and CPU usage will be high.
- To avoid packet loss, consider the following:
 - Use store-only (when you do not specify the display option) while capturing live packets rather than decode and display, which is an CPU-intensive operation (especially in detailed mode).
 - If you use the default buffer size, packets may be dropped. Increase buffer size and avoid packet loss.
 - Writing to flash disk is a CPU-intensive operation, so the capture rate may not be sufficient.
 - The Wireshark capture session operates normally in streaming mode where packets are both captured and processed. However, when you specify a buffer size of at least 32 MB but less than 80MB, the session automatically turns on lock-step mode in which a Wireshark capture session is split into two phases: capture and process. In the capture phase, the packets are stored in the temporary buffer. The duration parameter in lock-step mode serves as capture duration rather than session duration. When the buffer is full or the capture duration has ended, a session transitions to the process phase, wherein it stops accepting packets and starts processing packets in the buffer. With the second approach (lock-step mode), a higher capture throughput can be achieved. Last, when you specify a buffer size of at least 80MB, the session turns on lock-step mode with high-speed capture. This is similar to lock-step mode except that it captures the packets directly from the hardware queue and passes the packet to the wireshark packet queue.
 - The streaming capture mode supports approximately 1500 pps; lock-step mode supports approximately 45 Mbps (measured with 256-byte packets); lock-step mode with high speed capture supports roughly 750Mbps (measure with 256-byte packets). When the matching traffic rate exceeds this number, you may experience packet loss. Only one session can be started when using high-speed capture mode.
- If you want to decode and display live packets in the console window, ensure that the Wireshark session is bounded by a short capture duration.

**Warning**

A Wireshark session with either a longer duration limit or no capture duration (using a terminal with no auto-more support using the term len 0 command) may make the console or terminal unusable.

- When using Wireshark to capture live traffic that leads to high CPU, usage, consider applying a QoS policy temporarily to limit the actual traffic until the capture process concludes.
- All Wireshark-related commands are in EXEC mode; no configuration commands exist for Wireshark.

If you need to use access list or class-map in the Wireshark CLI, you must define an access list and class map with configuration commands.

- No specific order applies when defining a capture point; you can define capture point parameters in any order, provided that CLI allows this. The Wireshark CLI allows as many parameters as possible on a single line. This limits the number of commands required to define a capture point.
- All parameters except attachment points take a single value. Generally, you can replace the value with a new one by reentering the command. After user confirmation, the system accepts the new value and overrides the older one. A **no** form of the command is unnecessary to provide a new value; it is necessary to remove a parameter.
- Wireshark allows you to specify one or more attachment points. To add more than one attachment point, reenter the command with the new attachment point. To remove an attachment point, use the **no** form. You can specify an interface range as an attachment point.

For example, **monitor capture mycap int gi 3/1 in**, where interface gi 3/1 is an attachment point.

If you also need to attach gi 3/2, you specify it in another line, as follows:

monitor capture mycap int gi 3/2 in

- You cannot modify any parameters of a capture point while a session is active. To modify any parameter, stop the session, make the changes, and restart the session. Because an access list is generic to a switch and unrelated to the Wireshark process, it is alterable during a Wireshark session.
- The action you want to perform determines which parameters are mandatory. The Wireshark CLI allows you to specify or modify any parameter prior to entering the **start** command. When you issue the **start** command, Wireshark will start only after determining that all mandatory parameters have been provided.
- If the capture file already exists, it provides a warning and receives confirmation before proceeding. This prevents you from mistakenly overwriting a file.
- The core filter can be an explicit filter, access list, or class map. Specifying a newer filter of these types replaces the existing one.
- You can terminate a Wireshark session with an explicit **stop** command or by entering **q** in automore mode. The session could terminate itself automatically when a stop condition such as duration or packet capture limit is met.

Restrictions for Wireshark

- The CLI for configuring Wireshark requires that the feature be executed only from EXEC mode. Actions that usually occur in configuration submode (such as defining capture points), are handled at the EXEC mode instead. All key commands are not NVGEN'd and are not synchronized to the standby supervisor in NSF and SSO scenarios.
- When packet capture is enabled in the input direction, the matching packets undergo software-based lookup in the CPU for the first 15 seconds. During this time, CPU usage is high and capture rate is low.
- Packets captured in the output direction of an interface might not reflect the changes made by switch rewrite (includes TTL, VLAN tag, CoS, checksum, and MAC addresses).
- Capturing at a physical port that belongs to another logical port may not be supported. For example, capturing at EtherChannel member ports is not supported.
- Limiting circular file storage by file size is not supported.

- Wireshark cannot capture IPv6 packets if the capture point's class-map filter is attempting to match one of the following:
 - Extension headers followed by Hop-by-hop header (as per CSCtt16385)
 - DSCP values (as per CSCtx75765)

Information about Wireshark

**Note**

Wireshark is only supported on Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E, Catalyst 4500X-16, and Catalyst 4500X-32.

**Note**

Wireshark is supported on VSS and the functionality is the same as a standalone switch except for a few configuration differences as detailed in the [“Configuring Wireshark on VSS”](#) section on page 71-14.

Wireshark is a packet analyzer program, formerly known as Ethereal, which supports multiple protocols and presents information in a text-based user interface.

To understand what happens inside a network requires the ability to capture and analyze traffic. Prior to Cisco IOS Release XE 3.3.0SG, the Catalyst 4500 series switch offered only two features to address this need: SPAN and **debug platform packet**. Both are limited. SPAN is ideal for capturing packets, but can only deliver them by forwarding them to some specified local or remote destination; it provides no local display or analysis support. The **debug platform packet** command is specific to the Catalyst 4500 series switch and only works on packets that stem from the software process-forwarding path. Although it has limited local display capabilities, it has no analysis support.

So the need exists for a traffic capture and analysis mechanism that is applicable to both hardware and software forwarded traffic and that provides strong packet capture, display and analysis support, preferably using a well known interface.

Wireshark dumps packets to a file using a well known format called .pcap, and is applied or enabled on individual interfaces. You specify an interface in EXEC mode along with the filter and other parameters. The Wireshark application is applied only when you enter a **start** command and is removed only when Wireshark stops capturing packets either automatically or manually.

**Note**

In Cisco IOS Release XE 3.3.0SG, global packet capture on Wireshark is not supported.

These sections describe some key concepts for Wireshark:

- [Capture Points, page 71-6](#)
- [Attachment Points, page 71-6](#)
- [Filters, page 71-6](#)
- [Input and Output Classification, page 71-7](#)
- [Actions, page 71-8](#)
- [Storing Captured Packets to Buffer in Memory, page 71-8](#)
- [Decoding and Displaying Packets, page 71-9](#)
- [Activating and Deactivating Wireshark Capture Points, page 71-10](#)

- [Wireshark Features used in Switches, page 71-10](#)
- [Wireshark on VSS, page 71-11](#)

Capture Points

A capture point is the central policy definition of the Wireshark feature. The point describes all the characteristics associated with a given instance of Wireshark: what packets to capture, where to capture them from, what to do with the captured packets, and when to stop. Capture points can be modified after creation and do not become active until explicitly activated with a **start** command. This process is termed *activating the capture point* or *starting the capture point*. Capture points are identified by name and may also be manually or automatically deactivated or stopped.

Multiple capture points may be defined and activated simultaneously.

Attachment Points

An attachment point is a point in the logical packet process path associated with a capture point. Consider an attachment point as an attribute of the capture point. Packets that impact an attachment point are tested against the capture point's filters; packets that match are copied and sent to the capture point's associated Wireshark instance. A specific capture point can be associated with multiple attachment points, with limits on mixing attachment points of different types. Some restrictions apply when you specify attachment points of different types. Attachment points are directional (input or output or both) with the exception of the Layer 2 VLAN attachment point, which is always unidirectional.

Filters

Filters are attributes of a capture point that identify and limit the subset of traffic traveling through the attachment point of a capture point, which is copied and passed to Wireshark. To be displayed by Wireshark, a packet must pass through an attachment point, as well as all of the filters associated with the capture point.

A capture point has three types of filters:

- Core system filter—The core system filter is applied by hardware, and its match criteria is limited by hardware. This filter determines whether hardware-forwarded traffic is copied to software for Wireshark purposes.
- Capture filter—The capture filter is applied by Wireshark. The match criteria are more granular than those supported by the core system filter. Packets that pass the core filter but fail the capture filter are still copied and sent to the CPU/software, but are discarded by the Wireshark process. The capture filter syntax matches that of the display filter.

Note Wireshark on the Catalyst 4500 series switch does not use the syntax of the capture filter.

- Display filter—The display filter is applied by Wireshark, and its match criteria are similar to those of the capture filter. Packets that fail the display filter are not displayed.

Core System Filter

You can specify core system filter match criteria by using the class map or ACL, or explicitly by using the CLI.

In some installations, you need to obtain authorization to modify the switch configuration, which can lead to extended delays if the approval process is lengthy. This would limit the ability of network administrators to monitor and analyze traffic. To address this situation, Wireshark supports explicit specification of core system filter match criteria from the EXEC mode CLI. The disadvantage is that the match criteria that you can specify is a limited subset of what class map supports, such as MAC, IP source and destination addresses, ether-type, IP protocol, and TCP/UDP source and destination ports.

If you prefer to use configuration mode, you can define ACLs or have class maps refer capture points to them. Explicit and ACL-based match criteria are used internally to construct class maps and policy maps. These implicitly constructed class maps are not reflected in the switch running-config and are not NVGEN'd.

**Note**

The ACL and class map configuration are part of the system and not aspects of the Wireshark feature.

Capture Filter

The capture filter allows you to direct Wireshark to further filter incoming packets based on various conditions. Wireshark applies the capture filter immediately on receipt of the packet; packets that fail the capture filter are neither stored nor displayed.

A switch receives this parameter and passes it unchanged to Wireshark. Because Wireshark parses the application filter definition, the defining syntax is the one provided by the Wireshark display filter. This syntax and that of standard Cisco IOS differ, which allows you to specify ACL match criteria that cannot be expressed with standard syntax.

**Note**

The capture filter syntax matches that of the Wireshark display filter. The syntax for capture and display filters are identical in the Wireshark implementation on the Catalyst 4500 series switch.

Display Filter

With the display filter, you can direct Wireshark to further narrow the set of packets to display when decoding and displaying from a .pcap file. Because the syntax of the display filter is identical to the capture filter, the display filter is superfluous if a capture filter is also defined.

For more details on the syntax of capture and display filters, go to

<http://wiki.wireshark.org/DisplayFilters>

Input and Output Classification

There are four classification results for input and output classification. In the input direction, they are ordered role-based, security, QoS, and forwarding override. In the output direction they are ordered forwarding override, role-based, security, and QoS.

On the input side, the Wireshark capture feature is placed in the forwarding override result type, prioritized above the other FO features (such as multicast local source capture, PBR and ingress WCCP). The packets captured by Wireshark are before any redirection by PBR or WCCP. Because security ACLs are applied ahead of FO-related features, packets that are dropped by security ACLs are not captured by Wireshark.

On the output side, the Wireshark capture feature is placed in the forwarding override result type, prioritized below the other FO features (such as egress WCCP). Wireshark captures packets only if the other egress FO features do not apply.

Actions

Wireshark can be invoked on live traffic or on a previously existing .pcap file. When invoked on live traffic, it can perform four types of actions on packets that pass its capture and display filters:

- Captures to buffer in memory to decode and analyze and store
- Stores to a .pcap file
- Decodes and displays
- Stores and displays

When invoked on a .pcap file only, only the decode and display action is applicable.

Storing Captured Packets to Buffer in Memory

Packets can be stored in the capture buffer in memory for subsequent decode, analysis, or storage to a .pcap file.

The capture buffer can be linear or circular mode. In linear mode, new packets are discarded when the buffer is full. In circular mode, if the buffer is full, the oldest packet are discarded to accommodate the new packet. Although the buffer can also be cleared when needed, this mode is mainly used for debugging network traffic.

Storing Captured Packets to a .pcap File

Wireshark can store captured packets to a .pcap file. The capture file can be located on the following storage devices:

- Catalyst 4500 series switch on-board flash storage (bootflash:)
- external flash disk (slot0:)
- USB drive (usb0:)

Note Do not attempt to use Wireshark with any other devices.

When configuring a Wireshark capture point, you can associate a filename. When the capture point is activated, Wireshark creates a file with the specified name and writes packets to it. If the file already exists when the file is associated or the capture point is activated, Wireshark queries you as to whether the file can be overwritten. Only one capture point may be associated with a given filename.

If the destination of the Wireshark writing process is full, Wireshark fails with partial data in the file. You must ensure that there is sufficient space in the file system before you start the capture session. With Cisco IOS Release IOS XE 3.3.0SG, the file system full status is not detected for some storage devices.

You can reduce the required storage space by retaining only a segment, instead of the entire packet. Typically, you do not require details beyond the first 64 or 128 bytes. The default behavior is to store the entire packet.

To avoid possible packet drops when processing and writing to the file system, Wireshark can optionally use a memory buffer to temporarily hold packets as they arrive. Memory buffer size can be specified when the capture point is associated with a .pcap file.

Decoding and Displaying Packets

Wireshark can decode and display packets to the console. This functionality is possible for capture points applied to live traffic and for capture points applied to a previously existing .pcap file.

Note

Decoding and displaying packets may be CPU intensive.

Wireshark can decode and display packet details for a wide variety of packet formats. The details are displayed by entering the **monitor capture name start** command with one of the following keyword options, which place you into a display and decode mode:

- **brief**—Displays one line per packet (the default).
- **detailed**—Decodes and displays all the fields of all the packets whose protocols are supported. Detailed mode require more CPU than the other two modes.
- **(hexadecimal) dump**—Displays one line per packet as a hexadecimal dump of the packet data and the printable characters of each packet.

When we enter the **capture** command with the decode and display option, the Wireshark output is returned to Cisco IOS and displayed on the console unchanged.

Displaying Live Traffic

Wireshark receives copies of packets from the Catalyst 4500 series switch core system. Wireshark applies its capture and display filters to discard uninteresting packets, and then decodes and displays the remaining packets.

Displaying from the .pcap File

Wireshark can decode and display packets from a previously stored .pcap file and direct the display filter to selectively displayed packets. A capture filter is not applicable in this situation.

Storing and Displaying Packets

Functionally, this mode is a combination of the previous two modes. Wireshark stores packets in the specified .pcap file and decodes and displays them to the console. Only the core and capture filters are applicable here.

Activating and Deactivating Wireshark Capture Points

After a Wireshark capture point has been defined with its attachment points, filters, actions, and other options, it must be activated. Until the capture point is activated, it does not actually capture packets.

Before a capture point is activated, some sanity checks are performed. A capture point cannot be activated if it has neither a core system filter nor attachment points defined. Attempting to activate a capture point that generates an error.

The capture and display filters are specified as needed.

After Wireshark capture points are activated, they can be deactivated in multiple ways. A capture point that is storing only packets to a .pcap file can be halted manually or configured with time or packet limits, after which the capture point halts automatically. Only packets that pass the Wireshark capture filter are counted against the packet limit threshold.

When a Wireshark capture point is activated, a fixed rate filter is applied automatically in the hardware so that the CPU is not flooded with Wireshark-directed packets. The disadvantage of the rate filter is that you cannot capture contiguous packets beyond the established rate even if more resources are available.

Wireshark Features used in Switches

This section describes how Wireshark features function in the Catalyst 4500 series switch environment:

- Layer 2 security features—Packets that are dropped by Layer 2 security features (such as port security, MAC address filtering, and spanning tree) are not captured by Wireshark. This differs from the behavior of SPAN.
- Classification-based security features—Packets that are dropped by input classification-based security features (such as ACLs and IPSG) are not caught by Wireshark capture points that are connected to attachment points at the same layer. In contrast, packets that are dropped by output classification-based security features are caught by Wireshark capture points that are connected to attachment points at the same layer. The logical model is that the Wireshark attachment point occurs after the security feature lookup on the input side, and symmetrically before the security feature lookup on the output side.

Wireshark capture policies connected to Layer 2 attachment points in the input direction capture packets dropped by Layer 3 classification-based security features. Symmetrically, Wireshark capture policies attached to Layer 3 attachment points in the output direction capture packets dropped by Layer 2 classification-based security features.

- Routed ports and Layer 3 port channels—When a routed port or Layer 3 port channel is used as a Wireshark attachment point, the policy that is applied to capture the packets is treated as attached at Layer 3. Wireshark only captures packets that are being routed by the interface.
- VLANs—When a VLAN is used as a Wireshark attachment point, packets are captured in both input and output directions. A packet that is bridged in the VLAN generates two copies, one on input and one on output.
- Private VLANs—Secondary PVLANS are disallowed as Wireshark attachment points. Using a primary PVLAN as a Wireshark attachment point enables capture of packets in the primary PVLAN and all associated secondary PVLANS. The entire PV domain becomes the attachment point.
- Redirection features—In the input direction, features traffic redirected by Layer 3 (such as PBR and WCCP), are logically later than Layer 3 Wireshark attachment points. Wireshark captures these packets even though they might later be redirected out another Layer 3 interface. Symmetrically, output features redirected by Layer 3 (such as egress WCCP) are logically prior to Layer 3 Wireshark attachment points, and Wireshark will not capture them.

- Classification copy features—Features that generate copies of packets from the role-based and Security lookup types are compatible with Wireshark. Multiple copies of these packets are generated.
- SPAN—Wireshark cannot capture packets on interface configured as a SPAN source or destination.

Wireshark on VSS

Wireshark is supported on the VSS, and usage is similar to the Standalone switch. You need to create and delete capture points for the VSS active and VSS standby switches on the VSS active switch. You need to start and stop capture operations on VSS active switch, once you have issued the attachment points for a capture session on the active switch.

How to Configure Wireshark

To configure Wireshark, follow these general steps:

- Step 1** Define, modify or delete a capture point.
- Step 2** Activate or deactivate a capture point.

Default Wireshark Configuration

Table 71-1 shows the default Wireshark configuration.

Table 71-1 Default Wireshark Configuration

Feature	Default Setting
Duration	No limit
Packets	No limit
Packet-length	No limit (full packet)
File size	No limit
Ring file storage	No
Buffer storage mode	Linear

Defining, Modifying, or Deleting a Capture Point

Although listed in sequence, the steps to specify values for the options can be executed in any order. You can also specify them in one, two, or several lines. Except for attachment points, which can be multiple, you can replace any value with a more recent value by redefining the same option, in the following order:

- Step 1** Define the name that identifies the capture point.
- Step 2** Specify the attachment point with which the capture point is associated.

Multiple attachment points can be specified. Range support is also available both for adding and removing attachment points.

- Step 3** Define the core system filter, defined either explicitly, through ACL or through a class map.
- Step 4** Specify the session limit (in seconds or packets captured).
- Step 5** Specify the packet segment length to be retained by Wireshark.
- Step 6** Specify the file association, if the capture point intends to capture packets rather than merely display them.
- Step 7** Specify the size of the memory buffer used by Wireshark to handle traffic bursts.

To filter the capture point, use the following commands:

Command	Purpose
[no] monitor capture mycap match { any mac <i>mac-match-string</i> ipv4 <i>ipv4-match-string</i> ipv6 <i>ipv6-match-string</i> }	Defines an explicitly in-line core filter. To remove the filter, use the no form of this command.
[no] monitor capture mycap match mac { <i>src-mac-addr</i> <i>src-mac-mask</i> any host <i>src-mac-addr</i> } { <i>dest-mac-addr</i> <i>dest-mac-mask</i> any host <i>dest-mac-addr</i> }	Specifies use of a filter for MAC. To remove the filter, use the no form of this command.
[no] monitor capture mycap match {ipv4 ipv6} [<i>src-prefix/length</i> any host <i>src-ip-addr</i>] [<i>dest-prefix/length</i> any host <i>dest-ip-addr</i>]	Specifies a filter for IPv4/IPv6, use one of the formats. To remove the filters, use the no form of this command.
[no] monitor capture mycap match {ipv4 ipv6} proto { tcp udp } [<i>src-prefix/length</i> any host <i>src-ip-addr</i>] [eq gt lt neq <0-65535>] [<i>dest-prefix/length</i> any host <i>dest-ip-addr</i>] [eq gt lt neq <0-65535>]	

To define a capture point, use the following commands:

Command	Purpose
monitor capture name [{ interface <i>name</i> vlan <i>num</i> control-plane } { in out both }	Specifies one or more attachment points with direction. To remove the attachment point, use the no form of this command.
monitor capture name [[file location <i>filename</i> [buffer-size <1-100>] [ring <2-10>] [size <1-100>]] [buffer [circular] size <1-100>]]	Specifies the capture destination. To remove the details, use the no form of this command.
[no] monitor capture name limit { duration <i>seconds</i> } [packet-length <i>size</i>] [packets <i>num</i>]	Specifies capture limits. To remove the limits, use the no form of this command.

To clear the buffer contents, use the following command

Command	Purpose
monitor capture [clear export <i>filename</i>]	Clears capture buffer contents or stores the packets to a file.

To start and stop a capture point, use the following command:

Command	Purpose
monitor capture <i>name</i> start [capture-filter <i>filter-string</i>] [display [display-filter <i>filter-string</i>]] [brief detailed dump stop]	To start or stop a capture point, use the monitor capture command.

Examples

Associating or Disassociating a Capture File

```
Switch# monitor capture point mycap file location bootdisk:mycap.pcap

Switch# no monitor capture mycap file
```

Specifying a Memory Buffer Size for Packet Burst Handling

```
Switch# monitor capture mycap buffer-size 1000000
```

Defining an Explicit Core System Filter to Match Both IPv4 and IPv6 TCP Traffic

```
Switch# monitor capture mycap match any protocol tcp
```

Defining a Core System Filter Using an Existing ACL or Class Map

```
Switch# monitor capture mycap match access-list myacl

Switch# monitor capture mycap match class-map mycm
```

Activating and Deactivating a Capture Point

A capture point cannot be activated unless an attachment point and a core system filter have been defined and the associated filename (if any) does not already exist. A capture point with no associated filename can only be activated to display. If no capture or display filters are specified, all of the packets captured by the core system filter are displayed. The default display mode is **brief**.

To activate or deactivate a capture point, perform these tasks:

Command	Purpose
monitor capture <i>name</i> start [capture-filter <i>filter-string</i>] [display [display-filter <i>filter-string</i>]] [brief detailed dump]	Activates a capture point.
monitor capture <i>name</i> stop	Deactivates a capture point.
Example: Switch# monitor capture mycap start capture-filter "net 10.1.1.0 0.0.0.255 and port 80" Switch# monitor capture mycap start display display-filter "net 10.1.1.0 0.0.0.255 and port 80"	

Configuring Wireshark on VSS

To configure Wireshark in the VSS active switch, perform the following step:

```
Switch_VSS# monitor capture mycap match any interface gi2/1/1 in file location
bootflash:text.pcap
```

Monitoring Wireshark

The commands in the following table are used to monitor Wireshark.

Table 71-2 Wireshark Monitoring Commands

Command	Purpose
<code>show monitor capture point name</code>	Displays the capture point state so that you can see what capture points are defined, what their attributes are, and whether they are active. When capture point <i>name</i> is specified, it displays specific capture point's details.
<code>show monitor capture file name</code> <code>[display-filter filter-string] [brief detailed dump]</code>	Activates Wireshark using an existing .pcap file as the source for packets. If no display filter is specified, all of the packets in the file are displayed. The default display mode is brief .

Configuration Examples for Wireshark

Example: Displaying a Brief Output from a .pcap File

You can display the output from a .pcap file by entering:

```
Switch# show monitor capture file bootflash:mycap.pcap
 1  0.000000  10.1.1.140 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
 2  1.000000  10.1.1.141 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
 3  2.000000  10.1.1.142 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
 4  3.000000  10.1.1.143 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
 5  4.000000  10.1.1.144 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
 6  5.000000  10.1.1.145 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
 7  6.000000  10.1.1.146 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
 8  7.000000  10.1.1.147 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
 9  8.000000  10.1.1.148 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
10  9.000000  10.1.1.149 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
11 10.000000  10.1.1.150 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
12 11.000000  10.1.1.151 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
13 12.000000  10.1.1.152 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
14 13.000000  10.1.1.153 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
15 14.000000  10.1.1.154 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
16 15.000000  10.1.1.155 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
17 16.000000  10.1.1.156 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
18 17.000000  10.1.1.157 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
19 18.000000  10.1.1.158 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
20 19.000000  10.1.1.159 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
21 20.000000  10.1.1.160 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
22 21.000000  10.1.1.161 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
23 22.000000  10.1.1.162 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
24 23.000000  10.1.1.163 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
25 24.000000  10.1.1.164 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
26 25.000000  10.1.1.165 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
27 26.000000  10.1.1.166 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
28 27.000000  10.1.1.167 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
29 28.000000  10.1.1.168 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
```

```

30 29.000000 10.1.1.169 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
31 30.000000 10.1.1.170 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
32 31.000000 10.1.1.171 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
33 32.000000 10.1.1.172 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
34 33.000000 10.1.1.173 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
35 34.000000 10.1.1.174 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
36 35.000000 10.1.1.175 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
37 36.000000 10.1.1.176 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
38 37.000000 10.1.1.177 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
39 38.000000 10.1.1.178 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
40 39.000000 10.1.1.179 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
41 40.000000 10.1.1.180 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
42 41.000000 10.1.1.181 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
43 42.000000 10.1.1.182 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
44 43.000000 10.1.1.183 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
45 44.000000 10.1.1.184 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
46 45.000000 10.1.1.185 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
47 46.000000 10.1.1.186 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
48 47.000000 10.1.1.187 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
49 48.000000 10.1.1.188 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
50 49.000000 10.1.1.189 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
51 50.000000 10.1.1.190 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
52 51.000000 10.1.1.191 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
53 52.000000 10.1.1.192 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
54 53.000000 10.1.1.193 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
55 54.000000 10.1.1.194 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
56 55.000000 10.1.1.195 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
57 56.000000 10.1.1.196 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
58 57.000000 10.1.1.197 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
59 58.000000 10.1.1.198 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002

```

Example: Displaying Detailed Output from a .pcap File

You can display the detailed .pcap file output by entering:

```

Switch# show monitor capture file bootflash:mycap.pcap detailed
Frame 1: 256 bytes on wire (2048 bits), 256 bytes captured (2048 bits)
  Arrival Time: Mar 21, 2012 14:35:09.111993000 PDT
  Epoch Time: 1332365709.111993000 seconds
  [Time delta from previous captured frame: 0.000000000 seconds]
  [Time delta from previous displayed frame: 0.000000000 seconds]
  [Time since reference or first frame: 0.000000000 seconds]
  Frame Number: 1
  Frame Length: 256 bytes (2048 bits)
  Capture Length: 256 bytes (2048 bits)
  [Frame is marked: False]
  [Frame is ignored: False]

Usage Examples for Wireshark

Example: Simple Capture and Display

This example shows how to monitor traffic in the Layer 3 interface Gigabit 3/1:

Step 1 Define a capture point to match on the relevant traffic by entering:

```

Switch# monitor capture mycap interface gi 3/1 in match ipv4 any any
Switch# monitor capture mycap limit duration 60 packets 100

```

Note To avoid high CPU utilization, a low packet count and duration as limits has been set.

Step 2 Confirm that the capture point has been correctly defined by entering:

```

Switch# show monitor capture mycap parameter
      monitor capture mycap interface GigabitEthernet3/1 in
      monitor capture mycap match ipv4 any any
      monitor capture mycap limit packets 100 duration 60
Switch# show monitor capture mycap
Status Information for Capture mycap
Target Type:
  Interface: GigabitEthernet3/1, Direction: in
Status : Inactive
Filter Details:
  IPv4
    Source IP: any
    Destination IP: any
    Protocol: any
File Details:
  File not associated
Buffer Details:
  Buffer Type: LINEAR (default)
Limit Details:
  Number of Packets to capture: 100
  Packet Capture duration: 60

```

Step 3 Start the capture process and display the results.

```
Switch# monitor capture mycap start display
0.000000 10.1.1.30 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.31 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.32 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.33 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.34 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.35 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.36 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.37 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.38 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.39 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
```

Step 4 Delete the capture point by entering:

```
Switch# no monitor capture mycap
```

Example: Simple Capture and Store

This example shows how to capture packets to a filter.

Step 1 Define a capture point to match on the relevant traffic and associate it to a file by entering:

```
Switch# monitor capture mycap interface gi 3/1 in match ipv4 any any
Switch# monitor capture mycap limit duration 60 packets 100
Switch# monitor cap mycap file location bootflash:mycap.pcap
```

Step 2 Confirm that the capture point has been correctly defined by entering:

```
Switch# show monitor capture mycap parameter
monitor capture mycap interface GigabitEthernet3/1 in
monitor capture mycap match ipv4 any any
monitor capture mycap file location bootflash:mycap.pcap
monitor capture mycap limit packets 100 duration 60
Switch# show monitor capture mycap
Target Type:
Interface: GigabitEthernet3/1, Direction: in
Status : Inactive
Filter Details:
IPv4
Source IP: any
Destination IP: any
Protocol: any
File Details:
Associated file name: bootflash:mycap.pcap
Buffer Details:
Buffer Type: LINEAR (default)
Limit Details:
Number of Packets to capture: 100
Packet Capture duration: 60
```

Step 3 Launch packet capture by entering:

```
Switch# monitor capture mycap start
```

Step 4 After sufficient time has passed, stop the capture by entering:

```
Switch# monitor capture mycap stop
```

**Note**

Alternatively, you could let the capture operation stop automatically after the time has elapsed or the packet count has been met.

The **mycap.pcap** file now contains the captured packets.

Step 5 Display the packets by entering:

```
Switch# show monitor capture file bootflash:mycap.pcap
0.000000 10.1.1.30 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.31 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.32 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.33 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.34 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.35 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.36 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.37 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.38 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.39 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
```

Step 6 Delete the capture point by entering:

```
Switch# no monitor capture mycap
```

Example: Using Buffer Capture

This example shows how to use buffer capture:

Step 1 Launch a capture session with the buffer capture option by entering:

```
Switch# monitor capture mycap interface gi 3/1 in
Switch# monitor capture mycap match ipv4 any any
Switch# monitor capture mycap buffer circular size 1
Switch# monitor capture mycap start
```

Step 2 Determine whether the capture is active by entering:

```
Switch# show monitor capture mycap

Status Information for Capture mycap
Target Type:
  Interface: GigabitEthernet3/1, Direction: in
Status : Active
Filter Details:
  IPv4
    Source IP: any
    Destination IP: any
  Protocol: any
File Details:
  File not associated
Buffer Details:
  Buffer Type: CIRCULAR
  Buffer Size (in MB): 1
Limit Details:
  limit not set
```

Step 3 Display the packets in the buffer by entering:

```
Switch# show monitor capture mycap buffer brief
0.000000 10.1.1.215 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.216 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.217 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.218 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.219 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.220 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.221 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.222 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.223 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.224 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
10.000000 10.1.1.225 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
11.000000 10.1.1.226 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
12.000000 10.1.1.227 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
13.000000 10.1.1.228 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
14.000000 10.1.1.229 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
15.000000 10.1.1.230 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
16.000000 10.1.1.231 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
17.000000 10.1.1.232 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
18.000000 10.1.1.233 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
19.000000 10.1.1.234 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
20.000000 10.1.1.235 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
21.000000 10.1.1.236 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
```

Notice that the packets have been buffered.

Step 4 Display the packets in other display modes.

```
Switch# show monitor capture mycap buffer detailed
Frame 1: 256 bytes on wire (2048 bits), 256 bytes captured (2048 bits)

```

Step 5 Clear the buffer once, wait for 10 seconds, then stop the traffic by entering:

```
Switch# monitor capture mycap clear
```

Wait for 10 seconds and stop the traffic.

Confirm that the same set of packets are displayed after this time gap by entering:

```

Switch# show monitor capture mycap buffer brief
0.000000 10.1.1.2 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.3 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.4 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.5 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.6 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.7 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.8 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.9 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.10 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.11 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002

```

[Wait for about 10 secs]

```

Switch# show monitor capture mycap buffer brief
0.000000 10.1.1.2 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.3 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.4 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.5 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.6 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.7 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.8 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.9 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.10 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.11 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002

```

[Wait for about 10 secs]

```

Switch# show monitor capture mycap buffer brief
0.000000 10.1.1.2 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.3 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.4 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.5 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.6 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.7 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.8 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.9 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.10 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.11 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002

```

Step 6 Clear the packets from the buffer by entering:

```
Switch# monitor capture mycap clear
```

Step 7 Confirm that the buffer is now empty by entering:

```
Switch# show monitor capture mycap buffer brief
```

Wait about 10 seconds.

Step 8 Display the buffer contents.

```
Switch# show monitor capture mycap buffer brief
```

Step 9 Restart the traffic, wait about 10 seconds, then display buffer contents by entering:

```
Switch# show monitor capture mycap buffer brief
0.000000 10.1.1.2 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.3 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.4 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.5 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.6 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.7 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.8 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.9 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.10 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.11 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
10.000000 10.1.1.12 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
```

Step 10 Store the buffer contents to the mycap1.pcap file in the internal bootflash: storage device.

```
Switch# monitor capture mycap export bootflash:mycap1.pcap
Exported Successfully
```

Step 11 Check that the file has been created and that it contains the packets by entering:

```
Switch# dir bootflash:mycap1.pcap
Directory of bootflash:/mycap1.pcap

14758  -rw-          20152  Apr 15 2012 16:00:28 -07:00  mycap1.pcap

831541248 bytes total (831340544 bytes free)
Switch# show monitor capture file bootflash:mycap1.pcap brief
 1  0.000000 10.1.1.2 -> 20.1.1.2 UDP Source port: 20001 Destination port:
20002
 2  1.000000 10.1.1.3 -> 20.1.1.2 UDP Source port: 20001 Destination port:
20002

20002
 9  8.000000 10.1.1.10 -> 20.1.1.2 UDP Source port: 20001 Destination port:
20002
10  9.000000 10.1.1.11 -> 20.1.1.2 UDP Source port: 20001 Destination port:
20002
11 10.000000 10.1.1.12 -> 20.1.1.2 UDP Source port: 20001 Destination port:
20002
12 11.000000 10.1.1.13 -> 20.1.1.2 UDP Source port: 20001 Destination port:
20002
13 12.000000 10.1.1.14 -> 20.1.1.2 UDP Source port: 20001 Destination port:
20002
14 13.000000 10.1.1.15 -> 20.1.1.2 UDP Source port: 20001 Destination port:
20002
15 14.000000 10.1.1.16 -> 20.1.1.2 UDP Source port: 20001 Destination port:
20002
```

```
16 15.000000 10.1.1.17 -> 20.1.1.2 UDP Source port: 20001 Destination port:
20002
```

Step 12 Stop the packet capture and display the buffer contents by entering:

```
Switch# monitor capture mycap stop
Switch# show monitor capture mycap buffer brief
0.000000 10.1.1.2 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.3 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.4 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.5 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.6 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.7 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.8 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.9 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.10 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.11 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
10.000000 10.1.1.12 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
11.000000 10.1.1.13 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
```

Step 13 Clear the buffer and then try to display packets from the buffer by entering:

```
Switch# monitor capture mycap clear
Switch# show monitor capture mycap buffer brief
```

Step 14 Delete the capture point by entering:

```
Switch# no monitor capture mycap
```

Example: Capture Sessions

The following examples shows how to start or stop a capture session in various modes:

```
Switch# monitor capture mycap int gi 3/1 in match ipv4 any any
Switch# monitor capture mycap file location bootflash:mycap.pcap
Switch# monitor capture mycap limit packets 100 duration 60

Switch# monitor capture mycap start
Switch#
Switch# monitor capture mycap stop
Switch# monitor capture mycap start capture-filter "udp.port == 20001"
Switch# monitor capture mycap stop
Switch# monitor capture mycap start capture-filter "udp.port == 20001" display
A file by the same capture file name already exists, overwrite?[confirm]

0.000000 10.1.1.9 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
0.000000 10.1.1.10 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
0.000000 10.1.1.11 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
0.000000 10.1.1.12 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002

```

Switch#

Example: Capture and Store in Lock-step Mode

This example captures live traffic and stores the packets in lock-step mode to achieve a high capture rate.

Note

The capture rate might be slow for the first 15 seconds. If possible and needed, start the traffic 15 seconds after the capture session has started.

Step 1 Define a capture point to match on the relevant traffic and associate it to a file by entering:

```

Switch# monitor capture mycap interface gi 3/1 in match ipv4 any any
Switch# monitor capture mycap limit duration 60 packets 100
Switch# monitor cap mycap file location bootflash:mycap.pcap buffer-size 64

```

Step 2 Confirm that the capture point has been correctly defined by entering:

```

Switch# show monitor capture mycap parameter
  monitor capture mycap interface GigabitEthernet3/1 in
  monitor capture mycap match ipv4 any any
  monitor capture mycap file location bootflash:mycap.pcap buffer-size 64
  monitor capture mycap limit packets 100000 duration 60
Switch# show monitor capture mycap
Target Type:
  Interface: GigabitEthernet3/1, Direction: in
Status : Inactive
Filter Details:
  IPv4
  Source IP: any
  Destination IP: any
  Protocol: any
File Details:
  Associated file name: bootflash:mycap.pcap
Buffer Details:
  Buffer Type: LINEAR (default)
Limit Details:
  Number of Packets to capture: 100
  Packet Capture duration: 60

```

Step 3 Launch packet capture by entering:

```
Switch# monitor capture mycap start
```

Let the capture operation stop automatically after the time has elapsed or the packet count has been met.

The **mycap.pcap** file now contains the captured packets.

Step 4 Display the packets by entering:

```

Switch# show monitor capture file bootflash:mycap.pcap
0.000000 10.1.1.30 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.31 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.32 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.33 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002

```

```

4.000000  10.1.1.34 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
5.000000  10.1.1.35 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
6.000000  10.1.1.36 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
7.000000  10.1.1.37 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
8.000000  10.1.1.38 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
9.000000  10.1.1.39 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002

```

Step 5 Delete the capture point by entering:

```
Switch# no monitor capture mycap
```

Example: Simple Capture and Store in Lock-step with High-speed Mode

This example shows how to capture live traffic and store the packets in lock-step with high-speed mode to achieve high capture rate.

Note

The capture rate might be slow for the first 15 seconds. If possible and necessary, start the traffic 15 seconds after the capture session starts.

Step 1 Define a capture point to match on the relevant traffic and associate it to a file by entering:

```

Switch# monitor capture mycap interface gi 3/1 in match ipv4 any any
Switch# monitor capture mycap limit duration 60 packets 100
Switch# monitor cap mycap file location bootflash:mycap.pcap buffer-size 90

```

Step 2 Confirm that the capture point has been correctly defined by entering:

```

Switch# show monitor capture mycap parameter
  monitor capture mycap interface GigabitEthernet3/1 in
  monitor capture mycap match ipv4 any any
  monitor capture mycap file location bootflash:mycap.pcap buffer-size 90
  monitor capture mycap limit packets 100000 duration 60
Switch# show monitor capture mycap
Target Type:
  Interface: GigabitEthernet3/1, Direction: in
Status : Inactive
Filter Details:
  IPv4
    Source IP: any
    Destination IP: any
    Protocol: any
File Details:
  Associated file name: bootflash:mycap.pcap
Buffer Details:
  Buffer Type: LINEAR (default)
Limit Details:
  Number of Packets to capture: 100
  Packet Capture duration: 60

```

Step 3 Launch packet capture by entering:

```
Switch# monitor capture mycap start
```

Let the capture operation stop automatically after the time has elapsed or the packet count has been met.

The **mycap.pcap** file now contains the captured packets.

Step 4 Display the packets by entering:

```
Switch# show monitor capture file bootflash:mycap.pcap
0.000000 10.1.1.30 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.31 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.32 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.33 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.34 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.35 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.36 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.37 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.38 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.39 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
```

Step 5 Delete the capture point by entering:

```
Switch# no monitor capture mycap
```

Example: Simple Capture and Store of Packets in Egress Direction

This example shows how to capture live traffic and store the packets in egress direction using lock-step with high-speed mode.

Step 1 Define a capture point to match on the relevant traffic and associate it to a file by entering:

```
Switch# monitor capture mycap interface gi 3/1 out match ipv4 any any
Switch# monitor capture mycap limit duration 60 packets 100
Switch# monitor cap mycap file location bootflash:mycap.pcap buffer-size 90
```

Step 2 Confirm that the capture point has been correctly defined by entering:

```
Switch# show monitor capture mycap parameter
monitor capture mycap interface GigabitEthernet3/1 out
monitor capture mycap match ipv4 any any
monitor capture mycap file location bootflash:mycap.pcap buffer-size 90
monitor capture mycap limit packets 100000 duration 60
Switch# show monitor capture mycap
Target Type:
Interface: GigabitEthernet3/1, Direction: out
Status : Inactive
Filter Details:
IPv4
Source IP: any
Destination IP: any
Protocol: any
File Details:
Associated file name: bootflash:mycap.pcap
Buffer Details:
Buffer Type: LINEAR (default)
Limit Details:
Number of Packets to capture: 100
Packet Capture duration: 60
```

Step 3 Launch packet capture by entering:

```
Switch# monitor capture mycap start
```

Note

Let the capture operation stop automatically after the time has elapsed or the packet count has been met.

The mycap.pcap file now contains the captured packets.

Step 4 Display the packets by entering:

```
Switch# show monitor capture file bootflash:mycap.pcap
0.000000 10.1.1.30 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.31 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.32 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.33 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.34 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.35 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.36 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.37 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.38 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.39 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
```

Step 5 Delete the capture point by entering:

```
Switch# no monitor capture mycap
```

VSS Specific Examples

Example: Capturing and Storing in a file

This example shows how to do a simple capture and store operation after the attachment point is issued on the VSS active switch:

Step 1 Launch a capture session by entering the following commands in VSS active switch:

```
vss_dut1# monitor capture mycap interface gi 1/1/1 in
vss_dut1# monitor capture mycap match ipv4 any any
vss_dut1# monitor capture mycap file location bootflash:mycap.pcap
vss_dut1# monitor capture mycap limit packets 10 duration 10
vss_dut1# monitor capture mycap start
```

Step 2 After the capture session concludes, check that the capture file has stored the packets:

```
*Nov 15 00:04:08.337 PDT: %BUFCAP-6-ENABLE: Capture Point mycap enabled.
*Nov 15 00:04:08.339 PDT: Policy name = mycap, Instance ID = 4
vss_dut1#
*Nov 15 00:04:13.736 PDT: %BUFCAP-6-DISABLE_ASYNC: Capture Point mycap disabled. Reason :
Wireshark Session Ended
vss_dut1# dir bootflash:mycap.pcap
Directory of bootflash:/mycap.pcap
72971 -rw-      824 Nov 15 2012 00:04:13 -07:00 mycap.pcap
822910976 bytes total (304648192 bytes free)
```

Example: Capturing and Storing in a File with Display

This example shows how to perform a basic capture and store operation with the display option in brief mode after the attachment point is issued on the VSS active switch:

Step 1 Prepare a capture session by entering the following commands in VSS active switch:

```
vss_dut1# monitor capture mycap interface gi 1/1/1 in
vss_dut1# monitor capture mycap match ipv4 any any
```

```
vss_dut1# monitor capture mycap file location bootflash:mycap.pcap
vss_dut1# monitor capture mycap limit packets 60 duration 60
```

Step 2 Start the capture session with display option in brief mode:

```
vss_dut1# monitor capture mycap start display

*Nov 14 23:43:20.506 PDT: Policy name = mycap, Instance ID = 3
 0.000000 20.1.1.2 -> 30.1.1.2 TCP [TCP ZeroWindow] 0 > 0 [<None>] Seq=1 Win=0
Len=6
 0.595022 20.1.1.2 -> 30.1.1.2 TCP [TCP ZeroWindow] [TCP Retransmission] 0 > 0
[<None>] Seq=1 Win=0 Len=6
 1.012008 20.1.1.2 -> 30.1.1.2 TCP [TCP ZeroWindow] [TCP Retransmission] 0 > 0
[<None>] Seq=1 Win=0 Len=6
 1.500026 20.1.1.2 -> 30.1.1.2 TCP [TCP ZeroWindow] [TCP Retransmission] 0 > 0
[<None>] Seq=1 Win=0 Len=6
 2.005005 20.1.1.2 -> 30.1.1.2 TCP [TCP ZeroWindow] [TCP Retransmission] 0 > 0
[<None>] Seq=1 Win=0 Len=6
 2.500026 20.1.1.2 -> 30.1.1.2 TCP [TCP ZeroWindow] [TCP Retransmission] 0 > 0
[<None>] Seq=1 Win=0 Len=6
 3.000000 20.1.1.2 -> 30.1.1.2 TCP [TCP ZeroWindow] [TCP Retransmission] 0 > 0
[<None>] Seq=1 Win=0 Len=6
...
```

Example: Circular Buffer Usage

This example shows how to do a simple capture and store operation with display option after the attachment point is issued on the VSS active switch:

Step 1 Prepare the capture session by entering the following commands in VSS active switch:

```
vss_dut1# monitor capture mycap interface gi 2/1/1 in
vss_dut1# monitor capture mycap match ipv4 any any
vss_dut1# monitor capture mycap buffer size 1 circular
vss_dut1# monitor capture mycap limit packets 10
```

Step 2 Start the session in VSS active switch. Periodically, check that the packets are stored in the capture file.

```
vss_dut1# monitor capture mycap start
vss_dut1# show monitor capture mycap buffer
0.000000 10.10.10.20 -> 10.10.10.10 TCP [TCP ZeroWindow] 2000 > 3000 [<None>] Seq=1
Win=0 Len=6[Malformed Packet]
 0.000000 10.10.10.20 -> 10.10.10.10 TCP [TCP ZeroWindow] [TCP Out-Of-Order] 2000 >
3000 [<None>] Seq=1 Win=0 Len=6[Malformed Packet]
 0.000000 10.10.10.20 -> 10.10.10.10 TCP [TCP ZeroWindow] [TCP Out-Of-Order] 2000 >
3000 [<None>] Seq=1 Win=0 Len=6[Malformed Packet]
 0.000000 10.10.10.20 -> 10.10.10.10 TCP [TCP ZeroWindow] [TCP Out-Of-Order] 2000 >
3000 [<None>] Seq=1 Win=0 Len=6[Malformed Packet]

Configuring Enhanced Object Tracking

This chapter describes how to configure enhanced object tracking on the Catalyst 4500 series switch. This feature provides a more complete alternative to the Hot Standby Routing Protocol (HSRP) tracking mechanism, which allows you to track the line-protocol state of an interface. If the line protocol state of an interface goes down, the HSRP priority of the interface is reduced and another HSRP device with a higher priority becomes active. The enhanced object tracking feature separates the tracking mechanism from HSRP and creates a separate, standalone tracking process that can be used by processes other than HSRP. This allows tracking other objects in addition to the interface line-protocol state. A client process, such as HSRP, can register an interest in tracking objects and request notification when the tracked object changes state. This feature increases the availability and speed of recovery of a routing system and decreases outages and outage duration.

Unless otherwise noted, the term *switch* refers to a Catalyst 4500 series switch.

The chapter includes these sections:

- [Understanding Enhanced Object Tracking, page 72-1](#)
- [Configuring Enhanced Object Tracking Features, page 72-2](#)
- [Monitoring Enhanced Object Tracking, page 72-12](#)

Note

For more details on enhanced object tracking, refer to this URL:

http://www.cisco.com/en/US/docs/ios/ios_xe/ipapp/configuration/guide/ipapp_eot_xe.html

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Understanding Enhanced Object Tracking

Each tracked object has a unique number that is specified in the tracking command-line interface (CLI). Client processes use this number to track a specific object. The tracking process periodically polls the tracked object for value changes and sends any changes (as up or down values) to interested client processes, either immediately or after a specified delay. Several clients can track the same object, and can take different actions when the object changes state.

You can also track a combination of objects in a list by using either a weight threshold or a percentage threshold to measure the state of the list. You can combine objects using Boolean logic. A tracked list with a Boolean “AND” function requires that each object in the list be in an up state for the tracked object to be up. A tracked list with a Boolean “OR” function needs only one object in the list to be in the up state for the tracked object to be up.

Configuring Enhanced Object Tracking Features

- [Default Configuration, page 72-2](#)
- [Tracking Interface Line-Protocol or IP Routing State, page 72-2](#)
- [Configuring a Tracked List, page 72-3](#)
- [Configuring HSRP Object Tracking, page 72-7](#)
- [Configuring Other Tracking Characteristics, page 72-8](#)
- [Configuring IP SLAs Object Tracking, page 72-8](#)
- [Configuring Static Routing Support, page 72-10](#)

Default Configuration

No type of object tracking is configured.

Tracking Interface Line-Protocol or IP Routing State

You can track either the interface line protocol state or the interface IP routing state. When you track the IP routing state, these three conditions are required for the object to be up:

- IP routing must be enabled and active on the interface.
- The interface line-protocol state must be up.
- The interface IP address must be known.

If all three of these conditions are not met, the IP routing state is down.

To track the line-protocol state or IP routing state of an interface, perform the following task:

	Command	Purpose
Step 1	configure terminal	Enters global configuration mode.
Step 2	track <i>object-number</i> interface <i>interface-id</i> line-protocol	(Optional) Creates a tracking list to track the line-protocol state of an interface and enter tracking configuration mode. <ul style="list-style-type: none"> • The <i>object-number</i> identifies the tracked object and can be from 1 to 500. • The interface <i>interface-id</i> is the interface being tracked.
Step 3	delay { up <i>seconds</i> [down <i>seconds</i>] [up <i>seconds</i>] down <i>seconds</i> }	(Optional) Specifies a period of time in seconds to delay communicating state changes of a tracked object. The range is from 1 to 180 seconds.
Step 4	exit	Returns to global configuration mode.

	Command	Purpose
Step 5	track <i>object-number</i> interface <i>interface-id</i> ip routing	(Optional) Creates a tracking list to track the IP routing state of an interface, and enter tracking configuration mode. IP-route tracking tracks an IP route in the routing table and the ability of an interface to route IP packets. <ul style="list-style-type: none"> The <i>object-number</i> identifies the tracked object and can be from 1 to 500. The interface <i>interface-id</i> is the interface being tracked.
Step 6	delay { up <i>seconds</i> [down <i>seconds</i>] [up <i>seconds</i>] down <i>seconds</i> }	(Optional) Specifies a period of time in seconds to delay communicating state changes of a tracked object. The range is from 1 to 180 seconds.
Step 7	end	Returns to privileged EXEC mode.
Step 8	show track <i>object-number</i>	Verifies that the specified objects are being tracked.
Step 9	copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example configures the tracking of an interface line-protocol state and verifies the configuration:

```
Switch(config)# track 33 interface gigabitethernet 1/0/1 line-protocol
Switch(config-track)# end
Switch# show track 33
Track 33
  Interface GigabitEthernet1/0/1 line-protocol
  Line protocol is Down (hw down)
    1 change, last change 00:18:28
```

Configuring a Tracked List

You can configure a tracked list of objects with a Boolean expression, a weight threshold, or a percentage threshold. A tracked list contains one or more objects. An object must exist before it can be added to the tracked list.

- You configure a Boolean expression to specify calculation by using either “AND” or “OR” operators.
- When you measure the tracked list state by a weight threshold, you assign a weight number to each object in the tracked list. The state of the tracked list is determined by whether or not the threshold was met. The state of each object is determined by comparing the total weight of all objects against a threshold weight for each object.
- When you measure the tracked list by a percentage threshold, you assign a percentage threshold to all objects in the tracked list. The state of each object is determined by comparing the assigned percentages of each object to the list.

Configuring a Tracked List with a Boolean Expression

Configuring a tracked list with a Boolean expression enables calculation by using either “AND” or “OR” operators. For example, when tracking two interfaces using the “AND” operator, *up* means that both interfaces are up, and *down* means that either interface is down.

To configure a tracked list of objects with a Boolean expression, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>track track-number list boolean {and or}</code>	Configures a tracked list object, and enter tracking configuration mode. The <i>track-number</i> can be from 1 to 500. <ul style="list-style-type: none"> boolean—Specify the state of the tracked list based on a Boolean calculation. and—Specify that the list is up if all objects are up or down if one or more objects are down. or—Specify that the list is up if one object is up or down if all objects are down.
Step 3	<code>object object-number [not]</code>	Specifies the object to be tracked. The range is from 1 to 500. The keyword not negates the state of the object, which means that when the object is up, the tracked list detects the object as down. Note An object must exist before you can add it to a tracked list.
Step 4	<code>delay {up seconds [down seconds] [up seconds] down seconds}</code>	(Optional) Specifies a period of time in seconds to delay communicating state changes of a tracked object. The range is from 1 to 180 seconds.
Step 5	<code>end</code>	Returns to privileged EXEC mode.
Step 6	<code>show track object-number</code>	Verifies that the specified objects are being tracked.
Step 7	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Use the **no track track-number** global configuration command to delete the tracked list.

This example configures track list 4 with a Boolean AND expression that contains two objects with one object state negated. If the list is up, the list detects that object 2 is down:

```
Switch(config)# track 4 list boolean and
Switch(config-track)# object 1
Switch(config-track)# object 2 not
Switch(config-track)# exit
```

Configuring a Tracked List with a Weight Threshold

To track by weight threshold, configure a tracked list of objects, specify that weight is used as the threshold, and configure a weight for each of its objects. The state of each object is determined by comparing the total weight of all objects that are up against a threshold weight for each object.

You cannot use the Boolean “NOT” operator in a weight threshold list.

Beginning in privileged EXEC mode, follow these steps to configure a tracked list of objects by using a weight threshold and to configure a weight for each object:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>track track-number list threshold weight</code>	Configures a tracked list object and enter tracking configuration mode. The <i>track-number</i> can be from 1 to 500. <ul style="list-style-type: none"> threshold—Specify the state of the tracked list based on a threshold. weight—Specify that the threshold is based on weight.
Step 3	<code>object object-number [weight weight-number]</code>	Specifies the object to be tracked. The range is from 1 to 500. The optional weight weight-number specifies a threshold weight for the object. The range is from 1 to 255. Note An object must exist before you can add it to a tracked list.
Step 4	<code>threshold weight {up number / [down number]}</code>	Specifies the threshold weight. <ul style="list-style-type: none"> up number—The valid range is from 1 to 255. down number—(Optional) The range depends on the number selected for the up number. If you configure the up number as 25, the range shown for the down number is 0 to 24.
Step 5	<code>delay {up seconds [down seconds] [up seconds] down seconds}</code>	(Optional) Specifies a period of time in seconds to delay communicating state changes of a tracked object. The range is from 1 to 180 seconds.
Step 6	<code>end</code>	Returns to privileged EXEC mode.
Step 7	<code>show track object-number</code>	Verifies that the specified objects are being tracked.
Step 8	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Use the **no track track-number** global configuration command to delete the tracked list.

The example configures track list 4 to track by weight threshold. If object 1 and object 2 are down, then track list 4 is up because object 3 satisfies the up threshold value of up 30. But if object 3 is down, both objects 1 and 2 must be up in order to satisfy the threshold weight.

```
Switch(config)# track 4 list threshold weight
Switch(config-track)# object 1 weight 15
Switch(config-track)# object 2 weight 20
Switch(config-track)# object 3 weight 30
Switch(config-track)# threshold weight up 30 down 10
Switch(config-track)# exit
```

This configuration can be useful if object 1 and object 2 represent two small bandwidth connections and object 3 represents one large bandwidth connection. The configured **down 10** value means that once the tracked object is up, it will not go down until the threshold value is equal to or lower than 10, which in this example means that all connections are down.

Configuring a Tracked List with a Percentage Threshold

To track by percentage threshold, configure a tracked list of objects, specify that a percentage will be used as the threshold, and specify a percentage for all objects in the list. The state of the list is determined by comparing the assigned percentage of each object to the list.

You cannot use the Boolean “NOT” operator in a percentage threshold list.

To configure a tracked list of objects by using a percentage threshold, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>track track-number list threshold percentage</code>	Configures a tracked list object and enter tracking configuration mode. The <i>track-number</i> can be from 1 to 500. <ul style="list-style-type: none"> threshold—Specify the state of the tracked list based on a threshold. percentage—Specify that the threshold is based on percentage.
Step 3	<code>object object-number</code>	Specifies the object to be tracked. The range is from 1 to 500. Note An object must exist before you can add it to a tracked list.
Step 4	<code>threshold percentage {up number / [down number]}</code>	Specifies the threshold percentage. <ul style="list-style-type: none"> up number—The valid range is from 1 to 100. down number—(Optional) The range depends on the number selected for the up number. If you configure the up number as 25, the range shown for the down number is 0 to 24.
Step 5	<code>delay {up seconds [down seconds] [up seconds] down seconds}</code>	(Optional) Specifies a period of time in seconds to delay communicating state changes of a tracked object. The range is from 1 to 180 seconds.
Step 6	<code>end</code>	Returns to privileged EXEC mode.
Step 7	<code>show track object-number</code>	Verifies that the specified objects are being tracked.
Step 8	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Use the **no track track-number** global configuration command to delete the tracked list.

This example configures tracked list 4 with three objects and a specified percentages to measure the state of the list:

```
Switch(config)# track 4 list threshold percentage
Switch(config-track)# object 1
Switch(config-track)# object 2
Switch(config-track)# object 3
Switch(config-track)# threshold percentage up 51 down 10
Switch(config-track)# exit
```

Configuring HSRP Object Tracking

To configure a standby HSRP group to track an object and change the HSRP priority based on the object state, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<pre>track object-number {interface interface-id {line-protocol ip routing} ip route ip-address/prefix-length {metric threshold reachability} list {boolean {and or}} {threshold {weight percentage}}}</pre>	<p>(Optional) Creates a tracking list to track the configured state and enter tracking configuration mode.</p> <ul style="list-style-type: none"> The <i>object-number</i> range is from 1 to 500. Enter interface <i>interface-id</i> to select an interface to track. Enter line-protocol to track the interface line protocol state or enter ip routing to track the interface IP routing state. Enter ip route <i>ip-address/prefix-length</i> to track the state of an IP route. Enter metric threshold to track the threshold metric or enter reachability to track if the route is reachable. <p>The default up threshold is 254 and the default down threshold is 255.</p> <ul style="list-style-type: none"> Enter list to track objects grouped in a list. Configure the list as described on the previous pages. <ul style="list-style-type: none"> For boolean, see the “Configuring a Tracked List with a Boolean Expression” section on page 72-4. For threshold weight, see the “Configuring a Tracked List with a Weight Threshold” section on page 72-5. For threshold percentage, see the “Configuring a Tracked List with a Percentage Threshold” section on page 72-6. <p>Note Repeat this step for each interface to be tracked.</p>
Step 3	<code>exit</code>	Returns to global configuration mode.
Step 4	<code>interface interface-id</code>	Enters interface configuration mode.
Step 5	<code>standby [group-number] ip [ip-address [secondary]]</code>	<p>Creates (or enable) the HSRP group by using its number and virtual IP address.</p> <ul style="list-style-type: none"> (Optional) <i>group-number</i>—Enter a group number on the interface for which HSRP is being enabled. The range is 0 to 255; the default is 0. If there is only one HSRP group, you do not need to enter a group number. (Optional on all but one interface) <i>ip-address</i>—Specify the virtual IP address of the hot standby router interface. You must enter the virtual IP address for at least one of the interfaces; it can be learned on the other interfaces. (Optional) secondary—Specify that the IP address is a secondary hot standby router interface. If this keyword is omitted, the configured address is the primary IP address.

	Command	Purpose
Step 6	standby [<i>group-number</i>] track <i>object-number</i> [decrement <i>priority-decrement</i>]	Configures HSRP to track an object and change the hot standby priority based on the state of the object. <ul style="list-style-type: none"> (Optional) <i>group-number</i>—Enter the group number to which the tracking applies. <i>object-number</i>—Enter a number representing the object to be tracked. The range is from 1 to 500; the default is 1. (Optional) decrement <i>priority-decrement</i>—Specify the amount by which the hot standby priority for the router is decremented (or incremented) when the tracked object goes down (or comes back up). The range is from 1 to 255; the default is 10.
Step 7	end	Returns to privileged EXEC mode.
Step 8	show standby	Verifies the standby router IP address and tracking states.
Step 9	copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring Other Tracking Characteristics

You can also use the enhanced object tracking for tracking other characteristics.

- You can track the reachability of an IP route by using the **track ip route reachability** global configuration command.
- You can use the **track ip route metric threshold** global configuration command to determine if a route is above or below threshold.
- You can use the **track resolution** global configuration command to change the metric resolution default values for routing protocols.
- You can use the **track timer** tracking configuration command to configure the tracking process to periodically poll tracked objects.

Use the **show track** privileged EXEC command to verify enhanced object tracking configuration.

Configuring IP SLAs Object Tracking

Cisco IOS IP Service Level Agreements (IP SLAs) is a network performance measurement and diagnostics tool that uses active monitoring by generating traffic to measure network performance. Cisco IP SLAs operations collects real-time metrics that you can use for network troubleshooting, design, and analysis.

For more information about Cisco IP SLAs on the switch, see [Chapter 80, “Configuring Cisco IOS IP SLA Operations.”](#) For IP SLAs command information see the *Cisco IOS IP SLAs Command Reference, Release 12.4T*.

Object tracking of IP SLAs operations allows clients to track the output from IP SLAs objects and use this information to trigger an action. Every IP SLAs operation maintains an SNMP operation return-code value, such as *OK* or *OverThreshold*, that can be interpreted by the tracking process. You can track two

aspects of IP SLAs operation: state and reachability. For state, if the return code is OK, the track state is up; if the return code is not OK, the track state is down. For reachability, if the return code is OK or OverThreshold, reachability is up; if not OK, reachability is down.

To track the state of an IP SLAs operation or the reachability of an IP SLAs IP host, perform this task:

	Command	Purpose
Step 1	configure terminal	Enters global configuration mode.
Step 2	track object-number ip sla operation-number state	Enters tracking configuration mode to track the state of an IP SLAs operation. <ul style="list-style-type: none"> The <i>object-number</i> range is from 1 to 500. The <i>operation-number</i> range is from 1 to 2147483647.
Step 3	delay {up seconds [down seconds] [up seconds] down seconds}	(Optional) Specifies a period of time in seconds to delay communicating state changes of a tracked object. The range is from 1 to 180 seconds.
Step 4	exit	Returns to global configuration mode.
Step 5	track object-number ip sla operation-number reachability	Enters tracking configuration mode to track the reachability of an IP SLAs IP host. <ul style="list-style-type: none"> The <i>object-number</i> range is from 1 to 500. The <i>operation-number</i> range is from 1 to 2147483647.
Step 6	delay {up seconds [down seconds] [up seconds] down seconds}	(Optional) Specifies a period of time in seconds to delay communicating state changes of a tracked object. The range is from 1 to 180 seconds.
Step 7	end	Returns to privileged EXEC mode.
Step 8	show track object-number	Displays tracking information to verify the configuration.
Step 9	copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to configure and display IP SLAs state tracking:

```
Switch(config)# track 2 200 state
Switch(config)# end
Switch# show track 2
Track 2
  Response Time Reporter 1 state
  State is Down
    1 change, last change 00:00:47
  Latest operation return code: over threshold
  Latest RTT (milliseconds) 4
  Tracked by:
    HSRP Ethernet0/1 3
```

This example output shows whether a route is reachable:

```
Switch(config)# track 3 500 reachability
Switch(config)# end
Switch# show track 3
Track 3
  Response Time Reporter 1 reachability
  Reachability is Up
    1 change, last change 00:00:47
  Latest operation return code: over threshold
  Latest RTT (milliseconds) 4
  Tracked by:
    HSRP Ethernet0/1 3
```

Configuring Static Routing Support

Static routing support using enhanced object tracking provides the ability for the switch to use ICMP pings to identify when a preconfigured static route or a DHCP route goes down. When tracking is enabled, the system tracks the state of the route and informs the client when that state changes. Static route object tracking uses Cisco IP SLAs to generate ICMP pings to monitor the state of the connection to the primary gateway.

For more information about Cisco IP SLAs support on the switch, see [Chapter 80, “Configuring Cisco IOS IP SLA Operations.”](#)

- For more information about static route object tracking, see:
http://www.cisco.com/en/US/docs/ios/dial/configuration/guide/dia_rel_stc_rtg_bckup_support_TS_D_Island_of_Content_Chapter.html

You use this process to configure static route object tracking:

-
- | | |
|---------------|--|
| Step 1 | Configure a primary interface for static routing or for DHCP.ex |
| Step 2 | Configure an IP SLAs agent to ping an IP address using a primary interface and a track object to monitor the state of the agent. |
| Step 3 | Configure a default static default route using a secondary interface. This route is used only if the primary route is removed. |
-

Configuring a Primary Interface

To configure a primary interface for static routing, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>interface interface-id</code>	Selects a primary or secondary interface and enter interface configuration mode.
Step 3	<code>description string</code>	Adds a description to the interface.
Step 4	<code>ip address ip-address mask [secondary]</code>	Sets the primary or secondary IP address for the interface.
Step 5	<code>exit</code>	Returns to global configuration mode.

To configure a primary interface for DHCP, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>interface interface-id</code>	Selects a primary or secondary interface and enter interface configuration mode.
Step 3	<code>description string</code>	Adds a description to the interface.
Step 4	<code>ip dhcp client route track number</code>	Configures the DCHP client to associate any added routes with the specified track number. Valid numbers are from 1 to 500.

	Command	Purpose
Step 5	<code>ip address dhcp</code>	Acquires an IP address on an Ethernet interface from DHCP.
Step 6	<code>exit</code>	Returns to global configuration mode.

Configuring a Cisco IP SLAs Monitoring Agent and Track Object

To configure network monitoring with Cisco IP SLAs, perform this task:

Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>ip sla operation-number</code>	Begins configuring a Cisco IP SLAs operation and enter IP SLA configuration mode.
Step 3	<code>icmp-echo {destination-ip-address / destination hostname [source- ipaddr {ip-address / hostname source-interface interface-id]}</code>	Configures a Cisco IP SLAs end-to-end ICMP echo response time operation and enter IP SLAs ICMP echo configuration mode.
Step 4	<code>timeout milliseconds</code>	Sets the amount of time for which the operation waits for a response from its request packet.
Step 5	<code>frequency seconds</code>	Sets the rate at which the operation is sent into the network.
Step 6	<code>threshold milliseconds</code>	Sets the rising threshold (hysteresis) that generates a reaction event and stores history information for the operation.
Step 7	<code>exit</code>	Exits IP SLAs ICMP echo configuration mode.
Step 8	<code>ip sla schedule operation-number [life {forever seconds}] start-time time pending now after time] [ageout seconds] [recurring]</code>	Configures the scheduling parameters for a single IP SLAs operation.
Step 9	<code>track object-number ip sla operation-number {state reachability}</code>	Tracks the state of a Cisco IOS IP SLAs operation and enter tracking configuration mode.
Step 10	<code>end</code>	Returns to privileged EXEC mode.
Step 11	<code>show track object-number</code>	Displays tracking information to verify the configuration.
Step 12	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Configuring a Routing Policy and Default Route

- To configure a routing policy for backup static routing by using object tracking, perform the following task. For more details about the commands in the procedure, see: http://www.cisco.com/en/US/docs/ios/dial/configuration/guide/dia_rel_stc_rtg_bckup_support_TS_D_Island_of_Content_Chapter.html

Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>access-list access-list-number</code>	Defines an extended IP access list. Configure any optional characteristics.
Step 3	<code>route-map map-tag [permit deny] [sequence-number]</code>	Enters route-map configuration mode and define conditions for redistributing routes from one routing protocol to another.

Step 4	<code>match ip address {access-list number / access-list name}</code>	Distributes any routes that have a destination network number address that is permitted by a standard or extended access list or performs policy routing on packets. You can enter multiple numbers or names.
Step 5	<code>set ip next-hop dynamic dhcp</code>	For DHCP networks only. Sets the next hop to the gateway that was most recently learned by the DHCP client.
Step 6	<code>set interface interface-id</code>	For static routing networks only. Indicates where to send output packets that pass a match clause of a route map for policy routing.
Step 7	<code>exit</code>	Exits route-map configuration mode.
Step 8	<code>ip local policy route-map map-tag</code>	Identifies a route map to use for local policy routing.
Step 9	<code>ip route prefix mask {ip-address / interface-id [ip-address]} [distance] [name] [permanent track track-number] [tag tag]</code>	For static routing networks only. Establishes static routes. Entering track track-number specifies that the static route is installed only if the configured track object is up.
Step 10	<code>end</code>	Returns to privileged EXEC mode.
Step 11	<code>show ip route track table</code>	Displays information about the IP route track table.
Step 12	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

For configuration examples, see:

http://www.cisco.com/en/US/tech/tk801/tk133/technologies_configuration_example09186a0080093f7e.shtml

Monitoring Enhanced Object Tracking

Use the privileged EXEC or user EXEC commands in [Table 72-1](#) to display enhanced object tracking information.

Table 72-1 Commands for Displaying Tracking Information

Command	Purpose
<code>show ip route track table</code>	Displays information about the IP route track table.
<code>show track [object-number]</code>	Displays information about the all tracking lists or the specified list.
<code>show track brief</code>	Displays a single line of tracking information output.
<code>show track interface [brief]</code>	Displays information about tracked interface objects.
<code>show track ip [object-number] [brief] route</code>	Displays information about tracked IP-route objects.
<code>show track resolution</code>	Displays the resolution of tracked parameters.
<code>show track timers</code>	Displays tracked polling interval timers.

Configuring System Message Logging

This chapter describes how to configure system message logging on the Catalyst 4500 series switch.

This chapter consists of these sections:

- [About System Message Logging, page 73-1](#)
- [Configuring System Message Logging, page 73-2](#)
- [Displaying the Logging Configuration, page 73-12](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About System Message Logging

By default, a switch sends the output from system messages and **debug** privileged EXEC commands to a logging process. The logging process controls the distribution of logging messages to various destinations, such as the logging buffer, terminal lines, or a UNIX syslog server, depending on your configuration. The process also sends messages to the console.

Note

The syslog format is compatible with 4.3 BSD UNIX.

When the logging process is disabled, messages are sent only to the console. The messages are sent as they are generated, so message and debug output are interspersed with prompts or output from other commands. Messages are displayed on the console after the process that generated them has finished.

You can set the severity level of the messages to control the type of messages displayed on the consoles and each of the destinations. You can time-stamp log messages or set the syslog source address to enhance real-time debugging and management. For information on possible messages, see the system message guide for this release.

You can access logged system messages by using the switch command-line interface (CLI) or by saving them to a properly configured syslog server. The switch software saves syslog messages in an internal buffer on the switch. If the switch fails, the log is lost unless you had saved it to flash memory.

You can remotely monitor system messages by viewing the logs on a syslog server or by accessing the switch through Telnet or using the console port.

Configuring System Message Logging

These sections describe how to configure system message logging:

- [System Log Message Format, page 73-2](#)
- [Default System Message Logging Configuration, page 73-3](#)
- [Disabling Message Logging, page 73-3](#)
- [Setting the Message Display Destination Device, page 73-4](#)
- [Synchronizing Log Messages, page 73-5](#)
- [Enabling and Disabling Timestamps on Log Messages, page 73-6](#)
- [Enabling and Disabling Sequence Numbers in Log Messages \(Optional\), page 73-7](#)
- [Defining the Message Severity Level \(Optional\), page 73-8](#)
- [Limiting Syslog Messages Sent to the History Table and to SNMP \(Optional\), page 73-9](#)
- [Configuring UNIX Syslog Servers, page 73-10](#)

System Log Message Format

System log messages can contain up to 80 characters and a percent sign (%), which follows the optional sequence number or time-stamp information, if configured. Messages are displayed in this format:

seq no:timestamp: %facility-severity-MNEMONIC:description

The part of the message preceding the percent sign depends on the setting of the **service sequence-numbers**, **service timestamps log datetime**, **service timestamps log datetime [localtime] [msec] [show-timezone]** command or the **service timestamps log uptime** global configuration command.

[Table 73-1](#) describes the elements of syslog messages.

Table 73-1 **System Log Message Elements**

Element	Description
<i>seq no:</i>	Stamps log messages with a sequence number only if the service sequence-numbers global configuration command is configured. For more information, see the “ Enabling and Disabling Sequence Numbers in Log Messages (Optional) ” section on page 73-7 .
<i>timestamp</i> formats: <i>mm/dd hh:mm:ss</i> or <i>hh:mm:ss</i> (short uptime) or <i>d h</i> (long uptime)	Date and time of the message or event. This information appears only if the service timestamps log [datetime log] global configuration command is configured. For more information, see the “ Enabling and Disabling Timestamps on Log Messages ” section on page 73-6 .

Table 73-1 System Log Message Elements (continued)

Element	Description
<i>facility</i>	The facility to which the message refers (for example, SNMP, SYS, and so forth). For a list of supported facilities, see Table 73-4 on page 73-12 .
<i>severity</i>	Single-digit code from 0 to 7 that is the severity of the message. For a description of the severity levels, see Table 73-3 on page 73-8 .
<i>MNEMONIC</i>	Text string that uniquely describes the message.
<i>description</i>	Text string containing detailed information about the event being reported.

This example shows a partial switch system message:

```
00:00:46: %LINK-3-UPDOWN: Interface Port-channel1, changed state to up
00:00:47: %LINK-3-UPDOWN: Interface GigabitEthernet1/0/1, changed state to up
00:00:47: %LINK-3-UPDOWN: Interface GigabitEthernet1/0/2, changed state to up
00:00:48: %LINEPROTO-5-UPDOWN: Line protocol on Interface Vlan1, changed state to down
00:00:48: %LINEPROTO-5-UPDOWN: Line protocol on Interface GigabitEthernet1/0/1, changed
state to down 2
*Mar  1 18:46:11: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
18:47:02: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
*Mar  1 18:48:50.483 UTC: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
```

Default System Message Logging Configuration

[Table 73-2](#) shows the default system message logging configuration.

Table 73-2 Default System Message Logging Configuration

Feature	Default Setting
System message logging to the console	Enabled.
Console severity	Debugging (and numerically lower levels; see Table 73-3 on page 73-8).
Logging file configuration	No filename specified.
Logging buffer size	4096 bytes.
Logging history size	1 message.
Timestamps	Disabled.
Synchronous logging	Disabled.
Logging server	Disabled.
Syslog server IP address	None configured.
Server facility	Local7 (see Table 73-4 on page 73-12).
Server severity	Informational (and numerically lower levels; see Table 73-3 on page 73-8).

Disabling Message Logging

Message logging is enabled by default. It must be enabled to send messages to any destination other than the console. When enabled, log messages are sent to a logging process, which logs messages to designated locations asynchronously to the processes that generated the messages.

To disable message logging, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# no logging on	Disables message logging.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show running-config or show logging	Verifies your entries.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Disabling the logging process can slow down the switch because a process must wait until the messages are written to the console before continuing. When the logging process is disabled, messages are displayed on the console as soon as they are produced, often appearing in the middle of command output.

The **logging synchronous** global configuration command also affects the display of messages to the console. When this command is enabled, messages appear only after you press Return. For more information, see the [“Synchronizing Log Messages”](#) section on page 73-5.

To reenable message logging after it has been disabled, use the **logging on** global configuration command.

Setting the Message Display Destination Device

If message logging is enabled, you can send messages to specific locations in addition to the console.

To specify the locations that receive messages, perform this task, beginning in privileged EXEC mode:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# logging buffered [size]	<p>Logs messages to an internal buffer on the switch. The default buffer size is 4096. The range is 4096 to 2147483647 bytes.</p> <p>If the switch, the log file is lost unless you previously saved it to flash memory. See Step 4.</p> <p>Note Do not make the buffer size too large because the switch could run out of memory for other tasks. Use the show memory privileged EXEC command to view the free processor memory on the switch. However, this value is the maximum available, and the buffer size should <i>not</i> be set to this amount.</p>

	Command	Purpose
Step 3	Switch(config)# logging <i>host</i>	Logs messages to a UNIX syslog server host. For <i>host</i> , specify the name or IP address of the host to be used as the syslog server. To build a list of syslog servers that receive logging messages, enter this command more than once. For complete syslog server configuration steps, see the “Configuring UNIX Syslog Servers” section on page 73-10.
Step 4	Switch(config)# end	Returns to privileged EXEC mode.
Step 5	Switch# terminal monitor	Logs messages to a nonconsole terminal during the current session. Terminal parameter-setting commands are set locally and do not remain in effect after the session has ended. You must perform this step for each session to see the debugging messages.
Step 6	Switch# show running-config	Verifies your entries.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

The **logging buffered** global configuration command copies logging messages to an internal buffer. The buffer is circular, so newer messages overwrite older messages after the buffer is full. To display the messages that are logged in the buffer, use the **show logging** privileged EXEC command. The first message displayed is the oldest message in the buffer. To clear the contents of the buffer, use the **clear logging** privileged EXEC command.

To disable logging to the console, use the **no logging console** global configuration command. To disable logging to a file, use the **no logging file** [*severity-level-number* | *type*] global configuration command.

Synchronizing Log Messages

You can synchronize unsolicited messages and **debug** privileged EXEC command output with solicited device output and prompts for a specific console port line or virtual terminal line. You can identify the types of messages to be output asynchronously based on the level of severity. You can also configure the maximum number of buffers for storing asynchronous messages for the terminal after which messages are dropped.

When synchronous logging of unsolicited messages and **debug** command output is enabled, unsolicited device output appears on the console or printed after solicited device output appears or printed. Unsolicited messages and **debug** command output appears on the console after the prompt for user input is returned. Unsolicited messages and **debug** command output are not interspersed with solicited device output and prompts. After the unsolicited messages are displayed, the console again displays the user prompt.

To configure synchronous logging, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# line [console vty] <i>line-number</i> [<i>ending-line-number</i>]	Specifies the line to be configured for synchronous logging of messages. <ul style="list-style-type: none"> Use the console keyword for configurations that occur using the switch console port. Use the line vty line-number command to specify which vty lines are to have synchronous logging enabled. You use a vty connection for configurations that occur through a Telnet session. The range of line numbers is from 0 to 15. <p>You can change the setting of all 16 vty lines at once by entering: line vty 0 15</p> <p>Or you can change the setting of the single vty line being used for your current connection. For example, to change the setting for vty line 2, enter: line vty 2</p> <p>When you enter this command, the mode changes to line configuration.</p>
Step 3	Switch(config)# logging synchronous [level [<i>severity-level</i> all] limit <i>number-of-buffers</i>]	Enables synchronous logging of messages. <ul style="list-style-type: none"> (Optional) For level severity-level, specify the message severity level. Messages with a severity level equal to or higher than this value are printed asynchronously. Low numbers mean greater severity and high numbers mean lesser severity. The default is 2. (Optional) Specifying level all means that all messages are printed asynchronously regardless of the severity level. (Optional) For limit number-of-buffers, specify the number of buffers to be queued for the terminal after which new messages are dropped. The range is 0 to 2147483647. The default is 20.
Step 4	Switch(config)# end	Returns to privileged EXEC mode.
Step 5	Switch# show running-config	Verifies your entries.
Step 6	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To disable synchronization of unsolicited messages and debug output, use the **no logging synchronous** [**level severity-level** | **all**] [**limit number-of-buffers**] line configuration command.

Enabling and Disabling Timestamps on Log Messages

Note

By default, log messages are not time-stamped.

To enable time-stamping of log messages, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# service timestamps log uptime or Switch(config)# service timestamps log datetime [msec] [localtime] [show-timezone]	Enables log time-stamps. The first command enables time-stamps on log messages, showing the time since the system was rebooted. The second command enables time-stamps on log messages. Depending on the options selected, the timestamp can include the date, time in milliseconds relative to the local time zone, and the time zone name.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show running-config	Verifies your entries.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To disable time-stamps for both debug and log messages, use the **no service timestamps** global configuration command.

This example shows part of a logging display with the **service timestamps log datetime** global configuration command enabled:

```
*Mar 1 18:46:11: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
```

This example shows part of a logging display with the **service timestamps log uptime** global configuration command enabled:

```
00:00:46: %LINK-3-UPDOWN: Interface Port-channel1, changed state to up
```

Enabling and Disabling Sequence Numbers in Log Messages (Optional)

Because more than one log message can have the same timestamp, you can display messages with sequence numbers so that you can unambiguously refer to a single message. By default, sequence numbers in log messages are not displayed.

To enable sequence numbers in log messages, perform this task, which is optional.

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# service sequence-numbers	Enables sequence numbers.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show running-config	Verifies your entries.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To disable sequence numbers, use the **no service sequence-numbers** global configuration command.

This example shows part of a logging display with sequence numbers enabled:

```
000019: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
```

Defining the Message Severity Level (Optional)

You can limit messages displayed to the selected device by specifying the severity level of the message, which are described in [Table 73-3](#).

To define the message severity level, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# logging console level	Limits messages logged to the console. By default, the console receives debugging messages and numerically lower levels (see Table 73-3 on page 73-8).
Step 3	Switch(config)# logging monitor level	Limits messages logged to the terminal lines. By default, the terminal receives debugging messages and numerically lower levels (see Table 73-3 on page 73-8).
Step 4	Switch(config)# logging trap level	Limits messages logged to the syslog servers. By default, syslog servers receive informational messages and numerically lower levels (see Table 73-3 on page 73-8). For complete syslog server configuration steps, see the “Configuring UNIX Syslog Servers” section on page 73-10 .
Step 5	Switch(config)# end	Returns to privileged EXEC mode.
Step 6	Switch# show running-config or Switch# show logging	Verifies your entries.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Note

Specifying a *level* causes messages at that level and numerically lower levels to be displayed at the destination.

To disable logging to the console, use the **no logging console** global configuration command. To disable logging to a terminal other than the console, use the **no logging monitor** global configuration command. To disable logging to syslog servers, use the **no logging trap** global configuration command.

[Table 73-3](#) describes the *level* keywords. It also lists the corresponding UNIX syslog definitions from the most severe level to the least severe level.

Table 73-3 Message Logging Level Keywords

Level Keyword	Level	Description	Syslog Definition
emergencies	0	System unstable	LOG_EMERG
alerts	1	Immediate action needed	LOG_ALERT
critical	2	Critical conditions	LOG_CRIT
errors	3	Error conditions	LOG_ERR
warnings	4	Warning conditions	LOG_WARNING
notifications	5	Normal but significant condition	LOG_NOTICE

Table 73-3 Message Logging Level Keywords (continued)

Level Keyword	Level	Description	Syslog Definition
informational	6	Informational messages only	LOG_INFO
debugging	7	Debugging messages	LOG_DEBUG

The software generates four other categories of messages:

- Error messages about software or hardware malfunctions, displayed at levels **warnings** through **emergencies**. These types of messages mean that the functionality of the switch is affected. For information on how to recover from these malfunctions, see the system message guide for this release.
- Output from the **debug** commands, displayed at the **debugging** level. Debug commands are typically used only by the Technical Assistance Center.
- Interface up or down transitions and system restart messages, displayed at the **notifications** level. This message is only for information; switch functionality is not affected.
- Reload requests and low-process stack messages, displayed at the **informational** level. This message is only for information; switch functionality is not affected.

Limiting Syslog Messages Sent to the History Table and to SNMP (Optional)

If you enabled syslog message traps to be sent to an SNMP network management station by using the **snmp-server enable trap** global configuration command, you can change the level of messages sent and stored in the switch history table. You also can change the number of messages that are stored in the history table.

Messages are stored in the history table because SNMP traps are not guaranteed to reach their destination. By default, one message of the level **warning** and numerically lower levels (see [Table 73-3 on page 73-8](#)) are stored in the history table even if syslog traps are not enabled.

To change the level and history table size defaults, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# logging history level ¹	Changes the default level of syslog messages stored in the history file and sent to the SNMP server. See Table 73-3 on page 73-8 for a list of <i>level</i> keywords. By default, warnings, errors, critical, alerts, and emergencies messages are sent.
Step 3	Switch(config)# logging history size number	Specifies the number of syslog messages that can be stored in the history table. The default is to store one message. The range is 0 to 500 messages.
Step 4	Switch(config)# end	Returns to privileged EXEC mode.
Step 5	Switch# show running-config	Verifies your entries.
Step 6	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

1. [Table 73-3](#) lists the level keywords and severity level. For SNMP usage, the severity level values increase by 1. For example, emergencies equal 1, not 0, and critical equals 3, not 2.

When the history table is full (it contains the maximum number of message entries specified with the **logging history size** global configuration command), the oldest message entry is deleted from the table to allow the new message entry to be stored.

To return the logging of syslog messages to the default level, use the **no logging history** global configuration command. To return the number of messages in the history table to the default value, use the **no logging history size** global configuration command.

Configuring UNIX Syslog Servers

The next sections describe how to configure the UNIX server syslog daemon and how to define the UNIX system logging facility.

Logging Messages to a UNIX Syslog Daemon

Before you can send system log messages to a UNIX syslog server, you must configure the syslog daemon on a UNIX server. This procedure is optional.

Note

Some recent versions of UNIX syslog daemons no longer accept by default syslog packets from the network. If applies to your system, use the UNIX **man syslogd** command to decide what options must be added to or removed from the syslog command line to enable logging of remote syslog messages.

Log in as root, and perform these steps:

Step 1 Add a line such as the following to the file `/etc/syslog.conf`:

```
local7.debug /usr/adm/logs/cisco.log
```

The **local7** keyword specifies the logging facility to be used; see [Table 73-4 on page 73-12](#) for information on the facilities. The **debug** keyword specifies the syslog level; see [Table 73-3 on page 73-8](#) for information on the severity levels. The syslog daemon sends messages at this level or at a more severe level to the file specified in the next field. The file must already exist, and the syslog daemon must have permission to write to it.

Step 2 Create the log file by entering these commands at the UNIX shell prompt:

```
$ touch /var/log/cisco.log
$ chmod 666 /var/log/cisco.log
```

Step 3 Ensure that the syslog daemon reads the new changes:

```
$ kill -HUP `cat /etc/syslog.pid`
```

For more information, see the **man syslog.conf** and **man syslogd** commands on your UNIX system.

Configuring the UNIX System Logging Facility

When sending system log messages to an external device, you can cause the switch to identify its messages as originating from any of the UNIX syslog facilities.

To configure UNIX system facility message logging, perform this task (which is optional):

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# logging host	Logs messages to a UNIX syslog server host by entering its IP address. To build a list of syslog servers that receive logging messages, enter this command more than once.
Step 3	Switch(config)# logging trap level	Limits messages logged to the syslog servers. By default, syslog servers receive informational messages and lower. See Table 73-3 on page 73-8 for <i>level</i> keywords.
Step 4	Switch(config)# logging facility facility-type	Configures the syslog facility. See Table 73-4 on page 73-12 for <i>facility-type</i> keywords. The default is local7 .
Step 5	Switch(config)# end	Returns to privileged EXEC mode.
Step 6	Switch# show running-config	Verifies your entries.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To remove a syslog server, use the **no logging host** global configuration command, and specify the syslog server IP address. To disable logging to syslog servers, enter the **no logging trap** global configuration command.

Table 73-4 lists the UNIX system facilities supported by the software. For more information about these facilities, consult the operator's manual for your UNIX operating system.

Table 73-4 Logging Facility-Type Keywords

Facility Type Keyword	Description
auth	Authorization system
cron	Cron facility
daemon	System daemon
kern	Kernel
local0-7	Locally defined messages
lpr	Line printer system
mail	Mail system
news	USENET news
sys9-14	System use
syslog	System log
user	User process
uucp	UNIX-to-UNIX copy system

Displaying the Logging Configuration

To display the logging configuration and the contents of the log buffer, use the **show logging** privileged EXEC command. For information about the fields in this display, see the *Cisco IOS Configuration Fundamentals Command Reference, Release 12.3*.

Onboard Failure Logging (OBFL)

This chapter includes the following major sections:

- [Prerequisites for OBFL, page 74-1](#)
- [Restrictions for OBFL, page 74-2](#)
- [Information About OBFL, page 74-2](#)
- [Default Settings for OBFL, page 74-8](#)
- [Enabling OBFL, page 74-8](#)
- [Configuration Examples for OBFL, page 74-9](#)

Note

For more information about Onboard Failure Logging, see:

http://www.cisco.com/en/US/docs/ios/12_0s/feature/guide/12sobfl.html

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Prerequisites for OBFL

None.

Restrictions for OBFL

They include:

- **Software Restrictions**—If a device (router or switch) intends to use *linear* flash memory as its OBFL storage media, Cisco IOS software must reserve a minimum of two physical sectors (or physical blocks) for the OBFL feature. Because an erase operation for a linear flash device is done on per-sector (or per-block) basis, one extra physical sector is needed. Otherwise, the minimum amount of space reserved for the OBFL feature on any device must be at least 8 KB.
- **Firmware Restrictions**—If a line card or port adapter runs an operating system or firmware that is different from the Cisco IOS operating system, the line card or port adapter must provide device driver level support or an interprocess communications (IPC) layer that allows the OBFL file system to communicate to the line card or port adapter. This requirement is enforced to allow OBFL data to be recorded on a storage device attached to the line card or port adapter.
- **Hardware Restrictions**—To support the OBFL feature, a device must have at least 8 KB of nonvolatile memory space reserved for OBFL data logging.

Information About OBFL

- [Overview of OBFL, page 74-2](#)
- [Information about Data Collected by OBFL, page 74-2](#)

Overview of OBFL

The Onboard Failure Logging (OBFL) feature collects data such as operating temperatures, hardware uptime, interrupts, and other important events and messages from system hardware installed in a Cisco router or switch. The data is stored in nonvolatile memory and helps technical personnel diagnose hardware problems.

Information about Data Collected by OBFL

- [OBFL Data Overview, page 74-2](#)
- [Temperature, page 74-3](#)
- [Operational Uptime, page 74-4](#)
- [Interrupts, page 74-6](#)
- [Message Logging, page 74-7](#)

OBFL Data Overview

The OBFL feature records operating temperatures, hardware uptime, interrupts, and other important events and messages that can assist with diagnosing problems with hardware cards (or *modules*) installed in a Cisco router or switch. Data is logged to files stored in nonvolatile memory. When the onboard hardware is started up, a first record is made for each area monitored and becomes a base value for subsequent records. The OBFL feature provides a circular updating scheme for collecting continuous records and archiving older (historical) records, ensuring accurate data about the system. Data is

recorded in one of two formats: continuous information that displays a snapshot of measurements and samples in a continuous file, and summary information that provides details about the data being collected. The data is displayed using the **show logging onboard** command. The message “No historical data to display” is seen when historical data is not available.

Temperature

Temperatures surrounding hardware modules can exceed recommended safe operating ranges and cause system problems such as packet drops. Higher than recommended operating temperatures can also accelerate component degradation and affect device reliability. Monitoring temperatures is important for maintaining environmental control and system reliability. Once a temperature sample is logged, the sample becomes the base value for the next record. From that point on, temperatures are recorded either when there are changes from the previous record or if the maximum storage time is exceeded. Temperatures are measured and recorded in degrees Celsius.

Temperature Example

```
Switch# sh logging onboard temperature
```

```
-----
TEMPERATURE SUMMARY INFORMATION

```

Switch#

To interpret this data:

- Number of sensors is the total number of temperature sensors that will be recorded. A column for each sensor is displayed with temperatures listed under the number of each sensor, as available.
- Sampling frequency is the time between measurements.
- Maximum time of storage determines the maximum amount of time, in minutes, that can pass when the temperature remains unchanged and the data is not saved to storage media. After this time, a temperature record will be saved even if the temperature has not changed.
- The Sensor column lists the name of the sensor.
- The ID column lists an assigned identifier for the sensor.
- Maximum Temperature 0C shows the highest recorded temperature per sensor.
- Temp indicates a recorded temperature in degrees Celsius in the historical record. Columns following show the total time each sensor has recorded that temperature.
- Sensor ID is an assigned number, so that temperatures for the same sensor can be stored together.

Operational Uptime

The operational uptime tracking begins when the module is powered on, and information is retained for the life of the module.

Operational Uptime Example

Switch# **sh logging onboard uptime detail**

----- UPTIME SUMMARY INFORMATION -----

First customer power on : 04/13/2010 19:45:08

Switch#

The operational uptime application tracks the following events:

- Date and time the customer first powered on a component.
- Total uptime and downtime for the component in years, weeks, days, hours, and minutes.
- Total number of component resets.
- Total number of slot (module) changes.
- Current reset timestamp to include the date and time.
- Current slot (module) number of the component.
- Current uptime in years, weeks, days, hours, and minutes.

Interrupts

Interrupts are generated by system components that require attention from the CPU such as ASICs and NMIs. Interrupts are generally related to hardware limit conditions or errors that need to be corrected.

The continuous format records each time a component is interrupted, and this record is stored and used as base information for subsequent records. Each time the list is saved, a timestamp is added. Time differences from the previous interrupt are counted, so that technical personnel can gain a complete record of the component's operational history when an error occurs.

Interrupts Example

Switch# **sh logging onboard interrupt detail**

----- INTERRUPT SUMMARY INFORMATION

Name	ID	Offset	Bit	Count
dropped	2	0x0004	0	27323
ipp	6	0x5A00	0	983763
ipp high	10	0x700A	0	34105
ipp low	11	0x9000	0	30211

----- CONTINUOUS INTERRUPT INFORMATION

-----

```

Switch#

To interpret this data:

- Name is a description of the component including its position in the device.
- ID is an assigned field for data storage.
- Offset is the register offset from a component register's base address.
- Bit is the interrupt bit number recorded from the component's internal register.
- The timestamp shows the date and time that an interrupt occurred down to the millisecond.

Message Logging

The OBFL feature logs standard system messages. Instead of displaying the message to a terminal, the message is written to and stored in a file, so the message can be accessed and read at a later time. System messages range from level 1 alerts to level 7 debug messages, and these levels can be specified in the **hw module logging onboard** command.

Error Message Log Example

Switch# **sh logging onboard message det**

ERROR MESSAGE SUMMARY INFORMATION

Switch#

To interpret this data:

- A timestamp shows the date and time the message was logged.
- Facility-Sev-Name is a coded naming scheme for a system message, as follows:
 - The Facility code consists of two or more uppercase letters that indicate the hardware device (facility) to which the message refers.
 - Sev is a single-digit code from 1 to 7 that reflects the severity of the message.
 - Name is one or two code names separated by a hyphen that describe the part of the system from where the message is coming.
- The error message follows the Facility-Sev-Name codes. For more information about system messages, see the [Cisco IOS System and Error Messages](#) guide.
- Count indicates the number of instances of this message that is allowed in the history file. Once that number of instances has been recorded, the oldest instance will be removed from the history file to make room for new ones.
- The Persistence Flag gives a message priority over others that do not have the flag set.

Default Settings for OBFL

The OBFL feature is enabled by default. Because of the valuable information this feature offers technical personnel, it should not be disabled.

Enabling OBFL

To enable OBFL, perform this task:

	Command or Action	Purpose
Step 1	Router> enable	Enables privileged EXEC mode (enter your password if prompted).
Step 2	Router# configure terminal	Enters global configuration mode.
Step 3	Router(config)# hw-module module module-number logging onboard [message level {1-7}]	Enables OBFL on the specified hardware module. Note By default, all system messages sent to a device are logged by the OBFL feature. You can define a specific message level (only level 1 messages, as an example) to be logged using the message level keywords.
Step 4	Router(config)# end	Ends global configuration mode.

Configuration Examples for OBFL

The important OBFL feature is the information that is displayed by the **show logging onboard module** privileged EXEC command. This section provides the following examples of how to enable and display OBFL records.

- [Enabling OBFL Message Logging: Example](#)
- [OBFL Message Log: Example](#)
- [OBFL Component Uptime Report: Example](#)
- [OBFL Report for a Specific Time: Example](#)

Enabling OBFL Message Logging: Example

The following example shows how to configure OBFL message logging at level 3:

```
Router(config)# hw-module module 1 logging onboard message level 3
```

OBFL Message Log: Example

The following example shows how to display the system messages that are being logged for module 2:

```
Switch# show logging onboard module 2 message continuous

Configuring SNMP

This chapter describes how to configure the Simple Network Management Protocol (SNMP) on the Catalyst 4500 series switch.

This chapter consists of these sections:

- [About SNMP, page 75-1](#)
- [Configuring SNMP, page 75-5](#)
- [Displaying SNMP Status, page 75-16](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About SNMP

SNMP is an application-layer protocol that provides a message format for communication between managers and agents. The SNMP system consists of an SNMP manager, an SNMP agent, and a MIB. The SNMP manager can be part of a network management system (NMS) such as CiscoWorks. The agent and MIB reside on the switch. To configure SNMP on the switch, you define the relationship between the manager and the agent.

The SNMP agent contains MIB variables whose values the SNMP manager can request or change. A manager can get a value from an agent or store a value into the agent. The agent gathers data from the MIB, the repository for information about device parameters and network data. The agent can also respond to a manager's requests to get or set data.

An agent can send unsolicited traps to the manager. Traps are messages alerting the SNMP manager to a condition on the network. Traps can mean improper user authentication, restarts, link status (up or down), MAC address tracking, closing of a Transmission Control Protocol (TCP) connection, loss of connection to a neighbor, or other significant events.

This section includes information about these topics:

- [SNMP Versions, page 75-2](#)
- [SNMP Manager Functions, page 75-3](#)
- [SNMP Agent Functions, page 75-4](#)
- [SNMP Community Strings, page 75-4](#)
- [Using SNMP to Access MIB Variables, page 75-4](#)
- [SNMP Notifications, page 75-5](#)

SNMP Versions

The Catalyst 4500 series switch supports these SNMP versions:

- **SNMPv1**—The Simple Network Management Protocol, a Full Internet Standard, defined in RFC 1157.
- **SNMPv2C** replaces the Party-based Administrative and Security Framework of SNMPv2Classic with the community-string-based Administrative Framework of SNMPv2C while retaining the bulk retrieval and improved error handling of SNMPv2Classic. It has these features:
 - **SNMPv2**—Version 2 of the Simple Network Management Protocol, a Draft Internet Standard, defined in RFCs 1902 through 1907.
 - **SNMPv2C**—The community-string-based Administrative Framework for SNMPv2, an Experimental Internet Protocol defined in RFC 1901.
- **SNMPv3**—Version 3 of the SNMP is an interoperable standards-based protocol defined in RFCs 2273 to 2275. SNMPv3 provides secure access to devices by authenticating and encrypting packets over the network and includes these security features:
 - **Message integrity**—Ensures that a packet was not tampered with in transit
 - **Authentication**—Determines that the message is from a valid source
 - **Encryption**—Mixes the contents of a package to prevent it from being read by an unauthorized source

Note

To select encryption, enter the **priv** keyword. This keyword is available only when the crypto (encrypted) software image is installed.

Both SNMPv1 and SNMPv2C use a community-based form of security. The community of managers able to access the agent's MIB is defined by an IP address access control list and password.

SNMPv2C includes a bulk retrieval mechanism and more detailed error message reporting to management stations. The bulk retrieval mechanism retrieves tables and large quantities of information, minimizing the number of round-trips required. The SNMPv2C improved error-handling includes expanded error codes that distinguish different kinds of error conditions; these conditions are reported through a single error code in SNMPv1. Error return codes in SNMPv2C report the error type.

SNMPv3 provides for both security models and security levels. A security model is an authentication strategy set up for a user and the group within which you reside. A security level is the permitted level of security within a security model. A combination of the security level and the security model determine which security mechanism is used when handling an SNMP packet. Available security models are SNMPv1, SNMPv2C, and SNMPv3.

The following table identifies the characteristics of the different combinations of security models and levels.

Model	Level	Authentication	Encryption	Result
SNMPv1	noAuthNoPriv	Community string	No	Uses a community string match for authentication.
SNMPv2C	noAuthNoPriv	Community string	No	Uses a community string match for authentication.
SNMPv3	noAuthNoPriv	Username	No	Uses a username match for authentication.
SNMPv3	authNoPriv	MD5 or SHA	No	Provides authentication based on the HMAC-MD5 or HMAC-SHA algorithms.
SNMPv3	authPriv (requires the cryptographic software image)	MD5 or SHA	DES	Provides authentication based on the HMAC-MD5 or HMAC-SHA algorithms. Provides DES 56-bit encryption in addition to authentication based on the CBC-DES (DES-56) standard.

You must configure the SNMP agent to use the SNMP version supported by the management station. Because an agent can communicate with multiple managers, you can configure the software to support communications using SNMPv1, and SNMPv2C, and SNMPv3 protocols.

SNMP Manager Functions

The SNMP manager uses information in the MIB to perform the operations described in [Table 75-1](#).

Table 75-1 *SNMP Operations*

Operation	Description
get-request	Retrieves a value from a specific variable.
get-next-request	Retrieves a value from a variable within a table. ¹
get-bulk-request ²	Retrieves large blocks of data, such as multiple rows in a table, that would otherwise require the transmission of many small blocks of data.
get-response	Replies to a get-request, get-next-request, and set-request sent by an NMS.
set-request	Stores a value in a specific variable.
trap	An unsolicited message sent by an SNMP agent to an SNMP manager when some event has occurred.

1. With this operation, an SNMP manager does not need to know the exact variable name. A sequential search is performed to find the needed variable from within a table.
2. The **get-bulk** command only works with SNMPv2 or later.

SNMP Agent Functions

The SNMP agent responds to SNMP manager requests as follows:

- **Get a MIB variable**—The SNMP agent begins this function in response to a request from the NMS. The agent retrieves the value of the requested MIB variable and responds to the NMS with that value.
- **Set a MIB variable**—The SNMP agent begins this function in response to a message from the NMS. The SNMP agent changes the value of the MIB variable to the value requested by the NMS.

The SNMP agent also sends unsolicited trap messages to notify an NMS that a significant event has occurred on the agent. Examples of trap conditions include, but are not limited to, when a port or module goes up or down, when spanning-tree topology changes occur, and when authentication failures occur.

SNMP Community Strings

SNMP community strings authenticate access to MIB objects and function as embedded passwords. In order for the NMS to access the switch, the community string definitions on the NMS must match at least one of the three community string definitions on the switch.

A community string can have one of these attributes:

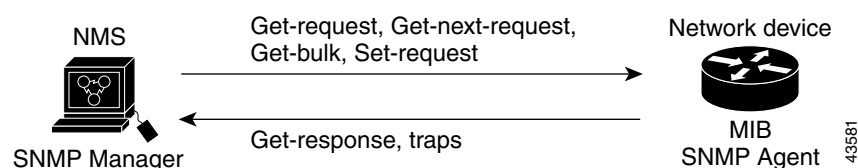

- **Read-only (RO)**—Gives read access to authorized management stations to all objects in the MIB except the community strings, but does not allow write access
- **Read-write (RW)**—Gives read and write access to authorized management stations to all objects in the MIB, but does not allow access to the community strings
- **Read-write-all**—Gives read and write access to authorized management stations to all objects in the MIB, including the community strings

Using SNMP to Access MIB Variables

An example of an NMS is the CiscoWorks network management software. CiscoWorks 2000 software uses the switch MIB variables to set device variables and to poll devices on the network for specific information. The results of a poll can be displayed as a graph and analyzed to troubleshoot internetworking problems, increase network performance, verify the configuration of devices, monitor traffic loads, and more.

As shown in [Figure 75-1](#), the SNMP agent gathers data from the MIB. The agent can send traps, or notification of certain events, to the SNMP manager, which receives and processes the traps. Traps alert the SNMP manager to a condition on the network such as improper user authentication, restarts, link status (up or down), MAC address tracking, and so forth. The SNMP agent also responds to MIB-related queries sent by the SNMP manager in *get-request*, *get-next-request*, and *set-request* format.

Figure 75-1 SNMP Network

SNMP Notifications

SNMP allows the switch to send notifications to SNMP managers when particular events occur. SNMP notifications can be sent as traps or inform requests. In command syntax, unless there is an option in the command to select either traps or informs, the keyword *traps* refers to either traps or informs, or both. Use the **snmp-server host** command to specify whether to send SNMP notifications as traps or informs.

**Note**

SNMPv1 does not support informs.

Traps are unreliable because the receiver does not send an acknowledgment when it receives a trap, and the sender cannot determine if the trap was received. When an SNMP manager receives an inform request, it acknowledges the message with an SNMP response protocol data unit (PDU). If the sender does not receive a response, the inform request can be sent again. Because they can be resent, informs are more likely than traps to reach their intended destination.

The characteristics that make informs more reliable than traps also consume more resources in the switch and in the network. Unlike a trap, which is discarded as soon as it is sent, an inform request is held in memory until a response is received or the request times out. Traps are sent only once, but an inform might be resent or retried several times. The retries increase traffic and contribute to a higher overhead on the network. Traps and informs require a trade-off between reliability and resources. If it is important that the SNMP manager receive every notification, use inform requests. If traffic on the network or memory in the switch is a concern and notification is not required, use traps.

Configuring SNMP

This section describes how to configure SNMP on your switch. It contains this configuration information:

- [Default SNMP Configuration, page 75-5](#)
- [SNMP Configuration Guidelines, page 75-6](#)
- [Disabling the SNMP Agent, page 75-7](#)
- [Configuring Community Strings, page 75-7](#)
- [Configuring SNMP Groups and Users, page 75-9](#)
- [Configuring SNMP Notifications, page 75-11](#)
- [Setting the Agent Contact and Location Information, page 75-14](#)
- [Limiting TFTP Servers Used Through SNMP, page 75-15](#)
- [SNMP Examples, page 75-15](#)

Default SNMP Configuration

[Table 75-2](#) shows the default SNMP configuration.

Table 75-2 **Default SNMP Configuration**

Feature	Default Setting
SNMP agent	Enabled
SNMP trap receiver	None configured
SNMP traps	None enabled except the trap for TCP connections (tty)
SNMP version	If no version keyword is present, the default is Version 1.
SNMPv3 authentication	If no keyword is entered, the default is the noauth (noAuthNoPriv) security level.
SNMP notification type	If no type is specified, all notifications are sent.

SNMP Configuration Guidelines

An SNMP *group* is a table that maps SNMP users to SNMP views. An SNMP *user* is a member of an SNMP group. An SNMP *host* is the recipient of an SNMP trap operation. An SNMP *engine ID* is a name for the local or remote SNMP engine.

When configuring SNMP, follow these guidelines:

- When configuring an SNMP group, do not specify a notify view. The **snmp-server host** global configuration command autogenerates a notify view for you and then adds it to the group associated with that user. Modifying the group's notify view affects all users associated with that group. For information about when you should configure notify views, see the *Cisco IOS Configuration Fundamentals Command Reference, Release 12.2*.
- To configure a remote user, specify the IP address or port number for the remote SNMP agent of the device where you reside.
- Before you configure remote users for a particular agent, configure the SNMP engine ID, using the **snmp-server engineID** global configuration with the **remote** option. The remote agent's SNMP engine ID and user password are used to compute the authentication and privacy digests. If you do not configure the remote engine ID first, the configuration command fails.
- When configuring SNMP informs, you need to configure the SNMP engine ID for the remote agent in the SNMP database before you can send proxy requests or informs to it.
- If a local user is not associated with a remote host, the switch does not send informs for the **auth** (authNoPriv) and the **priv** (authPriv) authentication levels.
- Changing the value of the SNMP engine ID has important side effects. A user's password (entered on the command line) is converted to an MD5 or SHA security digest based on the password and the local engine ID. The command-line password is then destroyed, as required by RFC 2274. Because of this deletion, if the value of the engine ID changes, the security digests of SNMPv3 users become invalid, and you need to reconfigure SNMP users by using the **snmp-server user username** global configuration command. Similar restrictions require the reconfiguration of community strings when the engine ID changes.

Disabling the SNMP Agent

To disable the SNMP agent, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# no snmp-server	Disables the SNMP agent operation.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show running-config	Verifies your entries.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

The **no snmp-server** global configuration command disables all running versions (Version 1, Version 2C, and Version 3) on the device. No specific Cisco IOS command exists to enable SNMP. The first **snmp-server** global configuration command that you enter enables all versions of SNMP.

Configuring Community Strings

You use the SNMP community string to define the relationship between the SNMP manager and the agent. The community string acts like a password to permit access to the agent on the switch. Optionally, you can specify one or more of these characteristics associated with the string:

- An access list of IP addresses of the SNMP managers that are permitted to use the community string to gain access to the agent
- A MIB view, which defines the subset of all MIB objects accessible to the given community
- Read and write or read-only permission for the MIB objects accessible to the community

To configure a community string on the switch, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# [no] snmp-server community string [view view-name] [ro rw] [access-list-number]	<p>Configures the community string.</p> <ul style="list-style-type: none"> For <i>string</i>, specify a string that acts like a password and permits access to the SNMP protocol. You can configure one or more community strings up to 117 characters. (Optional) For view, specify the view record accessible to the community. (Optional) Specify either read-only (ro) if you want authorized management stations to retrieve MIB objects, or specify read-write (rw) if you want authorized management stations to retrieve and modify MIB objects. By default, the community string permits read-only access to all objects. (Optional) For <i>access-list-number</i>, enter an IP standard access list numbered from 1 to 99 and 1300 to 1999. <p>To remove a specific community string, use the no snmp-server community string global configuration command.</p>
Step 3	Switch(config)# access-list access-list-number {deny permit} source [source-wildcard]	<p>(Optional) If you specified an IP standard access list number in Step 2, create the list, repeating the command as many times as necessary.</p> <ul style="list-style-type: none"> For <i>access-list-number</i>, enter the access list number specified in Step 2. The deny keyword denies access if the conditions are matched. The permit keyword permits access if the conditions are matched. For <i>source</i>, enter the IP address of the SNMP managers that are permitted to use the community string to gain access to the agent. (Optional) For <i>source-wildcard</i>, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore. <p>Recall that the access list is always terminated by an implicit deny statement for everything.</p>
Step 4	Switch(config)# end	Returns to privileged EXEC mode.
Step 5	Switch# show running-config	Verifies your entries.
Step 6	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Note

To disable access for an SNMP community, set the community string for that community to the null string (do not enter a value for the community string).

**Note**

You cannot use the **snmp-server enable informs** command. To enable the sending of SNMP inform notifications, use the **snmp-server enable traps** command combined with the **snmp-server host host-addr informs** command.

This example shows how to assign the string *comaccess* to SNMP, to allow read-only access, and to specify that IP access list 4 can use the community string to gain access to the switch SNMP agent:

```
Switch(config)# snmp-server community comaccess ro 4
```

Configuring SNMP Groups and Users

You can specify an identification name (engine ID) for the local or remote SNMP server engine on the switch. You can configure an SNMP server group that maps SNMP users to SNMP views, and you can add new users to the SNMP group.

To configure SNMP on the switch, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# snmp-server engineID { local <i>engineid-string</i> remote <i>ip-address</i> [udp-port <i>port-number</i>] <i>engineid-string</i> }	Configures a name for either the local or remote copy of SNMP. <ul style="list-style-type: none"> The <i>engineid-string</i> is a 24-character ID string with the name of the copy of SNMP. You need not specify the entire 24-character engine ID if it has trailing zeros. Specify only the portion of the engine ID up to the point where only zeros remain in the value. For example, to configure an engine ID of 123400000000000000000000, you can enter this: snmp-server engineID local 1234 If you select remote, specify the <i>ip-address</i> of the device that contains the remote copy of SNMP and the optional UDP port on the remote device. The default is 162.

Step 3

Command	Purpose
<pre>Switch(config)# snmp-server group groupname {v1 v2c v3 [auth noauth priv]} [read readview] [write writeview] [notify notifyview] [access access-list]</pre>	<p>Configures a new SNMP group on the remote device.</p> <ul style="list-style-type: none"> For <i>groupname</i>, specify the name of the group. Specify a security model: <ul style="list-style-type: none"> v1 is the least secure of the possible security models. v2c is the second least secure model. It allows transmission of informs and integers twice the normal width. v3, the most secure, requires you to select an authentication level: <ul style="list-style-type: none"> auth—Enables the Message Digest 5 (MD5) and the Secure Hash Algorithm (SHA) packet authentication. noauth—The noAuthNoPriv security level. It is the default if no keyword is specified. priv—Enables Data Encryption Standard (DES) packet encryption (also called <i>privacy</i>). <p>Note The priv keyword is available only when the crypto software image is installed.</p> <ul style="list-style-type: none"> (Optional) Enter read <i>readview</i> with a string (not to exceed 64 characters) that is the name of the view in which you can only view the contents of the agent. (Optional) Enter write <i>writeview</i> with a string (not to exceed 64 characters) that is the name of the view in which you enter data and configure the contents of the agent. (Optional) Enter notify <i>notifyview</i> with a string (not to exceed 64 characters) that is the name of the view in which you specify a notify, inform, or trap. (Optional) Enter access <i>access-list</i> with a string (not to exceed 64 characters) that is the name of the access list.

	Command	Purpose
Step 4	Switch(config)# snmp-server user <i>username groupname [remote host</i> <i>[udp-port port]] {v1 / v2c v3 [auth</i> <i>{md5 sha} auth-password]} [encrypted]</i> <i>[access access-list]</i>	Configures a new user to an SNMP group. <ul style="list-style-type: none"> • The <i>username</i> is your name on the host that connects to the agent. • The <i>groupname</i> is the name of the group to which you are associated. • (Optional) Enter remote to specify a remote SNMP entity to which you belong and the hostname or IP address of that entity with the optional UDP port number. The default is 162. • Enter the SNMP version number (v1, or v2c, or v3). If you enter v3, you have these additional options: <ul style="list-style-type: none"> – auth is an authentication level setting session, which can be either the HMAC-MD5-96 or the HMAC-SHA-96 authentication level, and requires a password string (not to exceed 64 characters). – encrypted specifies that the password appears in encrypted format. • (Optional) Enter access access-list with a string (not to exceed 64 characters) that is the name of the access list.
Step 5	Switch(config)# end	Returns to privileged EXEC mode.
Step 6	Switch# show running-config	Verifies your entries.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring SNMP Notifications

A trap manager is a management station that receives and processes traps. Traps are system alerts that the switch generates when certain events occur. By default, no trap manager is defined, and no traps are sent. Switches running Cisco IOS Release 12.2(31)SG and later releases can have an unlimited number of trap managers.

Note

Many commands use the word *traps* in the command syntax. Unless there is an option in the command to select either traps or informs, the keyword *traps* refers to either traps, informs, or both. Use the **snmp-server host** command to specify whether to send SNMP notifications as traps or informs.

Table 75-3 describes the supported switch traps (notification types). You can enable any or all of these traps and configure a trap manager to receive them.

Table 75-3 Switch Notification Types

Notification Type Keyword	Description
bgp	Generates BGP state change traps. Note This option is only available when the enhanced multilayer image is installed.
bridge	Generates STP bridge MIB traps.

Table 75-3 **Switch Notification Types (continued)**

Notification Type Keyword	Description
config	Generates a trap for SNMP configuration changes.
config-copy	Generates a trap for SNMP copy configuration changes.
cpu	Allows cpu-related traps.
eigrp	Enable EIGRP traps. Note This option is only available when the enhanced multilayer image is installed.
entity	Generates a trap for SNMP entity changes.
envmon	Generates environmental monitor traps. You can enable any or all of these environmental traps: fan, shutdown, supply, temperature.
flash	Generates SNMP FLASH notifications.
fru-ctrl	Enable SNMP entity FRU control traps.
hsrp	Generates a trap for Hot Standby Router Protocol (HSRP) changes.
ipmulticast	Generates a trap for IP multicast routing changes.
isis	Enable IS-IS traps. Note This option is only available when the enhanced multilayer image is installed.
mac-notification	Generates a trap for MAC address notifications.
msdp	Generates a trap for Multicast Source Discovery Protocol (MSDP) changes. Note This option is only available when the enhanced multilayer image is installed.
ospf	Generates a trap for Open Shortest Path First (OSPF) changes. You can enable any or all of these traps: Cisco specific, errors, link-state advertisement, rate limit, retransmit, and state changes. Note This option is only available when the enhanced multilayer image is installed.
pim	Generates a trap for Protocol-Independent Multicast (PIM) changes. You can enable any or all of these traps: invalid PIM messages, neighbor changes, and rendezvous point (RP)-mapping changes.
port-security	Generates SNMP port security traps. You can also set a maximum trap rate per second. The range is from 0 to 1000; the default is 0, which means that there is no rate limit.
rf	Enable all SNMP traps defined in Cisco-RF-MIB.
snmp	Generates a trap for SNMP-type notifications for authentication, cold start, warm start, link up or link down.
storm-control	Generates a trap for SNMP storm-control. You can also set a maximum trap rate per second. The range is from 0 to 1000; the default is 0 (no limit is imposed; a trap is sent at every occurrence).
stp	Generates SNMP STP Extended MIB traps.
syslog	Generates SNMP syslog traps.

Table 75-3 Switch Notification Types (continued)

Notification Type Keyword	Description
tty	Generates a trap for TCP connections. This trap is enabled by default.
vlan-membership	Generates a trap for SNMP VLAN membership changes.
vlancreate	Generates SNMP VLAN created traps.
vlandelete	Generates SNMP VLAN deleted traps.
vtp	Generates a trap for VLAN Trunking Protocol (VTP) changes.

You can use the **snmp-server host** global configuration command to a specific host to receive the notification types listed in [Table 75-3](#).

To configure the switch to send traps or informs to a host, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# snmp-server engineID remote ip-address engineid-string	Specifies the engine ID for the remote host.
Step 3	Switch(config)# snmp-server user username groupname remote host [udp-port port] {v1 / v2c v3 [auth {md5 sha} auth-password]} [encrypted] [access access-list]	Configures an SNMP user to be associated with the remote host created in Step 2. Note You cannot configure a remote user for an address without first configuring the engine ID for the remote host. If you try to configure the user before configuring the remote engine ID, you receive an error message, and the command is not executed.
Step 4	Switch(config)# snmp-server host host-addr [traps informs] [version {1 / 2c 3 [auth noauth priv]]} community-string [udp-port port] [notification-type]	Specifies the recipient of an SNMP trap operation. <ul style="list-style-type: none"> For <i>host-addr</i>, specify the name or Internet address of the host (the targeted recipient). (Optional) Enter traps (the default) to send SNMP traps to the host. (Optional) Enter informs to send SNMP informs to the host. (Optional) Specify the SNMP version (1, 2c, or 3). SNMPv1 does not support informs. (Optional) For Version 3, select authentication level auth, noauth, or priv. Note The priv keyword is available only when the crypto software image is installed. <ul style="list-style-type: none"> For <i>community-string</i>, enter the password-like community string sent with the notification operation. (Optional) For udp-port port, enter the remote device UDP port. (Optional) For <i>notification-type</i>, use the keywords listed in Table 75-3 on page 75-11. If no type is specified, all notifications are sent.

	Command	Purpose
Step 5	Switch(config)# snmp-server enable traps <i>notification-types</i>	Enables the switch to send traps or informs and specify the type of notifications to be sent. For a list of notification types, see Table 75-3 on page 75-11 , or enter this: snmp-server enable traps ? To enable multiple types of traps, you must enter a separate snmp-server enable traps command for each trap type.
Step 6	Switch(config)# snmp-server trap-source <i>interface-id</i>	(Optional) Specifies the source interface, which provides the IP address for the trap message. This command also sets the source IP address for informs.
Step 7	Switch(config)# snmp-server queue-length <i>length</i>	(Optional) Establishes the message queue length for each trap host. The range is 1 to 1000; the default is 10.
Step 8	Switch(config)# snmp-server trap-timeout <i>seconds</i>	(Optional) Defines how often to resend trap messages. The range is 1 to 1000; the default is 30 seconds.
Step 9	Switch(config)# end	Returns to privileged EXEC mode.
Step 10	Switch# show running-config	Verifies your entries.
Step 11	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

The **snmp-server host** command specifies which hosts receive the notifications. The **snmp-server enable trap** command globally enables the mechanism for the specified notification (for traps and informs). To enable a host to receive an inform, you must configure an **snmp-server host informs** command for the host and globally enable informs by using the **snmp-server enable traps** command.

To remove the specified host from receiving traps, use the **no snmp-server host** *host* global configuration command. The **no snmp-server host** command with no keywords disables traps, but not informs, to the host. To disable informs, use the **no snmp-server host informs** global configuration command. To disable a specific trap type, use the **no snmp-server enable traps** *notification-types* global configuration command.

Setting the Agent Contact and Location Information

To set the system contact and location of the SNMP agent so that these descriptions can be accessed using the configuration file, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# snmp-server contact <i>text</i>	Sets the system contact string. For example: snmp-server contact Dial System Operator at beeper 21555.
Step 3	Switch(config)# snmp-server location <i>text</i>	Sets the system location string. For example: snmp-server location Building 3/Room 222
Step 4	Switch(config)# end	Returns to privileged EXEC mode.

	Command	Purpose
Step 5	Switch# show running-config	Verifies your entries.
Step 6	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Limiting TFTP Servers Used Through SNMP

To limit the TFTP servers used for saving and loading configuration files through SNMP to the servers specified in an access list, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# snmp-server tftp-server-list access-list-number	Limits TFTP servers used for configuration file copies through SNMP to the servers in the access list. For <i>access-list-number</i> , enter an IP standard access list numbered from 1 to 99 and 1300 to 1999.
Step 3	Switch(config)# access-list access-list-number {deny / permit} source [source-wildcard]	Creates a standard access list, repeating the command as many times as necessary. <ul style="list-style-type: none"> For <i>access-list-number</i>, enter the access list number specified in Step 2. The deny keyword denies access if the conditions are matched. The permit keyword permits access if the conditions are matched. For <i>source</i>, enter the IP address of the TFTP servers that can access the switch. (Optional) For <i>source-wildcard</i>, enter the wildcard bits, in dotted decimal notation, to be applied to the source. Place ones in the bit positions that you want to ignore. <p>Note The access list is always terminated by an implicit deny statement for everything.</p>
Step 4	Switch(config)# end	Returns to privileged EXEC mode.
Step 5	Switch# show running-config	Verifies your entries.
Step 6	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

SNMP Examples

This example shows how to enable all versions of SNMP. The configuration permits any SNMP manager to access all objects with read-only permissions using the community string public. This configuration does not cause the switch to send any traps.

```
Switch(config)# snmp-server community public
```

This example shows how to permit any SNMP manager to access all objects with read-only permission using the community string public. The switch also sends VTP traps to the hosts 192.180.1.111 and 192.180.1.33 using SNMPv1 and to the host 192.180.1.27 using SNMPv2C. The community string public is sent with the traps.

```
Switch(config)# snmp-server community public
Switch(config)# snmp-server enable traps vtp
Switch(config)# snmp-server host 192.180.1.27 version 2c public
Switch(config)# snmp-server host 192.180.1.111 version 1 public
Switch(config)# snmp-server host 192.180.1.33 public
```

This example shows how to allow read-only access for all objects to members of access list 4 that use the comaccess community string. No other SNMP managers have access to any objects. SNMP Authentication Failure traps are sent by SNMPv2C to the host cisco.com using the community string public.

```
Switch(config)# snmp-server community comaccess ro 4
Switch(config)# snmp-server enable traps snmp authentication
Switch(config)# snmp-server host cisco.com version 2c public
```

This example shows how to send Entity MIB traps to the host cisco.com. The community string is restricted. The first line enables the switch to send Entity MIB traps in addition to any traps previously enabled. The second line specifies the destination of these traps and overwrites any previous **snmp-server host** commands for the host cisco.com.

```
Switch(config)# snmp-server enable traps entity
Switch(config)# snmp-server host cisco.com restricted entity
```

This example shows how to enable the switch to send all traps to the host myhost.cisco.com using the community string public:

```
Switch(config)# snmp-server enable traps
Switch(config)# snmp-server host myhost.cisco.com public
```

This example shows how to associate a user with a remote host and to send **auth** (authNoPriv) authentication-level informs when you enter global configuration mode:

```
Switch(config)# snmp-server engineID remote 192.180.1.27 00000063000100a1c0b4011b
Switch(config)# snmp-server group authgroup v3 auth
Switch(config)# snmp-server user authuser authgroup remote 192.180.1.27 v3 auth md5
mypassword
Switch(config)# snmp-server user authuser authgroup v3 auth md5 mypassword
Switch(config)# snmp-server host 192.180.1.27 informs version 3 auth authuser config
Switch(config)# snmp-server enable traps
Switch(config)# snmp-server inform retries 0
```

Displaying SNMP Status

To display SNMP input and output statistics, including the number of illegal community string entries, errors, and requested variables, use the **show snmp** privileged EXEC command. You can also use the other privileged EXEC commands in [Table 75-4](#) to display SNMP information. For information about the fields in the output displays, see the *Cisco IOS Configuration Fundamentals Command Reference, Release 12.4*.

Table 75-4 *Commands for Displaying SNMP Information*

Feature	Default Setting
<code>show snmp</code>	Displays SNMP statistics.
<code>show snmp engineID</code>	Displays information on the local SNMP engine and all remote engines that have been configured on the device.
<code>show snmp group</code>	Displays information on each SNMP group on the network.
<code>show snmp pending</code>	Displays information on pending SNMP requests.
<code>show snmp sessions</code>	Displays information on the current SNMP sessions.
<code>show snmp user</code>	Displays information on each SNMP user name in the SNMP users table.

**Note**

You cannot use the **snmp-server enable informs** command. To enable the sending of SNMP inform notifications, use the **snmp-server enable traps** command combined with the **snmp-server host *host-addr* informs** command.

Configuring Flexible NetFlow

Note

Flexible NetFlow is supported only on Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, 7-E, and Catalyst 4500X.

Flow is defined as a unique set of key fields attributes, which might include fields of packet, packet routing attributes, and input and output interface information. A NetFlow feature defines a flow as a sequence of packets that have the same values for the feature key fields. Flexible NetFlow (FNF) allows you to collect and optionally export a flow record that specifies various flow attributes. NetFlow collection supports IP, IPv6 and Layer 2 traffic.

Note

This chapter provides Catalyst 4500 switch specific information. For more information, refer to the URL:

http://www.cisco.com/en/US/products/ps6965/products_ios_protocol_option_home.html

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Note

When IP routing is disabled, on the interface configured with NetFlow Lite, packets are not received on NetFlow collector. Enable IP routing for the NetFlow collector to work.

This chapter addresses both VSS and non-VSS environments:

- [VSS Environment, page 76-1](#)
- [Non-VSS Environment, page 76-8](#)

VSS Environment

The following items apply to a Catalyst 4500 series switch that belongs to a Virtual Switch System (VSS):

1. The Catalyst 4500 series switch supports ingress flow statistics collection for switched and routed packets; it does not support Flexible Netflow on egress traffic.

2. Each switch in an VSS has an independent NFE (Netflow Engine). This means that when there is ingress traffic on both the VSS Active and Standby switches, each is capable of creating flows for its ingress traffic
3. Configuration is performed on the VSS Active switch, which is synchronized to the VSS Standby switch.
4. Netflow **show** commands including Top Talkers, aggregate cache, and **clear** commands must be executed independently on VSS Active and Standby switch. The VSS Standby console will be available via remote console access from the VSS Active switch.
5. Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, 7-E, and Catalyst 4500X support a 100,000 entry hardware flow table. Both VSS Active and Standby switch have independent hardware flow tables of 100,000 entries. The hardware flow table is shared by all the flow monitors on a switch. To prevent one monitor from using all the flow table entries, the number of entries that it uses on a switch can be limited by the **cache entries number** command. This limit is per flow monitor, irrespective of the number of targets it is attached to.

The following example illustrates how to configure the flow monitor *m1* cache to hold 1000 entries. With this configuration, interface gig 1/3/1 (on the VSS Active) can create a maximum of 1000 flows and interface gig 2/3/2 (on the VSS Standby) can create a maximum of 1000 flows:

```
flow exporter e1
    ! exporter specifies where the flow records are send to
    destination 20.1.20.4
!
flow record r1
    ! record specifies packet fields to collect
    match ipv4 source address
    match ipv4 destination address
    collect counter bytes long
    collect counter packets long
    collect timestamp sys-uptime first
    collect timestamp sys-uptime last
!
flow monitor m1
    ! monitor refers record configuration and optionally exporter
    ! configuration. It specifies the cache size i.e. how many unique flow
    ! records to collect
    record r1
    exporter e1
    cache timeout active 60
    cache timeout inactive 30
    cache entries 1000

!interface GigabitEthernet 1/3/1
    ! layer2-switched allows collection of flow records even when the packet is
    ! bridged
    ip flow monitor m1 layer2-switched input
!
interface GigabitEthernet 2/3/2
    ip flow monitor m1 input
!
```

6. Catalyst 4500-E Series Switches with Sup-8E have two ASICs, and the ASIC that the software programs for a given flow monitor depends on what the flow monitor is attached to. When a datalink flow monitor is attached to an SSID (WLAN), the software programs the ASIC on the Daughter Card that creates flows only for pure Layer 2 packets (no IP header). By contrast, when a datalink flow monitor is attached to a port, or a port VLAN, or a VLAN for example, the software programs the ASIC (Netflow Engine) that creates flows for all packets.

7. If the flow exporter is configured to export packets through a specific VRF and a reload is initiated, it is possible that the flow data is not exported from the VSS standby switch. As a workaround, reconfigure the exporter.
8. Flow collection is supported on multiple targets (Port, VLAN, per-port per-VLAN (FNF can be enabled on a specific VLAN on a given port)) and on a port-channel (FNF is configured on the port-channel interface, rather than individual member ports). These targets can be on the VSS Active or on the VSS Standby. For example, if the target is a VLAN, it can consist of ports belonging to both switches. If there is ingress traffic in that VLAN on both switches, flows will be created in their independent flow caches. However, no Netflow configuration can be applied on the Virtual Switch Link (VSL) ports.
9. 64 unique flow record configurations are supported.
10. Flow QoS/UBRL and FNF cannot be configured on the same target. (For information on Flow-based QoS, see the section [Flow-based QoS, page 44-10.](#))
11. 14,000 unique IPv6 addresses can be monitored.
12. On a given target, one monitor per traffic type is allowed. However, you can configure multiple monitors on the same target for different traffic types.

For example, the following configuration is allowed:

```
! vlan config 10
  ip flow monitor <name> input
  ipv6 flow monitor <name> input
!
```

The following configuration is not allowed:

```
!
interface GigabitEthernet 3/1
  ip flow monitor m1 input
  ip flow monitor m2 input
```

13. On a given target monitoring Layer 2 and Layer 3, simultaneous traffic is not supported:

```
interface channel-group 1
  datalink flow monitor m1 input
  ip flow monitor m2 input
```

!

14. Selection of Layer 2 and Layer 3 packet fields in a single flow record definition is not allowed. However, ingress 802.1Q VLAN Id of packet and Layer 3 packet field selection is allowed.
15. To attach a monitor to port or port-vlan targets, a flow record matching on ingress 802.1Q VLANId key field, must match on input interface also as key field.

Note

The **match datalink dot1q vlan input** option is unavailable prior to IOS Release XE 3.3.0; you would only see the **input** option starting with the IOS Release XE 3.3.0.

16. Flow monitor matching on ingress 802.1Q VLANId as key field cannot be attached on a VNET trunk port target.
17. Only permanent and normal flow cache types are supported.
18. Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, 7-E, and Catalyst 4500X do not support:
 - predefined records like traditional routers (**record netflow ipv4 original-input**)
 - flow-based sampler.

19. On VLAN interfaces, when you use the **interface** option with the **Cos**, **Tos**, **TTL** or **Packet length** options, the system displays inaccurate results for the interface input field.
20. The VSS active and standby switches independently export flows, to the same or different Netflow collectors depending on flow exporter configuration. An IP route to the Netflow collector must exist and it should be reachable from the VSS for flow export.
21. At the collector, the flow sequence numbers are local to a switch and will be monotonically increasing for each member of VSS. Additionally, the `SourceId` field of the v9 export packet uniquely identifies the VSS switch number that it was exported from.
22. The configuration of the flow exporter does not support the option **output features**.
23. Maximum number of VRFs that can be used for the flow exporter destination address configuration in VSS is 5. This limit includes the Global Routing Table and is common across all flow exporters in the VSS.

For example, when the user tries to configure an exporter destination address using a sixth VRF limit is exceeded, the following warning is displayed:

```
flow exporter e10
      destination 20.1.20.4 vrf blue
%%Warning - Netflow exporter on Cat4k VSS switch cannot exceed a total max of 5 vrfs
used for destination address
configuration. Flow exporter e10 cannot export in vrf blue.
```

24. Flow aging in flow cache is controlled through active and in-active timer configuration. The minimum for active and in-active aging timers is 5 seconds. The timers must be in units of 5 seconds.

Note Flows in the hardware table are deleted after 5 seconds of in-activity irrespective of the active or in-active timer configuration values. This allows you to create new hardware flows quickly.

25. First and Last-seen flow timestamp accuracy is within 3 seconds.
26. 2048 Flow monitors and records are supported.

When TTL is configured as a flow field, the following values are reported for a given packet TTL value. [Table 76-1](#) lists the packet TTL and reported values.
27. Cisco TrustSec (CTS) fields are supported. These fields use Netflow collector to monitor and troubleshoot the CTS network, and to segregate traffic based on source group tag (SGT) values.
 - When configuring the source group tag (**collect flow cts source group-tag**), note the following:

The system copies the packets to software before it retrieves the CTS field. A large number of flows mean that a large number of packets are copied to the software, possibly affecting CPU performance.

The maximum number of (unique) hosts allowed in the switch (IP addresses) is 12,000.

In case of burst packets, the software may not be able to retrieve the CTS field because the software queue is throttled.
 - When configuring the destination group tag (**collect flow cts destination group-tag**), note that this CTS field value is collected only if you have already configured an IP-to-SGT mapping.
 - When configuring switch-derived source group tags (**collect flow cts switch derived-sgt**), note that the switch derives this value locally.
 - When configuring CTS fields on Supervisor Engine 8-E and 9-E, note that CTS fields are not supported on wireless interfaces (WLAN) and SSID.

Table 76-1 TTL Map: TTL Configured

Packet TT Value	Reported Value
0	0
1	1
2-10	10
11-25	25
26-50	50
51-100	100
100-150	150
150-255	255

- When packet length is configured as a flow field, the following values are reported for a given packet length value. [Table 76-2](#) lists the packet length and reported values.

Table 76-2 Packet Length Map: Packet Length Configured

Packet Length	Reported Value
0-64	64
65-128	128
129-256	256
257-512	512
513-756	756
757-1500	1500
1500-4000	4000
4000+	8192

The following table lists the options available through FNF and the supported fields.

Table 76-3 Options Available through FNF and the Supported Fields

Field	Description	Comments
Data Link Fields (Layer 2 Flow Label + A94)		
dot1q priority	802.1Q user	
dot1q vlan	802.1Q VLAN ID	Ingress VLAN is supported as key field.
mac destination-address	Upstream destination MAC address	
mac source-address	Down stream source MAC address	
IPv4 Fields		
destination address	IPv4 destination address	Yes

Table 76-3 Options Available through FNF and the Supported Fields

Field	Description	Comments
DSCP	IPv4 DSCP (part of TOS)	
fragmentation flags	IPv4 fragmentation flags	Supported as a non key field. DF flag is not supported
is-multicast	Indicator of an IPv4 multicast packet (0 - if it's not, 1 - if it is)	Supported as a non-key field.
Precedence	IPv4 precedence	
Protocol	IPv4 protocol	
source address	IPv4 source address	
total length	IPv4 datagram	Values are reported based on Table 76-2 .
Total length minimum	Minimum packet size seen	
Total length maximum	Maximum packet size seen	
Tos	IPv4 Type of Service (TOS)	
ttl	Pv4 Time to Live (TTL)	Values are reported based on Table 76-1 .
ttl minimum		Supported as a non-key field.
ttl maximum		Supported as a non-key field.
CTS Fields		
flow cts destination group-tag		Supported as a non-key field; configuring the IPv4 destination address is a prerequisite to using this field.
flow cts source group-tag		Supported as a non-key field; configuring the IPv4 source address is a prerequisite to using this field.
flow cts switch derived-sgt	Switch-derived source group-tag	Supported as a non-key field; configuring the IPv4 source address is a prerequisite to using this field.
IPv6 Fields		
destination address	IPv6 destination address	
dscp	IPv6 DSCP (part of IPv6 traffic class)	
flow-label	IPv6 flow label	

Table 76-3 Options Available through FNF and the Supported Fields

Field	Description	Comments
is-multicast	Indicator of an IPv6 multicast packet (0 - if it's not, 1 - if it is)	Supported as a non-key field
hop-limit	IPv6 hop limit (replaces IPv4 ttl)	Values are reported based on Table 76-1 .
hop-limit minimum	IPv6 minimum hop limit value seen in the flow.	Supported as a non-key field.
hop-limit maximum	IPv6 maximum hop limit value seen in the flow.	Supported as a non-key field.
next-header	IPv6 next header type	Only first next header is reported
total length	IPv6 total packet length	Values are based on Table 76-2 .
Total length minimum	Minimum packet size seen	
Total length maximum	Maximum packet size seen	
protocol	IPv6 next header type in the last IPv6 extension header	
source address	IPv6 source address	
traffic-class	IPv6 traffic class	Yes
Routing Attributes		
forwarding-status	Forwarding status for the packet (forwarded, terminated in the router, dropped by ACL, RPF, CAR)	Supported as a non-key field
Layer 4 Header Fields		
Field	Description	Comments
TCP Header Fields		
destination-port TCP destination number	TCP destination port	
flags [ack] [fin] [psh] [rst] [syn] [urg]	TCP flags.	Supported as non-key fields.
source-port	TCP source port	
UDP Header Fields		
destination-port	UDP destination port	
source-port	UDP source port	
ICMP Header Fields		
code	ICMP code	

Table 76-3 Options Available through FNF and the Supported Fields

Field	Description	Comments
type	ICMP type	
IGMP Header Fields		
type	IGMP	
Interface Fields		
input	Input interface index	
output	Input interface index	Output interface can be supported only as non-key.
Flexible NetFlow feature related fields		
direction: input		
Counter Fields		
bytes	32 bit counters	
bytes long	64 bit counter	
packets	32 bit counters	
packets long	64 bit counter of the packets in the flow	
Timestamp		
first seen	Time-stamp of the first packet that is accounted in the flow (in milliseconds, starting from the router boot-up)	3 sec accuracy
last seen	Time-stamp of the last packet that is accounted in the flow (in milliseconds, starting from the router boot-up)	3 sec accuracy

Configuring Flow Monitor Cache Values

Setting active cache timeout to a small value may cause the flows to be exported more frequently to the remote collector. This also causes software to delete flows from the local cache after exporting. So, cache statistics reported by switch may not display the actual flows being monitored.

Non-VSS Environment

The following items apply to the Catalyst 4500 series switch:

The Catalyst 4500 series switch supports ingress flow statistics collection for switched and routed packets; it does not support Flexible Netflow on egress traffic.

1. Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E, and Catalyst 4500X support a 100,000 entry hardware flow table. The hardware flow table is shared by all the flow monitors on a switch. To prevent one monitor from using all the flow table entries, the number of entries that it uses on a switch can be limited by the **cache entries number** command. This limit is per flow monitor, irrespective of the number of targets it is attached to.

The following example illustrates how to configure the flow monitor *m1* cache to hold 1000 entries. With this configuration, interface gig 3/1 can create a maximum of 1000 flows and interface gig 3/2 can create a maximum of 1000 flows:

```
flow exporter e1
    ! exporter specifies where the flow records are sent to
    destination 20.1.20.4
!
flow record r1
    ! record specifies packet fields to collect
    match ipv4 source address
    match ipv4 destination address
    collect counter bytes long
    collect counter packets long
    collect timestamp sys-uptime first
    collect timestamp sys-uptime last
!
flow monitor m1
    ! monitor refers record configuration and optionally exporter
    ! configuration. It specifies the cache size i.e. how many unique flow
    ! records to collect
    record r1
    exporter e1
    cache timeout active 60
    cache timeout inactive 30

!interface GigabitEthernet 3/1
    ! layer2-switched allows collection of flow records even when the packet is
    ! bridged
    ip flow monitor m1 layer2-switched input
!
interface GigabitEthernet 3/2
    ip flow monitor m1 input
!
```

2. Catalyst 4500-E Series Switches with Sup-8E have two ASICs, and the ASIC that the software programs for a given flow monitor depends on what the flow monitor is attached to. When a datalink flow monitor is attached to an SSID (WLAN), the software programs the ASIC on the Daughter Card that creates flows only for pure Layer 2 packets (no IP header). By contrast, when a datalink flow monitor is attached to a port, or a port VLAN, or a VLAN for example, the software programs the ASIC (Netflow Engine) that creates flows for all packets.
3. Flow collection is supported on multiple targets (Port, VLAN, per-port per-VLAN (FNF can be enabled on a specific VLAN on a given port)) and on a port-channel (FNF is configured on the port-channel interface, rather than individual member ports).
4. 64 unique flow record configurations are supported.
5. Flow QoS/UBRL and FNF cannot be configured on the same target. (For information on Flow-based QoS, see the section [Flow-based QoS, page 44-10.](#))
6. 14,000 unique IPv6 addresses can be monitored.

7. On a given target, one monitor per traffic type is allowed. However, you can configure multiple monitors on the same target for different traffic types.

For example, the following configuration is allowed:

```
! vlan config 10
  ip flow monitor <name> input
  ipv6 flow monitor <name> input
!
```

The following configuration is not allowed:

```
!
interface GigabitEthernet 3/1
  ip flow monitor m1 input
  ip flow monitor m2 input
```

8. On a given target monitoring Layer 2 and Layer 3, simultaneous traffic is not supported:

```
interface channel-group 1
  datalink flow monitor m1 input
  ip flow monitor m2 input
!
```

9. Selection of Layer 2 and Layer 3 packet fields in a single flow record definition is disallowed. However, ingress 802.1Q VLAN Id of packet and Layer 3 packet field selection is allowed.
10. To attach a monitor to port or port-vlan targets, a flow record matching on ingress 802.1Q VLAN Id as the key field, must also match on the input interface as the key field.

Note Flow monitor matching on ingress 802.1Q VLAN Id as the key field cannot be attached on a VNET trunk port target.

11. Only permanent and normal flow cache types are supported.
12. Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, 7-E, and Catalyst 4500X do not support:
- predefined records like traditional routers (**record netflow ipv4 original-input**)
 - flow based sampler.
13. On VLAN interfaces, when you use the **interface** option with the **Cos,Tos**, **TTL** or **Packet length** options, the system displays inaccurate results for the interface input field.
14. The configuration of the flow exporter does not support the option **output features**.
15. Flow aging in flow cache is controlled through active and in-active timer configuration. The minimum for active and in-active aging timers is 5 seconds. The timers must be in units of 5 seconds.

Note Flows in the hardware table are deleted after 5 seconds of in-activity irrespective of the active or in-active timer configuration values. This allows you to create new hardware flows quickly.

16. First and Last-seen flow timestamp accuracy is within 3 seconds.
17. 2048 Flow monitors and records are supported.
- When TTL is configured as a flow field, the following values are reported for a given packet TTL value. [Table 76-4](#) lists the packet TTL and reported values.
18. Cisco TrustSec (CTS) fields are supported. These fields use Netflow collector to monitor and troubleshoot the CTS network, and to segregate traffic based on source group tag (SGT) values.
- When configuring the source group tag (**collect flow cts source group-tag**), note the following:

The system copies the packets to software before it retrieves the CTS field. A large number of flows mean that a large number of packets are copied to the software, possibly affecting CPU performance.

The maximum number of (unique) hosts allowed in the switch (IP addresses) is 12,000.

In case of burst packets, the software may not be able to retrieve the CTS field because the software queue is throttled.

- When configuring the destination group tag (**collect flow cts destination group-tag**), note that this CTS field value is collected only if you have already configured an IP-to-SGT mapping.
- When configuring switch-derived source group tags (**collect flow cts switch derived-sgt**), note that the switch derives this value locally.
- When configuring CTS fields on Supervisor Engine 8-E and 9-E, note that CTS fields are not supported on wireless interfaces (WLAN) and SSID.

Table 76-4 TTL Map: TTL Configured

Packet TT Value	Reported Value
0	0
1	1
2-10	10
11-25	25
26-50	50
51-100	100
100-150	150
150-255	255

- When packet length is configured as a flow field, the following values are reported for a given packet length value. [Table 76-5](#) lists the packet length and reported values.

Table 76-5 Packet Length Map: Packet Length Configured

Packet Length	Reported Value
0-64	64
65-128	128
129-256	256
257-512	512
513-756	756
757-1500	1500
1500-4000	4000
4000+	8192

The following table lists the options available through FNF and the supported fields.

Table 76-6 Options Available through FNF and the Supported Fields

Field	Description	Comments
Data Link Fields (Layer 2 Flow Label + A94)		
dot1q priority	802.1Q user	
dot1q vlan	802.1Q VLAN ID	Ingress VLAN is supported as key field.
mac destination-address	Upstream destination MAC address	
mac source-address	Down stream source MAC address	
IPv4 Fields		
destination address	IPv4 destination address	Yes
DSCP	IPv4 DSCP (part of TOS)	
fragmentation flags	IPv4 fragmentation flags	Supported as a non-key field. DF flag is not supported
is-multicast	Indicator of an IPv4 multicast packet (0 - if it's not, 1 - if it is)	Supported as a non-key field.
Precedence	IPv4 precedence	
Protocol	IPv4 protocol	
source address	IPv4 source address	
total length	IPv4 datagram	Values are reported based on Table 76-5 .
Total length minimum	Minimum packet size seen	
Total length maximum	Maximum packet size seen	
Tos	IPv4 Type of Service (TOS)	
ttl	Pv4 Time to Live (TTL)	Values are reported based on Table 76-4 .
ttl minimum		Supported as a non-key field.
ttl maximum		Supported as a non-key field.
CTS Fields		

Table 76-6 Options Available through FNF and the Supported Fields

Field	Description	Comments
flow cts destination group-tag		Supported as a non-key field; configuring the IPv4 destination address is a prerequisite to using this field.
flow cts source group-tag		Supported as a non-key field; configuring the IPv4 source address is a prerequisite to using this field.
flow cts switch derived-sgt	Switch-derived source group-tag	Supported as a non-key field; configuring the IPv4 source address is a prerequisite to using this field.
IPv6 Fields		
destination address	IPv6 destination address	
dscp	IPv6 DSCP (part of IPv6 traffic class)	
flow-label	IPv6 flow label	
is-multicast	Indicator of an IPv6 multicast packet (0 - if it's not, 1 - if it is)	Supported as a non-key field
hop-limit	IPv6 hop limit (replaces IPv4 ttl)	Values are reported based on Table 76-4 .
hop-limit minimum	IPv6 minimum hop limit value seen in the flow.	Supported as a non-key field.
hop-limit maximum	IPv6 maximum hop limit value seen in the flow.	Supported as a non-key field.
next-header	IPv6 next header type	Only first next header is reported
total length	IPv6 total packet length	Values are based on Table 76-5 .
Total length minimum	Minimum packet size seen	
Total length maximum	Maximum packet size seen	
protocol	IPv6 next header type in the last IPv6 extension header	

Table 76-6 Options Available through FNF and the Supported Fields

Field	Description	Comments
source address	IPv6 source address	
traffic-class	IPv6 traffic class	Yes
Routing Attributes		
forwarding-status	Forwarding status for the packet (forwarded, terminated in the router, dropped by ACL, RPF, CAR)	Supported as a non-key field
Layer 4 Header Fields		
Field	Description	Comments
TCP Header Fields		
destination-port TCP destination number	TCP destination port	
flags [ack] [fin] [psh] [rst] [syn] [urg]	TCP flags.	Supported as non-key fields.
source-port	TCP source port	
UDP Header Fields		
destination-port	UDP destination port	
source-port	UDP source port	
ICMP Header Fields		
code	ICMP code	
type	ICMP type	
IGMP Header Fields		
type	IGMP	
Interface Fields		
input	Input interface index	
output	Output interface index	Output interface can be supported only as non-key.
Flexible NetFlow feature related fields		
direction: input		
Counter Fields		
bytes	32 bit counters	
bytes long	64 bit counter	
packets	32 bit counters	
packets long	64 bit counter of the packets in the flow	
Timestamp		

Table 76-6 *Options Available through FNF and the Supported Fields*

Field	Description	Comments
first seen	Time-stamp of the first packet that is accounted in the flow (in milliseconds, starting from the router boot-up)	3 sec accuracy
last seen	Time-stamp of the last packet that is accounted in the flow (in milliseconds, starting from the router boot-up)	3 sec accuracy

Configuring Flow Monitor Cache Values

Setting active cache timeout to a small value may cause the flows to be exported more frequently to the remote collector. This also causes software to delete flows from the local cache after exporting. So, cache statistics reported by switch may not display the actual flows being monitored.

Configuring Ethernet OAM and CFM

Ethernet Operations, Administration, and Maintenance (OAM) is a protocol for installing, monitoring, and troubleshooting Ethernet networks to increase management capability within the context of the overall Ethernet infrastructure. Starting with Cisco IOS Release 15.0(2)SG, the Catalyst 4500 series switch supports Standardized (Draft 8.1) IEEE 802.1ag Connectivity Fault Management (CFM) and IEEE 802.3ah Ethernet OAM discovery, link monitoring, remote fault detection, and remote loopback. It also supports IP Service Level Agreements (SLAs) for CFM, and ITU-T Y.1731 fault management. Ethernet OAM manager controls the interworking between CFM and 802.3ah OAM protocols.

This chapter provides information about configuring CFM and the Ethernet OAM protocol. It defines the differences between the ratified CFM 802.1ag standard (draft 8.1) and the previous version supported on the switch in Cisco IOS (draft 1.0). It also includes configuration information for CFM ITU-TY.1731 fault management support in this release.

Note

For complete command and configuration information for Ethernet OAM, CFM, and Y.1731, see the Cisco IOS Carrier Ethernet Configuration Guide at this URL:

<http://www.cisco.com/en/US/docs/ios-xml/ios/cether/configuration/15-mt/ce-15-mt-book.html>

For syntax of the commands used in this chapter, see The Cisco IOS Carrier Ethernet Command Reference at this URL:

<http://www.cisco.com/en/US/docs/ios-xml/ios/cether/command/ce-cr-book.html>

For complete command and configuration information for CFM, see the Cisco IOS feature module at this URL:

http://www.cisco.com/en/US/docs/ios/cether/configuration/guide/ce_cfm.html

The command reference for this release is at this URL:

[Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch.](#)

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

This chapter contains these sections:

About Ethernet CFM

Ethernet CFM is an end-to-end per-service-instance (per-VLAN) Ethernet layer OAM protocol. It includes proactive connectivity monitoring, fault verification, and fault isolation. End-to-end can be provider-edge-to-provider-edge (PE-to-PE) device or customer-edge-to-customer-edge (CE-to-CE) device. Ethernet CFM, as specified by IEEE 802.1ag, is the standard for Layer 2 ping, Layer 2 traceroute, and end-to-end connectivity verification of the Ethernet network.

These sections contain conceptual information about Ethernet CFM:

- [Ethernet CFM and OAM Definitions, page 77-2](#)
- [CFM Domain, page 77-3](#)
- [Maintenance Associations and Maintenance Points, page 77-4](#)
- [CFM Messages, page 77-5](#)
- [Crosscheck Function and Static Remote MEPs, page 77-5](#)
- [SNMP Traps and Fault Alarms, page 77-5](#)
- [Configuration Error List, page 77-6](#)
- [IP SLAs Support for CFM, page 77-6](#)

Ethernet CFM and OAM Definitions

The following table describes many of the terms in this chapter that are related to OAM and CFM features:

Term	Definition
CC	Continuity Check
CFM	Connectivity Fault Management
EI	Ethernet Infrastructure or EVC Infrastructure
EVC	Ethernet Virtual Circuit
MEP	Maintenance Endpoint
MIP	Maintenance Intermediate Point
OAM	Operations Administration and Maintenance
UNI	User to Network Interface

CFM Domain

A CFM maintenance domain is a management space on a network that is owned and operated by a single entity and defined by a set of internal boundary ports. You assign a unique maintenance level (from 0 to 7) to define the domain hierarchy. The larger the domain, the higher the level. For example, as shown in [Figure 77-1](#), a service-provider domain would be larger than an operator domain and might have a maintenance level of 6, while the operator domain maintenance level would be 3 or 4.

As shown in [Figure 77-2](#), domains cannot intersect or overlap because that would require management by more than one entity, which is not allowed. Domains can touch or nest (if the outer domain has a higher maintenance level than the nested domain). Nesting domains can be useful when a service provider contracts with one or more operators to provide Ethernet service. Each operator has its own maintenance domain and the service provider domain is a superset of the operator domains. Maintenance levels of nesting domains should be communicated among the administering organizations. CFM exchanges messages and performs operations on a per-domain basis.

Figure 77-1 CFM Maintenance Domains

Figure 77-2 Allowed Domain Relationships

Scenario A:
Touching Domains OK

Scenario B:
Nested Domains OK

Scenario C:
Intersecting Domains
Not Allowed

157282

Maintenance Associations and Maintenance Points

A maintenance association (MA) identifies a service that can be uniquely identified within the maintenance domain. The CFM protocol runs within a maintenance association. A maintenance point is a demarcation point on an interface that participates in CFM within a maintenance domain. Maintenance points drop all lower-level frames and forward all higher-level frames. There are two types of maintenance points:

- Maintenance end points (MEPs) are points at the edge of the domain that define the boundaries and confine CFM messages within these boundaries. Outward facing or Down MEPs communicate through the wire side (connected to the port). Inward facing or Up MEPs communicate through the relay function side, not the wire side.

Note CFM draft 1 referred to inward and outward-facing MEPs. CFM draft 8.1 refers to up and down MEPs, respectively. This document uses the CFM 8.1 terminology for direction.

CFM draft 1 supported only up MEPs on a per-port or per-VLAN basis. CFM 802.1ag supports up and down per-VLAN MEPs, as well as port MEPs, which are untagged down MEPs that are not associated with a VLAN. Port MEPs are configured to protect a single hop and used to monitor link state through CFM. If a port MEP is not receiving continuity check messages from its peer (static remote MEP), for a specified interval, the port is put into an operational down state in which only CFM and OAM packets pass through, and all other data and control packets are dropped.

- An up MEP sends and receives CFM frames through the relay function. It drops all CFM frames at its level or lower that come from the wire side, except traffic going to the down MEP. For CFM frames from the relay side, it processes the frames at its level and drops frames at a lower level. The MEP transparently forwards all CFM frames at a higher level, regardless of whether they are received from the relay or wire side. If the port on which MEP is configured is blocked by STP, the MEP can still send or receive CFM messages through the relay function. CFM runs at the provider maintenance level (UPE-to-UPE), specifically with up MEPs at the user network interface (UNI).
- A down MEP sends and receives CFM frames through the wire connected to the port on which the MEP is configured. It drops all CFM frames at its level or lower that come from the relay side. For CFM frames from the wire side, it processes all CFM frames at its level and drops CFM frames at lower levels except traffic going to the other lower-level down MEP. The MEP transparently forwards all CFM frames at a higher level, regardless of whether they are received from the relay or through the wire
- Maintenance intermediate points (MIPs) are internal to a domain, not at the boundary, and respond to CFM only when triggered by traceroute and loopback messages. They forward CFM frames received from MEPs and other MIPs, drop all CFM frames at a lower level (unless MIP filtering is enabled), and forward all CFM frames at a higher level and at a lower level and regardless of whether they are received from the relay or wire side. When MIP filtering is enabled, the MIP drops CFM frames at a lower level. MIPs also catalog and forward continuity check messages (CCMs), but do not respond to them.

In the first draft of CFM, MIP filtering was always enabled. In draft 8.1, MIP filtering is disabled by default, and you can configure it to be enabled or disabled. When MIP filtering is disabled, all CFM frames are forwarded.

You can manually configure a MIP or configure the switch to automatically create a MIP. You can configure a MEP without a MIP. In case of a configuration conflict, manually created MIPs take precedence over automatically created MIPs.

If port on which the MEP is configured is blocked by Spanning-Tree Protocol (STP), the MIP can receive and might respond to CFM messages from both the wire and relay side, but cannot forward any CFM messages. This differs from CFM draft 1, where STP blocked ports could not send or receive CFM messages.

CFM Messages

CFM uses standard Ethernet frames distinguished by EtherType or (for multicast messages) by MAC address. All CFM messages are confined to a maintenance domain and to a service-provider VLAN (S-VLAN). These CFM messages are supported:

- **Continuity Check (CC) messages**—multicast heartbeat messages exchanged periodically between MEPs that allow MEPs to discover other MEPs within a domain and allow MIPs to discover MEPs. CC messages are configured to a domain or VLAN. Enter the **continuity-check Ethernet service** configuration command to enable CCM.

The default continuity check message (CCM) interval on the switch is 10 seconds. You can set it to be 100 ms, 1 second, 1 minute, or 10 minutes by entering the **continuity-check interval Ethernet service mode** command. Because faster CCM rates are more CPU intensive, we do not recommend configuring a large number of MEPs running at 100 ms intervals.

- **Loopback messages**—unicast or multicast frames transmitted by a MEP at administrator request to verify connectivity to a particular maintenance point, indicating if a destination is reachable. A loopback message is similar to an Internet Control Message Protocol (ICMP) ping message. Refer to the **ping ethernet** privileged EXEC command.
- **Traceroute messages**—multicast frames transmitted by a MEP at administrator request to track the path (hop-by-hop) to a destination MEP. Traceroute messages are similar in concept to UDP traceroute messages. Refer to the **traceroute ethernet** privileged EXEC command.

Crosscheck Function and Static Remote MEPs

The crosscheck function verifies a post-provisioning timer-driven service between dynamically configured MEPs (using crosscheck messages) and expected MEPs (by configuration) for a service. It verifies that all endpoints of a multipoint service are operational. The crosscheck function is performed only one time and is initiated from the command-line interface (CLI).

CFM 802.1ag also supports static remote MEPs or static RMEP check. Unlike the crosscheck function, which is performed only once, configured static RMEP checks run continuously. To configure static RMEP check, enter the **continuity-check static rmeip** Ethernet CFM service mode command.

SNMP Traps and Fault Alarms

The MEPs generate two types of SNMP traps: CC traps and crosscheck traps. Supported CC traps are MEP up, MEP down, cross-connect (a service ID does not match the VLAN), loop, and configuration error. The crosscheck traps are service up, MEP missing (an expected MEP is down), and unknown MEP.

Fault alarms are unsolicited notifications sent to alert the system administrator when CFM detects a fault. In CFM draft 1, fault alarms were sent instantaneously when detected. In CFM 802.1ag, you can configure the priority level of alarms that trigger an SNMP trap or syslog message. You can also configure a delay period before a fault alarm is sent and the time before the alarm is reset.

Configuration Error List

CFM configuration errors in CFM 802.1ag can be misconfigurations or extra configuration commands detected during MEP configuration. They can be caused by overlapping maintenance associations. For example, if you create a maintenance association with a VLAN list and a MEP on an interface, a potential leak error could occur if other maintenance associations associated with the same VLAN exist at a higher level without any MEPs configured. You can display the configuration error list, which is informational only, by entering the **show ethernet cfm errors** configuration privileged EXEC command.

IP SLAs Support for CFM

The switch supports CFM with IP Service Level Agreements (SLAs), which gathers Ethernet layer network performance metrics. Available statistical measurements for the IP SLAs CFM operation include round-trip time, jitter (interpacket delay variance), and packet loss. You can schedule multiple IP SLA operations and use Simple Network Management Protocol (SNMP) trap notifications and syslog messages to monitor threshold violations proactively.

IP SLA integration with CFM gathers Ethernet layer statistical measurements by sending and receiving Ethernet data frames between CFM MEPs. Performance is measured between the source MEP and the destination MEP. Unlike other IP SLA operations that provide performance metrics for only the IP layer, IP SLAs with CFM provide performance metrics for Layer 2.

You can manually configure individual Ethernet ping or jitter operations. You can also configure an IP SLA automatic Ethernet operation that queries the CFM database for all MEPs in a given maintenance domain and VLAN. The operation then automatically creates individual Ethernet ping or jitter operations based on the discovered MEPs.

Because IP SLAs is a Cisco proprietary feature, interoperability between CFM draft 1 and CFM 802.1ag is handled automatically by the switch.

For more information about IP SLA operation with CFM, see the *IP SLAs for Metro-Ethernet* feature module at this URL:

http://www.cisco.com/en/US/docs/ios/12_2sr/12_2srb/feature/guide/sr_meth.html

Configuring Ethernet CFM

CFM draft 8.1 on Catalyst 4500 series switch mandates that you enter the **ethernet cfm ieee** command before configuring any other CFM CLI. Without this command, no other CFM CLIs are applied. Configuring Ethernet CFM requires that you configure the CFM domain. You can optionally configure and enable other CFM features (such as crosschecking, static remote MEP, port MEPs, CVLAN MEPs/MIPs, SNMP traps, and fault alarms). Some of the configuration commands and procedures differ from those used in CFM draft 1. CLIs in draft 1 that have been changed are no longer available; they have been deprecated and are not allowed. Only the CLIs mentioned in the following sections are required for draft 8.1.

Note

Upgrading software from CFM draft 1 to draft 8.1 causes a switch to silently drop the draft 1 configuration on the draft 8.1 image. Also, no CFM stateful sync happens between draft 1 and draft 8.1 images. After the upgrade, all CFM configurations must be reconfigured according to the procedures mentioned for draft 8.1.

To configure Ethernet CFM you must prepare the network and configuring services. You can optionally configure and enable crosschecking. These sections are included:

- [Ethernet CFM Default Configuration, page 77-7](#)
- [Ethernet CFM Configuration Guidelines, page 77-7](#)
- [Configuring the CFM Domain, page 77-8](#)
- [Configuring Ethernet CFM Crosscheck, page 77-11](#)
- [Configuring Static Remote MEP, page 77-13](#)
- [Configuring a Port MEP, page 77-14](#)
- [Configuring SNMP Traps, page 77-16](#)
- [Configuring Fault Alarms, page 77-16](#)
- [Configuring IP SLAs CFM Operation, page 77-18](#)
- [Configuring CFM on C-VLAN \(Inner VLAN\), page 77-24](#)

Ethernet CFM Default Configuration

CFM is globally disabled.

CFM is enabled on all interfaces when CFM is globally enabled.

A port can be configured as a flow point (MIP/MEP), a transparent port, or disabled (CFM disabled). By default, ports are transparent ports until configured as MEP, MIP, or disabled.

There are no MEPs or MIPs configured.

When configuring a MA, if you do not configure direction, the default is up (inward facing).

Ethernet CFM Configuration Guidelines

When configuring Ethernet CFM, consider these guidelines and restrictions:

- You must enter the **ethernet cfm ieee** global configuration command before configuring any other CFM CLI. If not, all other CFM CLIs are not applied.
- CFM is not supported on and cannot be configured on either routed ports or Layer 3 EtherChannels.
- You can configure a Layer 2 EtherChannel port channel as Up MEP, Down MEP, or MIP. However, such configurations are not supported on individual ports that belong to an EtherChannel. You cannot add a port with this configuration to an EtherChannel group.
- Port MEP is not supported and cannot be configured on Layer 2 EtherChannels.
- CFM is not supported and cannot be configured on VLAN interfaces.
- On isolated host, community host, or a promiscuous access port, only Down MEP is supported on isolated, community and primary VLANs, respectively.
- Up MEP is supported only on regular VLANs on PVLAN trunks. Down MEP is supported on regular VLANs as well as isolated VLANs on PVLAN secondary trunks. Similarly, Down MEP is supported on regular VLANs as well as primary VLANs on promiscuous trunk ports.
- The CFM service on a PVLAN ends at the PVLAN port. The translation of CFM service between PVLANs is not supported between the PVLAN ports.

- CFM Unicast packets (Loopback Messages and Traceroute Reply), are not allowed on Down MEP on STP blocked ports. The blocked port cannot respond to ping and traceroute. You must configure a port MEP at a lower level than any service (VLAN) MEPs on an interface.
- An 802.1Q (QinQ) tunnel port can be an Up MEP or a port MEP.
- A QinQ port cannot be a Down MEP or a MIP; you can configure the port as a MIP, but it is not active or visible in traceroute. Port MEP frames received on a QinQ interface are not tunneled and are processed locally.
- CFM on a C-VLAN is supported on Traditional and Selective QinQ and not supported on One-to-One VLAN Mapping on Trunk ports.
- Do not configure a port with tunnel mode using the native VLAN as the S-VLAN or the C-VLAN.
- For port MEP on a QinQ port, do not enter the **vlan dot1q tag native** global configuration command to enable tagging on native VLAN frames.
- If you are running CFM draft 1 and upgrade to a software version that supports CFM draft 8.1, the switch silently drops the draft 1 configuration on draft 8.1 image. Some of the CLIs have been changed from draft1 to draft8.1. You need to reconfigure all the required configurations on draft 8.1 image.

Configuring the CFM Domain

To configure the Ethernet CFM domain, configure a service to connect the domain to a VLAN, or configure a port to act as a MEP, perform this task. You can also enter the optional commands to configure other parameters, such as continuity checks.

	Command	Purpose
Step 1	<code>configure terminal</code>	Enter global configuration mode.
Step 2	<code>ethernet cfm ieee</code>	A must have configuration for draft 8.1. This is required to be configured before any other configuration.
Step 3	<code>ethernet cfm global</code>	Globally enable Ethernet CFM on the switch.
Step 4	<code>ethernet cfm traceroute cache [size entries / hold-time minutes]</code>	(Optional) Configure the CFM traceroute cache. You can set a maximum cache size or hold time. <ul style="list-style-type: none"> • (Optional) For size, enter the cache size in number of entry lines. The range is from 1 to 4095; the default is 100 lines. • (Optional) For hold-time, enter the maximum cache hold time in minutes. The range is from 1 to 65535; the default is 100 minutes.
Step 5	<code>ethernet cfm mip auto-create level level-id vlan vlan-id</code>	(Optional) Configure the switch to automatically create MIPs for VLAN IDS that are not associated with specific maintenance associations at the specified level. The level range is 0 to 7. Note Configure MIP auto-creation only for VLANs that MIPs should monitor. Configuring for all VLANs can be CPU and memory-intensive.
Step 6	<code>ethernet cfm mip filter</code>	(Optional) Enable MIP filtering, which means that all CFM frames at a lower level are dropped. The default is disabled.

	Command	Purpose
Step 7	ethernet cfm domain <i>domain-name</i> level <i>level-id</i>	Define a CFM domain, set the domain level, and enter ethernet-cfm configuration mode for the domain. The maintenance level number range is 0 to 7.
Step 8	id { <i>mac-address domain_number</i> dns <i>name</i> null }	(Optional) Assign a maintenance domain identifier. <ul style="list-style-type: none"> <i>mac-address domain_number</i>—Enter the MAC address and a domain number. The number can be from 0 to 65535. dns <i>name</i>—Enter a DNS name string. The name can be a maximum of 43 characters. null—Assign no domain name.
Step 9	service { <i>ma-name</i> <i>ma-number</i> <i>vpn-id vpn</i> } { vlan <i>vlan-id</i> [direction down] port }	Define a customer service maintenance association (MA) name or number or VPN ID to be associated with the domain, a VLAN ID or port MEP, and enter ethernet-cfm-service configuration mode. <ul style="list-style-type: none"> <i>ma-name</i>—a string of no more than 100 characters that identifies the MAID. <i>ma-number</i>—a value from 0 to 65535. <i>vpn-id vpn</i>—enter a VPN ID as the <i>ma-name</i>. vlan <i>vlan-id</i>—VLAN range is from 1 to 4094. You cannot use the same VLAN ID for more than one domain at the same level. (Optional) direction down—specify the service direction as down. port—Configure port MEP, a down MEP that is untagged and not associated with a VLAN.
Step 10	continuity-check	Enable sending and receiving of continuity check messages.
Step 11	continuity-check interval <i>value</i>	(Optional) Set the interval at which continuity check messages are sent. The available values are 100 ms, 1 second, 10 seconds, 1 minute and 10 minutes. The default is 10 seconds. Note Because faster CCM rates are more CPU-intensive, we do not recommend configuring a large number of MEPs running at 100 ms intervals.
Step 12	continuity-check loss-threshold <i>threshold-value</i>	(Optional) Set the number of continuity check messages to be missed before declaring that an MEP is down. The range is 2 to 255; the default is 3.
Step 13	maximum meps <i>value</i>	(Optional) Configure the maximum number of MEPs allowed across the network. The range is from 1 to 65535. The default is 100.

	Command	Purpose
Step 14	<code>sender-id {chassis none}</code>	(Optional) Include the sender ID TLVs, attributes containing type, length, and values for neighbor devices. <ul style="list-style-type: none"> chassis—Send the chassis ID (host name). none—Do not include information in the sender ID.
Step 15	<code>mip auto-create [lower-mep-only none]</code>	(Optional) Configure auto creation of MIPs for the service. <ul style="list-style-type: none"> lower-mep-only—Create a MIP only if there is a MEP for the service in another domain at the next lower active level. none—No MIP auto-create.
Step 16	<code>exit</code>	Return to ethernet-cfm configuration mode.
Step 17	<code>mip auto-create [lower-mep-only]</code>	(Optional) Configure auto creation of MIPs for the domain. <ul style="list-style-type: none"> lower-mep-only—Create a MIP only if there is a MEP for the service in another domain at the next lower active level.
Step 18	<code>mep archive-hold-time minutes</code>	(Optional) Set the number of minutes that data from a missing maintenance end point is kept before it is purged. The range is 1 to 65535; the default is 100 minutes.
Step 19	<code>exit</code>	Return to global configuration mode.
Step 20	<code>interface interface-id</code>	Specify an interface to configure, and enter interface configuration mode.
Step 21	<code>switchport mode trunk</code>	(Optional) Configure the port as a trunk port.
Step 22	<code>ethernet cfm mip level level-id</code>	(Optional) Configure a customer level or service-provider level maintenance intermediate point (MIP) for the interface. The MIP level range is 0 to 7. Note This step is not required if you have entered the ethernet cfm mip auto-create global configuration command or the mip auto-create ethernet-cfm or ethernet-cfm-srv configuration mode.
Step 23	<code>ethernet cfm mep domain domain-name mpid identifier {vlan vlan-id port}</code>	Configure maintenance end points for the domain, and enter ethernet cfm mep mode. <ul style="list-style-type: none"> domain domain-name—Specify the name of the created domain. mpid identifier—Enter a maintenance end point identifier. The identifier must be unique for each VLAN (service instance). The range is 1 to 8191. vlan vlan-id—Enter the service provider VLAN ID or IDs as a VLAN-ID (1 to 4094), a range of VLAN-IDs separated by a hyphen, or a series of VLAN IDs separated by comma. port—Configure port MEP.
Step 24	<code>cos value</code>	(Optional) Specify the class of service (CoS) value to be sent with the messages. The range is 0 to 7.

	Command	Purpose
Step 25	end	Return to privileged EXEC mode.
Step 26	show ethernet cfm maintenance-points {local remote}	Verify the configuration.
Step 27	show ethernet cfm errors [configuration]	(Optional) Display the configuration error list.
Step 28	copy running-config startup-config	(Optional) Save your entries in the configuration file.

Use the **no** versions of the commands to remove the configuration or return to the default configurations.

This is an example of the basic CFM configuration:

```
Switch(config)# ethernet cfm ieee
Switch(config)# ethernet cfm global
Switch(config)# ethernet cfm domain abc level 3
Switch(config-ecfm)# service test vlan 5
Switch(config-ecfm-srv)# continuity-check
Switch(config-ecfm-srv)# exit
Switch(config-ecfm)# exit
Switch(config)# interface gigabitethernet1/0/2
Switch(config-if)# ethernet cfm mep domain abc mpid 222 vlan 5
Switch(config-if-ecfm-mep)# exit
```

Configuring Ethernet CFM Crosscheck

To configure Ethernet CFM crosscheck, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ethernet cfm mep crosscheck start-delay delay	Configures the number of seconds that the device waits for remote MEPs to come up before the crosscheck is started. The range is 1 to 65535; the default is 30 seconds.
Step 3	Switch(config)# ethernet cfm domain domain-name level level-id	Defines a CFM domain, set the domain level, and enter ethernet-cfm configuration mode for the domain. The maintenance level number range is 0 to 7.
Step 4	Switch(config)# service {ma-name ma-number vpn-id vpn} { vlan vlan-id}	Define a customer service maintenance association name or number or VPN ID to be associated with the domain, and a VLAN ID, and enter ethernet-cfm-service configuration mode. <ul style="list-style-type: none"> <i>ma-name</i>—A string of no more than 100 characters that identifies the MAID. <i>ma-number</i>—A value from 0 to 65535. <i>vpn-id vpn</i>—Enter a VPN ID as the ma-name. <i>vlan vlan-id</i>—VLAN range is from 1 to 4094. You cannot use the same VLAN ID for more than one domain at the same level.
Step 5	Switch(config-ether-cfm)# mep mpid identifier	Define the MEP maintenance end point identifier in the domain and service. The range is 1 to 8191.
Step 6	Switch(config)# end	Returns to privileged EXEC mode.

	Command	Purpose
Step 7	Switch# ethernet cfm mep crosscheck {enable disable} domain <i>domain-name</i> {vlan { <i>vlan-id</i> any} port}	<ul style="list-style-type: none"> • Enable or disable CFM crosscheck for one or more VLANs or a port MEP in the domain. • domain <i>domain-name</i>—Specify the name of the created domain. • vlan {<i>vlan-id</i> any}—Enter the service provider VLAN ID or IDs as a VLAN-ID (1 to 4094), a range of VLAN-IDs separated by a hyphen, or a series of VLAN IDs separated by comma. Enter any for any VLAN. • port—Identify a port MEP
Step 8	Switch# show ethernet cfm maintenance-points remote crosscheck	Verifies the configuration.
Step 9	Switch# show ethernet cfm errors [configuration]	Enter this command after you enable CFM crosscheck to display the results of the crosscheck operation. Enter the configuration keyword to display the configuration error list.
Step 10	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no** form of each command to remove a configuration or to return to the default settings.

The following example illustrates how to configure Ethernet CFM crosscheck:

```
Switch(config)# ethernet cfm mep crosscheck start-delay 60
Switch(config)# ethernet cfm domain abc level 3
Switch(config-ecfm)# service test vlan 5
Switch(config-ecfm-srv)# mep mpid 23
Switch(config-ecfm-srv)# mep mpid 34
Switch(config-ecfm-srv)# end
Switch# ethernet cfm mep crosscheck enable domain abc vlan 5
```

```
Switch# show ethernet cfm maintenance-points remote crosscheck
```

```
-----
MPID Domain Name                               Lvl Type Id      Mep-Up

    23 abc                               0000.0000.0000   Vlan 5
      test                               RMEP missing    3    95s
Switch#
```

Configuring Static Remote MEP

To configure Ethernet CFM static remote MEP, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enter global configuration mode.
Step 2	<code>ethernet cfm domain domain-name level level-id</code>	Define a CFM domain, set the domain level, and enter ethernet-cfm configuration mode for the domain. The maintenance level number range is 0 to 7.
Step 3	<code>service {ma-name / ma-number / vpn-id vpn} {vlan vlan-id [direction down] port}</code>	Define a customer service maintenance association name or number or a VPN ID to be associated with the domain, and a VLAN ID or peer MEP, and enter ethernet-cfm-service configuration mode. <ul style="list-style-type: none"> <i>ma-name</i>—a string of no more than 100 characters that identifies the MAID. <i>ma-number</i>—a value from 0 to 65535. <i>vpn-id</i>—enter a VPN ID as the <i>ma-name</i>. vlan vlan-id—VLAN range is from 1 to 4094. You cannot use the same VLAN ID for more than one domain at the same level. (Optional) direction down—specify the service direction as down. port—Configure port MEP, a down MEP that is untagged and not associated with a VLAN.
Step 4	<code>continuity-check</code>	Enable sending and receiving of continuity check messages.
Step 5	<code>mep mpid identifier</code>	Define the static remote maintenance end point identifier. The range is 1 to 8191.
Step 6	<code>continuity-check static rmp</code>	Enable checking of the incoming continuity check message from a remote MEP that is configured in the MEP list.
Step 7	<code>end</code>	Return to privileged EXEC mode.
Step 8	<code>show ethernet cfm maintenance-points remote static</code>	Verify the configuration.
Step 9	<code>show ethernet cfm errors [configuration]</code>	Enter this command after you enable CFM crosscheck to display the results of the crosscheck operation. Enter the configuration keyword to display the configuration error list.
Step 10	<code>copy running-config startup-config</code>	(Optional) Save your entries in the configuration file.

Use the **no** form of each command to remove a configuration or to return to the default settings.

The following example illustrates how to configure Ethernet CFM static remote MEP:

```
Switch(config)# ethernet cfm domain abc level 3
Switch(config-ecfm)# service test vlan 5
Switch(config-ecfm-srv)# continuity-check
Switch(config-ecfm-srv)# mep mpid 23
```

```

Switch(config-ecfm-srv) # mep mpid 34
Switch(config-ecfm-srv) # continuity-check static rmep

Switch# show ethernet cfm maintenance-points remote static
-----
MPID Domain Name                               Lvl Type Id      Mep-Up
  MA Name
-----
    23 abc                                     3 Vlan 5          No
      test
    34 abc                                     3 Vlan 5          No
      test
Switch# show ethernet cfm errors
-----
MPID Domain Id                               Mac Address      Type Id
  MA Name                               Reason          Lvl  Age
-----
    34 abc                               0000.0000.0000   Vlan 5

Switch#

```

Configuring a Port MEP

A port MEP is a down MEP that is not associated with a VLAN and that uses untagged frames to carry CFM messages. You configure port MEPs on two connected interfaces. Port MEPs are always configured at a lower domain level than native VLAN MEPs.

To configure Ethernet CFM port MEPs, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ethernet cfm domain <i>domain-name level level-id</i>	Defines a CFM domain, set the domain level, and enter ethernet-cfm configuration mode for the domain. The maintenance level number range is 0 to 7.
Step 3	Switch(config-ecfm)# service { <i>ma-name</i> / <i>ma-number</i> / <i>vpn-id</i> } port	Defines a customer service maintenance association name or number or VPN ID to be associated with the domain, define a port MEP, and enter ethernet-cfm-service configuration mode. <ul style="list-style-type: none"> • <i>ma-name</i>—a string of no more than 100 characters that identifies the MAID. • <i>ma-number</i>—a value from 0 to 65535. • <i>vpn-id vpn</i>—enter a VPN ID as the <i>ma-name</i>.
Step 4	Switch(config-ecfm-srv)# mep mpid <i>identifier</i>	Defines the static remote maintenance end point identifier in the domain and service. The range is 1 to 8191.
Step 5	Switch(config-ecfm-srv)# continuity-check	Enables sending and receiving of continuity check messages.

	Command	Purpose
Step 6	Switch(config-ecfm-srv)# continuity-check interval <i>value</i>	(Optional) Sets the interval at which continuity check messages are sent. The available values are 1 second, 10 seconds, 1 minute, and 10 minutes. The default is 10 seconds. Note Because faster CCM rates are more CPU-intensive, we do not recommend configuring a large number of MEPs running at 1 s intervals.
Step 7	Switch(config-ecfm-srv)# continuity-check loss-threshold <i>threshold-value</i>	(Optional) Sets the number of continuity check messages to be missed before declaring that an MEP is down. The range is 2 to 255; the default is 3.
Step 8	Switch(config-ecfm-srv)# continuity-check static rmep	Enables checking of the incoming continuity check message from a remote MEP that is configured in the MEP list.
Step 9	Switch(config-ecfm-srv)# exit	Returns to ethernet-cfm configuration mode.
Step 10	Switch(config-ecfm)# exit	Returns to global configuration mode.
Step 11	Switch(config)# interface <i>interface-id</i>	Identifies the port MEP interface and enter interface configuration mode.
Step 12	Switch(config-if)# ethernet cfm mep domain <i>domain-name</i> mpid identifier port	Configures the interface as a port MEP for the domain. <ul style="list-style-type: none"> domain <i>domain-name</i>—Specify the name of the created domain. mpid identifier—Enter a maintenance end point identifier. The identifier must be unique for each VLAN (service instance). The range is 1 to 8191.
Step 13	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 14	Switch)# show ethernet cfm maintenance-points remote static	Verifies the configuration.
Step 15	Switch)# show ethernet cfm errors [<i>configuration</i>]	Enters this command after you enable CFM crosscheck to display the results of the crosscheck operation. Enter the configuration keyword to display the configuration error list.
Step 16	Switch)# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no** form of each command to remove a configuration or to return to the default settings.

This is a sample configuration for a port MEP:

```
Switch(config)# ethernet cfm domain abc level 3
Switch(config-ecfm)# service PORTMEP port
Switch(config-ecfm-srv)# mep mpid 222
Switch(config-ecfm-srv)# continuity-check
Switch(config-ecfm-srv)# continuity-check static rmep
Switch(config-ecfm-srv)# exit
Switch(config-ecfm)# exit
Switch(config)# interface gigabitethernet1/0/1
Switch(config-if)# ethernet cfm mep domain abc mpid 111 port
Switch(config-if)# end
```

Configuring SNMP Traps

To configure traps for Ethernet CFM, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# snmp-server enable traps ethernet cfm cc [mep-up] [mep-down] [config] [loop] [cross-connect]	(Optional) Enables Ethernet CFM continuity check traps.
Step 3	Switch(config)# snmp-server enable traps ethernet cfmalarm	(Optional) Enables Ethernet CFM fault alarm trap.
Step 4	Switch(config)# snmp-server enable traps ethernet cfm crosscheck [mep-unknown] [mep-missing] [service-up]	(Optional) Enable s Ethernet CFM crosscheck traps.
Step 5	Switch(config)# end	Returns to privileged EXEC mode.
Step 6	Switch# show running-config	Verifies your entries.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no** form of each command to remove a configuration or to return to the default settings.

The following example illustrates how to configure SNMP traps:

```
Switch(config)# snmp-server enable traps ethernet cfm alarm
Switch(config)# snmp-server enable traps ethernet cfm cc mep-down
Switch(config)# snmp-server enable traps ethernet cfm crosscheck mep-missing
```

Configuring Fault Alarms

To configure Ethernet CFM fault alarms, perform this task.

Note

You can configure fault alarms in either global configuration or Ethernet CFM interface MEP mode. When a conflict exists, the interface MEP mode configuration takes precedence.

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>ethernet cfm alarm notification {all error-xcon mac-remote-error-xcon none remote-error-xcon xcon}</code>	<p>Globally enables Ethernet CFM fault alarm notification for the specified defects:</p> <ul style="list-style-type: none"> • all—report all defects. • error-xcon—Report only error and connection defects. • mac-remote-error-xcon—Report only MAC-address, remote, error, and connection defects. • none—Report no defects. • remote-error-xcon—Report only remote, error, and connection defects. • xcon—Report only connection defects.
Step 3	<code>ethernet cfm alarm delay value</code>	(Optional) Sets a delay period before a CFM fault alarm is sent. The range is 2500 to 10000 milliseconds (ms). The default is 2500 ms.
Step 4	<code>ethernet cfm alarm reset value</code>	(Optional) Specifies the time period before the CFM fault alarm is reset. The range is 2500 to 10000 milliseconds (ms). The default is 10000 ms.
Step 5	<code>ethernet cfm logging alarm ieee</code>	Configures the switch to generate system logging messages for the alarms.
Step 6	<code>interface interface-id</code>	(Optional) Specifies an interface to configure, and enter interface configuration mode.
Step 7	<code>ethernet cfm mep domain domain-name mpid identifier vlan vlan-id</code>	<p>Configures maintenance end points for the domain, and enter ethernet cfm interface mep mode.</p> <ul style="list-style-type: none"> • domain domain-name—Specify the name of the created domain. • mpid identifier—Enter a maintenance end point identifier. The identifier must be unique for each VLAN (service instance). The range is 1 to 8191. • vlan vlan-id—Enter the service provider VLAN ID or IDs as a VLAN-ID (1 to 4094), a range of VLAN-IDs separated by a hyphen, or a series of VLAN IDs separated by comma.
Step 8	<code>alarm notification {all error-xcon mac-remote-error-xcon none remote-error-xcon xcon}</code>	<p>(Optional) Enables Ethernet CFM fault alarm notification for the specified defects on the interface.</p> <p>Note The Ethernet CFM interface MEP alarm configuration takes precedence over the global configuration.</p>
Step 9	<code>alarm {delay value reset value}</code>	<p>(Optional) Sets an alarm delay period or a reset period.</p> <p>Note The Ethernet CFM interface MEP alarm configuration takes precedence over the global configuration.</p>

	Command	Purpose
Step 10	end	Returns to privileged EXEC mode.
Step 11	show running-config	Verifies your entries.
Step 12	copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no** form of each command to remove a configuration or to return to the default settings.

The following example illustrates how to configure Ethernet CFM fault alarms:

```
Switch(config)# ethernet cfm alarm notification remote-error-xcon
Switch(config)# ethernet cfm logging alarm ieee
Switch(config)# interface gigabitethernet1/2
Switch(config-if)# ethernet cfm mep domain abc mpid 222 vlan 5
Switch(config-if-ecfm-mep)# alarm notification mac-remote-error-xcon
Switch(config-if)# end
```

Configuring IP SLAs CFM Operation

You can manually configure an IP SLA's Ethernet ping or jitter echo operation, or you can configure IP SLAs Ethernet operation with endpoint discovery. You can also configure multiple operation scheduling. For accurate one-way delay statistics, the clocks on the endpoint switches must be synchronized. You can configure the endpoint switches with Network Time Protocol (NTP) so that the switches are synchronized to the same clock source.

For detailed information about configuring IP SLAs Ethernet operations, see the *Cisco IOS IP SLAs for Metro-Ethernet* feature module at this URL:

http://www.cisco.com/en/US/docs/ios-xml/ios/ipsla/configuration/15-1s/Configuring_Cisco_IOS_IP_SLAs_for_Metro-Ethernet.html

and

http://www.cisco.com/en/US/docs/ios-xml/ios/ipsla/configuration/xr-2/Configuring_IP_SLAs_for_Metro-Ethernet.html

For detailed information about IP SLAs operations, see the *Cisco IOS IP SLAs Configuration Guide, Release 12.4T* at this URL:

http://www.cisco.com/en/US/products/ps6441/products_installation_and_configuration_guides_list.html

For detailed information about IP SLAs commands, see the command reference at this URL:

http://www.cisco.com/en/US/docs/ios/ipsla/command/reference/sla_book.html

This section includes these procedures:

- [Manually Configuring an IP SLAs CFM Probe or Jitter Operation, page 77-19](#)
- [Configuring an IP SLAs Operation with Endpoint Discovery, page 77-21](#)

Manually Configuring an IP SLAs CFM Probe or Jitter Operation

To manually configure an IP SLAs Ethernet echo (ping) or jitter operation, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ip sla operation-number	Creates an IP SLAs operation, and enters IP SLAs configuration mode.
Step 3	Switch(config-ip-sla)# ethernet echo mpid identifier domain domain-name vlan vlan-id or ethernet jitter mpid identifier domain domain-name vlan vlan-id [interval interpacket-interval] [num-frames number-of frames transmitted]	Configures the IP SLAs operation as an echo (ping) or jitter operation, and enter IP SLAs Ethernet echo configuration mode. <ul style="list-style-type: none"> Enter echo for a ping operation or jitter for a jitter operation. For mpid identifier, enter a maintenance endpoint identifier. The identifier must be unique for each VLAN (service instance). The range is 1 to 8191. For domain domain-name, enter the CFM domain name. For vlan vlan-id, the VLAN range is from 1 to 4095. (Optional—for jitter only) Enter the interval between sending of jitter packets. (Optional—for jitter only) Enter the num-frames and the number of frames to be sent.
Step 4	Switch(config-ip-sla-ethernet-monitor)# cos cos-value	(Optional) Sets a class of service value for the operation. Before configuring the cos parameter on the switch, you must globally enable QoS by entering the mls qos global configuration command.
Step 5	Switch(config-ip-sla-ethernet-monitor)# frequency seconds	(Optional) Sets the rate at which the IP SLAs operation repeats. The range is from 1 to 604800 seconds; the default is 60 seconds.
Step 6	Switch(config-ip-sla-ethernet-monitor)# history history-parameter	(Optional) Specifies parameters for gathering statistical history information for the IP SLAs operation.
Step 7	Switch(config-ip-sla-ethernet-monitor)# owner owner-id	(Optional) Configures the SNMP owner of the IP SLAs operation.
Step 8	Switch(config-ip-sla-ethernet-monitor)# request-data-size bytes	(Optional) Specifies the protocol data size for an IP SLAs request packet. The range is from 0 to the maximum size allowed by the protocol being used; the default is 66 bytes.
Step 9	Switch(config-ip-sla-ethernet-monitor)# tag text	(Optional) Creates user-specified identifier for an IP SLAs operation.
Step 10	Switch(config-ip-sla-ethernet-monitor)# threshold milliseconds	(Optional) Specifies the upper threshold value in milliseconds (ms) for calculating network monitoring statistics. The range is 0 to 2147483647; the default is 5000.

	Command	Purpose
Step 11	Switch(config-ip-sla-ethernet-monitor)# timeout <i>milliseconds</i>	(Optional) Specifies the amount of time in ms that the IP SLAs operation waits for a response from its request packet. The range is 0 to 604800000; the default value is 5000.
Step 12	Switch(config-ip-sla-ethernet-monitor)# exit	Returns to global configuration mode.
Step 13	Switch(config)# ip sla schedule <i>operation-number</i> [ageout <i>seconds</i>] [life { forever <i>seconds</i> }] [recurring] [start-time { <i>hh:mm</i> { <i>:ss</i> } [<i>month day</i> <i>day month</i>] pending now after <i>hh:mm:ss</i> }]	Schedules the time parameters for the IP SLAs operation. <ul style="list-style-type: none"> <i>operation-number</i>—Enter the IP SLAs operation number. (Optional) ageout <i>seconds</i>—Enter the number of seconds to keep the operation in memory when it is not actively collecting information. The range is 0 to 2073600 seconds. The default is 0 seconds. (Optional) life—Set the operation to run indefinitely (forever) or for a specific number of <i>seconds</i>. The range is from 0 to 2147483647. The default is 3600 seconds (1 hour) (Optional) recurring—Set the probe to be automatically scheduled every day. (Optional) start-time—Enter the time for the operation to begin collecting information: <ul style="list-style-type: none"> To start at a specific time, enter the hour, minute, second (in 24-hour notation), and day of the month. Enter pending to select no information collection until a start time is selected. Enter now to start the operation immediately. Enter after <i>hh:mm:ss</i> to show that the operation should start after the entered time has elapsed.
Step 14	Switch(config)# end	Returns to privileged EXEC mode.
Step 15	Switch# show ip sla configuration [<i>operation-number</i>]	Shows the configured IP SLAs operation.
Step 16	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To remove an IP SLAs operation, enter the **no ip sla operation-number** global configuration command.

The following example shows how to configure an IP SLA CFM Probe or Jitter Operation:

```
Switch(config)# ip sla 1
Switch(config-ip-sla)# ethernet echo mpid 23 domain abc vlan 5
Switch(config-ip-sla-ethernet-echo)# exit
Switch(config)# ip sla schedule 1 start-time now

Switch# show ip sla configuration 1
IP SLAs, Infrastructure Engine-II.

Switch#

Configuring an IP SLAs Operation with Endpoint Discovery

To use IP SLAs to automatically discover the CFM endpoints for a domain and VLAN ID, perform this task. You can configure ping or jitter operations to the discovered endpoints.

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ip sla ethernet-monitor <i>operation-number</i>	Begins configuration of an IP SLAs automatic Ethernet operation, and enter IP SLAs Ethernet monitor configuration mode.

	Command	Purpose
Step 3	<pre>Switch(config-ip-sla-ethernet-monitor)# type echo domain <i>domain-name</i> vlan <i>vlan-id</i> [exclude-mpids <i>mp-ids</i>] or type jitter domain <i>domain-name</i> vlan <i>vlan-id</i> [exclude-mpids <i>mp-ids</i>] [interval <i>interpacket-interval</i>] [num-frames <i>number-of</i> <i>frames transmitted</i>]</pre>	<p>Configures the automatic Ethernet operation to create echo (ping) or jitter operation and enters IP SLAs Ethernet echo configuration mode.</p> <ul style="list-style-type: none"> Enter type echo for a ping operation or type jitter for a jitter operation. For mpid identifier, enter a maintenance endpoint identifier. The range is 1 to 8191. For domain domain-name, enter the CFM domain name. For vlan vlan-id, the VLAN range is from 1 to 4095. (Optional) Enter exclude-mpids mp-ids to exclude the specified maintenance endpoint identifiers. (Optional—for jitter only) Enter the interval between sending of jitter packets. (Optional—for jitter only) Enter the num-frames and the number of frames to be sent.
Step 4	<pre>Switch(config-ip-sla-ethernet-echo)# cos <i>cos-value</i></pre>	(Optional) Sets a class of service value for the operation.
Step 5	<pre>Switch(config-ip-sla-ethernet-echo)# owner <i>owner-id</i></pre>	(Optional) Configures the SNMP owner of the IP SLAs operation.
Step 6	<pre>Switch(config-ip-sla-ethernet-echo)# request-data-size <i>bytes</i></pre>	(Optional) Specifies the protocol data size for an IP SLAs request packet. The range is from 0 to the maximum size allowed by the protocol being used; the default is 66 bytes.
Step 7	<pre>Switch(config-ip-sla-ethernet-echo)# tag <i>text</i></pre>	(Optional) Creates a user-specified identifier for an IP SLAs operation.
Step 8	<pre>Switch(config-ip-sla-ethernet-echo)# threshold <i>milliseconds</i></pre>	(Optional) Specifies the upper threshold value in milliseconds for calculating network monitoring statistics. The range is 0 to 2147483647; the default is 5000.
Step 9	<pre>Switch(config-ip-sla-ethernet-echo)# timeout <i>milliseconds</i></pre>	(Optional) Specifies the amount of time in milliseconds that the IP SLAs operation waits for a response from its request packet. The range is 0 to 604800000; the default value is 5000.
Step 10	<pre>Switch(config-ip-sla-ethernet-echo)# exit</pre>	Returns to global configuration mode.

	Command	Purpose
Step 11	Switch(config)# ip sla schedule <i>operation-number</i> [ageout <i>seconds</i>] [life { forever <i>seconds</i> }] [recurring] [start-time { <i>hh:mm</i> { <i>:ss</i> } [<i>month</i> <i>day</i> <i>day</i> <i>month</i>] pending now after <i>hh:mm:ss</i> }]	Schedules the time parameters for the IP SLAs operation. <ul style="list-style-type: none"> • <i>operation-number</i>—Enter the IP SLAs operation number. • (Optional) ageout <i>seconds</i>—Enter the number of seconds to keep the operation in memory when it is not actively collecting information. The range is 0 to 2073600 seconds. The default is 0 seconds. • (Optional) life—Set the operation to run indefinitely (forever) or for a specific number of <i>seconds</i>. The range is from 0 to 2147483647. The default is 3600 seconds (1 hour) • (Optional) recurring—Set the probe to be automatically scheduled every day. • (Optional) start-time—Enter the time for the operation to begin collecting information: <ul style="list-style-type: none"> – To start at a specific time, enter the hour, minute, second (in 24-hour notation), and day of the month. – Enter pending to select no information collection until a start time is selected. – Enter now to start the operation immediately. – Enter after <i>hh:mm:ss</i> to show that the operation should start after the entered time has elapsed.
Step 12	Switch(config)# end	Returns to privileged EXEC mode.
Step 13	Switch# show ip sla ethernet-monitor configuration [<i>operation-number</i>]	Shows the configured IP SLAs Auto Ethernet Monitor operation.
Step 14	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To remove an IP SLAs operation, enter the **no ip sla operation-number** global configuration command.

The following example shows how to configure an IP SLAs Operation with Endpoint Discovery:

```
Switch(config)# ip sla ethernet-monitor 10
Switch(config-ip-sla-ethernet-monitor)# type echo domain abc vlan 34
Switch(config-ip-sla-ethernet-params)# exit
Switch(config)# ip sla ethernet-monitor schedule 10 schedule-period 60 start-time now
Switch(config)# exit
```

```
Switch# show ip sla ethernet-monitor configuration 10
Entry Number : 10
Modification time : *10:12:01.725 UTC Mon Nov 29 2010
Operation Type : echo
Domain Name : abc
VLAN ID : 5

```

Switch#

Configuring CFM on C-VLAN (Inner VLAN)

IEEE 802.1ag CFM brings in a support that allows customers to provision maintenance intermediate points (MIPs) and Up maintenance endpoints (MEPs) on the C-VLAN (inner VLAN) component of QinQ ports to provide visibility on the C-VLAN. C-VLANs are now supported on 802.1q tunnel ports. This allows monitoring or troubleshooting when QinQ is enabled on the provider edge (PE) device.

For more information about this feature and the supported commands, see:

http://www.cisco.com/en/US/docs/ios/cether/configuration/guide/ce_cfm-ieee_cvlan.html

The switch supports 802.1q-tunnel-port mode.

To configure Ethernet CFM CVLAN Up MEPs, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ethernet cfm domain <i>domain-name level level-id</i>	Define a CFM domain, set the domain level, and enter ethernet-cfm configuration mode for the domain. The maintenance level number range is 0 to 7.
Step 3	Switch(config-ecfm)# service { <i>ma-name</i> <i>ma-number</i> <i>vpn-id</i> } vlan <i>svlan-id</i> inner-vlan <i>cvlan-id</i>	Define a customer service maintenance association name or number or VPN ID to be associated with the domain, define a CVLAN service, and enter ethernet-cfm-service configuration mode. <ul style="list-style-type: none"> • <i>ma-name</i>—a string of no more than 100 characters that identifies the MAID. • <i>ma-number</i>—a value from 0 to 65535. • <i>vpn-id</i> <i>vpn</i>—enter a VPN ID as the ma-name. • vlan <i>svlan-id</i>—VLAN range is from 1 to 4094. This identifies the outer VLAN (service provider vlan id) that CFM frames go out with. • inner-vlan <i>cvlan-id</i>—VLAN range is from 1 to 4094. This identifies the inner VLAN (customer VLAN) that is monitored through CFM.
Step 4	Switch(config-ecfm-arv)# continuity-check	Enables sending and receiving of continuity check messages.

	Command	Purpose
Step 5	Switch(config-ecfm-arv)# continuity-check interval <i>value</i>	(Optional) Set the interval at which continuity check messages are sent. The available values are 1 second, 10 seconds, 1 minute and 10 minutes. The default is 10 seconds. Note Because faster CCM rates are more CPU-intensive, we do not recommend configuring a large number of MEPs running at 1 s intervals.
Step 6	Switch(config-ecfm-arv)# continuity-check loss-threshold <i>threshold-value</i>	(Optional) Set the number of continuity check messages to be missed before declaring that an MEP is down. The range is 2 to 255; the default is 3.
Step 7	Switch(config-ecfm-arv)# exit	Returns to Return to ethernet-cfm configuration mode.
Step 8	Switch(config-ecfm)# exit	Returns to global configuration mode.
Step 9	Switch(config)# interface <i>interface-id</i>	Identify the CVLAN MEP interface and enter interface configuration mode.
Step 10	Switch(config-if)# ethernet cfm mep domain <i>domain-name</i> mpid identifier service { <i>ma-name</i> <i>ma-number</i> <i>vpn-id</i> }]	Configure the interface as a CVLAN Up MEP for the domain. <ul style="list-style-type: none"> • domain <i>domain-name</i>—Specify the name of the created domain. • mpid identifier—Enter a maintenance end point identifier. The identifier must be unique for each VLAN (service instance). The range is 1 to 8191. • service {<i>ma-name</i> <i>ma-number</i> <i>vpn-id</i>}—Use the same service identifier that was used for configuring CVLAN Service above in Step3.
Step 11	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 12	Switch# show ethernet cfm maintenance-points local	Verify the configuration.
Step 13	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no** form of each command to remove a configuration or to return to the default settings.

This is a sample configuration for a CVLAN Up MEP:

```
Switch(config)# ethernet cfm domain abc level 3
Switch(config-ecfm)# service CVLANMEP vlan 10 inner-vlan 20
Switch(config-ecfm-srv)# continuity-check
Switch(config-ecfm-srv)# exit
Switch(config-ecfm)# exit
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# ethernet cfm mep domain abc mpid 1020 service CVLANMEP
Switch(config-if)# end
```

Similarly, a manual configuration of MIP for CVLAN is configured using the **ethernet cfm mip level level-id vlan svlan-id inner-vlan cvlan-id** command.

Feature Support and Behavior

CFM S-VLAN component support:

- Up MEPs at any level (0 to 7).

Up MEPs use the port access VLAN ID (the outer tag or S-VLAN).

CFM frames sent and received by Up MEPs have a single VLAN tag, and the VLAN identifier is the port access VLAN ID (S-VLAN). Because the 802.1q tunnel interface marks the endpoint of the S-VLAN, the associated S-VLAN component should mark the endpoint of the CFM domain running over the S-VLAN space.

CFM C-VLAN component support:

- Up MEP functions at any level (0 to 7).

Up MEPs use two tags: an outer tag with a VLAN ID that is the port access VLAN (S-VLAN) and an inner tag with a selected C-VLAN that is allowed through the 802.1q tunnel port. CFM frames sent and received by these Up MEPs are always double-tagged.

- MIP functions at any level (0 to 7).

MIPs process CFM frames that are single-tagged when coming from the wire-side and double-tagged when coming from the relay-function side.

- Transparent point functions.

Supported maintenance points on 802.1q tunnels:

- Up MEP on the C-VLAN component for selective or all-to-one bundling
- Up MEP on the S-VLAN
- Port MEP
- MIP support on C-VLAN component for selective or all-to-one bundling

Note

The switch supports only manual configuration of MIPs. It does not support MIP autocreation on C-VLANs.

Platform Restrictions and Limitations

- Maximum supported MEPs per switch at each continuity check message (CCM) interval:
 - 1600 MEP local and 1600 MEP remote (on C-VLAN and S-VLAN) with 10-second intervals
 - 250 MEP local and 250 MEP remote (on C-VLAN and S-VLAN) with 1-second intervals
- Maximum supported MIPs at each CCM interval:
 - 300 MIPs at 10 seconds
 - 125 MIPs at 1 second
- There could be issues detecting cross-connect errors on the Catalyst 4500 series switch.
- These features are not supported:
 - CFM C-component on the native VLAN
 - Down MEP on S or C-VLAN (provider network port)
 - MIP on S-VLAN (provider network port)
 - CFM C-VLAN alarm indication signal (AIS)

- 802.3ah interworking with CFM C-VLAN
- CFM C-VLAN IP SLAs
- CFM C-VLAN MIP autocreation
- CFM C-VLAN with One-to-One VLAN mapping on Trunk ports.

Understanding CFM ITU-T Y.1731 Fault Management

The ITU-T Y.1731 feature provides new CFM functionality for fault and performance management for service providers in large network. The switch supports Ethernet Alarm Indication Signal (ETH-AIS), Ethernet Remote Defect Indication (ETH-RDI), Ethernet Locked Signal (ETH-LCK), and Ethernet Multicast Loopback Message (MCAST-LBM) functionality for fault detection, verification, and isolation.

- [Y.1731 Terminology, page 77-27](#)
- [Alarm Indication Signals, page 77-28](#)
- [Ethernet Remote Defect Indication, page 77-28](#)
- [Multicast Ethernet Loopback, page 77-29](#)

Y.1731 Terminology

- Server MEP—the combination of the server layer termination function and server or Ethernet adaptation layer termination function or server or Ethernet adaptation function, where the server layer termination function is expected to run OAM mechanisms specific to the server layer. The supported mechanisms are link up, link down, and 802.3ah.
- Server layer—a virtual MEP layer capable of detecting fault conditions.
- Defect conditions:
 - Loss of continuity (LOC): the MEP stopped receiving CCM frames from a peer MEP
 - Mismatch: the MEP received a CCM frame with a correct maintenance level (matching the MEP level) but an incorrect maintenance ID.
 - Unexpected MEP: the MEP received a CCM frame with the correct maintenance level (matching the MEP's level) and correct maintenance ID, but an unexpected MEP ID.
 - Unexpected maintenance level: the MEP received a CCM frame with an incorrect maintenance level.
 - Unexpected period: the MEP received a CCM frame with a correct maintenance level, a correct maintenance ID, a correct MEP ID, but a different transmission period field.
- Signal fail—the MEP declares a signal fail condition when it detects a defect condition.
- Alarm Indication Signal (AIS) condition—the MEP received an AIS frame.
- Remote Defect Indication (RDI) condition—The MEP received a CCM frame with the RDI field set.

Alarm Indication Signals

The Ethernet Alarm Signal function (ETH-AIS) is used to suppress alarms after defects are detected at the *server* (sub) layer, which is a virtual MEP layer capable of detecting fault conditions. A fault condition could be a signal fail condition, an AIS condition, or a LCK condition.

**Note**

Although the configuration is allowed, you should not configure AIS in networks running STP. An STP configuration might cause AIS interruption or redirection.

When a MEP or a service MEP (SMEP) detects a connectivity fault at a specific maintenance association level, it multicasts AIS frames in the direction away from the detected failure at the client maintenance association level. The frequency of AIS frame transmission is based on the AIS transmission period. The first AIS frame is always sent immediately following the detection of the defect condition. We recommend a transition period of 1 second in a network of only a few VLANs to ensure that the first AIS frame is sent immediately following error detection. We recommend a 60-second interval in a network of multiple (up to 4094) VLANs to prevent stressing the network with 1-second transmissions.

A MEP that receives a frame with ETH-AIS information cannot determine the specific server with the defect condition or the set of peer MEPs for which it should suppress alarms. Therefore, it suppresses alarms for all peer MEPs, whether or not they are connected.

When a MEP receives an AIS frame, it examines it to be sure that the Maintenance Entity Group (MEG) level matches its own MEG and then detects the AIS default condition. (A MEG is Y.1731 terminology for maintenance association in 802.1ag.) After this detection, if no AIS frames are received for an interval of 3.5 times the AIS transmission period, the MEP clears the AIS defect condition. For example, if the AIS timer is set for 60 seconds, the AIS timer period expires after 3.5 times 60, or 210 seconds.

The AIS condition is terminated when a valid CCM is received with all error conditions cleared or when the AIS period timer expires (the default time is 60 seconds).

Ethernet Remote Defect Indication

When Ethernet OAM continuity check (ETH-CC) transmission is enabled, the Ethernet Remote Defect Indication (ETH-RDI) function uses a bit in the CFM CC message to communicate defect conditions to the MEP peers. For ETH-RDI functionality, you must configure the MEP MEG level, the ETH-CC transmission period, and the ETH-CC frame priority. ETH-RDI does not require any MIP configuration.

When a MEP receives frames with ETH-RDI information, it determines that its peer MEP has encountered a defect condition and sets the RDI files in the CCM frames for the duration of the defect condition. When the defect condition clears, the MEP clears the RDI field.

When a MEP receives a CCM frame, it examines it to ensure that its MEG level is the same and if the RDI field is set, it detects an RDI condition. For point-to-point Ethernet connections, a MEP can clear the RDI condition when it receives the first frame from its peer MEP with the RDI field cleared. However, for multipoint Ethernet connectivity, the MEP cannot determine the associated subset of peer MEPs with which the sending MEP has seen the defect condition. It can clear the RDI condition after it receives CCM frames with the RDI field cleared from its entire list of peer MEPs.

Multicast Ethernet Loopback

The multicast Ethernet loopback (ETH-LB) function verifies bidirectional connectivity of a MEP with its peer MEPs and is an on-demand OAM function. When the feature is invoked on a MEP by entering the **ping** privileged EXEC command, the MEP sends a multicast frame with ETH-LB request information to peer MEPs in the same MEG. The MEP expects to receive a unicast frame with ETH-LB reply information from its peer MEPs within a specified time period. A MEP receiving a multicast frame with ETH-LB request information validates the frame and transmits a frame with reply information.

To configure multicast ETH-LB, you configure the MEG level of the MEP and the priority of the multicast frames with ETH-LB requests. Multicast frames with ETH-LB request information are always marked as drop ineligible. No MIP configuration is required.

The MEP sends multicast LB message frames on an on-demand basis. After sending a multicast LBM frame, the MEP expects to receive LB reply frames within 5 seconds.

When a MEP receives a valid LBM frame, it generates an LB reply frame and sends it to the requested MEP after a random delay in the range of 0 to 1 second. The validity of the frame is determined on its having the correct MEG level.

When a MEP sends a multicast LBM frame and receives an LB reply frame within 5 seconds, the LB reply frame is valid.

Configuring Y.1731 Fault Management

To configure Y.1731 fault management, you must enable CFM and configure MIPs on the participating interfaces. AIS messages are generated only on interfaces with a configured MIP.

- [Default Y.1731 Configuration, page 77-29](#)
- [Configuring ETH-AIS, page 77-29](#)
- [Using Multicast Ethernet Loopback, page 77-31](#)

Default Y.1731 Configuration

ETH-AIS and ETH-LCK are enabled by default when CFM is enabled.

When you configure ETH-AIS or ETH-LCK, you must configure CFM before ETH-AIS or ETH-LCK is operational.

ETH-RDI is set automatically when continuity check messages are enabled.

Configuring ETH-AIS

Beginning in privileged EXEC mode, follow these steps to configure Ethernet AIS on a switch:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>ethernet cfm ais link-status global</code>	Configures AIS-specific SMEP commands by entering config-ais-link-cfm mode.

	Command	Purpose
Step 3	level <i>level-id</i> or disable	Configures the maintenance level for sending AIS frames transmitted by the SMEP. The range is 0 to 7. or Disables generation of ETH-AIS frames.
Step 4	period <i>value</i>	Configures the SMEP AIS transmission period interval. Allowable values are 1 second or 60 seconds.
Step 5	exit	Returns to global configuration mode.
Step 6	ethernet cfm domain <i>domain-name</i> level <i>level-id</i>	Defines a CFM domain, set the domain level, and enter ethernet-cfm configuration mode for the domain. The maintenance level number range is 0 to 7.
Step 7	service { <i>ma-name</i> / <i>ma-number</i> / <i>vpn-id</i> <i>vpn</i> } { vlan <i>vlan-id</i> [direction down] port }	Defines a customer service maintenance association (MA) name or number to be associated with the domain, or a VLAN ID or VPN-ID, and enter ethernet-cfm-service configuration mode. <ul style="list-style-type: none"> • <i>ma-name</i>—a string of no more than 100 characters that identifies the MAID. • <i>ma-number</i>—a value from 0 to 65535. • <i>vpn-id</i>—enter a VPN ID as the <i>ma-name</i>. • vlan <i>vlan-id</i>—VLAN range is from 1 to 4094. You cannot use the same VLAN ID for more than one domain at the same level. • (Optional) direction down—specify the service direction as down. • port—Configure port MEP, a down MEP that is untagged and not associated with a VLAN.
Step 8	ais level <i>level-id</i>	(Optional) Configures the maintenance level for sending AIS frames transmitted by the MEP. The range is 0 to 7.
Step 9	ais period <i>value</i>	(Optional) Configures the MEP AIS transmission period interval. Allowable values are 1 second or 60 seconds.
Step 10	ais expiry-threshold <i>value</i>	(Optional) Sets the expiring threshold for the MA as an integer. The range is 2 to 255. The default is 3.5.
Step 11	no ais suppress-alarms	(Optional) Overrides the suppression of redundant alarms when the MEP goes into an AIS defect condition after receiving an AIS message.
Step 12	exit	Returns to ethernet-cfm configuration mode.
Step 13	exit	Returns to global configuration mode.
Step 14	interface <i>interface-id</i>	Specifies an interface ID, and enter interface configuration mode.
Step 15	[no] ethernet cfm ais link-status	Enables or disable sending AIS frames from the SMEP on the interface.
Step 16	ethernet cfm ais link-status period <i>value</i>	Configures the ETH-AIS transmission period generated by the SMEP on the interface. Allowable values are 1 second or 60 seconds.

	Command	Purpose
Step 17	<code>ethernet cfm ais link-status level <i>level-id</i></code>	Configures the maintenance level for sending AIS frames transmitted by the SMEP on the interface. The range is 0 to 7.
Step 18	<code>end</code>	Returns to privileged EXEC mode.
Step 19	<code>show ethernet cfm smep [<i>interface interface-id</i>]</code>	Verifies the configuration.
Step 20	<code>show ethernet cfm error</code>	Displays received ETH-AIS frames and other errors.
Step 21	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Use the **no** form of the commands to return to the default configuration or to remove a configuration. To disable the generation of ETH-AIS frames, enter the **disable** config-ais-link-cfm mode command.

This is an example of the output from the **show ethernet cfm smep** command when Ethernet AIS has been enabled:

```
Switch# show ethernet cfm smep
SMEP Settings:
-----
Interface: GigabitEthernet1/0/3
LCK-Status: Enabled
LCK Period: 60000 (ms)
Level to transmit LCK: Default
AIS-Status: Enabled
AIS Period: 60000 (ms)
Level to transmit AIS: Default
Defect Condition: AIS
```

Using Multicast Ethernet Loopback

You can use the **ping** privileged EXEC command to verify bidirectional connectivity of a MEP, as in this example:

```
Switch# ping ethernet multicast domain CD vlan 10
Type escape sequence to abort.
Sending 5 Ethernet CFM loopback messages to 0180.c200.0037, timeout is 5 seconds:
Reply to Multicast request via interface FastEthernet1/0/3, from 001a.a17e.f880, 8 ms
Total Loopback Responses received: 1
```

Managing and Displaying Ethernet CFM Information

You can use the privileged EXEC commands in these tables to clear Ethernet CFM information.

Table 77-1 Clearing CFM Information

Command	Purpose
<code>clear ethernet cfm ais domain <i>domain-name</i> mpid <i>id</i> {vlan <i>vlan-id</i> port}</code>	Clears MEPs with matching domain and VLAN ID out of AIS defect condition.
<code>clear ethernet cfm ais link-status interface <i>interface-id</i></code>	Clears a SMEP out of AIS defect condition.
<code>clear ethernet cfm error</code>	Clears all CFM error conditions, including AIS.

You can use the privileged EXEC commands in [Table 77-2](#) to display Ethernet CFM information.

Table 77-2 **Displaying CFM Information**

Command	Purpose
<code>show ethernet cfm domain [brief]</code>	Displays CFM domain information or brief domain information.
<code>show ethernet cfm errors [configuration domain-id]</code>	Displays CFM continuity check error conditions logged on a device since it was last reset or the log was last cleared. When CFM crosscheck is enabled, displays the results of the CFM crosscheck operation.
<code>show ethernet cfm maintenance-points local [detail domain interface level mep mip]</code>	Displays maintenance points configured on a device.
<code>show ethernet cfm maintenance-points remote [crosscheck detail domain static]</code>	Displays information about a remote maintenance point domains or levels or details in the CFM database.
<code>show ethernet cfm mpdb</code>	Displays information about entries in the MIP continuity-check database.
<code>show ethernet cfm smep [interface interface-id]</code>	Displays Ethernet CFM SMEP information.
<code>show ethernet cfm traceroute-cache</code>	Displays the contents of the traceroute cache.

This is an example of output from the `show ethernet cfm domain brief` command:

```
Switch# show ethernet cfm domain brief
Domain Name                               Index Level Services Archive(min)
level5                                   1      5      1      100
level3                                   2      3      1      100
test                                     3      3      3      100
name                                     4      3      1      100
test1                                    5      2      1      100
lck                                      6      1      1      100Total Services : 1
```

This is an example of output from the `show ethernet cfm errors` command:

```
Switch# show ethernet cfm errors
-----
MPID Domain Id                               Mac Address      Type  Id  Lvl
      MAName                               Reason              Age
-----
6307 level3                                0021.d7ee.fe80   Vlan  7   3
      vlan7                                Receive RDI       5s
```

This is an example of output from the `show ethernet cfm maintenance-points local detail` command:

Hold-time: 100 Minutes

```

You can use the privileged EXEC commands in [Table 77-3](#) to display IP SLAs Ethernet CFM information.

Table 77-3 **Displaying IP SLAs CFM Information**

Command	Purpose
show ip sla configuration [<i>entry-number</i>]	Displays configuration values including all defaults for all IP SLAs operations or a specific operation.
show ip sla ethernet-monitor configuration [<i>entry-number</i>]	Displays the configuration of the IP SLAs automatic Ethernet operation.
show ip sla statistics [<i>entry-number</i> / aggregated / details]	Displays current or aggregated operational status and statistics.

About Ethernet OAM Protocol

The Ethernet OAM protocol for installing, monitoring, and troubleshooting Metro Ethernet networks and Ethernet WANs relies on an optional sublayer in the data link layer of the OSI model. Normal link operation does not require Ethernet OAM. You can implement Ethernet OAM on any full-duplex point-to-point or emulated point-to-point Ethernet link for a network or part of a network (specified interfaces).

OAM frames, called OAM protocol data units (OAM PDUs) use the slow protocol destination MAC address 0180.c200.0002. They are intercepted by the MAC sublayer and cannot propagate beyond a single hop within an Ethernet network. Ethernet OAM is a relatively slow protocol, with a maximum transmission rate of 10 frames per second, resulting in minor impact to normal operations. However, because the CPU must poll error counters frequently, when you enable link monitoring, the number of required CPU cycles is proportional to the number of interfaces that must be polled.

Ethernet OAM has two major components:

- The *OAM client* establishes and manages Ethernet OAM on a link and enables and configures the OAM sublayer. During the OAM discovery phase, the OAM client monitors OAM PDUs received from the remote peer and enables OAM functionality. After the discovery phase, it manages the rules of response to OAM PDUs and the OAM remote loopback mode.
- The *OAM sublayer* presents two standard IEEE 802.3 MAC service interfaces facing the superior and inferior MAC sublayers. It provides a dedicated interface for the OAM client to pass OAM control information and PDUs to and from the client. The sublayer includes these components:
 - The *control block* provides the interface between the OAM client and other OAM sublayer internal blocks.
 - The *multiplexer* manages frames from the MAC client, the control block, and the parser and passes OAM PDUs from the control block and loopback frames from the parser to the subordinate layer.
 - The *parser* classifies frames as OAM PDUs, MAC client frames, or loopback frames and sends them to the appropriate entity: OAM PDUs to the control block, MAC client frames to the superior sublayer, and loopback frames to the multiplexer.

OAM Features

These OAM features are defined by IEEE 802.3ah:

- *Discovery* identifies devices in the network and their OAM capabilities. It uses periodic OAM PDUs to advertise OAM mode, configuration, and capabilities; PDU configuration; and platform identity. An optional phase allows the local station to accept or reject the configuration of the peer OAM entity.
- *Link monitoring* detects and indicates link faults under a variety of conditions and uses the event notification OAM PDU to notify the remote OAM device when it detects problems on the link. Error events include when the number of symbol errors, the number of frame errors, the number of frame errors within a specified number of frames, or the number of error seconds within a specified period exceeding a configured threshold.
- *Remote failure indication* conveys a slowly deteriorating quality of an OAM entity to its peers by communicating these conditions: Link Fault means a loss of signal, Dying Gasp means an unrecoverable condition, and Critical Event means an unspecified vendor-specific critical event. The switch can receive and process but not generate Link Fault or Critical Event OAM PDUs. It can generate Dying Gasp OAM PDUs to show that Ethernet OAM is disabled, the interface is shut down, the interface enters the error-disabled state, or the switch is reloading. It can respond to, but not generate, Dying Gasp PDUs based on loss of power.
- *Remote loopback mode* ensures link quality with a remote peer during installation or troubleshooting. In this mode, when the switch receives a frame that is not an OAM PDU or a pause frame, it sends it back on the same port. The link appears to you to be functioning. You can use the returned loopback acknowledgement to test delay, jitter, and throughput.

OAM Messages

Ethernet OAM messages or PDUs are standard length, untagged Ethernet frames between 64 and 1518 bytes. They do not go beyond a single hop and have a maximum transmission rate of 10 OAM PDUs per second. Message types are information, event notification, loopback control, or vendor-specific OAM PDUs.

Enabling and Configuring Ethernet OAM

This section includes this information:

- [Ethernet OAM Default Configuration, page 77-35](#)
- [Ethernet OAM Configuration Guidelines, page 77-35](#)
- [Enabling Ethernet OAM on an Interface, page 77-36](#)
- [Enabling Ethernet OAM Remote Loopback, page 77-37](#)
- [Configuring Ethernet OAM Link Monitoring, page 77-38](#)
- [Configuring Ethernet OAM Remote Failure Indications, page 77-42](#)
- [Configuring Ethernet OAM Templates, page 77-45](#)

Ethernet OAM Default Configuration

The default configuration is as follows:

- Ethernet OAM is disabled on all interfaces.
- When Ethernet OAM is enabled on an interface, link monitoring is automatically turned on.
- Remote loopback is disabled.
- No Ethernet OAM templates are configured.

Ethernet OAM Configuration Guidelines

Follow these guidelines when configuring Ethernet OAM:

- The switch does not support monitoring of egress frames sent with cyclic redundancy code (CRC) errors. The **ethernet oam link-monitor transmit crc** interface-configuration or template-configuration commands are visible but are not supported on the switch. The commands are accepted but are not applied to an interface.
- For a remote failure indication, the switch does not generate Link Fault or Critical Event OAM PDUs. However, if these PDUs are received from a link partner, they are processed. The switch generates and receives Dying Gasp OAM PDUs when Ethernet OAM is disabled, the interface is shut down, the interface enters the error-disabled state, or the switch is reloading. It can respond to, but not generate, Dying Gasp PDUs based on loss of power.
- The switch does not support Ethernet OAM loopback on ports that belong to an EtherChannel, ISL trunk, and promiscuous trunk.

Enabling Ethernet OAM on an Interface

To enable Ethernet OAM on an interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Defines an interface to configure as an EOM interface, and enters interface configuration mode.
Step 3	Switch(config-if)# ethernet oam	Enables Ethernet OAM on the interface.
Step 4	Switch(config-if)# ethernet oam [max-rate <i>oampdus</i> min-rate <i>seconds</i> mode { active passive } timeout <i>seconds</i>]	<p>Configures these optional OAM parameters:</p> <ul style="list-style-type: none"> (Optional) Enter max-rate <i>oampdus</i> to configure the maximum number of OAM PDUs sent per second. The range is from 1 to 10. (Optional) Enter min-rate <i>seconds</i> to configure the minimum transmission rate in seconds when one OAM PDU is sent per second. The range is from 1 to 10. (Optional) Enter mode active to set OAM client mode to active. active is the default. (Optional) Enter mode passive to set OAM client mode to passive. <p>Note When Ethernet OAM mode is enabled on two interfaces passing traffic, at least one must be in the active mode.</p> <ul style="list-style-type: none"> (Optional) Enter timeout <i>seconds</i> to set a time for OAM client timeout. The range is from 2 to 30.
Step 5	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 6	Switch# show ethernet oam status [interface <i>interface-id</i>]	Verifies the configuration.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Enter the **no ethernet oam** interface configuration command to disable Ethernet OAM on the interface.

This example shows how to set basic OAM parameters on the switch:

```
Switch(config)# int gi1/3
Switch(config-if)# ethernet oam
Switch(config-if)# ethernet oam max-rate 9
Switch(config-if)# ethernet oam mode passive
Switch(config-if)# end
Switch# show ethernet oam status int gi1/2
GigabitEthernet1/2

General
-----
Admin state:          enabled
Mode:                 passive
PDU max rate:         9 packets per second
PDU min rate:         1 packet per 1 second
Link timeout:         5 seconds
High threshold action: no action
```

```

Link fault action:      no action

```

Enabling Ethernet OAM Remote Loopback

You must enable Ethernet OAM remote loopback on an interface for the local OAM client to initiate OAM remote loopback operations. Changing this setting causes the local OAM client to exchange configuration information with its remote peer. Remote loopback is disabled by default.

Remote loopback has these limitations:

- Only data packets are looped back.
- You cannot configure Ethernet OAM remote loopback on ISL ports or ports that belong to an EtherChannel.
- Remote loopback can be supported on a max of 16 ports.

To enable Ethernet OAM remote loopback on an interface, follow these steps:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Defines an interface to configure as an EOM interface, and enters interface configuration mode.

	Command	Purpose
Step 3	Switch(config-if)# ethernet oam remote-loopback { supported timeout <i>seconds</i> }	Enables Ethernet remote loopback on the interface or set a loopback timeout period. <ul style="list-style-type: none"> Enter supported to enable remote loopback. Enter timeout <i>seconds</i> to set a remote loopback timeout period. The range is from 1 to 10 seconds.
Step 4	Switch(config-if)# ethernet oam remote-loopback { start stop } { interface <i>interface-id</i> }	Turns on or turn off Ethernet OAM remote loopback on an interface.
Step 5	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 6	Switch# show ethernet oam status [interface <i>interface-id</i>]	Verifies the configuration.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no ethernet oam remote-loopback** {**supported** | **timeout**} interface configuration command to disable remote loopback support or remove the timeout setting.

This example shows how to enable OAM Remote Loopback:

```
Switch(config)# int gi1/3
Switch(config-if)# ethernet oam
Switch(config-if)# ethernet oam remote-loopback supported
Switch(config-if)# end
Switch# show running int gi1/1
Building configuration...

Current configuration : 209 bytes
!
interface GigabitEthernet1/1
 switchport trunk encapsulation dot1q
 switchport trunk allowed vlan 1,19
 switchport mode trunk
 ethernet oam remote-loopback supported
 ethernet oam
end

Switch# ethernet oam remote-loopback start int gi1/1
it is a intrusive loopback.
Therefore, while you test Ethernet OAM MAC connectivity,
you will be unable to pass traffic across that link.
Proceed with Remote Loopback? [confirm]

Switch# ethernet oam remote-loopback stop int gi1/1
Switch#
*Apr  9 12:52:39.793: %ETHERNET_OAM-6-LOOPBACK: Interface Gi1/1 has exited the master
loopback mode.
```

Configuring Ethernet OAM Link Monitoring

You can configure high and low thresholds for link-monitoring features. If no high threshold is configured, the default is **none**; no high threshold is set. If you do not set a low threshold, the default is a value lower than the high threshold.

Link event PDUs for rxcrc and trxcrc errors are not generated because they are nonstandard.

To configure Ethernet OAM link monitoring on an interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Defines an interface, and enters interface configuration mode.
Step 3	Switch(config-if)# ethernet oam link-monitor supported	Enables the interface to support link monitoring. it is the default. You need to enter this command only if it has been disabled by previously entering the no ethernet oam link-monitor supported command.
Step 4	Switch(config-if)# ethernet oam link-monitor symbol-period { threshold { high { <i>high symbols</i> none } low { <i>low-symbols</i> }} window <i>symbols</i> } Repeat this step to configure both high and low thresholds.	(Optional) Configures high and low thresholds for an error-symbol period that trigger an error-symbol period link event. <ul style="list-style-type: none"> Enter threshold high <i>high-symbols</i> to set a high threshold in number of symbols. The range is 1 to 65535. The default is none. Enter threshold high none to disable the high threshold if it was set. it is the default. Enter threshold low <i>low-symbols</i> to set a low threshold in number of symbols. The range is 0 to 65535. It must be lower than the high threshold. Enter window <i>symbols</i> to set the window size (in number of symbols) of the polling period. The range is 1 to 65535 symbols.
Step 5	Switch(config-if)# ethernet oam link-monitor frame { threshold { high { <i>high-frames</i> none } low { <i>low-frames</i> }} window <i>milliseconds</i> } Repeat this step to configure both high and low thresholds.	(Optional) Configures high and low thresholds for error frames that trigger an error-frame link event. <ul style="list-style-type: none"> Enter threshold high <i>high-frames</i> to set a high threshold in number of frames. The range is 1 to 65535. The default is none. Enter threshold high none to disable the high threshold if it was set. it is the default. Enter threshold low <i>low-frames</i> to set a low threshold in number of frames. The range is 0 to 65535. The default is 1. Enter window <i>milliseconds</i> to set the a window and period of time during which error frames are counted. The range is 10 to 600 and represents the number of milliseconds in multiples of 100. The default is 100.

Command	Purpose
<p>Step 6</p> <pre>Switch(config-if)# ethernet oam link-monitor frame-period {threshold {high {high-frames none} low {low-frames}}} window frames}</pre> <p>Repeat this step to configure both high and low thresholds.</p>	<p>(Optional) Configures high and low thresholds for the error-frame period that triggers an error-frame-period link event.</p> <ul style="list-style-type: none"> • Enter threshold high <i>high-frames</i> to set a high threshold in number of frames. The range is 1 to 65535. The default is none. • Enter threshold high none to disable the high threshold if it was set. it is the default. • Enter threshold low <i>low-frames</i> to set a low threshold in number of frames. The range is 0 to 65535. The default is 1. • Enter window <i>frames</i> to set the a polling window size in number of frames. The range is 1 to 65535; each value is a multiple of 10000 frames. The default is 1000.
<p>Step 7</p> <pre>Switch(config-if)# ethernet oam link-monitor frame-seconds {threshold {high {high-frames none} low {low-frames}}} window milliseconds}</pre> <p>Repeat this step to configure both high and low thresholds.</p>	<p>(Optional) Configures high and low thresholds for the frame-seconds error that triggers an error-frame-seconds link event.</p> <ul style="list-style-type: none"> • Enter threshold high <i>high-frames</i> to set a high error frame-seconds threshold in number of seconds. The range is 1 to 900. The default is none. • Enter threshold high none to disable the high threshold if it was set. it is the default. • Enter threshold low <i>low-frames</i> to set a low threshold in number of frames. The range is 1 to 900. The default is 1. • Enter window <i>frames</i> to set the a polling window size in number of milliseconds. The range is 100 to 9000; each value is a multiple of 100 milliseconds. The default is 1000.

	Command	Purpose
Step 8	<p>Switch(config-if)# ethernet oam link-monitor receive-crc {threshold {high {high-frames none} low {low-frames}} window milliseconds}</p> <p>Repeat this step to configure both high and low thresholds.</p>	<p>(Optional) Configures thresholds for monitoring ingress frames received with cyclic redundancy code (CRC) errors for a period of time.</p> <ul style="list-style-type: none"> Enter threshold high high-frames to set a high threshold for the number of frames received with CRC errors. The range is 1 to 65535 frames. Enter threshold high none to disable the high threshold. Enter threshold low low-frames to set a low threshold in number of frames. The range is 0 to 65535. The default is 1. Enter window milliseconds to set the a window and period of time during which frames with CRC errors are counted. The range is 10 to 1800 and represents the number of milliseconds in multiples of 100. The default is 100.
Step 9	Switch(config-if)# [no] ethernet link-monitor on	(Optional) Starts or stop (when the no keyword is entered) link-monitoring operations on the interface. Link monitoring operations start automatically when support is enabled.
Step 10	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 11	Switch# show ethernet oam status [interface interface-id]	Verifies the configuration.
Step 12	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

The **ethernet oam link-monitor transmit-crc {threshold {high {high-frames | none} | low {low-frames}} | window milliseconds}** command is visible on the switch and you can enter it, but it is not supported. Enter the **no** form of the command to disable the configuration. Use the **no** form of each command to disable the threshold setting.

Symbol error counters are supported on the following line cards and supervisor engine cards:

- Supervisor engine cards: WS-X4515, WS-X4516, WS-X4013+, WS-X4013+TS, WS-X4516-10GE, WS-X4013+10GE
- Line cards: WS-X4148-RJ, WS-X4124-RJ, WS-X4232, WS-X4232-RJ-XX, WS-X4148-RJ21, WS-X4504-FX-MT, WS-X4224-RJ21-XX, WS-X4124-FX-MT, WS-X4232-L3

The rest of the cards do not support symbol error counters.

This example shows how to configure Ethernet OAM link monitoring:

```
Switch(config)# interface gi1/1
Switch(config-if)# ethernet oam link-monitor receive-crc threshold high 1000
Switch(config-if)# ethernet oam link-monitor receive-crc threshold low 10
Switch(config-if)# ethernet oam link-monitor symbol-period threshold high 5000
Switch(config-if)# ethernet oam link-monitor symbol-period threshold low 5
Switch(config-if)# ethernet oam link-monitor frame threshold high 8000
Switch(config-if)# ethernet oam link-monitor frame threshold low 8
Switch(config-if)# ethernet oam link-monitor frame-period threshold high 9000
Switch(config-if)# ethernet oam link-monitor frame-period threshold low 9
```

```
Switch# show ethernet oam status int gi1/1
```

```

```

Configuring Ethernet OAM Remote Failure Indications

You can configure an error-disable action to occur on an interface when the following occur:

- Crossing the high thresholds configured on the interface for link monitoring
- On reception of Dying Gasp, executing **shut** on the interface
- On reception of Dying Gasp, **executing reload** command
- On reception of Dying Gasp, **executing no ethernet oam** command on the interface

To enable Ethernet OAM remote-failure indication actions on an interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Defines an interface and enters interface configuration mode.
Step 3	Switch(config-if)# ethernet oam remote-failure [dying-gasp] action error-disable-interface	Configures the Ethernet OAM remote-failure action on the interface. You can configure disabling the interface by selecting dying-gasp to shut down the interface when Ethernet OAM is disabled or the interface enters the error-disabled state.
Step 4	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 5	Switch# show ethernet oam status [interface <i>interface-id</i>]	Verifies the configuration.
Step 6	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to configure Ethernet OAM remote-failure action on the switch interface:

```
Switch# conf terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# int g1/1
Switch(config-if)# ethernet oam remote-failure dying-gasp action error
Switch(config-if)# ethernet oam link-monitor high-threshold action error
Switch(config-if)# end
Switch# show running-config int g1/1
Building configuration...

Receive-Frame CRC Error

Window: 10 x 100 milliseconds
 Low threshold: 10 error frame(s)
 High threshold: none

Transmit-Frame CRC Error: Not Supported

To enable Ethernet OAM failover action on an EtherChannel interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface port-channel <i>interface-id</i>	Defines an interface and enters interface configuration mode.
Step 3	Switch(config-if)# switchport mode <i>mode</i>	Configures the mode of the EtherChannel interface.
Step 4	Switch(config-if)# ethernet oam link-monitor high-threshold action failover	Configures the Ethernet OAM remote-failure action on the port channel interface to failover. This action is configurable only for link monitoring RFI. If failover is configured on the EtherChannel interface, the interface is not error-disabled if it is the last member port of the EtherChannel.
Step 5	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 6	Switch# show ethernet oam status [<i>interface</i> <i>interface-id</i>]	Verifies the configuration.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

The switch does not generate Link Fault or Critical Event OAM PDUs. However, if these PDUs are received from a link partner, they are processed. The switch supports sending and receiving Dying Gasp OAM PDUs when Ethernet OAM is disabled, the interface is shut down, the interface enters the

error-disabled state, or the switch is reloading. It can respond to but not generate Dying Gasp PDUs based on loss of power. Enter the **no ethernet remote-failure {critical-event | dying-gasp | link-fault} action** command to disable the remote failure indication action.

Configuring Ethernet OAM Templates

You can create a template for configuring a common set of options on multiple Ethernet OAM interfaces. The template can be configured to monitor frame errors, frame-period errors, frame-second errors, received CRS errors, and symbol-period errors and thresholds. You can also set the template to put the interface in error-disabled state if any high thresholds are exceeded. These steps are optional and can be performed in any sequence or repeated to configure different options.

To configure an Ethernet OAM template and to associate it with an interface, follow these steps:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# template <i>template-name</i>	Creates a template and enters template configuration mode.
Step 3	Switch(config-template)# ethernet oam link-monitor receive-crc {threshold {high {<i>high-frames</i> none} low {<i>low-frames</i>}} window <i>milliseconds</i>}	<p>(Optional) Configures thresholds for monitoring ingress frames received with cyclic redundancy code (CRC) errors for a period of time.</p> <ul style="list-style-type: none"> • Enter threshold high <i>high-frames</i> to set a high threshold for the number of frames received with CRC errors. The range is 1 to 65535 frames. • Enter threshold high none to disable the high threshold. • Enter threshold low <i>low-frames</i> to set a low threshold in number of frames. The range is 0 to 65535. The default is 1. • Enter window <i>milliseconds</i> to set the a window and period of time during which frames with CRC errors are counted. The range is 10 to 1800 and represents the number of milliseconds in multiples of 100. The default is 100.

Command	Purpose
Step 4 Switch(config-template)# ethernet oam link-monitor symbol-period { threshold { high { <i>high symbols</i> / none } low { <i>low-symbols</i> }} window <i>symbols</i> }	(Optional) Configures high and low thresholds for an error-symbol period that triggers an error-symbol period link event. <ul style="list-style-type: none"> • Enter threshold high <i>high-symbols</i> to set a high threshold in number of symbols. The range is 1 to 65535. • Enter threshold high none to disable the high threshold. • Enter threshold low <i>low-symbols</i> to set a low threshold in number of symbols. The range is 0 to 65535. It must be lower than the high threshold. • Enter window <i>symbols</i> to set the window size (in number of symbols) of the polling period. The range is 1 to 65535 symbols.
Step 5 Switch(config-template)# ethernet oam link-monitor frame { threshold { high { <i>high-frames</i> none } low { <i>low-frames</i> }} window <i>milliseconds</i> }	(Optional) Configures high and low thresholds for error frames that trigger an error-frame link event. <ul style="list-style-type: none"> • Enter threshold high <i>high-frames</i> to set a high threshold in number of frames. The range is 1 to 65535. You must enter a high threshold. • Enter threshold high none to disable the high threshold. • Enter threshold low <i>low-frames</i> to set a low threshold in number of frames. The range is 0 to 65535. The default is 1. • Enter window <i>milliseconds</i> to set the a window and period of time during which error frames are counted. The range is 10 to 600 and represents the number of milliseconds in a multiple of 100. The default is 100.
Step 6 Switch(config-template)# ethernet oam link-monitor frame-period { threshold { high { <i>high-frames</i> none } low { <i>low-frames</i> }} window <i>frames</i> }	(Optional) Configures high and low thresholds for the error-frame period that triggers an error-frame-period link event. <ul style="list-style-type: none"> • Enter threshold high <i>high-frames</i> to set a high threshold in number of frames. The range is 1 to 65535. You must enter a high threshold. • Enter threshold high none to disable the high threshold. • Enter threshold low <i>low-frames</i> to set a low threshold in number of frames. The range is 0 to 65535. The default is 1. • Enter window <i>frames</i> to set the a polling window size in number of frames. The range is 1 to 65535; each value is a multiple of 10000 frames. The default is 1000.

	Command	Purpose
Step 7	Switch(config-template)# ethernet oam link-monitor frame-seconds {threshold {high {high-seconds none} low {low-seconds}} window milliseconds}	(Optional) Configures frame-seconds high and low thresholds for triggering an error-frame-seconds link event. <ul style="list-style-type: none"> Enter threshold high high-seconds to set a high threshold in number of seconds. The range is 1 to 900. You must enter a high threshold. Enter threshold high none to disable the high threshold. Enter threshold low low-frames to set a low threshold in number of frames. The range is 1 to 900. The default is 1. Enter window frames to set the a polling window size in number of frames. The range is 100 to 9000; each value is a multiple of 100 milliseconds. The default is 1000.
Step 8	Switch(config-template)# ethernet oam link-monitor high threshold action error-disable-interface	(Optional) Configures the switch to put an interface in an error disabled state when a high threshold for an error is exceeded.
Step 9	Switch(config-template)# exit	Returns to global configuration mode.
Step 10	Switch(config)# interface interface-id	Defines an Ethernet OAM interface and enters interface configuration mode.
Step 11	Switch(config-if# source-template template-name	Associates the template to apply the configured options to the interface.
Step 12	Switch(config-if# end	Returns to privileged EXEC mode.
Step 13	Switch# show ethernet oam status [interface interface-id]	Verifies the configuration.
Step 14	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

The switch does not support monitoring egress frames with CRC errors. The **ethernet oam link-monitor transmit-crc {threshold {high {high-frames | none} | low {low-frames}} | window milliseconds}** command is visible on the switch and you can enter it, but it is not supported. Use the **no** form of each command to remove the option from the template. Use the **no source-template template-name** command to remove the source template association.

The following example illustrates how to configure an Ethernet OAM template and to associate it with an interface:

```
Switch# conf t
Switch(config)# template oam
Switch(config-template)# ethernet oam link-monitor receive-crc threshold high 1000
Switch(config-template)# ethernet oam link-monitor receive-crc threshold low 10
Switch(config-template)# ethernet oam link-monitor symbol-period threshold high 5000
Switch(config-template)# ethernet oam link-monitor symbol-period threshold low 5
Switch(config-template)# ethernet oam link-monitor frame threshold high 8000
Switch(config-template)# ethernet oam link-monitor frame threshold low 8
Switch(config-template)# ethernet oam link-monitor frame-period threshold high 9000
Switch(config-template)# ethernet oam link-monitor frame-period threshold low 9
Switch(config-template)# ethernet oam link-monitor high action error-disable-interface
Switch(config-template)# exit
Switch(config)# int gi1/2
Switch(config-if)# source template oam
Switch(config-if)# end
```

```

Switch# show ethernet oam status int gi1/2
GigabitEthernet1/2
General
-----
Admin state:          enabled
Mode:                 active
PDU max rate:         10 packets per second
PDU min rate:         1 packet per 1 second
Link timeout:         5 seconds
High threshold action: error disable interface
Link fault action:    no action
Dying gasp action:    no action
Critical event action: no action

Link Monitoring
-----
Status: supported (on)

Symbol Period Error

Low threshold:       10 error frame(s)
High threshold:      1000 error frame(s)

Transmit-Frame CRC Error: Not Supported

```

Displaying Ethernet OAM Protocol Information

To display Ethernet OAM protocol information, you can use the privileged EXEC commands in [Table 77-4](#).

Table 77-4 *Displaying Ethernet OAM Protocol Information*

Command	Purpose
show ethernet oam discovery [interface interface-id]	Displays discovery information for all Ethernet OAM interfaces or the specified interface.
show ethernet oam statistics [interface interface-id]	Displays detailed information about Ethernet OAM packets.
show ethernet oam status [interface interface-id]	Displays Ethernet OAM configuration for all interfaces or the specified interface.
show ethernet oam summary	Displays active Ethernet OAM sessions on the switch.

These examples show how to apply these commands:

```
Switch# show ethernet oam discovery

Ethernet CFM and Ethernet OAM Interaction

You can also configure the OAM Manager infrastructure to interact between CFM and Ethernet OAM. When the Ethernet OAM protocol is running on an interface that has CFM MEPs configured, Ethernet OAM informs CFM of the state of the interface. Interaction is unidirectional from the Ethernet OAM to the CFM protocol, and the only information exchanged is your (user) network interface port status.

The Ethernet OAM protocol notifies CFM when these conditions occur:

- Error thresholds are crossed at the local interface.

CFM responds to the notification by sending a port status of *Local_Excessive_Errors* in the Port StatusType Length Value (TLV).

- Ethernet OAM receives an OAM PDU from the remote side showing that an error threshold is exceeded on the remote endpoint.

CFM responds to the notification by sending a port status of *Remote_Excessive_Errors* in the Port Status TLV.

- The local port is set into loopback mode.

CFM responds by sending a port status of Test in the Port Status TLV.

- The remote port is set into loopback mode.

CFM responds by sending a port status of Test in the Port Status TLV.

This section includes this information:

- [Configuring Ethernet OAM Interaction with CFM, page 77-51](#)
- [Example: Configuring Ethernet OAM and CFM, page 77-53](#)

For more information about CFM and interaction with Ethernet OAM, see the Ethernet Connectivity Fault Management feature module at this URL:

http://www.cisco.com/en/US/docs/ios/12_2sr/12_2sra/feature/guide/srethcfm.html

Configuring Ethernet OAM Interaction with CFM

For Ethernet OAM to function with CFM, you must configure an Ethernet Virtual Circuit (EVC) and the OAM manager, and associate the EVC with CFM. You must use an inward facing MEP for interaction with the OAM manager.

Note

If you configure, change, or remove a UNI service type, EVC, Ethernet service instance, or CE-VLAN configuration, all configurations are verified to ensure that the UNI service types match the EVC configuration and that Ethernet service instances are matched with the CE-VLAN configuration. Configurations are rejected if the pairs do not match.

Configuring the OAM Manager

To configure the OAM manager on a PE device, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Defines an interface to configure as an Ethernet OAM interface and enter interface configuration mode.
Step 3	Switch(config-if)# ethernet cfm domain <i>domain-name</i> level <i>level-id</i>	Defines a CFM domain, set the domain level, and enter ethernet-cfm configuration mode for the domain. The maintenance level number range is 0 to 7.
Step 4	Switch(config-if)# service <i>csi-id</i> vlan <i>vlan-id</i>	Defines a universally unique customer service instance (CSI) and VLAN ID within the maintenance domain. <ul style="list-style-type: none"> <i>csi-id</i>—String of no more than 100 characters that identifies the CSI. <i>vlan-id</i>—VLAN range is from 1 to 4095. You cannot use the same VLAN ID for more than one domain at the same level.
Step 5	Switch(config-if)# exit	Returns to global configuration mode.
Step 6	Switch(config)# ethernet evc <i>evc-id</i>	Defines an EVC, and enter EVC configuration mode
Step 7	Switch(config-evc)# oam protocol cfm svlan <i>vlan-id</i> domain <i>domain-name</i>	Configures the EVC OAM protocol as CFM, and identify the service provider VLAN-ID (S-VLAN-ID) for the CFM domain maintenance level as configured in Steps 2 and 3.
Step 8	Switch(config-evc)# exit	Returns to global configuration mode.
Step 9	Repeat Steps 2 through 7 to define other CFM domains that you want OAM manager to monitor.	
Step 10	Switch(config)# ethernet cfm enable	Globally enables CFM.
Step 11	Switch(config)# end	Returns to privileged EXEC mode.
Step 12	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Enabling Ethernet OAM

To enable Ethernet OAM on an interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Defines an interface to configure as an Ethernet OAM interface and enter interface configuration mode.

	Command	Purpose
Step 3	Switch(config-if)# ethernet oam [max-rate <i>oampdus</i> / min-rate <i>seconds</i> / mode { active / passive } timeout <i>seconds</i>]	Enables Ethernet OAM on the interface <ul style="list-style-type: none"> • (Optional) Enter max-rate <i>oampdus</i> to set the maximum rate (per second) to send OAM PDUs. The range is 1 to 10 PDUs per second; the default is 10. • (Optional) Enter min-rate <i>seconds</i> to set the minimum rate in seconds. The range is 1 to 10 seconds. • (Optional) Set the OAM client mode as active or passive. The default is active. • (Optional) Enter timeout <i>seconds</i> to set the time after which a device declares the OAM peer to be nonoperational and resets its state machine. The range is 2 to 30 seconds; the default is 5 seconds.
Step 4	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.
Step 6	Switch# show ethernet cfm maintenance points remote	(Optional) Displays the port states as reported by Ethernet OAM.

Example: Configuring Ethernet OAM and CFM

These are configuration examples of the interworking between Ethernet OAM and CFM in a sample service provider network. This example network would contain a provider-edge switch connected to a customer edge switch at each endpoint. You must configure CFM, E-LMI, and Ethernet OAM between the customer edge and the provider edge switch.

Customer-edge switch 1 (CE1) configuration:

```
Switch# config terminal
Switch(config)# interface GigabitEthernet1/1
Switch(config-if)# switchport trunk allowed vlan 10
Switch(config-if)# switchport mode trunk
Switch(config-if)# ethernet oam remote-loopback supported
Switch(config-if)# ethernet oam
Switch(config-if)# exit
```

Provider-edge switch 1 (PE1) configuration:

```
Switch# config terminal
Switch(config)# interface FastEthernet1/20
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# ethernet cfm mip level 7
Switch(config-if)# ethernet cfm mep level 4 mpid 100 vlan 100
Switch(config-if)# ethernet oam remote-loopback supported
Switch(config-if)# ethernet oamt
```

Provider-edge switch 2 (PE2) configuration:

```
Switch# config terminal
Switch(config)# interface GigabitEthernet1/20
Switch(config-if)# switchport mode trunk
Switch(config-if)# ethernet cfm mip level 7
Switch(config-if)# ethernet cfm mep level 4 mpid 101 vlan 10
Switch(config-if)# ethernet oam remote-loopback supported
```

```
Switch(config-if)# ethernet oam
```

Customer-edge switch 2 (CE2) configuration:

```
Switch# config terminal
Switch(config)# interface GigabitEthernet1/1
Switch(config-if)# switchport trunk allowed vlan 10
Switch(config-if)# switchport mode trunk
Switch(config-if)# ethernet oam remote-loopback supported
Switch(config-if)# ethernet oam
Switch(config-if)# exit
```

These output examples show provider-edge switch port status of the configuration. Port status shows as *UP* at both switches.

Switch PE1:

```
Switch# show ethernet cfm maintenance points remote
MPID Level Mac Address      Vlan PortState InGressPort      Age(sec) Service ID
101 * 4      0015.633f.6900 10   UP          Gi1/1            27      blue
```

Switch PE2:

```
Switch# show ethernet cfm maintenance points remote
MPID Level Mac Address      Vlan PortState InGressPort      Age(sec) Service ID
100 * 4      0012.00a3.3780 10   UP          Gi1/1            8       blue
Total Remote MEPs: 1
```

This example shows the output when you start remote loopback on CE1 (or PE1). The port state on the remote PE switch shows as *Test* and the remote CE switch enters into error-disable mode.

```
Switch# ethernet oam remote-loopback start interface gigabitethernet 1/1
it is a intrusive loopback.
Therefore, while you test Ethernet OAM MAC connectivity,
you will be unable to pass traffic across that link.
Proceed with Remote Loopback? [confirm]
```

Switch PE1:

```
Switch# show ethernet cfm maintenance points remote
MPID Level Mac Address      Vlan PortState InGressPort      Age(sec) Service ID
101 * 4      0015.633f.6900 10   UP          Gi1/1            27      blue
```

Switch PE2:

```
Switch# show ethernet cfm maintenance points remote
MPID Level Mac Address      Vlan PortState InGressPort      Age(sec) Service ID
100 * 4      0012.00a3.3780 10   TEST       Gi1/1            8       blue
Total Remote MEPs: 1
```

In addition, if you shut down the CE1 interface that connects to PE1, the remote PE2 port shows a PortState of *Down*.

Configuring Y.1731 (AIS and RDI)

The Catalyst 4500 series switch supports Y.1731 Ethernet Alarm Indication Signal function (ETH-AIS) and Ethernet Remote Defect Indication function (ETH-RDI) to provide fault and performance management for service providers in large networks. This chapter describes how to configure Y.1731 ETH-AIS and ETH-RDI.

This chapter contains these sections:

- [AIS and RDI Terminology, page 78-1](#)
- [About Y.1731, page 78-2](#)
- [Configuring Y.1731, page 78-4](#)
- [Displaying Y.1731 Information, page 78-5](#)

For complete command and configuration information for Y.1731, see the Cisco IOS feature module at this URL:

<http://www.cisco.com/en/US/docs/ios-xml/ios/cether/configuration/12-2sr/ce-cfm-y1731.html>

AIS and RDI Terminology

Term	Definition
CC	Ethernet OAM Continuity Check
CCM	Ethernet OAM Continuity Check Message
CCDB	Ethernet OAM Continuity Check Database
CFM	Ethernet Connectivity Fault Management
EI	Ethernet Infrastructure or EVC Infrastructure
EVC	Ethernet Virtual Circuit
LMEP	Local Mep
MEP	Maintenance Endpoint
MIP	Maintenance Intermediate Point
OAM	Operations Administration and Maintenance
Service VLAN	The VLAN tag that uniquely identifies a Customer Service Instance within the Provider network

About Y.1731

These sections contain conceptual information about Y.1731:

- [Server MEP, page 78-2](#)
- [Alarm Indication Signal, page 78-2](#)
- [Ethernet Remote Defect Indication, page 78-3](#)

The advent of Ethernet as a metropolitan and WAN technology imposes a new set of Operations, Administration, and Maintenance (OAM) requirements on Ethernet's traditionally Enterprise-oriented functions. The expansion of this technology into the larger and more complex wider user base makes operational management of link uptime crucial. Isolating and responding to failures quickly directly affects the competitiveness of the service provider.

Server MEP

A Server MEP is a combined function of the server layer termination function and the server and ETH adaptation function. It issues frames with ETH-AIS information upon detecting a defect at the Server layer by the server layer termination function or the adaptation function.

A Virtual MEP represents the logical termination point of Connectivity Fault Management (CFM) MAs defined at the link or transport layer. A server MEP runs or is defined at Maintenance Level -1. For example, you could associate an outward-facing Server MEP with each termination point of IEEE 802.3ah OAM, or with each termination point of MPLS PW OAM.

Alarm Indication Signal

ETH-AIS allows you to suppress alarms when defects are detected at the server (sub) layer. Because of STP's ability to restore, you would not expect to apply ETH-AIS in the STP environments. For the Catalyst 4500 Metro switch, an administrator can enable and disable AIS in the STP environment.

You can enable or disable transmission of frames with ETH-AIS information on a MEP (or on a Server MEP).

You also can issue frames with ETH-AIS information at the client Maintenance Level by a MEP, including a Server MEP upon detecting defect conditions.

The defect conditions may include:

- Signal fail conditions with ETH-CC enabled
- AIS condition with ETH-CC disabled

For multipoint ETH connectivity, a MEP cannot determine the specific server (sub) layer entity that has encountered defect conditions upon receiving a frame with ETH-AIS information. More importantly, it cannot determine the associated subset of its peer MEPs for which it should suppress alarms because the received ETH-AIS information does not contain that information. When a MEP receives a frame with ETH-AIS information, it suppresses alarms for all peer MEPs whether there is still connectivity or not.

For a point-to-point ETH connection, however, a MEP has only one peer MEP. There is no ambiguity regarding the peer MEP for which it should suppress alarms when it receives the ETH-AIS information.

Only a MEP, including a Server MEP, is configured to issue frames with ETH-AIS information. Once the MEP detects a defect condition, it immediately starts transmitting periodic frames with ETH-AIS information at a configured client maintenance level. We send the AIS frames at a configured MIP level

for an interface. A MEP continues to transmit periodic frames with ETH-AIS information until the defect condition is removed. Upon receiving a frame with ETH-AIS information, a MEP detects AIS condition and suppresses loss of continuity alarms associated with all its peer MEPs. A MEP resumes loss of continuity alarm generation upon detecting loss of continuity defect conditions in the absence of AIS condition.

Ethernet Remote Defect Indication

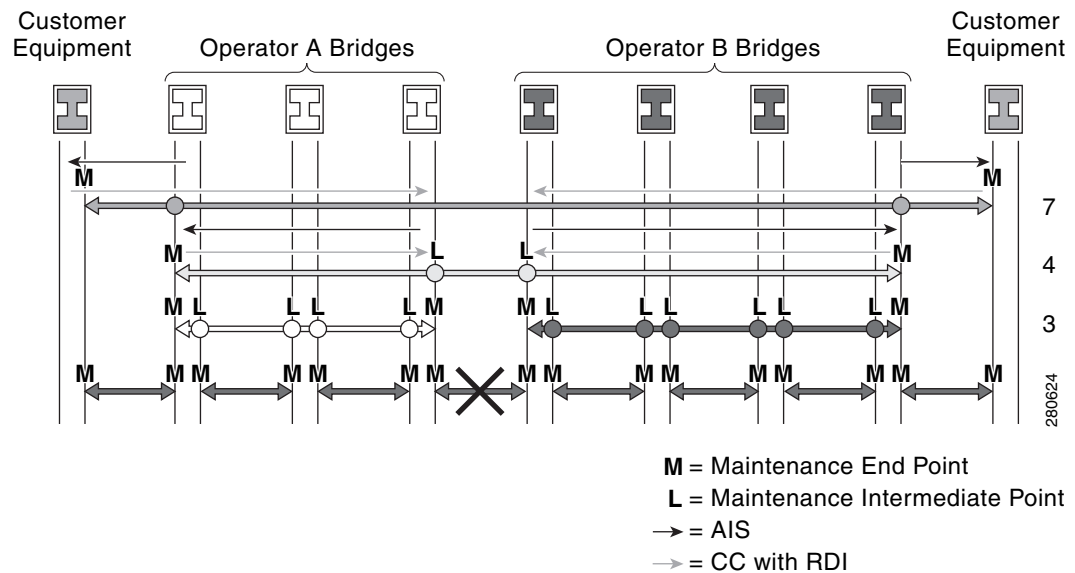

A MEP can use ETH-RDI to notify its peer MEPs that it detects a defect condition. ETH-RDI is used only when ETH-CC transmission is enabled.

ETH-RDI has the following two applications:

- Single-ended fault management—The receiving MEP detects an RDI defect condition, which is correlated with other defect conditions in this MEP and may cause a fault. The absence of received ETH-RDI information in a single MEP indicates the absence of defects in the entire maintenance.
- Contribution to far-end performance monitoring— It reflects a defect condition in the far-end which serves as input to the performance monitoring process.

A MEP that is in a defect condition transmits frames with ETH-RDI information. A MEP, upon receiving frames with ETH-RDI information, determines that its peer MEP has encountered a defect condition. For multipoint ETH connectivity, however, a MEP, upon receiving frames with ETH-RDI information, cannot determine the associated subset of its peer MEPs with which the MEP transmitting RDI information encounters defect conditions. It is because the transmitting MEP itself does not always have that information.

Figure 78-1 Generating and Propagating AIS Messages Upon a Defect (Link Fail)

Configuring Y.1731

Note

Y.1731 is enabled by default.

These sections are included:

- [Y.1731 Configuration Guidelines, page 78-4](#)
- [Configuring AIS Parameters, page 78-4](#)
- [Clearing MEP from the AIS Defect Condition, page 78-5](#)
- [Clearing SMEP from the AIS Defect Condition, page 78-5](#)

Y.1731 Configuration Guidelines

Configuration guidelines and restrictions for Y.1731 include the following:

- Because of STP’s restoration capability, do not expect ETH-AIS to be applied in the STP environments.
- AIS is enabled by default on a CFM maintenance domain. The following section illustrates the commands you can use to disable AIS on a maintenance domain. Likewise, RDI is a flag bit in the CC message. Provided CC transmission is enabled, the present RDI flag of the CC message is set to true or false.

Configuring AIS Parameters

To set the parameters for AIS, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch (config)# ethernet cfm ais domain name vlan range	Enters <i>config-ais-mep-cfm</i> submode to configure parameters for all local Meps belonging to that per Maintenance Association (MA). <i>name</i> refers to the domain name. <i>range</i> represents VLAN IDs 100, 200-300, 400, 500, or 1-4095 For the domain name vlan range command only configurations that are VLAN disjoint or congruent are accepted.
Step 3	Switch(config-ais-mep-cfm)# disable	Disables AIS transmission.
Step 4	Switch(config-ais-mep-cfm)# period period	Sets the AIS transmission period.
Step 5	Switch(config-ais-mep-cfm)# level level	Establishes a maintenance level to send AIS frames for MEPs belonging to MA. Valid levels are 0 to 7.

	Command	Purpose
Step 6	Switch(config-ais-mep-cfm) # expiry-threshold threshold	Sets the AIS expiry threshold. By default, expiry threshold is 3.5. With this CLI we can change the expiry threshold parameter for MA.
Step 7	Switch(config-ais-mep-cfm) # express alarm	Configures alarm suppression when an AIS message causes the MEP enters an AIS defect condition.
Step 8	Switch(config-ais-mep-cfm) # exit	Returns to global configuration.
Step 9	Switch(config)# [no] ethernet cfm ais link-status global	Enters <i>config-ais-link-cfm</i> submode, enabling you to configure parameters required to follow when link status goes down.
Step 10	Switch(config-if)# [no] ethernet cfm ais link-status period period	Configures ETH-AIS transmission period generated by the link-status on the interface.
Step 11	Switch(config-if)# [no] ethernet cfm ais link-status level level	Configures maintenance level to send AIS frames transmitted by the link-status on the interface.
Step 12	end	Returns to privileged EXEC mode.
Step 13	Switch# show ethernet cfm smep interface name Switch# show ethernet cfm maintenance-points local detail Switch# show ethernet cfm maintenance-points remote detail Switch# show ethernet cfm error	Verifies the configuration.
Step 14	Switch# show running-config	Verifies your entries.
Step 15	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no** versions of the commands to remove the configuration or return to the default configurations.

Clearing MEP from the AIS Defect Condition

To clear the MEP, enter one of the following commands:

```
Switch# clear ethernet cfm ais domain domain name mpid local mpid vlan vlan#
Switch# clear ethernet cfm ais domain domain name mpid local mpid evc evc_name
```

Clearing SMEP from the AIS Defect Condition

To clear the CSMP, enter one of the following commands:

```
Switch# clear ethernet cfm ais link-status interface interface_name
Switch# clear ethernet cfm error
```

Note

This operation also clears all error conditions including AIS.

Displaying Y.1731 Information

To display Y.1731 information, you can use the following commands ([Table 78-1](#)).

Table 78-1 **Displaying Y.1731 Information**

Command	Purpose
<code>show ethernet cfm maintenance-point local detail</code>	Displays AIS status and defect condition on local maintenance points.
<code>show ethernet cfm smep [interface <name>]</code>	Displays AIS status and defect condition on SMEP.
<code>show ethernet cfm error</code>	Displays errors due to AIS defect condition.
<code>show ethernet cfm maintenance-points remote [detail]</code>	Displays AIS status and defect Condition on remote maintenance points.

This example shows how to track the RDI defect and to verify the configuration parameters:

```

Configuring Call Home

This chapter describes how to configure the Call Home feature in Catalyst 4500 Series Switch.

This chapter includes the following sections:

- [About Call Home, page 79-1](#)
- [Obtaining Smart Call Home, page 79-2](#)
- [Configuring Call Home, page 79-3](#)
- [Configuring Contact Information, page 79-4](#)
- [Configuring Destination Profiles, page 79-5](#)
- [Subscribing to Alert Groups, page 79-6](#)
- [Configuring General E-Mail Options, page 79-9](#)
- [Enabling Call Home, page 79-10](#)
- [Testing Call Home Communications, page 79-10](#)
- [Configuring and Enabling Smart Call Home, page 79-13](#)
- [Displaying Call Home Configuration Information, page 79-13](#)
- [Call Home Default Settings, page 79-18](#)
- [Alert Group Trigger Events and Commands, page 79-18](#)
- [Message Contents, page 79-21](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Call Home

Call Home provides e-mail-based and web-based notification of critical system events. A versatile range of message formats are available for optimal compatibility with pager services, standard e-mail, or XML-based automated parsing applications. Common uses of this feature may include direct paging of

a network support engineer, e-mail notification to a Network Operations Center, XML delivery to a support website, and utilization of Cisco Smart Call Home services for direct case generation with the Cisco Systems Technical Assistance Center (TAC).

The Call Home feature can deliver alert messages containing information on configuration, diagnostics, environmental conditions, inventory, and syslog events.

The Call Home feature can deliver alerts to multiple recipients, referred to as *Call Home destination profiles*, each with configurable message formats and content categories. A predefined destination profile is provided for sending alerts to the Cisco TAC (callhome@cisco.com), and you also can define your own destination profiles.

Flexible message delivery and format options make it easy to integrate specific support requirements.

The Call Home feature offers the following advantages:

- Multiple message-format options:
 - Short Text—Suitable for pagers or printed reports.
 - Plain Text—Full formatted message information suitable for human reading.
 - XML—Matching readable format using Extensible Markup Language (XML) and Adaptive Markup Language (AML) document type definitions (DTDs). The XML format enables communication with the Cisco TAC.
- Multiple concurrent message destinations.
- Multiple message categories including configuration, diagnostics, environmental conditions, inventory, and syslog events.
- Filtering of messages by severity and pattern matching.
- Scheduling of periodic message sending.

Obtaining Smart Call Home

If you have a service contract directly with Cisco Systems, you can register your devices for the Smart Call Home service. Smart Call Home provides fast resolution of system problems by analyzing Call Home messages sent from your devices and providing background information and recommendations. For issues that can be identified as known, particularly GOLD diagnostics failures, Automatic Service Requests will be generated with the Cisco TAC.

Smart Call Home offers the following features:

- Boot-up diagnostics alerts for line cards and supervisor engines in the chassis.
- Analysis of Call Home messages from your device, and where appropriate Automatic Service Request generation, routed to the appropriate TAC team, including detailed diagnostic information to speed problem resolution.
- Secure message transport directly from your device or through a downloadable Transport Gateway (TG) aggregation point. You can use a TG aggregation point in cases requiring support for multiple devices or in cases where security requirements mandate that your devices may not be connected directly to the Internet.
- Web-based access to Call Home messages and recommendations, inventory and configuration information for all Call Home devices. Provides access to associated field notices, Security Advisories, and End-of-Life information.

You need to register the following items:

- The SMARTnet contract number for your switch
- Your e-mail address
- Your Cisco.com ID

For detailed information on Smart Call Home, refer to the Smart Call Home page at this URL:

http://supportforums.cisco.com/community/netpro/solutions/smart_services/smartcallhome

Configuring Call Home

How you configure Call Home depends on how you intend to use the feature. Consider the following information before you configure Call Home:

- At least one destination profile (predefined or user-defined) must be configured. The destination profile(s) used depends on whether the receiving entity is a pager, e-mail, or automated service such as Cisco Smart Call Home.
 - If the destination profile uses e-mail message delivery, you must specify a Simple Mail Transfer Protocol (SMTP) server.
 - If the destination profile uses secure HTTP (HTTPS) message transport, you must configure a trustpoint certificate authority (CA).
- The contact e-mail, phone, and street address information should be configured so that the receiver can determine the origin of messages received.
- The switch must have IP connectivity to an e-mail server or the destination HTTP server using the **ip domain name** command.
- If Cisco Smart Call Home is used, an active service contract must cover the device being configured.

To configure Call Home, follow these steps:

-
- | | |
|---------------|--|
| Step 1 | Configure your site's contact information. |
| Step 2 | Configure destination profiles for each of your intended recipients. |
| Step 3 | Subscribe each destination profile to one or more alert groups, and set alert options. |
| Step 4 | Configure e-mail settings or HTTPS settings (including CA certificate), depending on the transport method. |
| Step 5 | Enable the Call Home feature. |
| Step 6 | Test Call Home messages. |
-

Tip

From the Smart Call Home web application, you can download a basic configuration script to assist you in the configuration of the Call Home feature for use with Smart Call Home and the Cisco TAC. The script will also assist in configuring the trustpoint CA for secure communications with the Smart Call Home service. The script, provided on an as-is basis, can be downloaded from this URL:

http://supportforums.cisco.com/community/netpro/solutions/smart_services/smartcallhome

Configuring Contact Information

Each switch must include a contact e-mail address. You can optionally include a phone number, street address, contract ID, customer ID, and site ID.

To assign the contact information, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch(config)# call-home	Enters the Call Home configuration submode.
Step 3	Switch(cfg-call-home)# contact-email-addr <i>email-address</i>	Assigns the customer's e-mail address. Enter up to 200 characters in e-mail address format with no spaces.
Step 4	Switch(cfg-call-home)# phone-number <i>+phone-number</i>	(Optional) Assigns the customer's phone number. Note The number must begin with a plus (+) prefix, and may contain only dashes (-) and numbers. Enter up to 16 characters. If you include spaces, you must enclose your entry in quotes ("").
Step 5	Switch(cfg-call-home)# street-address <i>street-address</i>	(Optional) Assigns the customer's street address where RMA equipment can be shipped. Enter up to 200 characters. If you include spaces, you must enclose your entry in quotes ("").
Step 6	Switch(cfg-call-home)# customer-id <i>text</i>	(Optional) Identifies the customer ID. Enter up to 64 characters. If you include spaces, you must enclose your entry in quotes ("").
Step 7	Switch(cfg-call-home)# site-id <i>text</i>	(Optional) Identifies the customer site ID. Enter up to 200 characters. If you include spaces, you must enclose your entry in quotes ("").
Step 8	Switch(cfg-call-home)# contract-id <i>text</i>	(Optional) Identifies the customer's contract ID for the switch. Enter up to 64 characters. If you include spaces, you must enclose your entry in quotes ("").

This example shows the configuration of contact information:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# call-home
Switch(cfg-call-home)# contact-email-addr username@example.com
Switch(cfg-call-home)# phone-number +1-800-555-4567
Switch(cfg-call-home)# street-address "1234 Picaboo Street, Any city, Any state, 12345"
Switch(cfg-call-home)# customer-id Customer1234
Switch(cfg-call-home)# site-id Site1ManhattanNY
Switch(cfg-call-home)# contract-id Company1234
Switch(cfg-call-home)# exit
Switch(config)#
```

Configuring Destination Profiles

A destination profile contains the required delivery information for an alert notification. At least one destination profile is required. You can configure multiple destination profiles of one or more types.

You can use the predefined destination profile or define a desired profile. If you define a new destination profile, you must assign a profile name.

Note

If you use the Cisco Smart Call Home service, the destination profile must use the XML message format.

You can configure the following attributes for a destination profile:

- **Profile name**—A string that uniquely identifies each user-defined destination profile. The profile name is limited to 31 characters and is not case-sensitive. You cannot use **all** as a profile name.
- **Transport method**—The transport mechanism, either e-mail or HTTP (including HTTPS), for delivery of alerts.
 - For user-defined destination profiles, e-mail is the default, and you can enable either or both transport mechanisms. If you disable both methods, e-mail will be enabled.
 - For the predefined Cisco TAC profile, you can enable either transport mechanism, but not both.
- **Destination address**—The actual address related to the transport method to which the alert should be sent.
- **Message formatting**—The message format used for sending the alert.
 - For user-defined destination profiles, the format options are long-text, short-text, or XML. The default is XML.
 - For the predefined Cisco TAC profile, only XML is allowed.
- **Message size**—The maximum destination message size. The valid range is 50 to 3,145,728 bytes and the default is 3,145,728 bytes.

To create and configure a destination profile, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch(config)# call-home	Enters the Call Home configuration submode.
Step 3	Switch(cfg-call-home)# profile name	Enters the Call Home destination profile configuration submode for the specified destination profile. If the specified destination profile does not exist, it is created.
Step 4	Switch(cfg-call-home-profile)# [no] destination transport-method {email http}	(Optional) Enables the message transport method. The no option disables the method.
Step 5	Switch(cfg-call-home-profile)# destination address {email email-address http url}	Configures the destination e-mail address or URL to which Call Home messages will be sent. Note When entering a destination URL, include either http:// or https:// , depending on whether the server is a secure server. If the destination is a secure server, you must also configure a trustpoint CA.
Step 6	Switch(cfg-call-home-profile)# destination preferred-msg-format {long-text short-text xml}	(Optional) Configures a preferred message format. The default is XML.

	Command	Purpose
Step 7	Switch(cfg-call-home-profile)# destination message-size-limit <i>bytes</i>	(Optional) Configures a maximum destination message size for the destination profile.
Step 8	Switch(cfg-call-home-profile)# active	Enables the destination profile. By default, the profile is enabled when it is created.
Step 9	Switch(cfg-call-home-profile)# exit	Exits the Call Home destination profile configuration submode and returns to the Call Home configuration submode.
Step 10	Switch(cfg-call-home)# end	Returns to privileged EXEC mode.
Step 11	Switch# show call-home profile { <i>name</i> all }	Displays the destination profile configuration for a specified profile or all configured profiles.

Copying a Destination Profile

To create a new destination profile by copying an existing profile, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch(config)# call-home	Enters the Call Home configuration submode.
Step 3	Switch(cfg-call-home)# copy profile <i>source-profile target-profile</i>	Creates a new destination profile with the same configuration settings as the existing destination profile.

Subscribing to Alert Groups

An alert group is a predefined subset of Call Home alerts supported on the switch. Different types of Call Home alerts are grouped into different alert groups depending on their type. These alert groups are available:

- Configuration
- Diagnostic
- Environment
- Inventory
- Syslog

The triggering events for each alert group are listed in the [“Alert Group Trigger Events and Commands” section on page 79-18](#), and the contents of the alert group messages are listed in the [“Message Contents” section on page 79-21](#).

You can select one or more alert groups to be received by a destination profile.

Note

A Call Home alert is only sent to destination profiles that have subscribed to the alert group containing that Call Home alert. In addition, the alert group must be enabled.

To subscribe a destination profile to an alert group, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch(config)# call-home	Enters Call Home configuration submode.
Step 3	Switch(cfg-call-home)# alert-group { all configuration diagnostic environment inventory syslog }	Enables the specified alert group. Use the keyword all to enable all alert groups. By default, all alert groups are enabled.
Step 4	Switch(cfg-call-home)# profile name	Enters the Call Home destination profile configuration submode for the specified destination profile.
Step 5	Switch(cfg-call-home-profile)# subscribe-to-alert-group configuration [periodic { daily <i>hh:mm</i> monthly <i>date hh:mm</i> weekly <i>day hh:mm</i> }]	Subscribes this destination profile to the Configuration alert group. The Configuration alert group can be configured for periodic notification, as described in the “ Configuring Periodic Notification ” section on page 79-8.
	Switch(cfg-call-home-profile)# subscribe-to-alert-group all	Subscribes to all available alert groups.
Step 6	Switch(cfg-call-home-profile)# subscribe-to-alert-group diagnostic [severity <i>catastrophic</i> <i>disaster</i> <i>fatal</i> <i>critical</i> <i>major</i> <i>minor</i> <i>warning</i> <i>notification</i> <i>normal</i> <i>debugging</i>]	Subscribes this destination profile to the Diagnostic alert group. The Diagnostic alert group can be configured to filter messages based on severity, as described in the “ Configuring Message Severity Threshold ” section on page 79-8.
Step 7	Switch(cfg-call-home-profile)# subscribe-to-alert-group environment [severity <i>catastrophic</i> <i>disaster</i> <i>fatal</i> <i>critical</i> <i>major</i> <i>minor</i> <i>warning</i> <i>notification</i> <i>normal</i> <i>debugging</i>]	Subscribes this destination profile to the Environment alert group. The Environment alert group can be configured to filter messages based on severity, as described in the “ Configuring Message Severity Threshold ” section on page 79-8.
Step 8	Switch(cfg-call-home-profile)# subscribe-to-alert-group inventory [periodic { daily <i>hh:mm</i> monthly <i>date hh:mm</i> weekly <i>day hh:mm</i> }]	Subscribes this destination profile to the Inventory alert group. The Inventory alert group can be configured for periodic notification, as described in the “ Configuring Periodic Notification ” section on page 79-8.
Step 9	Switch(cfg-call-home-profile)# subscribe-to-alert-group syslog [severity <i>catastrophic</i> <i>disaster</i> <i>fatal</i> <i>critical</i> <i>major</i> <i>minor</i> <i>warning</i> <i>notification</i> <i>normal</i> <i>debugging</i>] [pattern <i>string</i>]	Subscribes this destination profile to the Syslog alert group. The Syslog alert group can be configured to filter messages based on severity, as described in the “ Configuring Message Severity Threshold ” section on page 79-8. You can specify a pattern to be matched in the syslog message. If the pattern contains spaces, you must enclose it in quotes (“”).
Step 10	Switch(cfg-call-home-profile)# exit	Exits the Call Home destination profile configuration submode.

Configuring Periodic Notification

When you subscribe a destination profile to either the Configuration or the Inventory alert group, you can choose to receive the alert group messages asynchronously or periodically at a specified time. The sending period can be one of the following:

- **Daily**—Specify the time of day to send, using an hour:minute format *hh:mm*, with a 24-hour clock (for example, 14:30).
- **Weekly**—Specify the day of the week and time of day in the format *day hh:mm*, where the day of the week is spelled out (for example, monday).
- **Monthly**—Specify the numeric date, from 1 to 31, and the time of day, in the format *date hh:mm*.

Configuring Message Severity Threshold

When you subscribe a destination profile to the Diagnostic, Environment, or Syslog alert group, you can set a threshold for sending alert group messages based on the message's level of severity. Any message with a value lower than the threshold is not sent to the destination.

The severity threshold is configured using the keywords in [Table 79-1](#), and ranges from catastrophic (level 9, highest level of urgency) to debugging (level 0, lowest level of urgency). If no severity threshold is configured, the default is normal (level 1).

Note

Call Home severity levels differ from the system message logging severity levels.

Table 79-1 Severity and Syslog Level Mapping

Level	Keyword	Syslog Level	Description
9	catastrophic	N/A	Network-wide catastrophic failure
8	disaster	N/A	Significant network impact
7	fatal	Emergency (0)	System unusable
6	critical	Alert (1)	Critical conditions, immediate attention needed
5	major	Critical (2)	Major conditions
4	minor	Error (3)	Minor conditions
3	warning	Warning (4)	Warning conditions
2	notification	Notice (5)	Basic notification and informational messages; possibly independently insignificant
1	normal	Information (6)	Normal event signifying return to normal state
0	debugging	Debug (7)	Debugging messages

Configuring Syslog Pattern Matching

When you subscribe a destination profile to the Syslog alert group, you can optionally specify a text pattern to be matched within each syslog message. If you configure a pattern, a Syslog alert group message will be sent only if it contains the specified pattern and meets the severity threshold. If the pattern contains spaces, you must enclose it in quotes (") when configuring it. You can specify up to five patterns for each destination profile.

Configuring General E-Mail Options

To use the e-mail message transport, you must configure at least one Simple Mail Transfer Protocol (SMTP) e-mail server address. You can configure the from and reply-to e-mail addresses, and you can specify up to four backup e-mail servers. You can also set a rate limit on e-mail or HTTP messages.

Starting with Cisco IOS Release 15.0(2)SG, you can configure the vrf and source interface or source IP address to send the e-mail messages. If you want to configure similar options to send http messages, you must enter the **ip http client source-interface** *interface-name* command where the source-interface can be associated with the vrf you want to set.

To configure general e-mail options, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch(config)# call-home	Enters Call Home configuration submode.
Step 3	Switch(cfg-call-home)# mail-server {ipv4-address name} priority number	Assigns an e-mail server address and its relative priority among configured e-mail servers. Provide either of these: <ul style="list-style-type: none"> The e-mail server's IP address The e-mail server's fully qualified domain <i>name</i> (FQDN) of 64 characters or less. Assign a priority <i>number</i> between 1 (highest priority) and 100 (lowest priority).
Step 4	Switch(cfg-call-home)# sender from email-address	(Optional) Assigns the e-mail address that will appear in the from field in Call Home e-mail messages. If no address is specified, the contact e-mail address is used.
Step 5	Switch(cfg-call-home)# sender reply-to email-address	(Optional) Assigns the e-mail address that will appear in the reply-to field in Call Home e-mail messages.
Step 6	Switch(cfg-call-home)# rate-limit number	(Optional) Specifies a limit on the number of messages sent per minute, from 1 to 60. The default is 20.
Step 7	Switch(cfg-call-home)# vrf vrf-name	(Optional) Specifies the VRF instance to send Call Home e-mail messages. If no VRF is specified, the global routing table is used.
Step 8	Switch(cfg-call-home)# source-interface interface-name	(Optional) Specifies the source interface name to send Call Home e-mail messages. If no source interface name or source ip address is specified, an interface in the routing table is used.
Step 9	Switch(cfg-call-home)# source-ip-address ip-address	(Optional) Specifies the source IP address to send Call Home e-mail messages. If no source IP address or source interface name is specified, an interface in the routing table is used. Note At one time, you can specify the source-interface name or the source-ip-address, but not both.

The following notes apply when configuring general e-mail options:

- Backup e-mail servers can be defined by repeating the **mail-server** command using different priority numbers.

- The **mail-server priority number** parameter can be configured from 1 to 100. The server with the highest priority (lowest priority number) will be tried first.

This example shows the configuration of general e-mail parameters, including a primary and secondary e-mail server:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# call-home
Switch(cfg-call-home)# mail-server smtp.example.com priority 1
Switch(cfg-call-home)# mail-server 192.168.0.1 priority 2
Switch(cfg-call-home)# sender from username@example.com
Switch(cfg-call-home)# sender reply-to username@example.com
Switch(cfg-call-home)# exit
Switch(config)#
```

Enabling Call Home

To enable or disable the Call Home feature, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch(config)# service call-home	Enables the Call Home feature.

Testing Call Home Communications

You can test Call Home communications by sending messages manually using two command types.

- To send a user-defined Call Home test message, use the **call-home test** command.
- To send a specific alert group message, use the **call-home send** command.

Sending a Call Home Test Message Manually

To manually send a Call Home test message, perform this task:

	Command	Purpose
Step 1	Switch# call-home test ["test-message"] profile name	Sends a test message to the specified destination profile. The user-defined test message text is optional, but must be enclosed in quotes (") if it contains spaces. If no user-defined message is configured, a default message will be sent.

This example shows how to manually send a Call Home test message:

```
Switch# call-home test "test of the day" profile Ciscotac1
```

Sending a Call Home Alert Group Message Manually

To manually trigger a Call Home alert group message, perform this task:

	Command	Purpose
Step 1	Switch# call-home send alert-group configuration [profile name]	Sends a configuration alert group message to one destination profile if specified, or to all subscribed destination profiles.
	Switch# call-home send alert-group diagnostic { module number slot/subslot slot/bay } [profile name]	Sends a diagnostic alert group message to the configured destination profile if specified, or to all subscribed destination profiles. You must specify the module or port whose diagnostic information should be sent.
	Switch# call-home send alert-group inventory [profile name]	Sends an inventory alert group message to one destination profile if specified, or to all subscribed destination profiles.

When manually sending Call Home alert group messages, note the following guidelines:

- You can only manually send the configuration, diagnostic, and inventory alert groups.
- When you manually trigger a configuration, diagnostic, or inventory alert group message and you specify a destination profile name, a message is sent to the destination profile regardless of the profile's active status, subscription status, or severity setting.
- When you manually trigger a configuration or inventory alert group message and do not specify a destination profile name, a message is sent to all active profiles that have either a normal or periodic subscription to the specified alert group.
- When you manually trigger a diagnostic alert group message and do not specify a destination profile name, the command will cause the following actions:
 - For any active profile that subscribes to diagnostic events with a severity level of less than minor, a message is sent regardless of whether the module or interface has observed a diagnostic event.
 - For any active profile that subscribes to diagnostic events with a severity level of minor or higher, a message is sent only if the specified module or interface has observed a diagnostic event of at least the subscribed severity level; otherwise, no diagnostic message is sent to the destination profile.

This example shows how to send the configuration alert-group message to the destination profile:

```
Switch# call-home send alert-group configuration
```

This example shows how to send the diagnostic alert-group message to the destination profile for a specific module, slot/subslot, or slot/bay number.

```
Switch# call-home send alert-group diagnostic module 3 5/2
```

This example shows how to send the diagnostic alert-group message to all destination profiles for a specific module, slot/subslot, or slot/bay number.

```
Switch# call-home send alert-group diagnostic module 3 5/2 profile Ciscotac1
```

This example shows how to send the inventory call-home message:

```
Switch# call-home send alert-group inventory
```

Sending a Request for an Analysis and Report

You can use the **call-home request** command to submit information about your system to Cisco in order to receive helpful information specific to your system. You can request a variety of reports, including security alerts, known bugs, best practices, and command references.

To submit a request for report and analysis information from the Cisco Output Interpreter tool, perform one of these tasks:

Command	Purpose
Switch# call-home request output-analysis "show-command" [profile name] [ccoid user-id]	Sends the output of the specified show command for analysis. The show command must be contained in quotes ("").
Switch# call-home request { config-sanity bugs-list command-reference product-advisory } [profile name] [ccoid user-id]	Sends the output of a predetermined set of commands for analysis such as show running-config all , show version , or show module commands. In addition, the call-home request product-advisory command includes all inventory alert group commands. The keyword specified after the call home request command specifies the type of report required.

When manually sending a Call Home report and analysis request, note the following guidelines:

- If you specify a **profile** name value, the request is sent to the profile. If you do not specify a profile name, the request is sent to the Cisco TAC profile. The recipient profile does not need to be enabled for the Call Home request. The profile should specify the e-mail address where the transport gateway is configured so that the request message can be forwarded to the Cisco TAC and you can receive the reply from the Smart Call Home service.
- The **ccoid** user-id value is the registered identifier of the Smart Call Home user. If you specify a user-id, the response is sent to the e-mail address of the registered user. If do not specify a user-id, the response is sent to the contact e-mail address of the device.
- Based on the keyword specifying the type of report requested, the following information is returned:
 - **config-sanity**—Information on best practices as related to the current running configuration
 - **bugs-list**—Known bugs in the running version and in the currently applied features
 - **command-reference**—Reference links to all commands in the running configuration
 - **product-advisory**—Product Security Incident Response Team (PSIRT) notices, End of Life (EOL) or End of Sales (EOS) notices, or field notices (FN) that may affect devices in your network

This example shows a request for analysis of a user-specified **show** command:

```
Switch# call-home request output-analysis "show diagnostic result module all" profile TG
```

Sending the Output of a Command

You can use the **call-home send** command to execute a CLI command and e-mail the command output to Cisco or to an e-mail address that you specify.

To execute a CLI command and e-mail the command output, perform this task:

Command	Purpose
Switch# call-home send " <i>command</i> " [email <i>email-addr</i>] [service-number <i>SR</i>]	Executes the specified CLI command and e-mails the output.

When sending the output of a command, note the following guidelines:

- The specified CLI command can be any run command, including commands for all modules. The command must be contained in quotes ("").
- If an e-mail address is specified, the command output will be sent to that address. If no e-mail address is specified, the output will be sent to the Cisco TAC (attach@cisco.com). The e-mail will be sent in long text format with the service number, if specified, in the subject line.
- The service number is required only if no e-mail address is specified, or if a Cisco TAC e-mail address is specified.

This example shows how to send the output of a CLI command to a user-specified e-mail address:

```
Switch# call-home send "show diagnostic result module all" email support@example.com
```

Configuring and Enabling Smart Call Home

For application and configuration information of the Cisco Smart Call Home service, see the “FastStart” section of the *Smart Call Home User Guide* at this location:

<http://www.cisco.com/go/smartcall/>

The user guide includes configuration examples for sending Smart Call Home messages directly from your device or through a transport gateway (TG) aggregation point. You can use a TG aggregation point in cases requiring support for multiple devices or in cases where security requirements mandate that your devices may not be connected directly to the Internet.

Because the Smart Call Home service uses HTTPS as the transport method, you must also configure its CA as a trustpoint, as described in the *Smart Call Home User Guide*.

Displaying Call Home Configuration Information

To display the configured Call Home information, perform these tasks:

Command	Purpose
Switch# show call-home	Displays the Call Home configuration in summary.
Switch# show call-home detail	Displays the Call Home configuration in detail.
Switch# show call-home alert-group	Displays the available alert groups and their status.

Command	Purpose
Switch# show call-home mail-server status	Checks and displays the availability of the configured e-mail server(s).
Switch# show call-home profile {all name}	Displays the configuration of the specified destination profile. Use the keyword all to display the configuration of all destination profiles.
Switch# show call-home statistics	Displays the statistics of Call Home events.

Examples 79-1 to 79-7 show the results when using different options of the **show call-home** command.

Example 79-1 Configured Call Home Information

```
Switch# show call-home
call home feature : disable
  call home message's from address: switch@example.com
  call home message's reply-to address: support@example.com

vrf for call-home messages: Not yet set up

contact person's email address: technical@example.com

contact person's phone number: +1-408-555-1234
street address: 1234 Picaboo Street, Any city, Any state, 12345
customer ID: ExampleCorp
contract ID: X123456789
site ID: SantaClara
source ip address: Not yet set up
source interface: Not yet set up
Mail-server[1]: Address: smtp.example.com Priority: 1
Mail-server[2]: Address: 192.168.0.1 Priority: 2
Rate-limit: 20 message(s) per minute

Available alert groups:
  Keyword                State   Description
  -----
  configuration           Disable configuration info
  diagnostic              Disable diagnostic info
  environment             Disable environmental info
  inventory               Enable  inventory info
  syslog                  Disable syslog info

Profiles:
  Profile Name: campus-noc
  Profile Name: CiscoTAC-1

Switch#
```

Example 79-2 Configured Call Home Information in Detail

```
Switch# show call-home detail
Current call home settings:
call home feature : disable
  call home message's from address: switch@example.com
  call home message's reply-to address: support@example.com

vrf for call-home messages: Not yet set up

contact person's email address: technical@example.com

Call Home Default Settings

Table 79-2 lists the default Call Home settings.

Table 79-2 Default Call Home Settings

Parameters	Default
Call Home feature status	Disabled
User-defined profile status	Active
Predefined Cisco TAC profile status	Inactive
Transport method	E-mail
Message format type	XML
Destination message size for a message sent in long text, short text, or XML format	3,145,728
Alert group status	Enabled
Call Home message severity threshold	1 (normal)
Message rate limit for messages per minute	20

Alert Group Trigger Events and Commands

Call Home trigger events are grouped into alert groups, with each alert group assigned CLI commands to execute when an event occurs. The CLI command output is included in the transmitted message.

Table 79-3 lists the trigger events included in each alert group, including the severity level of each event and the executed CLI commands for the alert group.

Table 79-3 Call Home Alert Groups, Events, and Actions

Alert Group	Call Home Trigger Event	Syslog Event	Severity	Description and CLI Commands Executed
Syslog				Event logged to syslog. (Only sent to TAC if syslog level 0, 1, or 2) CLI commands executed: show logging show inventory
	SYSLOG	LOG_EMERG	7	System is unusable.

Table 79-3 Call Home Alert Groups, Events, and Actions (continued)

Alert Group	Call Home Trigger Event	Syslog Event	Severity	Description and CLI Commands Executed
	SYSLOG	LOG_ALERT	6	Action must be taken immediately.
	SYSLOG	LOG_CRIT	5	Critical conditions.
	SYSLOG	LOG_ERR	4	Error conditions.
	SYSLOG	LOG_WARNING	3	Warning conditions.
	SYSLOG	LOG_NOTICE	2	Normal but signification condition.
	SYSLOG	LOG_INFO	1	Informational.
	SYSLOG	LOG_DEBUG	0	Debug-level messages.
Environmental				<p>Events related to power, fan, and environment sensing elements, such as temperature alarms. (Sent to TAC.)</p> <p>CLI commands executed:</p> <p>show module show environment show logging show power show inventory</p>
	TEMP_FAILURE	TempHigh	5	The temperature of the chassis is above the normal threshold.
	TEMP_FAILURE	Critical Temp	5	The temperature of the chassis has risen above the critical threshold.
	TEMP_FAILURE	Shutdown Temp	5	The temperature of the chassis is very high and the system will be shut down.
	TEMP_FAILURE	Some Temp Sensors Failed	3	Some of the temperature sensors have failed.
	TEMP_FAILURE	All Temp Sensors Failed	5	All temperature sensors have failed.
	TEMP_RECOVER	TempOk	5	The temperature of the chassis is normal.
	POWER_FAILURE	PowerSupplyBad	5	A power supply has failed or has been turned off.
	POWER_RECOVERY	PowerSupplyGood	5	A failed power supply has been fixed.
	POWER_FAILURE	PowerSupplyFanBad	3	A power supply fan has failed.
	POWER_RECOVERY	PowerSupplyFanGood	3	A failed power supply fan has been fixed.
	POWER_RECOVERY	PowerSupplyOutputIncreased	3	A power supply output has increased.
	POWER_FAILURE	PowerSupplyOutputDecreased	3	A power supply output has decreased.

Table 79-3 Call Home Alert Groups, Events, and Actions (continued)

Alert Group	Call Home Trigger Event	Syslog Event	Severity	Description and CLI Commands Executed
	POWER_FAIL URE	InlinePowerSupplyBad	3	Inline power source from a power supply has failed or turned off.
	POWER_FAIL URE	MixedPowerSupplyInC hassis	3	Mixed power supplies have been detected in the chassis.
	POWER_FAIL URE	NotEnoughPowerChass is	6	There is insufficient power to support the system. The system might shut down.
	POWER_ RECOVERY	InlinePowerSupplyGoo d	3	A failed source for inline power has been fixed.
	FANTRAY_FA ILURE	FanTrayPartialFailure	3	Either a fan or thermistors in system fan tray has failed.
	FANTRAY_FA ILURE	FanTrayMismatch	3	The fantray, supervisor, chassis combination is disallowed.
	FANTRAY_FA ILURE	FanTrayBad	5	Fan tray has failed.
	FANTRAY_ RECOVERY	FanTrayGood	3/5	Failed fan tray has been fixed. The severity of the notification depends on the failure which has been recovered from.
	FANTRAY_ FAILURE	InsufficientFantray	6	There are not enough FanTray to support the system. This may be followed by a system shut down.
	CLOCK_ALA RM	ClockSwitchover	2	Clock module has switched over to another clock.
	CLOCK_ALA RM	Clock Faulty	3	The clock module has been found to be faulty.
Inventory				Inventory status should be provided whenever a unit is cold-booted, or when FRUs are inserted or removed. it is considered a noncritical event, and the information is used for status and entitlement. CLI commands executed: show module show version show inventory oid show idprom all show power
	INSERTION	Module	1	A line card or supervisor engine has been inserted into a slot.
	REMOVAL	Module	1	A line card or supervisor engine has been removed from a slot.

Table 79-3 Call Home Alert Groups, Events, and Actions (continued)

Alert Group	Call Home Trigger Event	Syslog Event	Severity	Description and CLI Commands Executed
Diagnostic Failure			1/3/4/5	Events related to standard or intelligent line cards. CLI commands executed: show module show version show inventory show buffers show logging show diagnostic result module x detail show diagnostic result module all
Test	TEST		1	User-generated test message. CLI commands executed: show module show version show inventory
Configuration			1	User-generated request for configuration. CLI commands executed: show module show inventory show version show running-config all show startup-config

Message Contents

The following tables display the content formats of alert group messages:

- [Table 79-4](#) describes the content fields of a short text message.
- [Table 79-5](#) describes the content fields that are common to all long text and XML messages. The fields specific to a particular alert group message are inserted at a point between the common fields. The insertion point is identified in the table.
- [Table 79-6](#) describes the inserted content fields for reactive messages (system failures that require a TAC case) and proactive messages (issues that might result in degraded system performance).
- [Table 79-7](#) describes the inserted content fields for an inventory message.

Table 79-4 Format for a Short Text Message

Data Item	Description
Device identification	Configured device name
Date/time stamp	Time stamp of the triggering event
Error isolation message	Plain English description of triggering event
Alarm urgency level	Error level such as that applied to a system message

Table 79-5 Common Fields for All Long Text and XML Messages

Data Item (Plain Text and XML)	Description (Plain Text and XML)	XML Tag (XML Only)
Time stamp	Date/timestamp of event in ISO time notation: YYYY-MM-DDTHH:MM:SS Note the T in between date and time, and note that the timezone/dst offset from UTC has already been added or subtracted.	CallHome/EventTime
Message name	Name of message.	For short text message only
Message type	Specifically "Call Home".	CallHome/Event/Type
Message group	Specifically "reactive". Optional in this case because default is "reactive".	CallHome/Event/SubType
Severity level	Severity level of message.	Body/Block/Severity
Source ID	This field is used to identify the product type for routing using the workflow engine. it is typically the product family name.	For long test mmessage only
Device ID	Unique Device Identifier (UDI) for end device generating message. This field should empty if the message is nonspecific to a fabric switch. Format: type@Sid@serial Where @:Separator character <ul style="list-style-type: none"> Type: If WS-C4503-E, product model number from backplane SEEPROM. Sid: "C" identifying serial ID as a chassis serial number. Serial: The serial number as identified by the Sid field. Example: "WS-C4503-E@C@SPE4465329F"	CallHome/Customer Data/ ContractData/ DeviceId
Customer ID	Optional user-configurable field used for contract information or other ID by any support service.	CallHome/Customer Data/ ContractData/ CustomerId
Contract ID	Optional user-configurable field used for contract information or other ID by any support service.	/CallHome/ Customer Data/ ContractData/ ContractId
Site ID	Optional user-configurable field used for Cisco-supplied site ID or other data meaningful to alternate support service.	CallHome/ CustomerData/ ContractData/ SiteId

Table 79-5 Common Fields for All Long Text and XML Messages (continued)

Data Item (Plain Text and XML)	Description (Plain Text and XML)	XML Tag (XML Only)
Server ID	<p>If message is generated from fabric switch, UDI of switch. If message is proxied or originated by MA, the MA should overwrite this field with the MA UDI.</p> <p>Format is type@Sid@serial</p> <p>Where</p> <p>@: Separator character</p> <ul style="list-style-type: none"> Type: If WS-C4510R, product model number from backplane SEEPROM. Sid: "C" identifying serial ID as a chassis serial number Serial: The serial number as identified by the Sid field. <p>Example: "WS-C4510R@C@CAT234765XR"</p>	For long text message only
Message description	Short text describing the error.	CallHome/ MessageDescription
Device name	Node that experienced the event. it is the host name of the device.	CallHome/ CustomerData/ SystemInfo/ Name
Contact name	Name of person to contact for issues associated with the node experiencing the event.	CallHome/CustomerData/Syst emInfo/Contact
Contact e-mail	E-mail address of person identified as contact for this unit.	CallHome/CustomerData/Syst emInfo/ContactEmail
Contact phone number	Phone number of the person identified as the contact for this unit.	CallHome/CustomerData/Syst emInfo/ContactPhoneNumber
Street address	Optional field containing street address for RMA part shipments associated with this unit.	CallHome/CustomerData/Syst emInfo/StreetAddress
Model name	Model name of the unit (such as WS-C4503). it is the specific model as part of a product family name.	CallHome/ Device/ Cisco_Chassis/Model
Serial number	Chassis serial number of the unit.	CallHome/ Device/ Cisco_Chassis/ SerialNumber
Chassis part number	Top assembly number of the chassis as read from SEEPROM (such as WS-C4503 = 73-10558).	CallHome/Device/Cisco_Chas sis/AdditionalInformation/ AD@name="PartNumber"

Fields specific to a particular alert group message are inserted here.

The following fields may be repeated if multiple CLI commands are executed for this alert group.

Command output name	The exact command that was run (such as the show running-config command).	/aml/attachments/attachment/ name
---------------------	--	--------------------------------------

Table 79-5 Common Fields for All Long Text and XML Messages (continued)

Data Item (Plain Text and XML)	Description (Plain Text and XML)	XML Tag (XML Only)
Attachment type	Specifically command output.	/aml/Attachments/attachment@type
MIME type	Normally text/plain or encoding type.	/aml/Attachments/Attachment/Data@encoding

Table 79-6 Inserted Fields for a Reactive or Proactive Event Message

Data Item (Plain Text and XML)	Description (Plain Text and XML)	XML Tag (XML Only)
Chassis hardware version	Hardware version of chassis	CallHome/Device/Cisco_Chassis/HardwareVersion
Supervisor module software version	Top-level software version	CallHome/Device/Cisco_Chassis/AdditionalInformation/AD@name="SoftwareVersion"
Affected FRU name	Name of the affected FRU generating the event message	CallHome/Device/Cisco_Chassis/Cisco_Card/Model
Affected FRU serial number	Serial number of affected FRU	CallHome/Device/Cisco_Chassis/Cisco_Card/SerialNumber
Affected FRU part number	Part number of affected FRU	CallHome/Device/Cisco_Chassis/Cisco_Card/PartNumber
FRU slot	Slot number of FRU generating the event message	CallHome/Device/Cisco_Chassis/Cisco_Card/LocationWithinContainer
FRU hardware version	Hardware version of affected FRU	CallHome/Device/Cisco_Chassis/Cisco_Card/HardwareVersion
FRU software version	Software version(s) running on affected FRU	CallHome/Device/Cisco_Chassis/Cisco_Card/SoftwareIdentity/VersionString

Table 79-7 Inserted Fields for an Inventory Event Message

Data Item (Plain Text and XML)	Description (Plain Text and XML)	XML Tag (XML Only)
Chassis hardware version	Hardware version of chassis	CallHome/Device/Cisco_Chassis/HardwareVersion
Supervisor module software version	Top-level software version	CallHome/Device/Cisco_Chassis/AdditionalInformation/AD@name="SoftwareVersion"
Affected FRU name	Name of the affected FRU generating the event message	CallHome/Device/Cisco_Chassis/Cisco_Card/Model

Table 79-7 *Inserted Fields for an Inventory Event Message (continued)*

Data Item (Plain Text and XML)	Description (Plain Text and XML)	XML Tag (XML Only)
Affected FRU s/n	Serial number of affected FRU	CallHome/Device/Cisco_Chassis/Cisco_Card/SerialNumber
Affected FRU part number	Part number of affected FRU	CallHome/Device/Cisco_Chassis/Cisco_Card/PartNumber
FRU slot	Slot number of FRU generating the event message	CallHome/Device/Cisco_Chassis/Cisco_Card/LocationWithinContainer
FRU hardware version	Hardware version of affected FRU	CallHome/Device/Cisco_Chassis/Cisco_Card/HardwareVersion
FRU software version	Software version(s) running on affected FRU	CallHome/Device/Cisco_Chassis/Cisco_Card/SoftwareIdentity/VersionString

Syslog Alert Notification in Long-Text Format Example

```

TimeStamp : 2009-02-06 12:57 GMT+00:00
Message Name : syslog
Message Type : Call Home
Message Group : reactive
Severity Level : 2
Source ID : Cat4500/4900
Device ID : WS-C4510R@C@1234567
Customer ID :
Contract ID :
Site ID :
Server ID : WS-C4510R@C@1234567
Event Description : *Feb 6 12:57:54.121: %CLEAR-5-COUNTERS: Clear counter on all
interfaces by console
System Name : Router
Contact Email : abc@example.com

Configuring Cisco IOS IP SLA Operations

This chapter describes how to use Cisco IOS IP Service Level Agreements (SLAs) on Catalyst 4500 series switch. Cisco IP SLAs is a part of Cisco IOS software that allows Cisco customers to analyze IP service levels for IP applications and services by using active traffic monitoring—the generation of traffic in a continuous, reliable, and predictable manner—for measuring network performance. With Cisco IOS IP SLAs, service provider customers can measure and provide service level agreements, and enterprise customers can verify service levels, verify outsourced service level agreements, and understand network performance. Cisco IOS IP SLAs can perform network assessments, verify quality of service (QoS), ease the deployment of new services, and assist with network troubleshooting.

The Catalyst 4500 series switch Base or Enterprise Services The switch also supports the Built-in Traffic Simulator using Cisco IOS IP SLAs video operations to generate synthetic traffic for a variety of video applications, such as Telepresence, IPTV and IP video surveillance camera. You can use the simulator tool:

- for network assessment before deploying applications that have stringent network performance requirements.
- along with the Cisco Mediatrace for post-deployment troubleshooting for any network related performance issues.

The traffic simulator includes a sophisticated scheduler that allows the user to run several tests simultaneously or periodically and over extended time periods (Supported only on switches running the Enterprise Services feature set).

This chapter consists of these sections:

- [Understanding Cisco IOS IP SLAs, page 80-2](#)
- [Configuring IP SLAs Operations, page 80-6](#)
- [Monitoring IP SLAs Operations, page 80-12](#)

Note

For information on configuring this feature, see the *Configuring Cisco IOS IP SLAs Video Operations* document at:

http://www.cisco.com/en/US/docs/ios-xml/ios/ipsla/configuration/12-2se/sla_video.html

For more information about IP SLAs, see the *Cisco IOS IP SLAs Configuration Guides*:

<http://www.cisco.com/c/en/us/td/docs/ios-xml/ios/ipsla/configuration/xe-3e/sla-xe-3e-book.html>

For command syntax information, see the command reference:

http://www.cisco.com/en/US/docs/ios/ipsla/command/reference/sla_book.html

Understanding Cisco IOS IP SLAs

Cisco IOS IP SLAs sends data across the network to measure performance between multiple network locations or across multiple network paths. It simulates network data and IP services and collects network performance information in real time. Cisco IOS IP SLAs generates and analyzes traffic either between Cisco IOS devices or from a Cisco IOS device to a remote IP device such as a network application server. Measurements provided by the various Cisco IOS IP SLAs operations can be used for troubleshooting, for problem analysis, and for designing network topologies.

Depending on the specific Cisco IOS IP SLAs operation, various network performance statistics are monitored within the Cisco device and stored in both command-line interface (CLI) and Simple Network Management Protocol (SNMP) MIBs. IP SLAs packets have configurable IP and application layer options such as source and destination IP address, User Datagram Protocol (UDP)/TCP port numbers, a type of service (ToS) byte (including Differentiated Services Code Point [DSCP] and IP Prefix bits), Virtual Private Network (VPN) routing/forwarding instance (VRF), and URL web address.

Because Cisco IP SLAs is Layer 2 transport independent, you can configure end-to-end operations over disparate networks to best reflect the metrics that an end user is likely to experience. IP SLAs collects a unique subset of these performance metrics:

- Delay (both round-trip and one-way)
- Jitter (directional)
- Packet loss (directional)
- Packet sequencing (packet ordering)
- Path (per hop)
- Connectivity (directional)
- Server or website download time

Because Cisco IOS IP SLAs is SNMP-accessible, it can also be used by performance-monitoring applications like CiscoWorks Internetwork Performance Monitor (IPM) and other third-party Cisco partner performance management products. You can find more details about network management products that use Cisco IOS IP SLAs:

<http://www.cisco.com/go/ipsla>

Using IP SLAs can provide these benefits:

- Service-level agreement monitoring, measurement, and verification.
- Network performance monitoring
 - Measures the jitter, latency, or packet loss in the network.
 - Provides continuous, reliable, and predictable measurements.
- IP service network health assessment to verify that the existing QoS is sufficient for new IP services.
- Edge-to-edge network availability monitoring for proactive verification and connectivity testing of network resources (for example, shows the network availability of an NFS server used to store business critical data from a remote site).
- Troubleshooting of network operation by providing consistent, reliable measurement that immediately identifies problems and saves troubleshooting time.
- Multiprotocol Label Switching (MPLS) performance monitoring and network verification (if the switch supports MPLS)

This section includes this information about IP SLAs functionality:

- [Using Cisco IOS IP SLAs to Measure Network Performance, page 80-3](#)
- [IP SLAs Responder and IP SLAs Control Protocol, page 80-4](#)
- [Response Time Computation for IP SLAs, page 80-4](#)
- [IP SLAs Operation Scheduling, page 80-5](#)
- [IP SLAs Operation Threshold Monitoring, page 80-5](#)

Using Cisco IOS IP SLAs to Measure Network Performance

You can use IP SLAs to monitor the performance between any area in the network—core, distribution, and edge—without deploying a physical probe. It uses generated traffic to measure network performance between two networking devices. [Figure 80-1](#) shows how IP SLAs begins when the source device sends a generated packet to the destination device. After the destination device receives the packet, depending on the type of IP SLAs operation, it responds with time-stamp information for the source to make the calculation on performance metrics. An IP SLAs operation performs a network measurement from the source device to a destination in the network using a specific protocol such as UDP.

Figure 80-1 *Cisco IOS IP SLAs Operation*

To implement IP SLAs network performance measurement, you need to perform these tasks:

1. Enable the IP SLAs responder, if required.
2. Configure the required IP SLAs operation type.
3. Configure any options available for the specified operation type.
4. Configure threshold conditions, if required.
5. Schedule the operation to run, then let the operation run for a period of time to gather statistics.
6. Display and interpret the results of the operation using the Cisco IOS CLI or a network management system (NMS) system with SNMP.

For more information about IP SLAs operations, see the operation-specific chapters in the *Cisco IOS IP SLAs Configuration Guide*:

http://www.cisco.com/en/US/products/ps6441/products_installation_and_configuration_guides_list.html

The switch does not support Voice over IP (VoIP) service levels using the gatekeeper registration delay operations measurements. Before configuring any IP SLAs application, you can use the **show ip sla application** privileged EXEC command to verify that the operation type is supported on your software image.

IP SLAs Responder and IP SLAs Control Protocol

The IP SLAs responder is a component embedded in the destination Cisco device that allows the system to anticipate and respond to IP SLAs request packets. The responder provides accurate measurements without the need for dedicated probes. The responder uses the Cisco IOS IP SLAs Control Protocol to provide a mechanism through which it can be notified on which port it should listen and respond. Only a Cisco IOS device can be a source for a destination IP SLAs Responder.

Note

The IP SLAs responder can be a Cisco IOS Layer 2, responder-configurable switch, such as a Catalyst 2960 switch. The responder does not need to support full IP SLAs functionality.

Figure 80-1 shows where the Cisco IOS IP SLAs responder fits in the IP network. The responder listens on a specific port for control protocol messages sent by an IP SLAs operation. Upon receipt of the control message, it enables the specified UDP or TCP port for the specified duration. During this time, the responder accepts the requests and responds to them. It disables the port after it responds to the IP SLAs packet, or when the specified time expires. MD5 authentication for control messages is available for added security.

You do not need to enable the responder on the destination device for all IP SLAs operations. For example, a responder is not required for services that are already provided by the destination router (such as Telnet or HTTP). You cannot configure the IP SLAs responder on non-Cisco devices and Cisco IOS IP SLAs can send operational packets only to services native to those devices.

Response Time Computation for IP SLAs

Switches and routers can take tens of milliseconds to process incoming packets due to other high priority processes. This delay affects the response times because the test-packet reply might be in a queue while waiting to be processed. In this situation, the response times would not accurately represent true network delays. IP SLAs minimizes these processing delays on the source device as well as on the target device (if the responder is being used) to determine true round-trip times. IP SLAs test packets use time stamping to minimize the processing delays.

When the IP SLAs responder is enabled, it allows the target device to take time stamps when the packet arrives on the interface at interrupt level and again just as it is leaving, eliminating the processing time. This time stamping is made with a granularity of sub-milliseconds (ms).

Figure 80-2 demonstrates how the responder works. Four time stamps are taken to make the calculation for round-trip time. At the target router, with the responder functionality enabled, time stamp 2 (TS2) is subtracted from time stamp 3 (TS3) to produce the time spent processing the test packet as represented

by delta. This delta value is then subtracted from the overall round-trip time. Notice that the same principle is applied by IP SLAs on the source router where the incoming time stamp 4 (TS4) is also taken at the interrupt level to allow for greater accuracy.

Figure 80-2 Cisco IOS IP SLAs Responder Time Stamping

An additional benefit of the two time stamps at the target device is the ability to track one-way delay, jitter, and directional packet loss. Because much network behavior is asynchronous, it is critical to have these statistics. However, to capture one-way delay measurements, you must configure both the source router and target router with Network Time Protocol (NTP) so that the source and target are synchronized to the same clock source. One-way jitter measurements do not require clock synchronization.

IP SLAs Operation Scheduling

When you configure an IP SLAs operation, you must schedule the operation to begin capturing statistics and collecting error information. You can schedule an operation to start immediately or to start at a certain month, day, and hour. You can use the pending option to set the operation to start at a later time. The pending option is an internal state of the operation that is visible through SNMP. The pending state is also used when an operation is a reaction (threshold) operation waiting to be triggered. You can schedule a single IP SLAs operation or a group of operations at one time.

You can schedule several IP SLAs operations by using a single command through the Cisco IOS CLI or the CISCO RTTMON-MIB. Scheduling the operations to run at evenly distributed times allows you to control the amount of IP SLAs monitoring traffic. This distribution of IP SLAs operations helps minimize the CPU utilization and thus improves network scalability.

For more details about the IP SLAs multioperations scheduling functionality, see the “IP SLAs—Multiple Operation Scheduling” chapter of the *Cisco IOS IP SLAs Configuration Guide*:

http://www.cisco.com/en/US/products/ps6441/products_installation_and_configuration_guides_list.html

IP SLAs Operation Threshold Monitoring

To support successful service level agreement monitoring, you must have mechanisms that notify you immediately of any possible violation. IP SLAs can send SNMP traps that are triggered by events such as these:

- Connection loss
- Timeout
- Round-trip time threshold
- Average jitter threshold

- One-way packet loss
- One-way jitter
- One-way mean opinion score (MOS)
- One-way latency

An IP SLAs threshold violation can also trigger another IP SLAs operation for further analysis. For example, the frequency could be increased or an ICMP path echo or ICMP path jitter operation could be initiated for troubleshooting.

Determining the type of threshold and the level to set can be complex, and depends on the type of IP service being used in the network.

http://www.cisco.com/en/US/products/ps6441/products_installation_and_configuration_guides_list.html

Configuring IP SLAs Operations

This section does not include configuration information for all available operations as the configuration information details are included in the *Cisco IOS IP SLAs Configuration Guide*. It does include several operations as examples, including configuring the responder, configuring UDP jitter operation, which requires a responder, and configuring ICMP echo operation, which does not require a responder.

For details about configuring other operations, see the *Cisco IOS IP SLAs Configuration Guide*:

http://www.cisco.com/en/US/products/ps6441/products_installation_and_configuration_guides_list.html

This section includes this information:

- [IP SLA Default Configuration, page 80-6](#)
- [IP SLA Configuration Guidelines, page 80-6](#)
- [Configuring the IP SLAs Responder, page 80-7](#)
- [Analyzing IP Service Levels by Using the UDP Jitter Operation, page 80-8](#)
- [Analyzing IP Service Levels by Using the ICMP Echo Operation, page 80-11](#)

IP SLA Default Configuration

By default, no IP SLAs operations are configured.

IP SLA Configuration Guidelines

For information on the IP SLAs commands, see the *Cisco IOS IP SLAs Command Reference, Release 12.4T* command reference:

http://www.cisco.com/en/US/docs/ios/ipsla/command/reference/sla_book.html

For detailed descriptions and configuration procedures, see the *Cisco IOS IP SLAs Configuration Guide, Release 12.4T* L:

http://www.cisco.com/en/US/products/ps6441/products_installation_and_configuration_guides_list.html

Note that not all of the IP SLAs commands or operations described in this guide are supported on the switch. The switch supports IP service level analysis by using UDP jitter, UDP echo, HTTP, TCP connect, ICMP echo, ICMP path echo, ICMP path jitter, FTP, DNS, and DHCP, as well as multiple operation scheduling and proactive threshold monitoring. It does not support VoIP service levels using the gatekeeper registration delay operations measurements.

Before configuring any IP SLAs application, you can use the **show ip sla application** privileged EXEC command to verify that the operation type is supported on your software image. This is an example of the output from the command:

```
Switch# show ip sla application
      IP SLAs
Version: 2.2.0 Round Trip Time MIB, Infrastructure Engine-II
Time of last change in whole IP SLAs: 22:17:39.117 UTC Fri Jun
Estimated system max number of entries: 15801

Estimated number of configurable operations: 15801
Number of Entries configured      : 0
Number of active Entries         : 0
Number of pending Entries        : 0
Number of inactive Entries       : 0

      Supported Operation Types
Type of Operation to Perform: 802.1agEcho
Type of Operation to Perform: 802.1agJitter
Type of Operation to Perform: dhcp
Type of Operation to Perform: dns
Type of Operation to Perform: echo
Type of Operation to Perform: ftp
Type of Operation to Perform: http
Type of Operation to Perform: jitter
Type of Operation to Perform: pathEcho
Type of Operation to Perform: pathJitter
Type of Operation to Perform: tcpConnect
Type of Operation to Perform: udpEcho

IP SLAs low memory water mark: 21741224
```

Configuring the IP SLAs Responder

The IP SLAs responder is available only on Cisco IOS software-based devices, including some Layer 2 switches that do not support full IP SLAs functionality, such as a Catalyst 2960 switch.

To configure the IP SLAs responder on the target device (the operational target), perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>ip sla responder {tcp-connect udp-echo} ipaddress ip-address port port-number</code>	Configures the switch as an IP SLAs responder. The keywords have these meanings: <ul style="list-style-type: none"> • tcp-connect—Enable the responder for TCP connect operations. • udp-echo—Enable the responder for User Datagram Protocol (UDP) echo or jitter operations. • ipaddress ip-address—Enter the destination IP address. • port port-number—Enter the destination port number. <p>Note The IP address and port number must match those configured on the source device for the IP SLAs operation.</p>
Step 3	<code>end</code>	Returns to privileged EXEC mode.
Step 4	<code>show ip sla responder</code>	Verifies the IP SLAs responder configuration on the device.
Step 5	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

To disable the IP SLAs responder, enter the **no ip sla responder** global configuration command. This example shows how to configure the device as a responder for the UDP jitter IP SLAs operation in the next procedure:

```
Switch(config)# ip sla responder udp-echo 172.29.139.134 5000
```

Analyzing IP Service Levels by Using the UDP Jitter Operation

Jitter means interpacket delay variance. When multiple packets are sent consecutively 10 ms apart from source to destination, if the network is behaving correctly, the destination should receive them 10 ms apart. But if there are delays in the network (like queuing, arriving through alternate routes, and so on) the arrival delay between packets might be more than or less than 10 ms with a positive jitter value meaning that the packets arrived more than 10 ms apart. If the packets arrive 12 ms apart, positive jitter is 2 ms; if the packets arrive 8 ms apart, negative jitter is 2 ms. For delay-sensitive networks, positive jitter values are undesirable, and a jitter value of 0 is ideal.

In addition to monitoring jitter, the IP SLAs UDP jitter operation can be used as a multipurpose data gathering operation. The packets IP SLAs generates carry packet sending and receiving sequence information and sending and receiving time stamps from the source and the operational target. Based on these, UDP jitter operations measure this data:

- Per-direction jitter (source to destination and destination to source)
- Per-direction packet-loss
- Per-direction delay (one-way delay)
- Round-trip delay (average round-trip time)

To configure UDP jitter operation on the source device, perform this task:

	Command	Purpose
Step 1	configure terminal	Enters global configuration mode.
Step 2	ip sla operation-number	Creates an IP SLAs operation, and enter IP SLAs configuration mode.
Step 3	udp-jitter { <i>destination-ip-address</i> <i>destination-hostname</i> } <i>destination-port</i> [source-ip { <i>ip-address</i> <i>hostname</i> }] [source-port <i>port-number</i>] [control { enable disable }] [num-packets <i>number-of-packets</i>] [interval <i>interpacket-interval</i>]	Configures the IP SLAs operation as a UDP jitter operation, and enter UDP jitter configuration mode. <ul style="list-style-type: none"> • <i>destination-ip-address</i> <i>destination-hostname</i>—Specify the destination IP address or hostname. • <i>destination-port</i>—Specify the destination port number in the range from 1 to 65535. • (Optional) source-ip {<i>ip-address</i> <i>hostname</i>}—Specify the source IP address or hostname. When a source IP address or hostname is not specified, IP SLAs chooses the IP address nearest to the destination • (Optional) source-port <i>port-number</i>—Specify the source port number in the range from 1 to 65535. When a port number is not specified, IP SLAs chooses an available port. • (Optional) control—Enable or disable sending of IP SLAs control messages to the IP SLAs responder. By default, IP SLAs control messages are sent to the destination device to establish a connection with the IP SLAs responder • (Optional) num-packets <i>number-of-packets</i>—Enter the number of packets to be generated. The range is 1 to 6000; the default is 10. • (Optional) interval <i>inter-packet-interval</i>—Enter the interval between sending packets in milliseconds. The range is 1 to 6000; the default value is 20 ms.
Step 4	frequency <i>seconds</i>	(Optional) Sets the rate at which a specified IP SLAs operation repeats. The range is from 1 to 604800 seconds; the default is 60 seconds.
Step 5	exit	Exits UDP jitter configuration mode, and return to global configuration mode.

Step 4	frequency <i>seconds</i>	(Optional) Sets the rate at which a specified IP SLAs operation repeats. The range is from 1 to 604800 seconds; the default is 60 seconds.
Step 5	exit	Exits UDP jitter configuration mode, and return to global configuration mode.

To disable the IP SLAs operation, enter the no **ip sla operation-number** global configuration command. This example shows how to configure a UDP jitter IP SLAs operation:

```
Switch(config)# ip sla 10
Switch(config-ip-sla)# udp-jitter 172.29.139.134 5000
Switch(config-ip-sla-jitter)# frequency 30
Switch(config-ip-sla-jitter)# exit
Switch(config)# ip sla schedule 5 start-time now life forever
Switch(config)# end
Switch# show ip sla configuration 10
IP SLAs, Infrastructure Engine-II.
```

```

Analyzing IP Service Levels by Using the ICMP Echo Operation

The ICMP echo operation measures end-to-end response time between a Cisco device and any devices using IP. Response time is computed by measuring the time taken between sending an ICMP echo request message to the destination and receiving an ICMP echo reply. Many customers use IP SLAs ICMP-based operations, in-house ping testing, or ping-based dedicated probes for response time measurements between the source IP SLAs device and the destination IP device. The IP SLAs ICMP echo operation conforms to the same specifications as ICMP ping testing, and the two methods result in the same response times.

Note

This operation does not require the IP SLAs responder to be enabled.

To disable the IP SLAs operation, enter the **no ip sla operation-number** global configuration command. This example shows how to configure an ICMP echo IP SLAs operation:

```

Switch(config)# ip sla 12
Switch(config-ip-sla)# icmp-echo 172.29.139.134
Switch(config-ip-sla-echo)# frequency 30
Switch(config-ip-sla-echo)# exit
Switch(config)# ip sla schedule 5 start-time now life forever
Switch(config)# end
Switch# show ip sla configuration 22
IP SLAs, Infrastructure Engine-II.

```

Monitoring IP SLAs Operations

To display IP SLAs operations configuration

Command	Purpose
<code>show ip sla authentication</code>	Displays IP SLAs authentication information.
<code>show ip sla responder</code>	Displays information about the IP SLAs responder.

Configuring RMON

This chapter describes how to configure Remote Network Monitoring (RMON) on your Catalyst 4500 series switch. RMON is a standard monitoring specification that defines a set of statistics and functions that can be exchanged between RMON-compliant console systems and network probes. RMON provides you with comprehensive network-fault diagnosis, planning, and performance-tuning information.

This chapter consists of these sections:

- [About RMON, page 81-1](#)
- [Configuring RMON, page 81-2](#)
- [Displaying RMON Status, page 81-5](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About RMON

RMON is an Internet Engineering Task Force (IETF) standard monitoring specification that allows various network agents and console systems to exchange network monitoring data. You can use the RMON feature with the Simple Network Management Protocol (SNMP) agent in the switch to monitor all the traffic flowing among switches on all connected LAN segments.

Figure 81-1 Remote Monitoring Example

The switch supports these RMON groups (defined in RFC 1757):

- Statistics (RMON group 1)—Collects Ethernet, Fast Ethernet, and Gigabit Ethernet statistics on an interface.
- History (RMON group 2)—Collects a history group of statistics on Ethernet, Fast Ethernet, and Gigabit Ethernet interfaces for a specified polling interval.
- Alarm (RMON group 3)—Monitors a specific MIB object for a specified interval, triggers an alarm at a specified value (rising threshold), and resets the alarm at another value (falling threshold). Alarms can be used with events; the alarm triggers an event, which can generate a log entry or an SNMP trap.
- Event (RMON group 9)—Determines the action to take when an event is triggered by an alarm. The action can be to generate a log entry or an SNMP trap.

Because switches supported by Cisco IOS Release 12.2(31)SG use hardware counters for RMON data processing, the monitoring is more efficient, and little processing power is required.

Configuring RMON

This section describes how to configure RMON on your switch. It contains this configuration information:

- [Default RMON Configuration, page 81-2](#)
- [Configuring RMON Alarms and Events, page 81-2](#)
- [Configuring RMON Collection on an Interface, page 81-4](#)

Default RMON Configuration

RMON is disabled by default; no alarms or events are configured.

Only RMON 1 is supported on the switch.

Configuring RMON Alarms and Events

You can configure your switch for RMON by using the command-line interface (CLI) or an SNMP-compatible network management station. We recommend that you use a generic RMON console application on the network management station (NMS) to take advantage of RMON's network management capabilities. You must also configure SNMP on the switch to access RMON MIB objects. For more information, see [Chapter 75, "Configuring SNMP."](#)

To enable RMON alarms and events, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# rmon alarm <i>number variable interval</i> { absolute delta } rising-threshold <i>value</i> [<i>event-number</i>] falling-threshold <i>value</i> [<i>event-number</i>] [owner <i>string</i>]	Sets an alarm on a MIB object. <ul style="list-style-type: none"> For <i>number</i>, specify the alarm number. The range is 1 to 65535. For <i>variable</i>, specify the MIB object to monitor. For <i>interval</i>, specify the time in seconds the alarm monitors the MIB variable. The range is 1 to 4294967295 seconds. Specify the absolute keyword to test each MIB variable directly; specify the delta keyword to test the change between samples of a MIB variable. For <i>value</i>, specify a number at which the alarm is triggered and one for when the alarm is reset. The range for the rising threshold and falling threshold <i>values</i> is -2147483648 to 2147483647. (Optional) For <i>event-number</i>, specify the event number to trigger when the rising or falling threshold exceeds its limit. (Optional) For owner <i>string</i>, specify the owner of the alarm.
Step 3	Switch(config)# rmon event <i>number</i> [description <i>string</i>] [log] [owner <i>string</i>] [trap <i>community</i>]	Adds an event in the RMON event table that is associated with an RMON event number. <ul style="list-style-type: none"> For <i>number</i>, assign an event number. The range is 1 to 65535. (Optional) For description <i>string</i>, specify a description of the event. (Optional) Use the log keyword to generate an RMON log entry when the event is triggered. (Optional) For owner <i>string</i>, specify the owner of this event. (Optional) For <i>community</i>, enter the SNMP community string used for this trap.
Step 4	Switch(config)# end	Returns to privileged EXEC mode.
Step 5	Switch# show running-config	Verifies your entries.
Step 6	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To disable an alarm, use the **no rmon alarm number** global configuration command on each alarm you configured. You cannot disable at once all the alarms that you configured. To disable an event, use the **no rmon event number** global configuration command. To learn more about alarms and events and how they interact with each other, see RFC 1757.

You can set an alarm on any MIB object. The following example configures RMON alarm number 10 by using the **rmon alarm** command. The alarm monitors the MIB variable ifEntry.20.1 once every 20 seconds until the alarm is disabled and checks the change in the variable's rise or fall. If the ifEntry.20.1 value shows a MIB counter increase of 15 or more, such as from 100000 to 100015, the alarm is triggered. The alarm in turn triggers event number 1, which is configured with the **rmon event** command. Possible events can include a log entry or an SNMP trap. If the ifEntry.20.1 value changes by 0, the alarm is reset and can be triggered again.

```
Switch(config)# rmon alarm 10 ifEntry.20.1 20 delta rising-threshold 15 1
falling-threshold 0 owner jjohnson
```

The following example creates RMON event number 1 by using the **rmon event** command. The event is defined as High ifOutErrors and generates a log entry when the event is triggered by the alarm. The user jjones owns the row that is created in the event table by this command. This example also generates an SNMP trap when the event is triggered.

```
Switch(config)# rmon event 1 log trap eventtrap description "High ifOutErrors" owner
jjones
```

Configuring RMON Collection on an Interface

You must first configure RMON alarms and events to display collection information.

To collect group history statistics on an interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Specifies the interface on which to collect history, and enter interface configuration mode.
Step 3	Switch(config-if)# rmon collection history <i>index</i> [buckets <i>bucket-number</i>] [interval <i>seconds</i>] [owner <i>ownername</i>]	Enables history collection for the specified number of buckets and time period. <ul style="list-style-type: none"> For <i>index</i>, identify the RMON group of statistics. The range is 1 to 65535. (Optional) For buckets <i>bucket-number</i>, specify the maximum number of buckets desired for the RMON collection history group of statistics. The range is 1 to 65535. The default is 50 buckets. (Optional) For interval <i>seconds</i>, specify the number of seconds in each polling cycle. (Optional) For owner <i>ownername</i>, enter the name of the owner of the RMON group of statistics. To disable history collection, use the no rmon collection history index interface configuration command.
Step 4	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 5	Switch# show running-config	Verifies your entries.

	Command	Purpose
Step 6	Switch# show rmon history	Displays the contents of the switch history table.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To collect group Ethernet statistics on an interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface interface-id	Specifies the interface on which to collect statistics, and enter interface configuration mode.
Step 3	Switch(config-if)# rmon collection stats index [owner ownername]	<p>Enables RMON statistic collection on the interface.</p> <ul style="list-style-type: none"> For <i>index</i>, specify the RMON group of statistics. The range is from 1 to 65535. (Optional) For owner ownername, enter the name of the owner of the RMON group of statistics. <p>To disable the collection of group Ethernet statistics, use the no rmon collection stats index interface configuration command.</p>
Step 4	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 5	Switch# show running-config	Verifies your entries.
Step 6	Switch# show rmon statistics	Displays the contents of the switch statistics table.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Displaying RMON Status

To display the RMON status, use one or more of the following privileged EXEC commands:

Command	Purpose
show rmon	Displays general RMON statistics.
show rmon alarms	Displays the RMON alarm table.
show rmon events	Displays the RMON event table.
show rmon history	Displays the RMON history table.
show rmon statistics	Displays the RMON statistics table.

Performing Diagnostics

You can use diagnostics to test and verify the functionality of the hardware components of your system (chassis, supervisor engines, modules, and ASICs) while your Catalyst 4500 series switch is connected to a live network. Diagnostics consists of packet-switching tests that test hardware components and verify the data path and control signals.

Online diagnostics are categorized as bootup, on-demand, schedule, or health-monitoring diagnostics. Bootup diagnostics run during bootup; on-demand diagnostics run from the CLI; scheduled diagnostics run at user-designated intervals or specified times when the switch is connected to a live network; and health-monitoring runs in the background.

Note

Diagnostic shell mode is not supported on Supervisor Engine 9-E, 8-E, and 7-E, in wired mode.

This chapter consists of these sections:

- [Configuring Online Diagnostics, page 82-1](#)
- [Performing Diagnostics, page 82-3](#)
- [Power-On Self-Test Diagnostics, page 82-10](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Configuring Online Diagnostics

These sections describe how to configure online diagnostics:

- [Configuring On-Demand Online Diagnostics, page 82-2](#)
- [Scheduling Online Diagnostics, page 82-2](#)

Configuring On-Demand Online Diagnostics

You can run on-demand online diagnostic tests from the CLI. You can set the execution action to either stop or continue the test when a failure is detected, or to stop the test after a specific number of failures occur with the failure count setting. The iteration setting allows you to configure a test to run multiple times.

To schedule online diagnostics, perform this task:

Command	Purpose
Switch# diagnostic ondemand {iteration iteration_count} {action-on-error {continue stop} [error_count]}	Configures on-demand diagnostic tests to run, how many times to run (iterations), and what action to take when errors are found.

This example shows how to set the on-demand testing iteration count:

```
Switch# diagnostic ondemand iterations 3
Switch#
```

This example shows how to set the execution action when an error is detected:

```
Switch# diagnostic ondemand action-on-error continue 2
Switch#
```

Scheduling Online Diagnostics

You can schedule online diagnostics to run at a designated time of day or on a daily, weekly, or monthly basis. You can schedule tests to run only once or to repeat at an interval. Use the **no** form of this command to remove the scheduling.

To configure online diagnostics, perform this task:

Command	Purpose
Switch(config)# diagnostic schedule module number test {test_id test_id_range all} [port {num num_range all} {on mm dd yyyy hh:mm} {daily hh:mm} {weekly day_of_week hh:mm}]	Schedules on-demand diagnostic tests on the specified module for a specific date and time, how many times to run (iterations), and what action to take when errors are found.

This example shows how to schedule diagnostic testing on a specific date and time for a specific port on module 6:

```
Switch(config)# diagnostic schedule module 6 test 2 port 3 on may 23 2009 23:32
Switch(config)#
```

This example shows how to schedule diagnostic testing to occur daily:

```
Switch(config)# diagnostic schedule module 6 test 2 port 3 daily 12:34
Switch(config)#
```

This example shows how to schedule diagnostic testing to occur weekly:

```
Switch(config)# diagnostic schedule module 6 test 2 port 3 weekly friday 09:23
Switch(config)#
```

Performing Diagnostics

After you configure online diagnostics, you can start or stop diagnostic tests or display the test results. You can also see which tests are configured and what diagnostic tests have already run.

These sections describe how to run online diagnostic tests after they have been configured:

- [Starting and Stopping Online Diagnostic Tests, page 82-3](#)
- [Displaying Online Diagnostic Tests and Test Results, page 82-4](#)
- [Displaying Data Path Online Diagnostics Test Results, page 82-7](#)
- [Line Card Online Diagnostics, page 82-8](#)
- [Troubleshooting with Online Diagnostics, page 82-8](#)

Note

Before you enable any online diagnostics tests, enable the logging console or monitor to observe all warning messages.

Note

When running disruptive tests, only run them when you are connected using the console. When disruptive tests complete, a warning message on the console will recommend that you reload the system to return to normal operation. Strictly follow this warning.

Starting and Stopping Online Diagnostic Tests

After you configure diagnostic tests, you can use the **start** and **stop** keywords to begin or end a test.

To start or stop an online diagnostic command, perform one of these tasks:

Command	Purpose
Switch# diagnostic start module <i>number test {test_id </i> <i>test_id_range minimal complete</i> <i> basic per-port </i> <i>non-disruptive all} [port {num </i> <i>port#_range all}]</i>	Starts a diagnostic test on a port or range of ports on the specified module.
Switch# diagnostic stop module <i>number</i>	Stops a diagnostic test on the specified module.

This example shows how to start a diagnostic test on module 6:

```
Switch# diagnostic start module 6 test 2
Diagnostic[module 6]: Running test(s) 2 Run interface level cable diags
Diagnostic[module 6]: Running test(s) 2 may disrupt normal system operation
Do you want to continue? [no]: yes
Switch#
*May 14 21:11:46.631: %DIAG-6-TEST_RUNNING: module 6: Running online-diag-tdr{ID=2} ...
*May 14 21:11:46.631: %DIAG-6-TEST_OK: module 6: online-diag-tdr{ID=2} has completed
successfully
Switch#
```

This example shows how to stop a diagnostic test on module 6:

```
Switch# diagnostic stop module 6
Diagnostic[module 6]: Diagnostic is not active.
```

The message indicates no active diagnostic on module 6

Displaying Online Diagnostic Tests and Test Results

You can display the configured online diagnostic tests and check the results of the tests with the **show diagnostic** command.

To display the configured diagnostic tests, perform this task:

Command	Purpose
Switch# show diagnostic {bootup cns content [module num] description [module num] events [module num] [event-type event-type] ondemand result [module num] [detail] schedule [module num] simulation status}	Displays the test results of online diagnostics and lists supported test suites.

This example shows how to display the online diagnostics configured on module 1:

```
Switch# show diagnostic content module 6
module 6:
Diagnostics test suite attributes:
  M/C/* - Minimal bootup level test / Complete bootup level test / NA
  B/* - Basic ondemand test / NA
  P/V/* - Per port test / Per device test / NA
  D/N/* - Disruptive test / Non-disruptive test / NA
  S/* - Only applicable to standby unit / NA
  X/* - Not a health monitoring test / NA
  F/* - Fixed monitoring interval test / NA
  E/* - Always enabled monitoring test / NA
  A/I - Monitoring is active / Monitoring is inactive
  cable-tdr/* - Interface cable diags / NA
  o/* - Ongoing test, always active / NA

ID   Test Name                               Attributes      Test Interval  Thre-
====  =====                               =====
1) linecard-online-diag -----> M**D***I**      not configured  n/a
2) online-diag-tdr -----> **PD***Icable- not configured  n/a
3) stub-rx-errors -----> ***N***A**      000 00:01:00.00 n/a
4) supervisor-rx-errors -----> ***N***A**      000 00:01:00.00 n/a
```

This example shows how to display the test description for a given test on a module:

```
Switch# show diagnostic description module 6 test 1

linecard-online-diag :
  Linecard online-diagnostics run after the system boots up but
  before it starts passing traffic. Each linecard port is placed in
  loopback, and a few packets are injected into the switching fabric
  from the cpu to the port. If the packets are successfully
```

received by the cpu, the port passes the test. Sometimes one port or a group of ports sharing common components fail. The linecard is then placed in partial faulty mode. If no ports can loop back traffic, the board is placed in faulty state.

Switch#

This example shows how to display the online diagnostic results for module 6:

Switch# **show diagnostic result module 6**

Current bootup diagnostic level: minimal

Displaying Data Path Online Diagnostics Test Results

A data path online diagnostic test verifies that the data paths between the supervisor engine and the linecards (defined as a number of stub ASICs) are functioning correctly. There is a direct connection between each stub ASIC on a line card and the supervisor engine. Error counters on the supervisor engine (supervisor-rx-trends) and each stub ASIC on a line card (stub-rx-trends) are monitored periodically. Error counters that continually increase indicate malfunctioning hardware in the data path and cause the test to fail. Data path online diagnostic tests are non-destructive and the error counters are polled every minute.

Errors on the stub end of the data path are reported as errors in traffic egressing to the line card from the supervisor engine switching ASICs. Some initial errors might be revealed as links are brought up, but they should not increase. An increasing count indicates a poor connection between the supervisor engine and a line card. If only one line card is affected, the cause is likely an incorrectly seated or faulty line card. The error counts include idle frames, so detection can occur when traffic is not flowing.

Errors on the supervisor end of the data path are reported as errors in traffic ingressing to the supervisor engine from linecards. The error counts should not increase and the detection includes idle frames. If the error counts increase for more than one line card, the likely cause is a faulty supervisor engine or chassis. If only one stub or line card is affected, the likely cause is a faulty line card or a defective mux buffer (for a redundant chassis).

In addition to running periodically, data path online diagnostics can be also be invoked on-demand in the following way:

```

Switch# diagnostic start module 1 test stub-rx-errors
*Apr 1 09:25:14.211: %DIAG-6-TEST_RUNNING: module 1: Running stub-rx-errors{ID=3} ...
*Apr 1 09:25:14.211: %DIAG-6-TEST_OK: module 1: stub-rx-errors{ID=3} has completed
Switch# diagnostic start module 1 test supervisor-rx-errors
*Apr 1 09:25:26.503: %DIAG-6-TEST_RUNNING: module 1: Running supervisor-rx-errors{ID=4}
...
*Apr 1 09:25:26.503: %DIAG-6-TEST_OK: module 1: supervisor-rx-errors{ID=4} has completed
successfully

```

Detailed information about the test results can be viewed as follows:

```
Switch# show diagnostic result module 1 test stub-rx-errors detail
```

Current bootup diagnostic level: minimal

Test results: (. = Pass, F = Fail, U = Untested)

Line Card Online Diagnostics

A line card online diagnostic test verifies that all ports on a line card are working correctly. The test can detect whether the path to the front panel port on the line card is broken. The test cannot indicate where along the path that the problem occurred.

Note

This test is run only for line cards that have stub chips.

Line card online diagnostics runs only once, when the line cards boot. This situation can happen when you insert a line card or power up a chassis.

Line card online diagnostics are performed by sending a packet from the CPU to every port on the line card. Because this packet is marked loopback, the CPU expects to see this packet return from the port. The packet first traverses the ASICs on the supervisor engine card, then travels by using the chassis backplane and the stub chip on the line cards to the PHYs. The PHY sends it back down the same path.

Note

The packet does not reach or exit the front panel port.

Troubleshooting with Online Diagnostics

A faulty line card occurs if any of the following conditions occurs.

- All ports fail
- All ports on a stub chip fail
- Only one port fails

For all of these situations, the output of the **show module** command would display the status of the line card as faulty:

```
Switch# show mod
Chassis Type : WS-C4507R
Power consumed by backplane : 40 Watts
```

Mod	Ports	Card Type	Model	Serial No.
1	6	Sup II+10GE 10GE (X2), 1000BaseX (SFP)	WS-X4013+10GE	JAB091502G0
2	6	Sup II+10GE 10GE (X2), 1000BaseX (SFP)	WS-X4013+10GE	JAB091502FC
3	48	100BaseX (SFP)	WS-X4248-FE-SFP	JAB093305RP
4	48	10/100BaseTX (RJ45)V	WS-X4148-RJ45V	JAE070717E5
5	48	10/100BaseTX (RJ45)V	WS-X4148-RJ45V	JAE061303U3
6	48	10/100BaseTX (RJ45)V	WS-X4148-RJ45V	JAE061303WJ
7	24	10/100/1000BaseT (RJ45)V, Cisco/IEEE	WS-X4524-GB-RJ45V	JAB0815059Q

M	MAC addresses	Hw	Fw	Sw	Status
1	000b.5f27.8b80 to 000b.5f27.8b85	0.2	12.2(27r)SG(12.2(37)SG	Ok
2	000b.5f27.8b86 to 000b.5f27.8b8b	0.2	12.2(27r)SG(12.2(37)SG	Ok
3	0005.9a80.6810 to 0005.9a80.683f	0.4			Ok
4	000c.3016.aae0 to 000c.3016.ab0f	2.6			Ok
5	0008.a3a3.4e70 to 0008.a3a3.4e9f	1.6			Ok
6	0008.a3a3.3fa0 to 0008.a3a3.3fcf	1.6			Faulty
7	0030.850e.3e78 to 0030.850e.3e8f	1.0			Ok

Mod	Redundancy role	Operating mode	Redundancy status
1	Active Supervisor	SSO	Active
2	Standby Supervisor	SSO	Standby hot

To troubleshoot a faulty line card, follow these steps:

Step 1 Enter the command **show diagnostic result module 3**.

If a faulty line card was inserted in the chassis, it will fail the diagnostics and the output will be similar to the following:

```
Current bootup diagnostic level: minimal

module 3:   SerialNo : JAB093305RP

Overall Diagnostic Result for module 3 : MAJOR ERROR
Diagnostic level at card bootup: minimal

Test results: (. = Pass, F = Fail, U = Untested)

1) linecard-online-diag -----> F
```

Switch#

Issue an RMA for the line card, contact TAC, and skip steps 2 and 3.

The output may display the following:

```
module 3:

Overall diagnostic result: PASS

Test results: (. = Pass, F = Fail, U = Untested)

1) linecard-online-diag -----> .
```

The message indicates that the line card passed online diagnostics either when it was inserted into the chassis the last time or when the switch was powered up (as reported by the “.”). You need to obtain additional information to determine the cause.

Step 2 Insert a different supervisor engine card and reinsert the line card.

If the line card passes the test, it suggests that the supervisor engine card is defective.

Issue an RMA for the supervisor engine, contact TAC, and skip step 3.

Because online diagnostics are not run on the supervisor engine card, you cannot use the **#show diagnostic module 1** command to test whether the supervisor engine card is faulty.

Step 3 Reinsert the line card in a different chassis.

If the line card passes the test, the problem is associated with the chassis.

Issue an RMA for the chassis and contact TAC.

Power-On Self-Test Diagnostics

The following topics are discussed:

- [Overview of Power-On Self-Test Diagnostics, page 82-10](#)
- [POST Result Example, page 82-11](#)
- [Power-On Self-Test Results, page 82-12](#)
- [Troubleshooting the Test Failures, page 82-18](#)

Overview of Power-On Self-Test Diagnostics

All Catalyst 4500 series switches have power-on self-test (POST) diagnostics that run whenever a supervisor engine boots. POST tests the basic hardware functionality for the supervisor switching engine, its associated packet memory and other on-board hardware components. The results of the POST impacts how the switch boots, because the health of the supervisor engine is critical to the operation of the switch. The switch might boot in a marginal or faulty state.

POST is currently supported on the following supervisor engines:

- WS-X4014
- WS-X4515
- WS-X4516
- WS-X4516-10GE
- WS-X4013+
- WS-X4013+TS
- WS-X4013+10GE
- WS-X45-SUP6L-E
- WS-X45-SUP7-E
- WS-X45-SUP7L-E
- WS-X45-SUP8-E

- WS-X45-SUP8L-E
- WS-X45-SUP9-E

The POST results are indicated with a period (.) or a Pass for Pass, an F for a Fail and a U for Untested.

POST Result Example

For all the supervisor engines, POST performs CPU, traffic, system, system memory, and feature tests.

For CPU tests, POST verifies appropriate activity of the supervisor engine SEEPROM, temperature sensor, and Ethernet end-of-band channel (EOBC), when used.

The following example illustrates the output of a CPU subsystem test:

```
[...]
Cpu Subsystem Tests ...
seeprom: . temperature_sensor: . eobc: .
[...]
```

For traffic tests, the POST sends packets from the CPU to the switch. These packets loop several times within the switch core and validate the switching, the Layer 2 and the Layer 3 functionality. To isolate the hardware failures accurately, the loop back is done both inside and outside the switch ports.

Switch#

Troubleshooting the Test Failures

A failure of any of the POST tests reflects a problem with the hardware on the supervisor engine. Cisco IOS boots the supervisor engine with limited functionality, allowing you to evaluate and display the diagnostic test results. To determine the failure cause, do one of the following:

- Evaluate whether the hardware failure is persistent by power cycling the supervisor engine to rerun the POST tests.

- Remove and reinsert the supervisor engine into the chassis to ensure that the seating is correct. Contact Cisco Systems customer support team for more information.

**Note**

On a redundant chassis, concurrent POST is supported on supervisor engines that are already inserted. However, if a second supervisor engine is inserted while the first one is loading, you might boot the first supervisor engine in a faulty Cisco IOS state (POST will abort, and some of the POST's tests will be bypassed). This situation only happens during concurrent bootup of the supervisor engines. You should not insert any additional supervisor engines in the empty supervisor engine slot while an already seated supervisor engine is running POST. The POST sequence is completed when the "Exiting to ios..." message is displayed.

Configuring WCCP Version 2 Services

This chapter describes how to configure the Catalyst 4500 Series Switches to redirect traffic to content engines (web caches) using Web Cache Communication Protocol (WCCP) Version 2

Note

Throughout this chapter, WCCP refers to WCCP Version 2. Version 1 is *not* supported.

This chapter consists of these sections:

- [Understanding WCCP, page 83-1](#)
- [Restrictions for WCCP, page 83-5](#)
- [Configuring WCCP, page 83-5](#)
- [Verifying and Monitoring WCCP Configuration Settings, page 83-9](#)
- [WCCP Configuration Examples, page 83-9](#)

Note

The tasks in this chapter assume that you have already configured content engines on your network. For specific information on hardware and network planning associated with Cisco Content Engines and WCCP, see the product literature and documentation links available on Cisco.com:

http://www.cisco.com/en/US/docs/ios/12_2/configfun/configuration/guide/fcf018_ps1835_TSD_Products_Configuration_Guide_Chapter.html

and

http://www.cisco.com/en/US/tech/tk122/tk717/tsd_technology_support_protocol_home.html

Understanding WCCP

These sections describe WCCP:

- [Overview, page 83-2](#)
- [Hardware Acceleration, page 83-2](#)
- [Understanding WCCP Configuration, page 83-3](#)
- [WCCP Features, page 83-3](#)

Overview

The Cisco IOS WCCP feature allows use of Cisco Content Engines (or other content engines running WCCP) to localize web traffic patterns in the network, enabling content requests to be fulfilled locally. Traffic localization reduces transmission costs and download time.

WCCP enables Cisco IOS routing platforms to transparently redirect content requests. The main benefit of transparent redirection of HTTP/non-HTTP requests is that users need not configure their browsers to use a web proxy. Instead, they can use the target URL to request content, and have their requests automatically redirected to a content engine. The word “transparent” in this case means that the end user does not know that a requested file (such as a web page) came from the content engine instead of from the originally specified server.

When a content engine receives a request, it attempts to service it from its own local content. If the requested information is not present, the content engine issues its own request to the originally targeted server to get the required information. When the content engine retrieves the requested information, it forwards it to the requesting client and caches it to fulfill future requests, thus maximizing download performance and substantially reducing transmission costs.

WCCP enables a series of content engines, called a *content engine cluster*, to provide content to a router or multiple routers. Network administrators can easily scale their content engines to handle heavy traffic loads using these clustering capabilities. Cisco clustering technology enables each content member to work in parallel, resulting in linear scalability. Clustering content engines greatly improves the scalability, redundancy, and availability of your caching solution. You can cluster up to 32 content engines to scale to your desired capacity.

Beginning in Cisco IOS XE Release 3.7.1E, WCCPv2 is supported on Virtual Switching System (VSS).

Beginning in Cisco IOS XE Release 3.8.0E, WCCPv2 supports traffic redirection to and from Virtual Routing and Forwarding (VRF) interfaces. Ensure that you configure the content engine running WCCP such that the forward and return traffic, to and from the content engine, is from interfaces that are a part of the same VRF. The VRF used for WCCP on an interface should match the VRF configured on that interface.

The feature is supported on Cisco Catalyst 4500E Series Switches with Supervisor Engine 9-E, 8-E, 7-E and Cisco Catalyst 4500-X switches, on the IP Base image and the Enterprise Services image.

Hardware Acceleration

Hardware Acceleration is enabled by default on Catalyst 4500 series switches. Layer 2 rewrite forwarding and Layer 2 return method are supported in hardware.

When the switch exhausts hardware (TCAM) or software resources, traffic is redirected in software. GRE return method is supported only in software.

Configure a directly connected content engine to negotiate use of the WCCP Layer 2 Redirection feature (with load balancing) based on the mask assignment table. The **show ip wccp web-cache detail** command displays the redirection method in use for each cache.

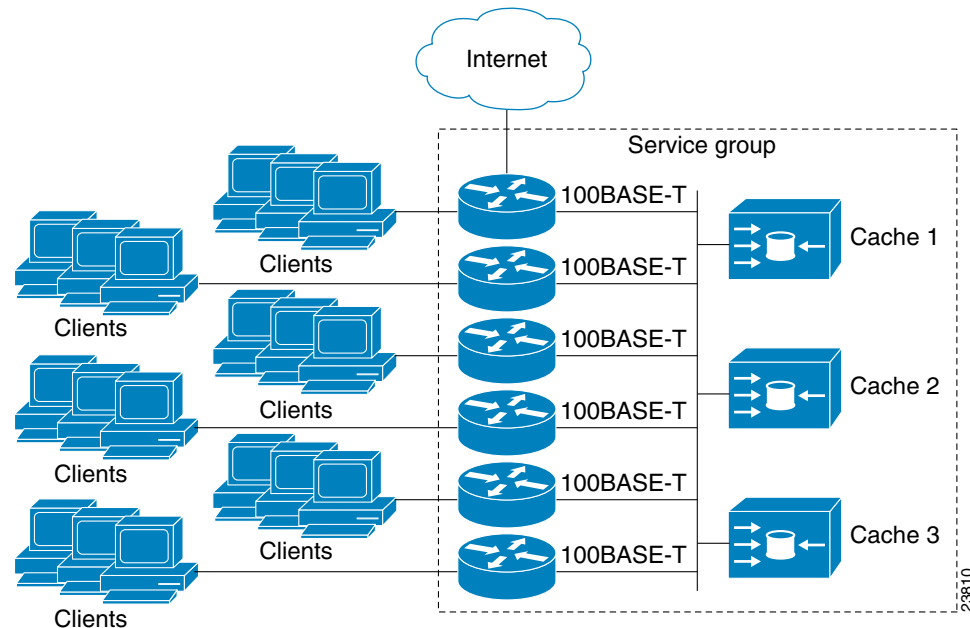

**Note**

You can configure the Cisco Content Engine Release 2.2 or later to use the WCCP Layer 2 Redirection feature with the mask assignment table.

Understanding WCCP Configuration

Multiple routers can use WCCP to service a cache cluster. [Figure 83-1](#) illustrates a sample configuration using multiple routers.

Figure 83-1 Cisco Content Engine Network Configuration Using WCCP

The subset of content engines within a cluster and routers connected to the cluster that are running the same service is known as a *service group*. Available services include TCP and User Datagram Protocol (UDP) redirection.

WCCP requires that each content engine be aware of all the routers in the service group. You must a list of IP addresses for each of the routers in the group configured on each content engine. The address of each router in the group must be explicitly specified for each content engine during configuration.

The following sequence of events describe how WCCP works:

1. Each WCCP client (content engine) is configured with a list of WCCP servers (routers).
2. Each content engine announces its presence with a `Here I Am` message and a list of routers with which it has established communication. The routers reply with their view (list) of content engines in the service group through `I See You` messages.
3. If the view is consistent across all content engines in the cluster, one content engine is designated as the lead and sets the policy that the switches deploy in redirecting traffic.

WCCP Features

These sections describe WCCP features:

- [HTTP and Non-HTTP Services Support](#)
- [Multiple Routers Support](#)
- [MD5 Security](#)

- [Web Content Packet Return](#)

HTTP and Non-HTTP Services Support

WCCP enables redirection of HTTP traffic (TCP port 80 traffic), as well as non-HTTP traffic (TCP and UDP). WCCP supports the redirection of packets intended for other ports, including those used for proxy-web cache handling, File Transfer Protocol (FTP) caching, FTP proxy handling, web caching for ports other than 80, and real audio, video, and telephony applications.

To accommodate the various types of services available, WCCP introduces the concept of multiple *service groups*. Service information is specified in the WCCP configuration commands using dynamic services identification numbers (such as 98) or a predefined service keywords (such as web-cache). This information is used to validate that service group members are all using or providing the same service.

Note

The Catalyst 4500 series switch supports up to eight service groups.

For information on supported WCCP version 2 services with ACNS version 5.2 software, refer to the *Release Notes for Cisco ACNS Software, Release 5.2.3*.

The content engines in service group specify traffic to be redirected by protocol (TCP or UDP) and port (source or destination). Each service group has a priority level assigned to it. Packets are matched against service groups in priority order and redirected by the highest priority service group that matches traffic characteristics.

Multiple Routers Support

WCCP enables you to attach multiple routers to a cluster of cache engines. The use of multiple routers in a service group enables redundancy, interface aggregation, and distribution of the redirection load.

MD5 Security

WCCP provides optional authentication that enables you to control which routers and content engines become part of the service group using passwords and the HMAC MD5 standard. Shared-secret MD5 one-time authentication (set using the **ip wccp [password [0-7] password]** global configuration command) enables messages to be protected against interception, inspection, and replay.

Web Content Packet Return

If a content engine is unable to provide a requested object it has cached due to error or overload, the content engine returns the request to the router for onward transmission to the originally specified destination server. WCCP verifies which requests have been returned from the content engine unserved. Using this information, the router can then forward the request to the originally targeted server (rather than attempting to resend the request to the content cluster). This provides error handling transparency to clients.

Typical reasons why a content engine would reject packets and initiate the packet return feature include the following:

- Instances when the content engine is overloaded and has no room to service the packets.
- Instances when the content engine is filtering for certain conditions that make caching packets counterproductive (such as, when IP authentication has been turned on).

Restrictions for WCCP

The following limitations apply to WCCP:

- Time To Live (TTL) value of Layer 3 switches servicing a cluster must be 15 seconds or less.
- A service group can comprise up to 32 content engines and 32 devices.
- All the content engines in a cluster must be configured to communicate with all the devices servicing the cluster.
- A total of eight active IPv4 and IPv6 service groups are supported on a switch. If used in pairs, up to four service-group pairs can be configured simultaneously.
- The Layer 2 rewrite forwarding method is supported in the hardware.
- The Layer 2 return method is supported in the hardware and is recommended.
- The content engine must be directly connected to the device.
- Input/output redirection configuration is not supported on content engines facing interfaces.
- WCCPv2 supports up to 256 distinct masks. However, a Catalyst 4500 series switch only supports a single mask.

Configuring WCCP

The following configuration tasks assume that you have already installed and configured the content engines you want to include in your network. You must configure the content engines in the cluster before configuring WCCP on your device. Refer to the [Cisco Content Engine User Guide](#) for content engine configuration and setup tasks.

IP must be configured on the device interface connected to the cache engines. Examples of device configuration tasks follow this section. For complete descriptions of the command syntax, refer to the *Cisco IOS Configuration Fundamentals Command Reference, Cisco IOS Release 12.3*.

These sections describe how to configure WCCP:

- [Configuring a Service Group Using WCCP, page 83-5](#) (Required)
- [Using Access Lists for a WCCP Service Group, page 83-8](#) (Optional)
- [Setting a Password for a Switch and Cache Engine, page 83-8](#) (Optional)

Configuring a Service Group Using WCCP

WCCP uses service groups based on logical redirection services. The standard service is the content engine, which intercepts TCP port 80 (HTTP) traffic and redirects that traffic to the content engines. This service is referred to as a well-known service, because the characteristics of the web cache service are known by both the router and content engines. A description of a well-known service is not required beyond a service identification (the command line interface (CLI) provides a **web-cache** keyword in the command syntax).

For information on supported WCCP services with ACNS version 5.2 software, refer to the *Release Notes for Cisco ACNS Software, Release 5.2.3*.

In addition to the web cache service, there can be up to seven dynamic services running concurrently on the switch.

**Note**

More than one service can run on a switch at the same time, and routers and content engines can be part of multiple service groups at the same time.

The dynamic services are defined by the content engines; the content engine instructs the router which protocol or ports to intercept, and how to distribute the traffic. The router itself does not have information on the characteristics of the dynamic service group's traffic, because this information is provided by the first content engine to join the group. In a dynamic service, up to eight ports can be specified within a single protocol TCP or UDP).

Cisco Content Engines, for example, use dynamic service 99 to specify a reverse-proxy service. However, other content engines may use this service number for some other service. The following configuration information deals with enabling general services on Cisco routers. Refer to the content engine documentation for information on configuring services on content engines.

To enable a service on a Catalyst 4500 series switch, perform this task:

	Command	Purpose
Step 1	<pre>Switch(config)# ip wccp [vrf vrf-name] [group-address groupaddress] [redirect-list access-list] [group-list access-list] [password password]</pre> <p>For IPv6</p> <pre>Switch(config)# ipv6 wccp [vrf vrf-name] [group-address groupaddress] [redirect-list access-list] [group-list access-list]</pre>	<p>Specifies the following:</p> <ul style="list-style-type: none"> • A dynamic service to enable on the switch, • The IP multicast address used by the service group (optional) • The redirect access list to control the traffic to be redirected (optional) • The group list to use for content engine membership (optional) • Whether to use MD5 authentication (optional) <p>Enables the WCCP service.</p>
Step 2	<pre>Switch(config-if)# [no] ip wccp check services all</pre> <p>For IPv6</p> <pre>Switch(config-if)# [no] ipv6 wccp check services all</pre>	<p>If a service matches the packet and the service has a redirect access list configured, then the IP packet will be checked against the access list. If the packet is rejected by the access-list, the packet will not be passed down to lower priority services unless the ip wccp check services all command is configured. After the ip wccp check services all command is configured, WCCP will continue to attempt to match the packet against any remaining low priority services configured on the interface.</p>
Step 3	<pre>Switch(config)# interface type number</pre>	<p>Specifies the client interface to be configured and enters interface configuration mode.</p>
Step 4	<pre>Switch(config-if)# ip wccp [vrf vrf-name]{web-cache service-number} redirect {in out}</pre> <p>For IPv6</p> <pre>Switch(config-if)# ipv6 wccp [vrf vrf-name] redirect in</pre>	<p>For IPv4, enables WCCP redirection for ingress or egress traffic on the specified client interface.</p> <p>For IPv6, enables WCCP redirection for ingress traffic on the specified client interface.</p>

	Command	Purpose
Step 5	Switch(config)# interface <i>type number</i>	Specifies the interface to be configured for egress redirection exclusion
Step 6	Switch(config-if)# ip wccp redirect exclude in	Specifies that packets received on this interface be excluded from egress redirection. This command MUST be configured on the content engine interface if Layer 2 return method is used by the content engine and egress redirection is configured on the server interface.

Specifying a Web Cache Service

To configure a web cache service and ingress redirection for IPv4 perform this task:

	Command	Purpose
Step 1	Switch(config)# ip wccp [vrf <i>vrf-name</i>] web-cache	Enables the web cache service on the switch.
Step 2	Switch(config)# interface <i>type number</i>	Targets a client interface number for which the web cache service runs, and enters interface configuration mode.
Step 3	Switch(config-if)# ip wccp [vrf <i>vrf-name</i>] web-cache redirect in	Enables the verification on packets to determine if they qualify to be redirected to a content engine, using the client interface specified in Step 2.

To configure a web cache service and egress redirection for IPv4 traffic, perform this task:

	Command	Purpose
Step 1	Switch(config)# ip wccp [vrf <i>vrf-name</i>] web-cache	Enables the web cache service on the switch.
Step 2	Switch(config)# interface <i>type number</i>	Targets a server interface number for the web cache service, and enters interface configuration mode.
Step 3	Switch(config-if)# ip wccp web-cache redirect out	Enables the verification on packets to determine if they qualify to be redirected to a content engine, using the client interface specified in Step 2.
Step 4	Switch(config)# interface <i>type number</i>	Specifies the content engine interface number, and enters interface configuration mode.
Step 5	Switch(config-if)# ip wccp redirect exclude in	Specifies that packets received on this interface be excluded from egress redirection. This prevents the packets returned by the content engine through the L2-return method or the packets generated by the content engine from being redirected back to the content engine.

Using Access Lists for a WCCP Service Group

A Catalyst 4500 series switch can use an access list to restrict the content engines that can join a service group.

To restrict a content engine, perform this task:

	Command	Purpose
Step 1	Switch(config)# access-list <i>access-list</i> permit ip host <i>host-address</i> [<i>destination-address</i> <i>destination-host</i> any]	Creates an access list based on the unicast address of the content engines.
Step 2	Switch(config)# ip wccp web-cache redirect-list <i>access-list</i> For IPv6 Switch(config)# ipv6 wccp [vrf <i>vrf-name</i>]{ <i>service-number</i> } redirect-list <i>access-list</i>	Indicates to the switch which content engines are allowed or disallowed to form a service group.

Setting a Password for a Switch and Cache Engine

MD5 password security requires that each content engine and Catalyst 4500 series switch that wants to join a service group be configured with the service group password. The password can consist of up to seven characters. Each content engine or Catalyst 4500 series switch in the service group authenticates the security component in a received WCCP packet immediately after validating the WCCP message header. Packets failing authentication are discarded.

To configure an MD5 password for use by the Catalyst 4500 series switch in WCCP communications, perform this task:

Command	Purpose
Switch(config)# ip wccp web-cache password <i>password</i>	Sets an MD5 password on the Catalyst 4500 series switch.

Verifying and Monitoring WCCP Configuration Settings

To verify and monitor the configuration settings for WCCP, use the following commands in EXEC mode:

Command	Purpose
Switch# show ip wccp [vrf vrf-name] [web-cache service-number] For IPv6 Switch# show ipv6 wccp [vrf vrf-name] Switch# show ip wccp [vrf vrf-name] { web-cache service-number } detail For IPv6 Switch# show ipv6 wccp [vrf vrf-name] detail Switch# show ip interface	Displays global information related to WCCP, including the protocol version that is currently running, the number of content engines in the routers service group, the content engine group is allowed to connect to the device, and the access list being used. Queries the device for information on which content engines of a specific service group that the device has detected. The information can be displayed for either the web cache service or for the specified dynamic service. Displays the status about whether redirection commands are configured on a client interface. For example, Web Cache Redirect is enabled / disabled.
Switch# show ip wccp [vrf vrf-name] { web-cache service-number } view For IPV6 Switch# show ipv6 wccp [vrf vrf-name] view	Displays the devices in a particular service group that have been detected and the content engines that are not visible to all other devices to which the current device is connected. The view keyword indicates a list of addresses of the service group. The information can be displayed for either the web cache service or the specified dynamic service. Note For further troubleshooting information, use the show ip wccp { web-cache service number } service command.

WCCP Configuration Examples

This section provides the following configuration examples:

- [Example: Performing a General WCCP Configuration, page 83-10](#)
- [Example: Running a Web Cache Service, page 83-10](#)
- [Example: Running a Reverse Proxy Service, page 83-10](#)
- [Example: Running TCP-Promiscuous Service, page 83-11](#)
- [Example: Running Redirect Access List, page 83-12](#)
- [Example: Using Access Lists, page 83-12](#)
- [Example: Setting a Password for a Switch and Content Engines, page 83-13](#)
- [Example: Verifying WCCP Settings, page 83-13](#)

Example: Performing a General WCCP Configuration

The following example shows a general WCCP configuration session. VLAN 20 is for the client interface. VLAN 50 is for the content engine interface.

```
Switch# configure terminal
Switch(config)# ip wccp web-cache group-address 224.1.1.100 password alaska1
Switch(config)# interface vlan 20
Switch(config-if)# ip wccp web-cache redirect in
Switch(config)# interface vlan 50
Switch(config-if)# ip wccp web-cache group-listen
```

The following example shows a general IPv6 WCCP configuration where GigabitEthernet 0/1/0 is the client interface and GigabitEthernet 0/2/0 is the content engine interface:

```
Switch# configure terminal
Switch(config)# ipv6 wccp interface GigabitEthernet 0/1/0
Switch(config)# ipv6 wccp check services all
Switch(config)# interface GigabitEthernet 0/1/0
Switch(config-if)# ipv6 wccp redirect in
Switch(config)# interface GigabitEthernet 0/2/0
```

Example: Running a Web Cache Service

The following example shows a web cache service configuration session with ingress redirection, for IPv4:

```
Switch# configure terminal
Switch(config)# ip wccp web-cache
Switch(config)# interface vlan 20
Switch(config-if)# ip wccp web-cache redirect in
Switch# copy running-config startup-config
Switch# show ip interface vlan 20 | include WCCP Redirect
```

```
WCCP Redirect inbound is enabled
WCCP Redirect exclude is disabled
```

The following example shows a web-cache service configuration session with ingress redirection, for an IPv4 VRF interface:

```
Switch# configure terminal
Switch(config)# ip wccp vrf test web-cache
Switch(config)# interface vlan 10
Switch(config-if)# vrf forwarding test
Switch(config-if)# ip wccp vrf test web-cache redirect in
Switch# copy running-config startup-config
```

Example: Running a Reverse Proxy Service

**Note**

The WCCP reverse proxy service is not supported for IPv6 traffic.

The following example assumes you are configuring a service group using Cisco Content Engines, which use dynamic service 99 to run a reverse proxy service. The following example illustrates how to configure egress redirection, where VLAN 40 reflects the server interface and VLAN 50 reflects the content engine interface:

```
Switch# configure terminal
Switch(config)# ip wccp 99
Switch(config)# interface vlan 40
Switch(config-if)# ip wccp 99 redirect in
Switch(config)# interface vlan 50
Switch(config-if)# ip wccp redirect exclude in
```

For IPv6

```
Switch# configure terminal
Switch(config)# ipv6 wccp 99
Switch(config)# interface vlan 40
Switch(config-if)# ipv6 wccp 99 redirect in
Switch(config)# interface vlan 50
```

Example: Running TCP-Promiscuous Service

The following example shows how to configure TCP promiscuous service, where VLAN 40 represents the server interface and VLAN 50 represents the content engine interface:

```
Switch# configure terminal
Switch(config)# ip wccp 61
Switch(config)# ip wccp 62
Switch(config)# interface vlan 30
Switch(config-if)# ip wccp 61 redirect in
Switch(config)# interface vlan 40
Switch(config-if)# ip wccp 62 redirect in
Switch(config)# interface vlan 50
Switch(config-if)# ip wccp redirect exclude in
```

For IPv6

```
Switch# configure terminal
Switch(config)# ipv6 wccp 51
Switch(config)# ipv6 wccp 52
Switch(config)# interface vlan 30
Switch(config-if)# ipv6 wccp 51 redirect in
Switch(config)# interface vlan 40
Switch(config-if)# ipv6 wccp 52 redirect in
```

The following example shows how to configure the TCP promiscuous service for IPv4 VRF interfaces, where VLAN 40 represents the server interface and VLAN 50 represents the content engine interface:

```
Switch# configure terminal
Switch(config)# ip wccp vrf abc 91
Switch(config)# ip wccp vrf abc 92
Switch(config)# interface vlan 30
Switch(config-if)# vrf forwarding abc s
Switch(config-if)# ip wccp vrf abc 91 redirect in
Switch(config)# interface vlan 40
Switch(config-if)# vrf forwarding abc
Switch(config-if)# ip wccp vrf abc 92 redirect in
Switch(config)# interface vlan 50
Switch(config-if)# vrf forwarding abc
```

Example: Running Redirect Access List

The following example shows how to redirect traffic only from subnet 10.1.1.0:

```
Switch(config)# ip access-list extended 100
Switch(config-ext-nacl)# permit ip 10.1.1.0 255.255.255.0 any
Switch(config-ext-nacl)# exit
Switch(config)# ip wccp web-cache redirect-list 100
Switch(config)# interface vlan 40
Switch(config-if)# ip wccp web-cache redirect in
Switch(config)# interface vlan 50
Switch(config-if)# ip wccp redirect exclude in
```

The following example shows how to redirect IPv6 traffic only from 2001::1/64 2004::1/64 eq www:

```
switch(config)# ipv6 access-list ACL_1
switch(config-ipv6-acl)# permit tcp 2001::1/64 2004::1/64 eq www
switch(config-ipv6-acl)# exit
switch(config)# ipv6 wccp 61 redirect-list ACL_1
switch(config)# interface vlan 40
switch(config-if)# ipv6 wccp 61 redirect in
```

Example: Using Access Lists

To achieve better security, you can use a standard access list to notify the Catalyst 4500 series switch to which IP addresses are valid for a content engine attempting to register with the current switch. The following example shows a standard access list configuration session where the access list number is 10 for some sample hosts:

```
switch(config)# access-list 10 permit host 11.1.1.1
switch(config)# access-list 10 permit host 11.1.1.2
switch(config)# access-list 10 permit host 11.1.1.3
switch(config)# ip wccp web-cache group-list 10
```

The following examples shows a standard access list configuration for IPv6:

```
switch(config)#ipv6 access-list ACL_1
switch(config-ipv6-acl)#permit tcp 2001::1/64 2004::1/64 eq www
switch(config)#ipv6 wccp 61 redirect-list ACL_1
```

Example: Setting a Password for a Switch and Content Engines

The following example shows a WCCP password configuration session where the password is `alaska1`:

```
Switch# configure terminal
Switch(config)# ip wccp web-cache password alaska1
```

Example: Verifying WCCP Settings

To verify your configuration changes, use the **more system:running-config EXEC** command. The following example shows that both the web cache service and dynamic service 99 are enabled on the Catalyst 4500 series switch:

WCCP Unicast Mode

```
Switch# more system:running-config

Building configuration...

Configuring MIB Support

This chapter describes how to configure SNMP and MIB support for the Cisco 4500 series switch. It includes the following sections:

- [Determining MIB Support for Cisco IOS Releases, page 84-1](#)
- [Using Cisco IOS MIB Tools, page 84-1](#)
- [Downloading and Compiling MIBs, page 84-2](#)
- [Enabling SNMP Support, page 84-4](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Determining MIB Support for Cisco IOS Releases

To determine which MIBs are included in the Cisco IOS release running on the Cisco 4500 series switch, follow these steps:

- Step 1** Go to the Cisco MIBs Support page:
<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>
- Step 2** Under Cisco Access Products, select a **Cisco 4500 switch** to display a list of MIBs supported on the Cisco 4500 switches.
- Step 3** Scroll through the list to find the release you are interested in.

Using Cisco IOS MIB Tools

This section describes how to access the Cisco MIB tools page. The MIB Locator finds MIBs in Cisco IOS software releases. You can find general MIB information, instructions about how to use the SNMP Object Navigator which translates SNMP object identifiers (OIDs) into SNMP names, and how to load Cisco MIBs.

To access the Cisco IOS MIB tools site, follow these steps:

Step 1 Go to the Cisco Products and Services page:
<http://tools.cisco.com/ITDIT/MIBS/servlet/index>

Step 2 Click **MIB Locator** to launch the application.

The MIB Locator application allows you to find a MIB in the following three ways.

- From the MIB Locator page, you can:
 - Click the drop-down menu and select the desired Cisco IOS software release.
 - From the Platform Family menu, select the appropriate feature set: **CAT4500-SUP2-PLUS**, **CAT4500-SUP2-PLUS-TS**, **CAT4500-SUP3**, **CAT4500-SUP4**, **CAT4500-SUP5**, **CAT4500-SUP5-10gGE2**. If you select the platform first, the system displays only those releases and feature sets that apply to the Cisco 4500 series switch.
 - From the Feature Set menu, select **Service Provider W/VIP**.
- From the MIB Locator page, you can search by image name. For example, enter the following and click the **Submit** button:
 c7200-js56i-mz.12.0-1
- From the MIB Locator page, you can search for the MIB from the list of MIBs in the menu. You can select one, or for multiple selections, hold down the **CTRL** key, then click the **Submit** button.

Note After you make a selection, follow the links and instructions.

Downloading and Compiling MIBs

The following sections provide information about how to download and compile MIBs for the Cisco 4500 series switch:

- [Guidelines for Working with MIBs, page 84-2](#)
- [Downloading MIBs, page 84-3](#)
- [Compiling MIBs, page 84-4](#)

Guidelines for Working with MIBs

While working with MIBs, consider the following guidelines:

- Mismatches on datatype definitions might cause compiler errors or warning messages. Although Cisco MIB datatype definitions are not mismatched, some standard RFC MIBs do mismatch. For example:

```
MIB A defines: SomeDatatype ::= INTEGER(0..100)
MIB B defines: SomeDatatype ::= INTEGER(1..50)
```

This example is considered to be a trivial error and the MIB loads successfully with a warning message.

The next example is considered as a nontrivial error (even though the two definitions are essentially equivalent), and the MIB is not successfully parsed.

```
MIB A defines: SomeDatatype ::= DisplayString
MIB B defines: SomeDatatype ::= OCTET STRING (SIZE(0..255))
```

If your MIB compiler treats these as errors, or you want to delete the warning messages, edit one of the MIBs that define this same datatype so that the definitions match.

- Many MIBs import definitions from other MIBs. If your management application requires MIBs to be loaded, and you experience problems with undefined objects, you might want to load the following MIBs in this order:

```
SNMPv2-SMI.my
SNMPv2-TC.my
SNMPv2-MIB.my
RFC1213-MIB.my
IF-MIB.my
CISCO-SMI.my
CISCO-PRODUCTS-MIB.my
CISCO-TC.my
```

- For additional information and SNMP technical tips, go to the following URL:
http://www.cisco.com/en/US/tech/tk648/tk362/technologies_tech_note09186a0080094aa5.shtml
- For a list of SNMP OIDs assigned to MIB objects, go to the following URL and click on **SNMP Object Navigator** and follow the links:
<http://tools.cisco.com/ITDIT/MIBS/servlet/index>

Note You must have a Cisco CCO name and password to access the MIB Locator.

- For information about how to download and compile Cisco MIBs, go to the following URL:
http://www.cisco.com/en/US/tech/tk648/tk362/technologies_tech_note09186a00800b4cee.shtml

Downloading MIBs

to download the MIBs onto your system if they are not already present, follow these steps:

-
- Step 1** Review the guidelines in the previous section (“[Guidelines for Working with MIBs](#)”).
- Step 2** Go to one of the following Cisco URLs. If the MIB you want to download is not there, try the other URL; otherwise, go to one of the URLs in Step 5.
- <ftp://ftp.cisco.com/pub/mibs/v2>
- <ftp://ftp.cisco.com/pub/mibs/v1>
- Step 3** Click the link for a MIB to download that MIB to your system.
- Step 4** Select **File > Save** or **File > Save As** to save the MIB on your system.
- Step 5** You can download industry-standard MIBs from the following URL:
- <http://www.oidview.com/mibs/0/md-0-1.html>
-

Compiling MIBs

If you plan to integrate the Cisco 4500 series switch with an SNMP-based management application, then you must also compile the MIBs for that platform. For example, if you are running HP OpenView on a UNIX operating system, you must compile Cisco 4500 series switch MIBs with the HP OpenView Network Management System (NMS). For instructions, see the NMS documentation.

Enabling SNMP Support

The following procedure summarizes how to configure the Cisco 4500 series switch for SNMP support.

For detailed information about SNMP commands, see the following Cisco documents:

- *Cisco IOS Release 15.0 Configuration Guides*, available at the following URL:
http://www.cisco.com/en/US/products/ps10591/products_installation_and_configuration_guides_list.html
- *Cisco IOS Release 12.3 Configuration Fundamentals and Network Management Command Reference*, Part 3: System Management Commands, “Router and Network Configuration Commands” section, available at the following URL:
http://www.cisco.com/en/US/docs/ios/12_3/configfun/command/reference/fun_r.html

To configure the Cisco 4500 series switch for SNMP support, follow these steps:

-
- Step 1** Establish your basic SNMP configuration using the command line interface (CLI) on the router. Note that these basic configuration commands are issued for SNMP version 2c. For SNMP version 3, you must also set up SNMP users and groups. Refer to the preceding list of documents for command and set up information.
- Define SNMP read-only and read-write communities:

```
Router (config)# snmp-server community Read_Only_Community_Name ro
Router (config)# snmp-server community Read_Write_Community_Name rw
```
 - Configure SNMP views (to limit the range of objects accessible to different SNMP user groups):

```
Router (config)# snmp-server view view_name oid-tree {included | excluded}
```
- Step 2** Identify (by IP address) the host to receive SNMP notifications from the router:

```
Router (config)# snmp-server host host
```
- Step 3** Configure the router to generate notifications. You can use keywords to limit the number and types of messages generated.

```
Router (config)# snmp-server enable traps [notification-type] [notification-option]
```
- Step 4** (Optional) Configure the router to generate SNMP notifications released to field replaceable units (FRUs):

```
Router (config)# snmp-server enable traps fru-ctrl
```
- Step 5** (Optional) Configure the router to generate SNMP notifications related to environmental monitoring:

```
Router (config)# snmp-server enable traps envmon
```
-

Configuring Easy Virtual Networks

Easy Virtual Network (EVN) is an IP-based virtualization technology that provides end-to-end virtualization of two or more Layer-3 networks. You can use a single IP infrastructure to provide separate virtual networks whose traffic paths remain isolated from each other.

This chapter contains the following sections

- [Prerequisites for Configuring Easy Virtual Network, page 85-1](#)
- [Restrictions for EVN, page 85-1](#)
- [About Easy Virtual Network, page 85-2](#)
- [Configuring Easy Virtual Networks, page 85-14](#)
- [Configuration Examples for Configuring EVN, page 85-18](#)
- [Troubleshooting EVN Configuration, page 85-22](#)

Prerequisites for Configuring Easy Virtual Network

- Implementing EVN in a network requires a single IP infrastructure that you want to virtualize into two or more logical networks or L3VPNs. EVN provides path isolation for the traffic on the different virtual networks.
- You must have a functioning campus design in place before adding virtualization to a network.
- You should understand virtual routing and forwarding (VRF) instances and how they are used to maintain traffic separation across the network.

Restrictions for EVN

- EIGRP command inheritance is not supported on VNET interfaces.
- The **vnet tag** command does not support management VRFs.
- We recommend that you configure a value between 2 and 1000 as the VNET tag. Configuring a value above this range will conflict with the switch internal VLAN assignments.
- An EVN trunk is allowed on any interface that supports 802.1q encapsulation, such as Fast Ethernet, Gigabit Ethernet, and port channels.
- There are additional platform and line-card restrictions for an EVN trunk. Check Cisco Feature Navigator, for supported platforms and line cards.

- A single IP infrastructure can be virtualized to provide up to 32 virtual networks end-to-end.
- If an EVN trunk is configured on an interface, you cannot configure VRF-Lite on the same interface.
- OSPFv3 is not supported; OSPFv2 is supported.
- The following features are not supported by EVN:
 - IS-IS
 - RIP
 - Route replication is not supported with BGP
 - Certain SNMP set operations
- The following are not supported on an EVN trunk:
 - Access control lists (ACLs)
 - BGP interface commands are not inherited
 - IPv6, except on vnet global
 - Network address translation (NAT)
 - NetFlow
 - Web Cache Communication Protocol (WCCP)

About Easy Virtual Network

Easy Virtual Network (EVN) builds on the existing IP-based virtualization mechanism known as VRF-Lite. EVN provides enhancements in path isolation, simplified configuration and management, and improved shared service support. EVN is backward compatible with VRF-Lite to enable seamless network migration from VRF-Lite to EVN.

EVN supports IPv4, static routes, Open Shortest Path First version 2 (OSPFv2), and Protocol Independent Multicast (PIM) and Multicast Source Discovery Protocol (MSDP) for IPv4 Multicast routing. EVN also supports Cisco Express Forwarding (CEF) and Simple Network Management Protocol (SNMP).

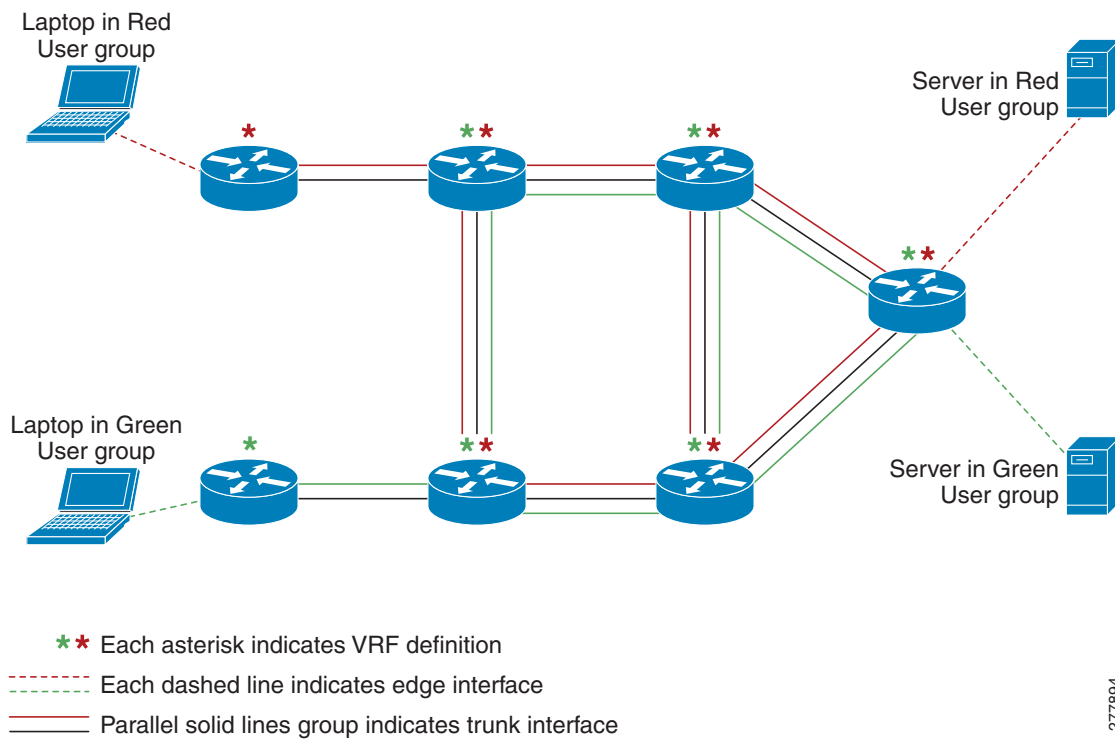

Virtual Network Tags Provide Path Isolation

It is not uncommon to have different user groups running on the same IP infrastructure. Various business reasons require traffic isolation between different groups. The figure below shows two user groups, Red and Green, running on the same network. Prior to network virtualization, there is no separation of traffic between the two groups. Users in the Red user group can access the server in the Green user group, and vice versa.

Without network virtualization, path isolation can be achieved by using access control, which is expensive to maintain, prone to error and does not support unique routing and forwarding tables per network.

Figure 85-1 Network without Virtualization

Virtual networks provide a coarse-grained segmentation of different user groups on one physical network. By configuring virtual networks, you can virtualize a single IP infrastructure to provide a number of virtual networks end to end. In the figure below, a single IP infrastructure is virtualized into two VPNs by creating two VRFs, Red and Green.

Figure 85-2 Network with Virtualization

In addition to utilizing VRFs to provide device-level separation, each virtual network has path isolation from the other. Path isolation is achieved by tagging the traffic so it carries the same tag value throughout the same virtual network. Each network device along the path uses the tags to provide separation among different VRFs. A single tag number ties VRF red, for example, on one device to VRF red on another device.

Virtual Network Tags

Each VPN and associated EVN has a tag value that you assign during configuration. The tag value is global, meaning that on each device, the same EVN must be assigned the same numerical tag value. Tag values range from 2 to 4094.

An EVN is allowed on any interface that supports 802.1q encapsulation, such as Fast Ethernet, Gigabit Ethernet, and port channels. To allow for backward compatibility with the VRF-Lite solution, the vLAN ID field in the 802.1q frame is used to carry the virtual network tag.

Traffic that carries a virtual network tag is called tagged traffic. Traffic that does not carry a virtual network tag is called untagged traffic.

Tags are illustrated in the following configuration with two VRFs, red and green:

```
! Define two VRFs, red and green.
vrf definition red
  vnet tag 101
!
  address-family ipv4
  exit-address-family
!
vrf definition green
  vnet tag 102
!
  address-family ipv4
  exit-address-family
!
```

A virtual network is defined as a VRF instance with a virtual network tag assigned.

vnet Global

A predefined EVN known as vnet global is on the device. It refers to the global routing context and it corresponds to the default RIB. In figure 2 and figure 3, vnet global is represented by a black line connecting devices. The vnet global carries untagged traffic. By default, interfaces belong to the vnet global. Furthermore, vnet global is always running on trunk interfaces. The vnet global is also known as the default routing table.

**Note**

IPv6 traffic is supported in vnet global only.

Edge Interfaces and EVN Trunk Interfaces

User devices are connected to a Layer 2 switch port, which is assigned to a VLAN. A VLAN can be thought of as a Layer 2 VPN. Customers will group all of the devices that need to be supported in a common Layer 3 VPN in a single VLAN. The point where data traffic is handed off between a VLAN and VRF is called an edge interface.

An edge interface connects a user device to the EVN and in effect defines the boundary of the EVN. Edge interfaces connect end devices such as hosts and servers that are not VRF-aware. Traffic carried over the edge interface is untagged. The edge interface classifies which EVN the received traffic belongs to. Each edge interface is configured to belong to only one EVN.

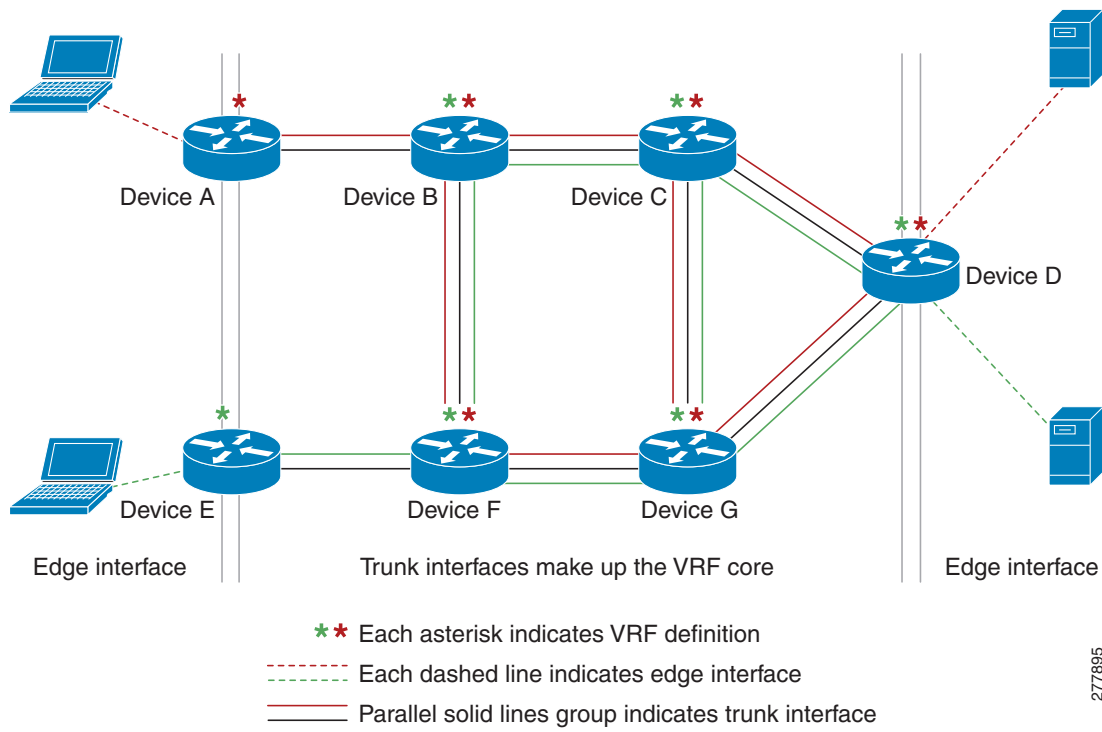

An EVN trunk interface connects VRF-aware devices together and provides the core with a means to transport traffic for multiple EVNs. Trunk interfaces carry tagged traffic. The tag is used to de-multiplex the packet into the corresponding EVN. A trunk interface has one subinterface for each EVN.

The **vnet trunk** command is used to define an interface as an EVN trunk interface.

An EVN interface uses two types of interfaces: edge interfaces and trunk interfaces. An interface can be an edge or trunk interface, but not both. Figure 3 illustrates devices A and D, which have edge interfaces that belong to VRF Red. Devices D and E have edge interfaces that belong to VRF Green.

Devices B, C, D, F, and G have trunk interfaces that make up the EVN core. These five devices have interfaces that belong to both VRF Red and VRF Green.

Figure 85-3 EVN Edge and EVN Trunk Interfaces

Identifying Trunk Interfaces in Display Output

Because a trunk interface carries multiple EVNs, sometimes it is not sufficient to display only the trunk interface name. When it is necessary to indicate that display output pertains to a particular EVN running on the trunk interface, the convention used is append a period and the virtual network tag, making the format interface.virtual-network-tag. Examples are gigabitethernet1/1/1.101 and gigabitethernet1/1/1.102.

By default, when a trunk interface is configured, all of the EVNs and associated virtual network tags are configured, and a virtual network subinterface is automatically created. As stated above, a period and the virtual network tag number are appended to the interface number.

In the following example, VRF red is defined with virtual network tag 3. Hence, the system created Fast Ethernet 0/0/0.3 (in VRF red).

```
Device# show running-config vrf red
```

```
Building configuration...
Current configuration : 1072 bytes
vrf definition red
  vnet tag 3
  !
  address-family ipv4
  exit-address-family
  !
```

You can display this hidden interface with the show derived-config command and see that all of the commands entered on Fast Ethernet 0/0/0 have been inherited by Fast Ethernet 0/0/0.3:

```
Device# show derived-config interface fastethernet0/0/0.3
```

```
Derived configuration : 478 bytes
!
interface FastEthernet0/0/0.3
  description Subinterface for VRF NG red
  vrf forwarding red
  encapsulation dot1Q 3
  ip address 10.1.1.1 255.255.255.0
end
```

Single IP Address on Trunk Interfaces

A trunk interface can carry traffic for multiple EVNs. To simplify the configuration process, all the subinterfaces and associated EVNs have the same IP address assigned. In other words, a trunk interface is identified by the same IP address in different EVN contexts. This is because each EVN has a unique routing and forwarding table, thereby enabling support for overlapping IP addresses across multiple EVNs.

Relationship Between VRFs Defined and VRFs Running on a Trunk Interface

By default, the trunk interfaces on a router will carry traffic for all VRFs defined by the vrf definition command. For example, in the following configuration, every VRF defined on the router is included on the interface:

```
interface FastEthernet 1/0/0 vnet trunk ip address 10.1.1.1 255.255.255.0
```

However, you might want to enable only a subset of VRFs over a certain trunk interface for traffic separation purposes. This is achieved by creating a VRF list, which is referenced in the **vnet trunk** command. When a trunk interface is enabled with a VRF list, only VRFs on the list are enabled on the interface. The exception is that vnet global is always enabled on the trunk interface.

In the following example, only the two specified VRFs on the list (red and green) are enabled on the interface:

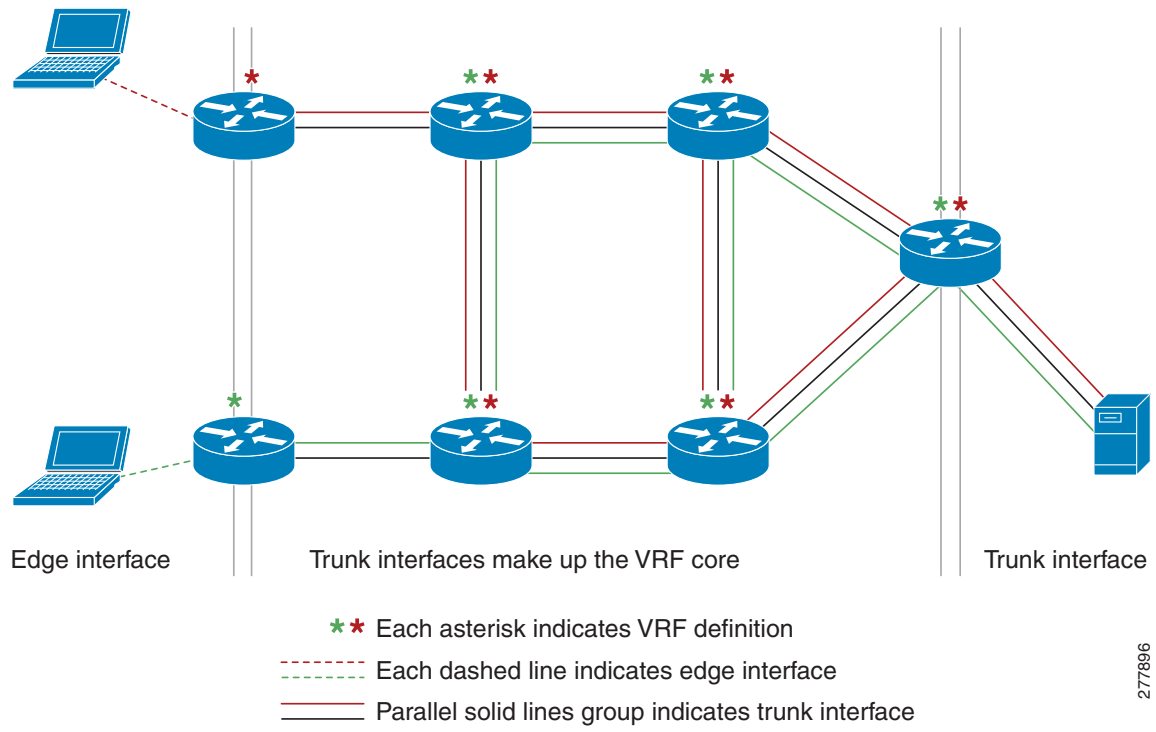

```
vrf list mylist
member red
member green
!
interface FastEthernet 1/0/0
vnet trunk list mylist
ip address 10.1.1.1 255.255.255.0
```

VRF Awareness

A device connected to a virtual network may not understand virtual network tags and can send and receive only untagged traffic. Such a device is referred to as VRF unaware. For example, a laptop computer is usually VRF unaware.

By contrast, a device that can send and receive tagged traffic and therefore takes the tag value into account when processing such traffic is known as VRF aware. For example, a VRF-aware server shared among different EVNs could use the virtual network tag to distinguish requests received and send responses. A VRF-aware device is connected to the EVN using a trunk interface, as shown in figure 4.

Figure 85-4 VRF Aware Server

277896

The term “VRF aware” can also be used to describe a software component running on the device. A software component is VRF aware if it can operate on different EVNs. For example, ping is VRF aware because it allows you to choose the EVN to which you want to send the ping packet.

Routing Protocols Supported by EVN

Each EVN runs a separate instance of a routing protocol. This allows each EVN to fine-tune its routing separately and also limits fate sharing. Different virtual networks may run different routing protocols concurrently.

EVN supports static routes, OSPFv2, and PIM, MSDP, and IGMP for multicast routing.

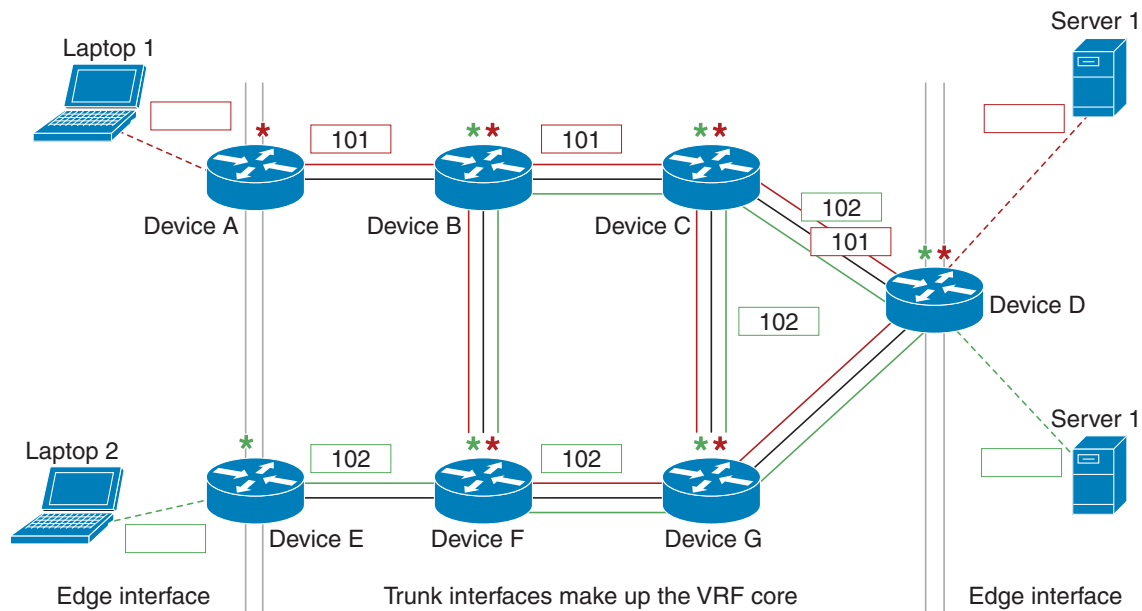

Packet Flow in a Virtual Network

Packets enter an EVN through an edge interface, traverse multiple trunk interfaces, and exit the virtual network through another edge interface. At the ingress edge interface, packets are mapped from a VLAN into a particular EVN. Once the packet is mapped to an EVN, it is tagged with the associated virtual network tag. The virtual network tag allows the trunk interface to carry packets for multiple EVNs. The packets remain tagged until they exit the EVN through the egress edge interface.

On the edge interface, the EVN associated with the interface is used for route lookup. On the trunk interface, the virtual network tag carried in the packet is used to locate the corresponding EVN for routing the packets.

If the egress interface is an edge interface, the packet is forwarded untagged. However, if the egress interface is a trunk interface, the packet is forwarded with the tag of the ingress EVN.

The figure below illustrates how traffic from two VRFs, red and green, can coexist on the same IP infrastructure, using the tags 101 and 102.

Figure 85-5 Packet Flow in a Virtual Network

* * Each asterisk indicates VRF definition

--- Each dashed line indicates edge interface

==== Parallel solid lines group indicates trunk interface

277897

The packet flow from Laptop 1 to Server 1 in VRF red occurs as follows:

1. Laptop 1 send an untagged packet to Server 1.
2. Device A receives the packet over an edge interface, which is associated with VRF red.
 - a. Device A does route lookup in VRF red and sees that the next hop is Device B through a trunk interface.
 - b. Device A encapsulates the packet with VRF red's tag (101) and sends it over the trunk interface.
3. Device B receives the packet over a trunk interface. Seeing virtual network tag 101, Device B identifies that the packet belongs to VRF red.
 - a. Device B does route lookup in VRF red and sees that the next hop is Device C through a trunk interface.
 - b. Device B encapsulates the packet with VRF red's tag (101) and sends it over the trunk interface.
4. Device C receives the packet over a trunk interface. Using virtual network tag 101, Device C identifies that the packet belongs to VRF red.
 - a. Device C does route lookup in VRF red and sees that the next hop is Device D through a trunk interface.
 - b. Device C encapsulates the packet with VRF red's tag (101) and sends it over the trunk interface.
5. Device D receives the packet over a trunk interface. Using virtual network tag 101, Device D identifies that the packet belongs to VRF red.
 - a. Device D does route lookup in VRF red and sees that the next hop is through an edge interface.
 - b. Device D sends the untagged packet over the edge interface to Server 1.
6. Server 1 receives the untagged packet originated from Laptop 1.

Command Inheritance on EVN Trunk Interfaces

One of the benefits of EVN is the ability to easily configure multiple EVNs on a common trunk interface without the need to configure each interface associated with an EVN individually. An EVN trunk interface takes advantage of the fact that the configuration requirements for different EVNs will be similar over a single trunk interface. When specific commands are configured on the trunk interface, they define default values that are inherited by all EVNs running over the same interface, including vnet global. If you feel that the settings are acceptable for all of the EVNs sharing an interface, then no individual configuration is necessary.

For example, the OSPF hello interval can be set for all EVNs over the trunk interface with the following configuration:

```
interface gigabitethernet1/1/1
 vnet trunk
 ip address 10.1.2.1 255.255.255.0
 ! set OSPF hello interval for all VRFs on this interface.
 ip ospf hello-interval 20
```

Overriding Command Inheritance Virtual Network Interface Mode

You can set up EVNs on the same trunk interface to have different configurations, by override inherited values using specific commands in virtual network interface mode for individual EVNs. In this mode, the command's settings override the Cisco default value or the value you set in interface configuration mode.

In interface configuration mode, entering the **vnet name** command causes the system to enter virtual network interface mode.

Beginning in Cisco IOS XE Release 3.9.1E, you can override the inherited IP address for subinterfaces. For more information, see [Changing the Inherited IP Address for Subinterfaces](#), page 85-17.

The following list displays the commands for which inherited values can be overridden:

Command	Values Inherited by EVNs on Interface?	Values Can Be Overridden in Virtual Network Interface Mode?
ip accounting	Yes	No
ip address	Yes	Yes
ip broadcast-address	Yes	No
ip directed broadcast	Yes	No
ip information-reply	Yes	No
ip irdp	Yes	No
ip load-sharing	Yes	No
ip mask-reply	Yes	No
ip mtu	Yes	No
ip proxy-arp	Yes	No
ip redirects	Yes	No

Command	Values Inherited by EVNs on Interface?	Values Can Be Overridden in Virtual Network Interface Mode?
ip unnumbered	Yes	No
ip unreachable	Yes	No
ip ospf process-id area	No	Yes
ip ospf authentication	Yes	Yes
ip ospf authentication-key	Yes	Yes
ip ospf cost	Yes	Yes
ip ospf database-filter	Yes	Yes
ip ospf dead-interval	Yes	Yes
ip ospf demand-circuit	Yes	Yes
ip ospf flood-reduction	Yes	Yes
ip ospf hello-interval	Yes	Yes
ip ospf ll	Yes	Yes
ip ospf message-digest-key	Yes	Yes
ip ospf mtu-ignore	Yes	Yes
ip ospf network	Yes	Yes
ip ospf priority	Yes	Yes
ip ospf resync-timeout	Yes	Yes
ip ospf shutdown	Yes	Yes
ip ospf transmit-delay	Yes	Yes
ip ospf transmit-interval	Yes	Yes
ip ospf ttl-security	Yes	Yes
ip ospf vnet area	No	No
ip igmp access-group	Yes	Yes
ip igmp explicit-tracking	Yes	Yes
ip igmp helper-address	Yes	Yes
ip igmp immediate-leave	Yes	Yes
ip igmp last-member-query-count	Yes	Yes
ip igmp last-member-query-interval	Yes	Yes
ip igmp limit	Yes	Yes
ip igmp mroute-proxy	Yes	Yes
ip igmp proxy-service	Yes	Yes
ip igmp querier-timeout	Yes	Yes
ip igmp query-interval	Yes	Yes
ip igmp query-max-response-time	Yes	Yes

Command	Values Inherited by EVNs on Interface?	Values Can Be Overridden in Virtual Network Interface Mode?
ip igmp tcn	Yes	Yes
ip igmp unidirectional-link	Yes	Yes
ip igmp v3lite	Yes	Yes
ip igmp version	Yes	Yes
ip multicast boundary	Yes	Yes
ip pim bidir-neighbor-filter	Yes	Yes
ip pim bsr-border	Yes	Yes
ip pim dense-mode	Yes	Yes
ip pim dr-priority	Yes	Yes
ip pim nbma-mode	Yes	Yes
ip pim neighbor-filter	Yes	Yes
ip pim passive	Yes	Yes
ip pim query-interval	Yes	Yes
ip pim sparse-dense-mode	Yes	Yes
ip pim sparse-mode	Yes	Yes
ip pim state-refresh	Yes	Yes
ip mfib cef	Yes	Yes
ip mfib forwarding	Yes	Yes

Removing Overrides and Restoring Values Inherited from EVN Trunk

The **no** and **default** keywords result in different outcomes, depending on whether they are used for a trunk interface or in virtual network interface mode. This section describes the different outcomes.

When the **no** or **default** keyword is entered before a command on a trunk interface, the trunk is restored to the system's default value for that command. (This is standard behavior resulting for the **no** or **default** keyword).

When the **default** keyword is entered before a command in virtual network interface mode, the override value is removed and the value that is inherited from the trunk is restored. The override value for the specific EVN is no longer in effect.

In the following example, the trunk interface is configured with an OSPF cost of 20, but VRF blue overrides that value with an OSPF cost of 30:

```
interface gigabitethernet 2/0/0
 vnet trunk
 ip address 10.1.1.1 255.255.255.0
 ! Set OSPF cost for all VRFs on this interface to 20.
 ip ospf cost 20
 vnet name blue
 ! Set OSPF cost for blue to 30.
 ip ospf cost 30
```

When the following commands are entered, the OSPF cost value is restored to 20, which is the cost inherited from the trunk interface. (Note that 20 is not the default value of the `ip ospf cost` command.)

```
Device(config-if)# vnet name blue
Device(config-if-vnet)# default ip ospf cost
```

Determining if No Form of Commands Appear in Configuration Files

If a command switches a feature on or off, the **no** form of the command appears in the configuration file when configured. Nonvolatile generation (NVGEN) overrides the setting from the EVN trunk, as shown in the following example:

```
interface gigabitethernet 2/0/0
 vnet trunk
 vnet name red
  no ip pim sparse-mode
  no ip route-cache cef
 vnet global
  ip ospf cost 100
```

If a command takes an argument in its syntax, such as **ip ospf cost cost**, the **no** form of the command will remove the configuration, but does not appear in the configuration file. That is, it will not be NVGEN'ed because the user could enter **ip ospf cost default-value** to override the inherited value.

EVN Compatibility with VRF-Lite

EVN is wire compatible with VRF-Lite. In other words, on the outside, 802.1q, SNMP MIBs, and all the EVN infrastructure will look exactly the same as VRF-Lite.

In the figure below, both devices have VRFs defined. The device on the left uses VRF-Lite, and the device on the right uses an EVN trunk with tags. The two configurations follow the figure.

Example: VRF-Lite Subinterface Configuration EVN Trunk Configuration

```
interface TenGigabitEthernet1/1/1
 ip address 10.122.5.31 255.255.255.254
 ip pim query-interval 333 msec
 ip pim sparse-mode
 logging event link-status
interface TenGigabitEthernet1/1/1.101
 description Subinterface for Red VRF
```

```
interface TenGigabitEthernet 1/1/1
 vnet trunk
 ip address 10.122.5.32 255.255.255.254
 pim sparse-mode
 logging event link-status
Global Configuration:
 vrf definition red
```

```

encapsulation dot1Q 101
ip vrf forwarding Red
ip address 10.122.5.31 255.255.255.254
ip pim query-interval 333 msec
ip pim sparse-mode
logging event subif-link-status
interface TenGigabitEthernet1/1/1.102
description Subinterface for Green VRF
encapsulation dot1Q 102
ip vrf forwarding Green
ip address 10.122.5.31 255.255.255.254
ip pim query-interval 333 msec
ip pim sparse-mode
logging event subif-link-status

vnet tag 101
vrf definition green
vnet tag 102

```

SQoS and EVN

Quality of Service (QoS) configurations are applied to the main physical interface on an EVN trunk. The QoS policy affects all traffic that flows out the physical interface in all the VRFs at the same time. In other words, QoS and network virtualization are mutually independent. For example, traffic marked with the DSCP value specified for voice will be put into the voice queue if the packet is from the red VRF, blue VRF, or green VRF. The traffic for all the VRFs is queued together.

Configuring Easy Virtual Networks

Note

We recommend that you draw your network topology, indicating the interfaces on each router that belong to the EVNs. The diagram facilitates tracking the interfaces you are configuring as edge interfaces and the interfaces you are configuring as trunk interfaces.

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# vrf definition <i>vrf name</i>	Configures a VRF routing table instance and enters VRF configuration mode.
Step 3	Switch(config-vrf)# description <i>string</i>	(Optional) Describes a VRF to help a network administrator review the configuration files. to it.You can specify up to 3 control-plane IP addresses for the edge device.
Step 4	Switch(config-vrf)# address-family ipv4	Enters address family configuration mode to configure a routing session using standard IP version 4 address prefixes.
Step 5	Switch(config-vrf-af)# exit-address-family	Exits address family configuration mode.
Step 6	Switch(config-vrf)# exit	Exits to global configuration mode.
Step 7		Repeat steps 2 to 7 to configure another VRF instance and associate a vnet tag.
Step 8	Switch(config)# interface <i>interface number</i>	Configures an interface type and enters interface configuration mode.

	Command	Purpose
Step 9	Switch(config-if)# ip address <i>ip address mask</i>	Sets a primary IP address for the interface.
Step 10	Switch(config-if)# vrf trunk [<i>list vrf-list name</i>]	Defines a trunk interface. By default, all VRFs defined with the vrf definition command run on all trunk interfaces on the router. Therefore, VRF red and VRF blue are now running on this interface. Use the list vrf-list-name command elements to restrict VRFs running on a trunk interface.
Step 11	Switch(config-if)# no shutdown	Restarts an interface.
Step 12	Switch(config-if)# exit	Returns to global configuration mode.
Step 13	Switch(config)# router ospf <i>process ID</i>	Configures an Open Shortest Path First (OSPF) routing process and associates it with a VRF. This OSPF instance has no VRF, so it is vnet global .
Step 14	Switch(config-router)# network <i>ip address wildcard area area ID</i>	Defines the interfaces and associated area IDs on which OSPF runs, and the area ID for those interfaces.
Step 15	Switch(config-if)# exit	Returns to global configuration mode.
Step 16	Switch(config)# router ospf <i>process ID vrf vrf name</i>	Configures an OSPF routing process and associates it with a VRF. Specifies a different process-id for each VRF because they each need their own OSPF instance.
Step 17	Switch(config-router)# network <i>ip address wildcard area area ID</i>	Defines the interfaces and associated area IDs on which OSPF runs, and the area ID for those interfaces.
Step 18	Switch(config-router)# end	Ends the configuration session and returns to privileged EXEC mode.

Enabling a Subset of VRFs over a Trunk Interface

To create a VRF list and enable only a subset of VRFs over a trunk interface, enter the following commands:

Note

This task presumes that the VRF has already been configured.

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# vrf list <i>vrf list name</i>	Defines a list of VRFs and enters VRF list configuration mode. The vrf-list-name argument may contain up to 32 characters. Quotation marks, spaces, and * are not allowed.
Step 3	Switch(config-vrf-list)# member <i>vrf name</i>	Specifies an existing VRF as a member of a VRF list. The VRF must be defined before it can be added to a list.

	Command	Purpose
Step 4	Repeat Step 3 to add other VRFs to the list.	(Optional) If you want a trunk interface with one VRF, your list only needs one VRF.
Step 5	Switch(config)# interface <i>type number</i>	Configures an interface and enters interface configuration mode.
Step 6	Switch(config-if)# vnet trunk list <i>vrf list name</i>	Defines a trunk interface and enables the VRFs that are in the VRF list. Use the vrf list name you defined earlier in this task.
Step 7	Switch(config-if)# ip address <i>ip address mask</i>	Sets a primary IP address for the interface.
Step 8	Switch(config-if)# end	Ends the configuration session and returns to privileged EXEC mode.
Step 9	Switch# show vrf list [<i>vrf list name</i>]	Displays information about the specified VRF list.

Configuring EVN Edge Interfaces

Perform this task to configure an edge interface, which connects a user device to a virtual network. Traffic carried over an edge interface is untagged. The edge interface determines which virtual network the received traffic belongs to. Each edge interface is mapped to only one virtual network.

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>type number</i>	Configures an interface type and enters interface configuration mode.
Step 3	Switch(config)# vrf forwarding <i>vrf name</i>	Defines an edge interface and determines the VRF to which the incoming traffic belongs. The vrf name must already be defined using the vrf definition command. Note Ensure that you are not on the trunk interface when you configure an edge interface.
Step 4	Switch(config-if)# ip address <i>ip address mask</i>	Sets a primary IP address for the interface.
Step 5	Switch(config-if)# end	Ends the configuration session and returns to privileged EXEC mode.

Verifying EVN Configuration

Enter the following commands to verify your configuration. All the existing VRF show commands are supported in virtual networks. If a device has a mix of VRFs and virtual networks, the various **show vrf** commands will include both VRFs and virtual networks in the output.

Command	Purpose
Switch# show vnet tag	Displays where each tag has been configured or used.
Switch# show running-config [<i>vrf vnet</i>] [<i>vrf-name</i>]	Displays the VRFs in the running configuration, displays the interfaces in the VRFs, and displays the protocol configurations for Multi-VRF.

Command	Purpose
Switch# show vrf list [vrf-list-name]	Displays information about VRF lists, such as the VRFs in each list.
Switch# show {vrf vnet}[ipv4 ipv6][interface brief detail lock] [vrf-name]	Displays information about the VRFs.
Switch# show {vrf vnet} counters	Displays information about the number of VRFs or virtual networks supported and configured.

Changing the Inherited IP Address for Subinterfaces

All subinterfaces created on the vnet interface inherit values from the main interface.

Beginning in Cisco IOS XE Release 3.9.1E, you can change the inherited IP address for subinterfaces in interface vnet configuration mode:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface interface name	Specifies the interface name and enters interface configuration mode.
Step 3	Switch(config-if-vnet)# (no) ip address ipv4 address mask	Sets the IP address for the VNET subinterface. The no ip address command on the vnet interface configuration mode will change the IP address of the subinterface back to match the IP address of the main interface.
Step 4	Switch(config-if-vnet)# ip address ipv4 address mask secondary	Sets the secondary IP address for the subinterface. A secondary IP from the main interface is not inherited if you set a secondary IP address for the subinterface.
Step 5	Switch(config-if-vnet)# do show interface ip brief	Displays the IP addresses for the main interface and the subinterfaces.

For example, consider the following configuration:

```
vrf definition vRED
vnet tag 131
!
address-family ipv4
exit-address-family

vrf definition vBLUE
vnet tag 132
!
address-family ipv4
exit-address-family

interface Eth0/0
no shutdown
vnet trunk
ip add 10.1.1.1 255.255.255.0

Switch(config-if)#int eth0/0
Switch(config-if)#vnet name vRED
```

```

Switch(config-if-vnet)# ip address 100.1.1.1 255.255.255.0
Switch(config-if-vnet)#do show ip interface brief
Interface                IP-Address      OK? Method Status      Protocol
Ethernet0/0              10.1.1.1        YES manual up          up
Ethernet0/0.131          100.1.1.1       YES manual up          up
Ethernet0/0.132          10.1.1.1       YES manual up          up

Switch(config)#int eth0/0
Switch(config-if)#vnet name vBLUE
Switch(config-if-vnet)#ip address 101.1.1.1 255.255.255.0
Switch(config-if-vnet)#do show ip interface brief
Interface                IP-Address      OK? Method Status      Protocol
Ethernet0/0              10.1.1.1        YES manual up          up
Ethernet0/0.131          100.1.1.1       YES manual up          up
Ethernet0/0.132          101.1.1.1       YES manual up          up

```

Configuration Examples for Configuring EVN

Example: Virtual Networks Using OSPF with network Commands

In this example, network commands associate a shared VRF interface with a base VRF and two named VRFs, red and blue. There are three OSPF instances because each VRF needs its own OSPF instance. OSPF 1 has no VRF, so it is vnet global.

```

vrf definition red
vnet tag 100
address-family ipv4
exit-address-family
!
vrf definition blue
vnet tag 200
address-family ipv4
exit-address-family
!
interface gigabitethernet 0/0/0
ip address 10.0.0.1 255.255.255.0
vnet trunk
vnet name red
ip ospf cost 100
!
router ospf 1
log-adjacency-changes detail
network 10.0.0.0 255.255.255.0 area 0
router ospf 2 vrf red
log-adjacency-changes
network 10.0.0.0 255.255.255.0 area 0
router ospf 3 vrf blue
log-adjacency-changes
network 10.0.0.0 255.255.255.0 area

```

Example: Virtual Networks Using OSPF with ip ospf vnet area Command

This example differs from the prior example regarding the association between OSPF instances and a particular interface. In this example, OSPF is running on all of the virtual networks of a trunk interface. The **ip ospf vnet area** command associates the GigabitEthernet 0/0/0 interface with the three OSPF instances.

```
vrf definition red
  vnet tag 100
  address-family ipv4
  exit-address-family
!
vrf definition blue
  vnet tag 200
  address-family ipv4
  exit-address-family
!
interface gigabitethernet 0/0/0
  ip address 10.0.0.1 255.255.255.0
  vnet trunk
  ip ospf vnet area 0
  vnet name red
    ip ospf cost 100
  vnet name blue
    ip ospf 3 area 2
!
router ospf 1
  log-adjacency-changes detail
router ospf 2 vrf red
  log-adjacency-changes
router ospf 3 vrf blue
  log-adjacency-changes
```

Example: Overriding Command Inheritance

In the following example, the OSPF cost of 30 for VRF blue overrides the OSPF cost of 20 for the other VRFs on the interface:

```
interface gigabitethernet 2/0/0
  vnet trunk
  ip address 10.1.1.1 255.255.255.0
  ! Set OSPF cost for all VRFs on this interface to 20.
  ip ospf cost 20
  vnet name blue
    description Subinterface for VRF NG blue
    ! Set OSPF cost for blue to 30.
    ip ospf cost 30
```

The show derived command indicates the subinterface changed to a cost of 30:

```
Device(config-if-vnet)# do show derived | s interface GigabitEthernet2/0/0

interface GigabitEthernet2/0/0
vnet trunk
ip address 10.1.1.1 255.255.255.0
ip ospf cost 20
interface GigabitEthernet2/0/0.200
description Subinterface for VRF NG blue
```

```
vrf forwarding blue
ip address 10.1.1.1 255.255.255.0
ip ospf cost 30
Device(config-if-vnet)#
```

Example: Enabling an Attribute to vnet Global Only

Similarly, you might want to enable an attribute to vnet global only. To do so, use the vnet global interface submode, as follows:

```
interface gigabitethernet1/1/1
vnet trunk
ip address 10.1.2.1 255.255.255.0
vnet global
! Set OSPF cost for global to 40.
ip ospf cost 40
```

Example: Command Inheritance and Virtual Network Interface Mode Override in a Multicast Environment

The following example illustrates command inheritance and virtual network interface mode override in a multicast network. A trunk interface leverages the fact that configuration requirements from different VRFs will be similar over the same trunk interface. Eligible commands configured on the trunk interface are inherited by all VRFs running over the same interface.

In this example, IP multicast (PIM sparse mode) is configured on the trunk interface, which has several VRFs:

```
vrf definition red
vnet tag 13
!
address-family ipv4
exit-address-family
!
ip multicast-routing
ip multicast-routing vrf red
interface GigabitEthernet0/1/0
vnet trunk
ip address 125.1.15.18 255.255.255.0
ip pim sparse-mode
```

The user decides that he does not want IP multicast configured for VRF red on GigabitEthernet 0/1/0, so he uses the virtual network interface mode override. IP Multicast is disabled for VRF red only. The `no ip pim` command disables all modes of Protocol Independent Multicast (PIM), including sparse mode, dense mode, and sparse-dense mode, for VRF red.

```
interface GigabitEthernet0/1/0
vnet trunk
ip address 125.1.15.18 255.255.255.0
ip pim sparse-mode
vnet name red
no ip pim
```

Example: EVN Using IP Multicast

The following example configures PIM sparse mode and leverages Anycast RP for RP redundancy. In this example, only one VRF is configured.

The example shows how to enable multicast routing globally and on each L3 interface. The black text indicates the group of commands configuring the global table; the red text indicates the group of commands configuring VRF red.

```

ip multicast-routing
interface GigabitEthernet 1/1/1
  description GigabitEthernet to core (Global)
  ip pim sparse-mode
vrf definition red
  vnet tag 100
!
  address-family ipv4
  exit-address-family
!
ip multicast-routing vrf red
!
interface gigabitethernet1/1/1.100
  description GigabitEthernet to core (VRF red)
  vrf forwarding red
  ip pim sparse-mode
Configure the RP in the VRF using Anycast RP.

interface loopback0
  description Anycast RP Global
  ip address 10.122.5.200 255.255.255.255
  ip pim sparse-mode
!
interface loopback1
  description MSDP Peering interface
  ip address 10.122.5.250 255.255.255.255
  ip pim sparse-mode
!
ip msdp peer 10.122.5.251 connect-source loopback 1
ip msdp originator-id loopback 1
ip pim rp-address 10.122.5.200
access-list 10 permit 239.0.0.0 0.255.255.255
!
!
interface loopback 10
  description Anycast RP VRF Red
  vrf forwarding red
  ip address 10.122.15.200 255.255.255.255
  ip pim sparse-mode
interface loopback 11
  description MSDP Peering interface VRF red
  vrf forwarding red
  ip address 10.122.15.250 255.255.255.255
  ip pim sparse-mode
!
ip msdp vrf red peer 10.122.15.251 connect-source loopback 11
ip msdp vrf red originator-id loopback 11
!
ip pim vrf red rp-address 10.122.15.200
access-list 11 permit 239.192.0.0 0.0.255.255

```

Troubleshooting EVN Configuration

Routing Context for EXEC Mode Reduces Repetitive VRF Specification

There may be occasions when you want to issue several EXEC commands to apply to a single virtual network. In order to reduce the repetitive entering of virtual routing and forwarding (VRF) names for multiple EXEC commands, the routing-context vrf command allows you to set the VRF context of such EXEC commands once, and then proceed using EXEC commands.

The table below shows four EXEC commands in Cisco IOS XE software without routing context and in routing context. Note that in the left column, each EXEC command must specify the VRF. In the right column, the VRF context is specified once and the prompt changes to reflect that VRF; there is no need to specify the VRF in each command.

EXEC Commands CLI without Routing Context	EXEC Commands CLI with Routing Context
	Device# routing-context vrf red Device%red#
Device# show ip route vrf red [Routing table output for VRF red]	Device%red# show ip route [Routing table output for VRF red]
Device# ping vrf red 10.1.1.1 [Ping result using VRF red]	Device%red# ping 10.1.1.1 [Ping result using VRF red]
Device# telnet vrf red 10.1.1.1 [Telnet to 10.1.1.1 in VRF red]	Device%red# telnet 10.1.1.1 [Telnet to 10.1.1.1 in VRF red]
Device# traceroute vrf red 10.1.1.1 [Traceroute output in VRF red]	Device%red# traceroute 10.1.1.1 [Traceroute output in VRF red]

traceroute Output Indicates VRF Name and VRF Tag

The output of the traceroute command is enhanced to make troubleshooting easier by displaying the incoming VRF name/tag and the outgoing VRF name/tag, as shown in the following example:

```
Device# traceroute vrf red 10.0.10.12
Type escape sequence to abort.
Tracing the route to 10.0.10.12
VRF info: (vrf in name/id, vrf out name/id)
 1 10.1.13.15 (red/13,red/13) 0 msec
   10.1.16.16 (red/13,red/13) 0 msec
   10.1.13.15 (red/13,red/13) 1 msec
 2 10.1.8.13 (red/13,red/13) 0 msec
   10.1.7.13 (red/13,red/13) 0 msec
   10.1.8.13 (red/13,red/13) 0 msec
 3 10.1.2.11 (red/13,blue/10) 1 msec 0 msec 0 msec
 4 * * *
```

Debug Output Filtering Per VRF

Using EVN, you can filter debug output per VRF by using the debug condition vrf command. The following is sample output from the debug condition vrf command:

```
Device# debug condition vrf red

Condition 1 set
CEF filter table debugging is on
CEF filter table debugging is on
D1#
*Aug 19 23:06:38.178: vrfmgr(0) Debug: Condition 1, vrf red triggered, count 1
```

CISCO-VRF-MIB

EVN provides a CISCO-VRF-MIB for VRF discovery and management.

ROM Monitor

he ROM monitor firmware runs when the router is powered up or reset. The firmware helps to initialize the processor hardware and boot the operating system software. You can use the ROM monitor to perform certain configuration tasks, such as recovering a lost password or downloading software over the console port. If there is no Cisco IOS software image loaded on the router, the ROM monitor runs the router.

This appendix contains the following sections:

- [Entering the ROM Monitor](#)
- [ROM Monitor Commands](#)
- [ROM Monitor Command Descriptions](#)
- [Configuration Register](#)
- [Console Download](#)
- [Debug Commands](#)
- [Exiting the ROM Monitor](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference* , you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Entering the ROM Monitor

To use the ROM monitor, you must be using a terminal or PC that is connected to the router over the console port. Refer to the installation chapter in the *Cisco 806 Router Hardware Installation Guide* that came with the router to connect the router to a PC or terminal.

To configure the router to boot up in ROM monitor mode the next time it is rebooted, perform this task:

	Command	Task
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# config-reg 0x0	Resets the configuration register.

	Command	Task
Step 3	Switch(config)# exit	Exits global configuration mode.
Step 4	Switch# reload	<p>Reboots the router with the new configuration register value. The router remains in ROM monitor and does not boot the Cisco IOS software.</p> <p>As long as the configuration value is 0x0, you must manually boot the operating system from the console. See the boot command in the “ROM Monitor Command Descriptions” section in this appendix.</p> <p>After the router reboots, it is in ROM monitor mode. The number in the prompt increments with each new line.</p>

ROM Monitor Commands

Enter **?** or **help** at the ROM monitor prompt to display a list of available commands and options, as follows:

```
rommon 1 > ?
alias          set and display aliases command
boot          boot up an external process
confreg       configuration register utility
dev           list the device table
dir           list files in file system
help          monitor builtin command help
history       monitor command history
meminfo       main memory information
repeat        repeat a monitor command
reset         system reset
set           display the monitor variables
sysret        print out info from last system return
unalias       unset an alias
unset         unset a monitor variable
```

Commands are case sensitive. You can halt any command by pressing the Break key on a terminal. If you are using a PC, most terminal emulation programs halt a command when you press the Ctrl and the Break keys at the same time. If you are using another type of terminal emulator or terminal emulation software, refer to the documentation for that product for information on how to send a Break command.

ROM Monitor Command Descriptions

Table 86-1 describes the most commonly used ROM monitor commands.

Table 86-1 Most Commonly Used ROM Monitor Commands

Command	Description
reset or i	Resets and initializes the router, similar to a power up.
dev	Lists boot device identifications on the router; for example: <pre>rommon 10> dev Devices in device table: id name flash: flash</pre>
dir device:	Lists the files on the named device; flash, for example: <pre>rommon 4 > dir flash: File size Checksum File name 2835276 bytes (0x2b434c) 0x2073 c806-oy6-mz</pre>
boot commands	For more information about the ROM monitor boot commands, refer to the <i>Cisco IOS Configuration Guide</i> and the <i>Cisco IOS Command Reference</i> .
b	Boots the first image in flash memory.
b flash: [filename]	Attempts to boot the image directly from the first partition of flash memory. If you do not enter a filename, this command will boot this first image in flash.

Configuration Register

The virtual configuration register is in nonvolatile RAM (NVRAM) and has the same functionality as other Cisco routers. You can view or modify the virtual configuration register from either the ROM monitor or the operating system software. Within ROM monitor, you can change the configuration register by entering the register value in hexadecimal format, or by allowing the ROM monitor to prompt you for the setting of each bit.

Changing the Configuration Register Manually

To change the virtual configuration register from the ROM monitor manually, enter the **confreg** command followed by the new value of the register in hexadecimal, as shown in the following example:

```
rommon 1 > confreg 0x2101
```

You must reset or power cycle for new config to take effect
 rommon 2 >

The value is always interpreted as hexadecimal. The new virtual configuration register value is written into NVRAM but does not take effect until you reset or reboot the router.

Changing the Configuration Register Using Prompts

Entering **confreg** without an argument displays the contents of the virtual configuration register and a prompt to alter the contents by describing the meaning of each bit.

In either case, the new virtual configuration register value is written into NVRAM but does not take effect until you reset or reboot the router.

The following display shows an example of entering the **confreg** command:

```
rommon 7> confreg

Configuration Summary
enabled are:
console baud: 9600
boot: the ROM Monitor

do you wish to change the configuration? y/n [n]: y
enable "diagnostic mode"? y/n [n]: y
enable "use net in IP bcast address"? y/n [n]:
enable "load rom after netboot fails"? y/n [n]:
enable "use all zero broadcast"? y/n [n]:
enable "break/abort has effect"? y/n [n]:
enable "ignore system config info"? y/n [n]:
change console baud rate? y/n [n]: y
enter rate: 0 = 9600, 1 = 4800, 2 = 1200, 3 = 2400 [0]: 0
change the boot characteristics? y/n [n]: y
enter to boot:
0 = ROM Monitor
1 = the boot helper image
2-15 = boot system
[0]: 0

Configuration Summary
enabled are:
diagnostic mode
console baud: 9600
boot: the ROM Monitor

do you wish to change the configuration? y/n [n]:

You must reset or power cycle for new config to take effect
```

Console Download

You can use console download, a ROM monitor function, to download over the router console port either a software image or a configuration file. After download, the file is either saved to the mini-Flash memory module or to main memory for execution (image files only).

Use console download when you do not have access to a Trivial File Transfer Protocol (TFTP) server.

Note

If you want to download a software image or a configuration file to the router over the console port, you must use the **ROM monitor** command.

**Note**

If you are using a PC to download a Cisco IOS image over the router console port at 115,200 bps, ensure that the PC serial port is using a 16550 universal asynchronous transmitter/receiver (UART). If the PC serial port is not using a 16550 UART, we recommend using a speed of 38,400 or less when downloading a Cisco IOS image over the console port.

Error Reporting

Because the ROM monitor console download uses the console to perform the data transfer, error messages are only displayed on the console when the data transfer is terminated.

If an error does occur during a data transfer, the transfer is terminated, and an error message is displayed. If you have changed the baud rate from the default rate, the error message is followed by a message telling you to restore the terminal to the baud rate specified in the configuration register.

With ROMMON version 15.1(1r)SG4 and 15.1(1r)SG5 on Supervisor Engine 8-E, the follow error message is displayed if the supervisor is idle for more than an hour. You can ignore this message; it does not affect device performance.

```
rommon 0 >ICMP: Unsupported type/opcode! d00
ICMP: Unsupported type/opcode! d00
ICMP: Unsupported type/opcode! d00
ICMP: Unsupported type/opcode! d00
ICMP: Unsupported type/opcode! d00
ICMP: Unsupported type/opcode! d00
ICMP: Unsupported type/opcode! d00
ICMP: Unsupported type/opcode! d00

Pinging 10.64.71.1
!!!!
10.64.71.1 is alive!

rommon 2 >version
```

Debug Commands

Most ROM monitor debugging commands are functional only when Cisco IOS software has crashed or is halted.

The following are ROM monitor debugging commands:

- **frame**—Displays an individual stack frame.
- **sysret**—Displays return information from the last booted system image.

This information includes the reason for terminating the image, a stack dump of up to eight frames, and, if an exception is involved, the address where the exception occurred.

For example:

```
rommon 8> sysret
System Return Info:
count: 19, reason: user break
pc:0x801111b0, error address: 0x801111b0
Stack Trace:
FP: 0x80005ea8, PC: 0x801111b0
FP: 0x80005eb4, PC: 0x80113694
```

```

FP: 0x80005f74, PC: 0x8010eb44
FP: 0x80005f9c, PC: 0x80008118
FP: 0x80005fac, PC: 0x80008064
FP: 0x80005fc4, PC: 0xffff03d70
FP: 0x80005ffc, PC: 0x00000000
FP: 0x00000000, PC: 0x00000000

```

- **meminfo**—Displays size in bytes, starting address, available range of main memory, the starting point and size of packet memory, and size of NVRAM.

For example:

```
rommon 9> meminfo
```

```

Main memory size: 40 MB.
Available main memory starts at 0x10000, size 40896KB
IO (packet) memory size: 5 percent of main memory.
NVRAM size: 32KB

```

Exiting the ROM Monitor

You must set the configuration register to a value from 0x2 to 0xF for the router to boot a Cisco IOS image from flash memory upon startup or reloading.

The following example shows how to reset the configuration register and cause the router to boot a Cisco IOS image stored in flash memory:

```
rommon 1 > confreg 0x2101
```

You must reset or power cycle for new config to take effect

```
rommon 2 >boot
```

The router will boot the Cisco IOS image in flash memory. The configuration register will change to 0x2101 the next time the router is reset or power cycled.

Zero-Touch Provisioning

To address network provisioning challenges, Cisco introduces a zero-touch provisioning model. Starting with Cisco IOS XE Release 3.10.1E, the feature is available on Cisco Catalyst 4500-X Series Switches and Cisco Catalyst 4500E Series Switches with Supervisor Engine 9-E and 8-E.

Note

The Zero-Touch Provisioning feature is enabled automatically; no configuration is required.

This chapter includes the following major sections:

- [Information About Zero-Touch Provisioning, page 87-1](#)
- [DHCP Server Configuration for Zero-Touch Provisioning, page 87-2](#)
- [Sample Zero-Touch Provisioning Configurations, page 87-2](#)
- [Zero-Touch Provisioning Boot Log, page 87-2](#)

Information About Zero-Touch Provisioning

Zero-Touch Provisioning Overview

To address network provisioning challenges, Cisco introduces a Zero-Touch Provisioning model. Zero-Touch Provisioning automates the process of installing configuration files on Cisco devices that are deployed in a network for the first time. It reduces manual tasks required to scale the network capacity.

When a device that supports Zero-Touch Provisioning boots up, and does not find the startup configuration (during fresh install on Day Zero), the device enters the Zero-Touch Provisioning mode. The device locates a Dynamic Host Control Protocol (DHCP) server, bootstraps itself with its interface IP address, gateway, and Domain Name System (DNS) server IP address, and enables Guest Shell. The device then obtains the IP address or URL of a TFTP server, and downloads the configuration file for the device.

Note

In case Zero-Touch Provisioning fails, the device falls back to AutoInstall to load configuration files. For more information, see [Using AutoInstall and Setup](#).

DHCP Server Configuration for Zero-Touch Provisioning

In Zero-Touch Provisioning, a DHCP server must be running on the same network as the new device that is being provisioned. Zero-Touch Provisioning is supported on both management ports and in-band ports.

When the new device is switched on, it retrieves the IP address information of the TFTP server where the configuration resides.

The DHCP server responds to DHCP discovery events with the following options:

- Option 150—(Optional) Contains a list of IP addresses that point to the TFTP server on the management network that hosts the configuration file for the new device.

After receiving these DHCP options, the device connects to the TFTP server, and downloads the configuration. The device, at this point does not have any route to reach the TFTP server, so it uses the default route provided by the DHCP server.

Sample Zero-Touch Provisioning Configurations

Sample DHCP Server Configuration on a Management Port

The following is a sample DHCP server configuration when connected via the management port on a device:

```
Device> enable
Device# configure terminal
Device(config)# ip dhcp excluded-address 10.1.1.1
Device(config)# ip dhcp excluded-address vrf Mgmt-vrf 10.1.1.1 10.1.1.10
Device(config)# ip dhcp pool pnp_device_pool
Device(config-dhcp)# vrf Mgmt-vrf
Device(config-dhcp)# network 10.1.1.0 255.255.255.0
Device(config-dhcp)# default-router 10.1.1.1
Device(config-dhcp)# option 150 ip 203.0.113.254
Device(config-dhcp)# option 67 ascii switch.cfg
Device(config-dhcp)# end
```

- Option 67 ascii switch.cfg points to the configuration file that needs to be used by the new device.

Once the DHCP server is running, boot a management-network connected device, and the rest of the configuration is automatic.

Zero-Touch Provisioning Boot Log

The following sample Zero-Touch Provisioning boot log displays that Guest Shell is successfully enabled, the Python script is downloaded to the Guest Shell, and the Guest Shell executes the downloaded Python script and configures the device for Day Zero.

```
% failed to initialize nvram

! <This message indicates that the startup configuration
is absent on the device. This is the first indication that the Day Zero work flow is going
to start.>
```

Acronyms and Abbreviations

Table 88-1 defines the acronyms and abbreviations used in this publication.

Table 88-1 **Acronyms**

Acronym	Expansion
ACE	access control entry
ACL	access control list
AFI	authority and format identifier
Agport	aggregation port
ALPS	Airline Protocol Support
AMP	Active Monitor Present
APaRT	Automated Packet Recognition and Translation
ARP	Address Resolution Protocol
AV	attribute value
AVVID	Architecture for Voice, Video and Integrated Data
BDD	binary decision diagrams
BECN	backward explicit congestion notification
BGP	Border Gateway Protocol
BPDU	bridge protocol data unit
BRF	bridge relay function
BSC	Bisync
BSTUN	Block Serial Tunnel
BUS	broadcast and unknown server
BVI	bridge-group virtual interface
CAM	content-addressable memory
CAR	committed access rate
CCA	circuit card assembly
CDP	Cisco Discovery Protocol
CEF	Cisco Express Forwarding
CGMP	Cisco Group Management Protocol

Table 88-1 **Acronyms (continued)**

Acronym	Expansion
CHAP	Challenge Handshake Authentication Protocol
CIR	committed information rate
CIST	Common and Internal Spanning Tree
CLI	command-line interface
CLNS	Connection-Less Network Service
CMNS	Connection-Mode Network Service
COPS	Common Open Policy Server
COPS-DS	Common Open Policy Server Differentiated Services
CoS	class of service
CPLD	Complex Programmable Logic Device
CRC	cyclic redundancy check
CRF	concentrator relay function
CST	Common Spanning Tree
CUDD	University of Colorado Decision Diagram
DBL	Dynamic Buffer Limiting
DCC	Data Country Code
dCEF	distributed Cisco Express Forwarding
DDR	dial-on-demand routing
DE	discard eligibility
DEC	Digital Equipment Corporation
DFI	Domain-Specific Part Format Identifier
DFP	Dynamic Feedback Protocol
DISL	Dynamic Inter-Switch Link
DLC	Data Link Control
DLSw	Data Link Switching
DMP	data movement processor
DNS	Domain Name System
DoD	Department of Defense
DOS	denial of service
DRAM	dynamic RAM
DSAP	destination service access point
DSCP	differentiated services code point
DSPU	downstream SNA Physical Units
DTP	Dynamic Trunking Protocol
DTR	data terminal ready
DXI	data exchange interface
