[ default | no ] congestion-control
```

- **default**
  Sets the congestion control to its default value.

- **no**
  Disables the congestion control functionality from the system. It is actually the default behavior.

**Usage**

Congestion control on the system is used to monitor the system for conditions that could potentially degrade performance when the system is under heavy load. Typically, these conditions are temporary (i.e. high CPU or memory utilization) and are quickly resolved. However, continuous or large numbers of these conditions within a specific time interval may impact the system’s ability to service subscriber sessions. The purpose of congestion control is to aid in the identification of such conditions and invoke policies for addressing the situation.

Congestion control operation is based on the configuration of the following:

- **Call disconnections on overload**: With this functionality, the system enables and disables the policy for disconnecting passive calls (chassis-wide) during an overload situation. It also configures and fine-tunes the overload-disconnect congestion control policy for an entire chassis.

- **Congestion condition thresholds**: Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). These thresholds function in a similar fashion to the operation thresholds that can be configured for the system (as described in later in this chapter). The primary difference is that when these thresholds are reached, not only is an SNMP trap generated (starCongestion), but a service congestion policy is invoked as well.

  A threshold tolerance is configured to dictate the percentage under the configured threshold that must be reached in order for the condition to be considered “cleared”. An SNMP trap (starCongestionClear) is then triggered.
- **Service congestion policies**: Congestion policies are configurable for each service (e.g., PDSN, GGSN, P-GW, SGSN, etc.). These policies dictate how services respond should the system detect that a congestion condition threshold has been crossed.

Since the congestion control functionality on the system is disabled by default, this command should be executed once congestion-control thresholds and policies have been configured. (Refer to the other congestion-control related commands for more information.)

**Example**

The following command enables the congestion control functionality on the system.

```
congestion-control
```
**congestion-control overload-disconnect**

This command enables and disables the policy for disconnecting passive calls (chassis-wide) during an overload situation. It also configures and fine-tunes the overload-disconnect congestion control policy for an entire chassis.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
`configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
congestion-control overload-disconnect [ iterations-per-stage integer | percent percentage_value | threshold { license-utilization percentage_value | max-sessions-per-service-utilization percentage_value | tolerance number } ]

default congestion-control overload-disconnect [ iterations-per-stage | percent | threshold { license-utilization | max-sessions-per-service-utilization | tolerance } ]

no congestion-control overload-disconnect
```

**default**

When “default” and one of the keywords is added to the command, the policy remains in its current state and the value for the specified keyword is reset to its default value.

When “default” and the command are entered without keywords, the overload-disconnect policy for congestion control is disabled.

**no**

Disables the overload-disconnect policy for congestion control.

**iterations-per-stage integer**

Specifies the number of calls to be disconnected during the defined number of seconds. `integer` is a value from 2 through 8. The default value is 8.

**percent percentage_value**

Specifies the percentage of calls to be disconnected, in stages, during an overload situation. `percentage_value` is an integer from 1 through 100. The default value is 5.
### threshold

**license-utilization**: Specifies the license-utilization percentage threshold for overload situations. If candidates are available, passive calls are disconnected when this threshold is exceeded. 

`percentage_value` is an integer from 1 through 100. The default value is 80.

**max-sessions-per-service-utilization**: Specifies a percentage of the maximum sessions per service. If candidates are available, passive calls are disconnected when this threshold is exceeded.

`percentage_value` is an integer from 1 through 100. The default value is 80.

**tolerance**: Specifies the percentage of calls the system disconnects below the values set for the other two thresholds. In either case, a Clear Traps message is sent after the number of calls goes below the corresponding threshold value. `number` is an integer from 1 through 25. The default value is 10.

### Usage

Use this command to set the policy for call disconnects when the chassis experiences call overload.

To verify the congestion-control configuration use `show congestion-control configuration` from the Exec mode.

To set overload-disconnect policies for individual subscribers, see `overload-disconnect` in Subscriber Configuration Mode Commands.

### Example

The following command sets an overload-disconnect policy for the chassis in which 5 calls would be disconnected very 5 seconds during an overload situation.

```
congestion-control overload-disconnect interactions-per-stage 5
```

Both of the following commands disable the overload-disconnect policy without changing the policy configuration.

```
default congestion-control overload-disconnect
```

or

```
no congestion-control overload-disconnect
```

To instruct the system to stop call disconnects when the number of calls goes down 85% of the total allowed calls for that service, enter both of the following commands to set the max-sessions-per-service-utilization value to 90% and the tolerance value to 5%:

```
congestion-control overload-disconnect threshold max-sessions-per-service-utilization 90
congestion-control overload-disconnect threshold tolerance 5
```
congestion-control policy

Configures congestion control policies.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

congestion-control policy { asngw-service | asnpc-service | cscf-service | fng-service | ggsn-service | ha-service | hnbgw-service | hsgw-service | ipsg-service | lma-service | lns-service | mipv6ha-service | pcc-af-service | pcc-policy-service | pdg-service | pdif-service | pdsn-service | pdsnclsdrp-service | pgw-service | phsgw-service | phspc-service | saegw-service | sgsn-service | sgw-service | wsg-service } action { drop | none | redirect | reject }

congestion-control policy epdg-service action { drop | none | reject }

congestion-control policy mme-service action { drop | none | reject | report-overload { permit-emergency-sessions | reject-new-sessions | reject-non-emergency-sessions } enodeb-percentage percentage }

congestion-control policy { critical mme-service action-profile action_profile_name | major mme-service action-profile action_profile_name | minor mme-service action-profile action_profile_name }

default congestion-control policy { asngw-service | asnpc-service | cscf-service | epdg-service | fng-service | ggsn-service | ha-service | hnbgw-service | hsgw-service | ipsg-service | lma-service | lns-service | mipv6ha-service | mme-service | pcc-af-service | pcc-policy-service | pdg-service | pdif-service | pdsn-service | pdsnclsdrp-service | pgw-service | phsgw-service | phspc-service | saegw-service | sgsn-service | sgw-service | wsg-service }

default
Specifies the Congestion Control policy action for the selected service to its default value.

asngw-service
Specifies the Congestion Control policy action for the ASN-GW service.

asnpc-service
Specifies the Congestion Control policy action for the ASN PC-LR service.
**critical**
For MME (starting with Release 14.0), this keyword associates the action-profile to be used for critical congestion thresholds for the MME service.

**cscf-service**
Specifies the Congestion Control policy action for the P-CSF/A-BG service. Supported policy actions are:
- **drop**: Specifies that the system should drop incoming packets containing new session requests.
- **none**: Specifies that the system should take no action.
- **redirect**: Specifies that the system should redirect new session requests to an alternate device.

**Important**: If this option is used, the IP address of the alternate device must be configured using the `policy overload redirect` command that is part of the CSCF policy rules configuration.

- **reject**: Specifies that the system processes new session request messages and responds with a reject message.

**epdg-service action**
Specifies the Congestion Control policy action for the ePDG service. Supported policy actions are:
- **drop**: Specifies that the system should drop incoming packets containing new session requests.
- **none**: Specifies that the system should take no action.
- **reject**: Specifies that the system processes new session request messages and responds with a reject message.

For ePDG type of session/calls, `redirect` action is not supported.

**fng-service**
Specifies the Congestion Control policy action for the FNG service.

**ggsn-service**
Specifies the Congestion Control policy action for the GGSN service.

**ha-service**
Specifies the Congestion Control policy action for the HA service.

**hnbgw-service**
Specifies the Congestion Control policy action for the HNB-GW service. Supported policy actions are:
- **drop**: Specifies that the system should drop incoming packets containing new session requests.
- **none**: Specifies that the system should take no action.
- **reject**: Specifies that the system processes new session request messages and responds with a reject message.
hsgw-service
Specifies the Congestion Control policy action for the HSGW service.
Supported policy actions are:
- drop: Specifies that the system should drop incoming packets containing new session requests.
- none: Specifies that the system should take no action.
- redirect: Specifies that the system should redirect new session requests to an alternate device.

**Important:** If this option is used, the IP address of the alternate device must be configured using the `policy overload redirect` command that is part of the HSGW service configuration.

- reject: Specifies that the system processes new session request messages and responds with a reject message.

ipsg-service
Specifies the Congestion Control Policy action for the IPSG service. The policy specifies how the IPSG service will respond when the system detects that a congestion condition threshold has been crossed.
Supported policy actions are:
- drop: Specifies that the system should drop incoming packets containing new session requests.
- none: Specifies that the system should take no action.

Default: none

lma-service
Specifies the Congestion Control policy action for the LMA service

lns-service
Specifies the Congestion Control policy action for the LNS service.

mipv6ha-service
Specifies the Congestion Control policy action for the MIPv6-HA service.

**major**
For MME (starting with Release 14.0), this keyword associates the action-profile to be used for major congestion thresholds for the MME service.

**minor**
For MME (starting with Release 14.0), this keyword associates the action-profile to be used for minor congestion thresholds for the MME service.

mme-service
Sets the congestion control policy for action to take when subscriber sessions exceeds the defined threshold limit.
For MME type of session/calls, `redirect` action is not supported.
Global Configuration Mode Commands (A-K)

**Important:** The `mme-service` keyword option is available only in releases prior to 14.0. In 14.0 and higher, you must first select either the critical, major or minor policy level first. Refer to the `congestion-action-profile` command in the LTE Policy Configuration mode to create action-profiles which in turn define the actions to be taken when thresholds are exceeded in Release 14.0 and higher for MME.

---

**pcc-af-service**

Specifies the Congestion Control policy action for the PCC Application Function (AF) service. Supported policy actions are:

- **drop:** Specifies that the system should drop incoming packets containing new session requests.
- **none:** Specifies that the system should take no action.
- **reject:** Specifies that the system processes new session request messages and responds with a reject message.

**pcc-policy-service**

Specifies the Congestion Control policy action for the PCC Policy service. Supported policy actions are:

- **drop:** Specifies that the system should drop incoming packets containing new session requests.
- **none:** Specifies that the system should take no action.
- **reject:** Specifies that the system processes new session request messages and responds with a reject message.

**pdg-service**

Specifies the Congestion Control policy action for the PDG service.

**pdif-service**

Specifies the Congestion Control policy action for the PDIF service.

**pdsn-service**

Specifies the Congestion Control policy action for the PDSN service.

**pgw-service**

Specifies the Congestion Control policy action for the P-GW service. Supported policy actions are:

- **drop:** Specifies that the system should drop incoming packets containing new session requests.
- **none:** Specifies that the system should take no action.
- **reject:** Specifies that the system processes new session request messages and responds with a reject message.

For P-GW sessions/calls, **redirect** action is not supported.

**saegw-service**

Specifies the Congestion Control policy action for the SAEGW service. Supported policy actions are:

- **drop:** Specifies that the system should drop incoming packets containing new session requests.
- **none:** Specifies that the system should take no action.
• **reject**: Specifies that the system processes new session request messages and responds with a reject message.

For SAEGW sessions/calls, **redirect** action is not supported.

---

**sgsn-service**

Specifies the Congestion Control policy - the congestion response actions for the SGSN service. Prior to Release 17.0, the supported policy actions in this command are:

- **drop**: Specifies that the system should drop incoming packets containing new session requests.
- **none**: Specifies that the system should take no action.
- **reject**: Specifies that the system processes new session request messages and responds with a reject message.

---

**sgw-service**

Specifies the Congestion Control policy action for the S-GW service. Supported policy actions are:

- **drop**: Specifies that the system should drop incoming packets containing new session requests.
- **none**: Specifies that the system should take no action.
- **reject**: Specifies that the system processes new session request messages and responds with a reject message.

For S-GW sessions/calls, **redirect** action is not supported.

---

**wsg-service**

Specifies the Congestion Control policy action for the WSG service. Supported policy actions are:

- **drop**: Specifies that the system should drop incoming packets containing new session requests.
- **none**: Specifies that the system should take no action.
- **reject**: Specifies that the system processes new session request messages and responds with a reject message.

---

**action { drop | none | redirect | reject }**

Specifies the policy action:

- **drop**: Specifies that the system should drop incoming packets containing new session requests.
- **none**: Specifies that the system should take no action. This is the default for PDIF-service.
- **redirect**: Specifies that the system should redirect new session requests to an alternate device.
  
  (CSCF, HA, HSGW, and PDSN only)

---

**Important**: If this option is used, the IP address of the alternate device must be configured using the **policy overload redirect** command that is part of the service configuration. Note that this option can not be used in conjunction with GGSN, MME, P-GW, SAEGW, or S-GW services.

- **reject**: Specifies that the system processes new session request messages and responds with a reject message.
Global Configuration Mode Commands (A-K)

congestion-control policy

(For PDSN and HA, the reply code is 130, “insufficient resources”. For the GGSN, the reply code is 199, “no resources available”.)

\[
\text{report-overload \{ permit-emergency-sessions | reject-new-sessions | reject-non-emergency-sessions \} enodeb-percentage percentage}
\]

**Important:** This set of keywords is supported only by the MME.

Enables the MME to report overload conditions to eNodeBs and take additional action to alleviate congestion situations.

- **permit-emergency-sessions**: Specifies that only emergency sessions are allowed to access the MME during the overload period.
- **reject-new-sessions**: Specifies that all new sessions destined for the MME will be rejected during the overload period.
- **reject-non-emergency-sessions**: Specifies that all non-emergency sessions will be rejected during the overload period.
- **enodeb-percentage percentage**: Configures the percentage of known eNodeBs that will receive the overload report. `percentage` must be an integer from 1 to 100.

**Usage**

Congestion policies can be configured for each service. When congestion control functionality is enabled, these policies dictate how services respond should the system detect that a congestion condition threshold has been crossed.

**Example**

The following command configures a congestion control policy of reject for PDSN services:

```
congestion-control policy psdn-service action reject
```

The following command configures a congestion control policy of reject for MME services:

```
congestion-control policy mme-service action reject
```
congestion-control threshold

Configures the congestion control threshold values that are to be monitored.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**

```plaintext
congestion-control threshold { license-utilization percent | max-sessions-per-service-utilization percent | message-queue-utilization percent | message-queue-wait-time time | port-rx-utilization percent | port-specific { slot/port | all } [ tx-utilization percent ] [ rx-utilization percent ] port-specific-rx-utilization critical | port-specific-tx-utilization critical | port-tx-utilization percent | service-control-cpu-utilization percent | system-cpu-utilization percent | system-memory-utilization percent | tolerance percent }

no congestion-control threshold port-specific { slot/port | all }

no congestion-control threshold port-specific { slot/port | all } [ rx-utilization percent ] [ tx-utilization percent ]

no congestion-control threshold port-specific-rx-utilization critical

no congestion-control threshold port-specific-tx-utilization critical

no congestion-control threshold { message-queue-utilization | message-queue-wait-time | port-rx-utilization percent | port-tx-utilization percent | service-control-cpu-utilization | system-cpu-utilization | system-memory-utilization }

default congestion-control threshold keyword
Sets the threshold keyword to its default value.

no congestion-control threshold port-specific { slot/port | all } This command disables port specific threshold monitoring on the specified port or on all ports. slot/port: Specifies the port for which port specific threshold monitoring is being configured. The slot and port must refer to an installed card and port.
all: Set port specific threshold monitoring for all ports on all cards.

```
no congestion-control threshold port-specific-rx-utilization critical
```
This command disables specific receive port utilization.

```
no congestion-control threshold port-specific-tx-utilization critical
```
This command disables specific transmit port utilization.

```
license-utilization percent
```
Default: 100
The percent utilization of licensed session capacity as measured in 10 second intervals.

`percent` can be configured to any integer value from 0 to 100.

```
max-sessions-per-service-utilization percent
```
Default: 80
The percent utilization of the maximum sessions allowed per service as measured in real-time. This threshold is based on the maximum number of sessions or PDP contexts configured for the a particular service. (Refer to the `bind` command for the PDSN, GGSN, SGSN, or HA services.)

`percent` can be an integer from 0 through 100.

```
message-queue-utilization percent
```
Default: 80
The percent utilization of the Demux Manager software task’s message queue as measured in 10 second intervals. The queue is capable of storing a maximum of 10000 messages.

`percent` can be an integer from 0 through 100.

```
message-queue-wait-time time
```
Default: 5
The maximum time (in seconds) messages can be held in queue as measured by packet time stamps.

`time` is measured in seconds and can be an integer from 1 through 30.

**Important:** In the event that this threshold is crossed, an SNMP trap is not triggered. The service congestion policy invocation resulting from the crossing of this threshold is enforced only for the packet that triggered the action.

```
[ no ] port-rx-utilization percent
```
Default: 80
The average percent utilization of port resources for all ports by received data as measured in 5-minute intervals.

`percent` can be an integer from 0 through 100.

```
[ no ] port-specific { slot/port | all } [ rx-utilization percent ] [ tx-utilization percent]
```
Default: Disabled
Sets port-specific thresholds. If you set port-specific thresholds, when any individual port-specific threshold is reached, congestion control is applied system-wide.

`slot/port`: Specifies the port for which port-specific threshold monitoring is being configured. The slot and port must refer to an installed card and port.
Global Configuration Mode Commands (A-K)

congestion-control threshold

**all**: Set port specific threshold monitoring for all ports on all cards.

**rx-utilization percent**: Default 80%. The average percent utilization of port resources for the specified port by received data as measured in 5-minute intervals. *percent* must be an integer from 0 through 100.

**tx-utilization percent**: Default 80%. The average percent utilization of port resources for the specified port by transmitted data as measured in 5-minute intervals. *percent* must be an integer from 0 through 100.

[ no ] port-tx-utilization percent

Default: 80

The average percent utilization of port resources for all ports by transmitted data as measured in 5-minute intervals.

*percent* can be an integer from 0 through 100.

service-control-cpu-utilization percent

Default: 80

The average percent utilization of CPUs on which a Demux Manager software task instance is running as measured in 10-second intervals.

*percent* can be an integer from 0 through 100.

system-cpu-utilization percent

Default: 80

The average percent utilization for all PSC/PSC2 CPUs available to the system as measured in 10-second intervals.

*percent* can be an integer from 0 through 100.

This threshold setting can be disabled with no congestion-control threshold system-cpu-utilization command. In case later you want to enable the same threshold setting congestion-control threshold system-cpu-utilization command will enable the CPU utilization threshold to preconfigured level.

system-memory-utilization percent

Default: 80

The average percent utilization of all CPU memory available to the system as measured in 10-second intervals.

*percent* can be an integer from 0 through 100.

tolerance percent

Default: 10

The percentage under a configured threshold that dictates the point at which the condition is cleared.

*percent* can be an integer from 0 through 100.

**Usage**

Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). These thresholds function in a similar fashion to the operation thresholds that can be configured for the system (as described in later in this chapter). The primary difference is that when these thresholds are reached, not only is an SNMP trap generated (starCongestion), but a service congestion policy is invoked as well.

The tolerance parameter establishes the threshold at which the condition is cleared. An SNMP trap (starCongestionClear) is generated for the clear condition, as well.
**Important:** The MME (version 14.0 and higher) supports three levels of thresholds – critical, major and minor – for each condition. Refer to the `congestion-control threshold` commands immediately following this command for information specific to the MME.

### Example

The following command configures a system CPU utilization threshold of 75%.

```
congestion-control threshold system-cpu-utilization 75
```

This setting will remain in configuration unless you specify another threshold value in place of 75. This threshold setting can be disabled with `no congestion-control threshold system-cpu-utilization` command but cannot be removed from configuration. Later if you want to enable the previously configured threshold value of 75 percent, you only need to enter the `congestion-control threshold system-cpu-utilization` command without specifying any threshold value. It will enable the CPU utilization threshold to preconfigured level of 75 percent.

For example, `no congestion-control threshold system-cpu-utilization` disables the configured threshold setting and `congestion-control threshold system-cpu-utilization` again enables the threshold setting of 75%.

The following command configures a threshold tolerance of 5%:

```
congestion-control threshold license-utilization tolerance 5
```

In the above examples, the starCongestion trap gets triggered if the license utilization goes above 75% and the starCongestionClear trap gets triggered if it reaches or goes below 70%.
congestion-control threshold license-utilization

Configures the congestion threshold levels for license utilization on the system.

⚠️ Important: This command applies to MME (version 14.0 and higher) and ePDG (version 14.1 and higher).

**Product**
- MME
- ePDG

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
- `configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
congestion-control threshold license-utilization { critical percent | major percent | minor percent }

default congestion-control threshold license-utilization
```

**default congestion-control threshold license-utilization**

Sets all license-utilization thresholds to the default values.

**critical percent**

Default: 100
The critical threshold value for percent utilization of licensed session capacity, measured in 10-second intervals.

`percent` can be configured to any integer value from 0 to 100.

**major percent**

Default: 0
The major threshold value for percent utilization of licensed session capacity, measured in 10-second intervals.

`percent` can be configured to any integer value from 0 to 100.

**minor percent**

Default: 0
The minor threshold value for percent utilization of licensed session capacity, measured in 10-second intervals.

`percent` can be configured to any integer value from 0 to 100.
Use this command to set the critical, major and minor threshold levels of licensed session capacity as a percentage as measured in 10-second intervals. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well. This command requires a valid product license.

Example

The following command configures a minor threshold level for license utilization of 25%.

```
congestion-control threshold license-utilization minor 25
```

This setting will remain in configuration unless you specify another minor threshold level in place of 25. The following command returns the critical, major, and minor thresholds levels to their default values:

```
default congestion-control threshold license-utilization
```
congestion-control threshold max-sessions-per-service-utilization

Configures the congestion thresholds for the maximum sessions allowed per service.

**Important:** This command applies to MME (version 14.0 and higher) and ePDG (version 14.1 and higher).

**Product**
- MME
- ePDG

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
  ```
  configure
  ```
  Entering the above command sequence results in the following prompt:
  ```
  [local] host_name(config) #
  ```

**Syntax**

```congestion-control threshold max-sessions-per-service-utilization { critical percent | major percent | minor percent }
```

**default congestion-control threshold max-sessions-per-service-utilization**

Sets all max-sessions-per-service-utilization thresholds to the default values.

- **critical percent**
  - Default: 80
  - The critical threshold value for percent utilization of the maximum sessions allowed per service. *percent* can be configured to any integer value from 0 to 100.

- **major percent**
  - Default: 0
  - The major threshold value for percent utilization of the maximum sessions allowed per service. *percent* can be configured to any integer value from 0 to 100.

- **minor percent**
  - Default: 0
  - The minor threshold value for percent utilization of the maximum sessions allowed per service. *percent* can be configured to any integer value from 0 to 100.
Usage

Use this command to set the critical, major and minor threshold levels of maximum sessions per service as a percentage measured in real-time. This threshold is based on the maximum number of sessions or PDP contexts configured for the a particular service. (Refer to the bind command for the PDSN, GGSN, SGSN, or HA services.)

Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well.

This command requires a valid product license.

Example

The following command configures a minor threshold level of 25%.

    congestion-control threshold max-sessions-per-service-utilization minor 25

This setting will remain in configuration unless you specify another minor threshold level in place of 25.

The following command returns the critical, major, and minor thresholds levels to their default values:

    default congestion-control threshold max-sessions-per-service-utilization
congestion-control threshold message-queue-utilization

Configures the congestion thresholds for the percent utilization of the Demux Manager software task’s message queue.

**Important:** This command applies to ePDG (version 14.1 and higher).

<table>
<thead>
<tr>
<th>Product</th>
<th>ePDG</th>
</tr>
</thead>
<tbody>
<tr>
<td>Privilege</td>

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
congestion-control threshold message-queue-utilization { critical percent | major percent | minor percent }

default congestion-control threshold message-queue-utilization
```

Sets all max-sessions-per-service-utilization thresholds to the default values.

### critical percent

Default: 80
The critical threshold value for percent utilization of the Demux Manager software task’s message queue as measured in 10-second intervals. 

**percent** can be configured to any integer value from 0 to 100.

### major percent

Default: 0
The major threshold value for percent utilization of the Demux Manager software task’s message queue as measured in 10-second intervals. 

**percent** can be configured to any integer value from 0 to 100.

### minor percent

Default: 0
The minor threshold value for percent utilization of the Demux Manager software task’s message queue as measured in 10-second intervals. 

**percent** can be configured to any integer value from 0 to 100.
Usage

Use this command to set the critical, major and minor threshold levels of percent utilization of the Demux Manager software task’s message queue as measured in 10-second intervals. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well.

This command requires a valid product license.

Example

The following command configures a minor threshold level of 25%.

    congestion-control threshold message-queue-utilization minor 25

This setting will remain in configuration unless you specify another minor threshold level in place of 25.

The following command returns the critical, major, and minor thresholds levels to their default values:

    default congestion-control threshold message-queue-utilization
congestion-control threshold message-queue-wait-time

Configures the congestion thresholds for the maximum time (in seconds) messages can be held in queue as measured by packet time stamps.

**Important:** This command applies to ePDG (version 14.1 and higher).

**Product**
ePDG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
congestion-control threshold message-queue-wait-time { critical time | major time | minor time }

default congestion-control threshold message-queue-wait-time
```

Sets all max-queue-wait-time thresholds to the default values.

**critical time**

Default: 5
The critical threshold value for the maximum time (in seconds) that messages can be held in queue as measured by packet time stamps.

\[ time \] is measured in seconds and can be an integer from 1 through 30.

**major time**

Default: 0
The major threshold value for the maximum time (in seconds) that messages can be held in queue as measured by packet time stamps.

\[ time \] is measured in seconds and can be an integer from 1 through 30.

**minor time**

Default: 0
The minor threshold value for the maximum time (in seconds) that messages can be held in queue as measured by packet time stamps.

\[ time \] is measured in seconds and can be an integer from 1 through 30.
Usage

Use this command to set the critical, major and minor threshold levels for the maximum time (in seconds) messages can be held in queue.
Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed a congestion action-profile is invoked, if configured.
This command requires a valid product license.

Example

The following command configures a major threshold level of 4 seconds.

    congestion-control threshold message-queue-wait-time major 4

This setting will remain in configuration unless you specify another minor threshold level in place of 4.
The following command returns the critical, major, and minor thresholds levels to their default values:

    default congestion-control threshold message-queue-wait-time
congestion-control threshold port-rx-utilization

Configures the congestion thresholds for average percent utilization of port resources for all ports by received data as measured in 5-minute intervals.

**Important:** This command applies to ePDG (version 14.1 and higher).

**Product**
- ePDG

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
- `configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
congestion-control threshold port-rx-utilization { critical percent | major percent | minor percent }
```

```
default congestion-control threshold port-rx-utilization
```

Sets all port-rx-utilization thresholds to the default values.

**critical percent**

Default: 80
The critical threshold value for average percent utilization of port resources for all ports by received data as measured in 5-minute intervals.
`percent` can be configured to any integer value from 0 to 100.

**major percent**

Default: 0
The major threshold value for average percent utilization of port resources for all ports by received data as measured in 5-minute intervals.
`percent` can be configured to any integer value from 0 to 100.

**minor percent**

Default: 0
The minor threshold value for average percent utilization of port resources for all ports by received data as measured in 5-minute intervals.
`percent` can be configured to any integer value from 0 to 100.
Usage

Use this command to set the critical, major and minor threshold levels of average percent utilization of port resources for all ports by received data as measured in 5-minute intervals. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well. This command requires a valid product license.

Example

The following command configures a minor threshold level of 25%.

```config
congestion-control threshold port-rx-utilization minor 25
```

This setting will remain in configuration unless you specify another minor threshold level in place of 25. The following command returns the critical, major, and minor thresholds levels to their default values:

```config
default congestion-control threshold port-rx-utilization
```
congestion-control threshold port-specific

Configures the congestion thresholds for specific port utilization.

**Important:** This command applies to ePDG (version 14.1 and higher).

**Product**
ePDG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**

```
congestion-control threshold port-specific { slot/port { tx-utilization { critical percent | major percent | minor percent } | rx-utilization { critical percent | major percent | minor percent } | all { critical percent | major percent | minor percent } } }
```

```
no congestion-control threshold port-specific { slot/port { critical | major | minor } | all { critical | major | minor } }
```

Sets all port-specific utilization thresholds to the default values.

**slot/port**
Default: Disabled
Specifies the port for which port specific threshold monitoring is being configured. The slot and port must refer to an installed card and port. If you set port-specific thresholds, when any individual port-specific threshold is reached, congestion control is applied system-wide.

**all**
Set threshold monitoring for all ports on all cards.

**rx-utilization**
Set threshold monitoring for received data only.

**tx-utilization**
Set threshold monitoring for transmitted data only.
critical percent
Default: 80
The critical threshold value for average percent utilization of the specified port resources as measured in 5-minute intervals.
percent can be configured to any integer value from 0 to 100.

major percent
Default: 0
The major threshold value for average percent utilization of the specified port resources as measured in 5-minute intervals.
percent can be configured to any integer value from 0 to 100.

minor percent
Default: 0
The minor threshold value for average percent utilization of the specified port resources as measured in 5-minute intervals.
percent can be configured to any integer value from 0 to 100.

Usage
Use this command to set the critical, major and minor threshold levels of average percent utilization of specified resources for all ports by transmitted data as measured in 5-minute intervals. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well.
This command requires a valid product license.

Example
The following command configures a minor threshold level of 5% for received data on port 1 of the card in slot 17.

    congestion-control threshold port-specific 17/1 rx-utilization minor 5

This setting will remain in configuration unless you specify another minor threshold level in place of 5.
congestion-control threshold port-rx-utilization

Configures the congestion thresholds for average percent utilization of port resources for all ports by received data as measured in 5-minute intervals.

**Important:** This command applies to ePDG (version 14.1 and higher).

**Product**
ePDG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**configure**
Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
congestion-control threshold port-rx-utilization { critical percent | major percent | minor percent }
```

```
default congestion-control threshold port-rx-utilization
```

Sets all port-rx-utilization thresholds to the default values.

**critical percent**

Default: 80
The critical threshold value for average percent utilization of port resources for all ports by received data as measured in 5-minute intervals.

`percent` can be configured to any integer value from 0 to 100.

**major percent**

Default: 0
The major threshold value for average percent utilization of port resources for all ports by received data as measured in 5-minute intervals.

`percent` can be configured to any integer value from 0 to 100.

**minor percent**

Default: 0
The minor threshold value for average percent utilization of port resources for all ports by received data as measured in 5-minute intervals.

`percent` can be configured to any integer value from 0 to 100.
Usage

Use this command to set the critical, major and minor threshold levels of average percent utilization of port resources for all ports by received data as measured in 5-minute intervals.
Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well.
This command requires a valid product license.

Example

The following command configures a minor threshold level of 25%.

    congestion-control threshold port-rx-utilization minor 25

This setting will remain in configuration unless you specify another minor threshold level in place of 25.
The following command returns the critical, major, and minor thresholds levels to their default values:

    default congestion-control threshold port-rx-utilization
congestion-control threshold port-tx-utilization

Configures the congestion thresholds for average percent utilization of port resources for all ports by transmitted data as measured in 5-minute intervals.

**Important:** This command applies to ePDG (version 14.1 and higher).

**Product**
ePDG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

congestion-control threshold port-tx-utilization { critical percent | major percent | minor percent }

default congestion-control threshold port-tx-utilization

default congestion-control threshold port-tx-utilization
Sets all port-tx-utilization thresholds to the default values.

critical percent

Default: 80
The critical threshold value for average percent utilization of port resources for all ports by transmitted data as measured in 5-minute intervals.
percent can be configured to any integer value from 0 to 100.

major percent

Default: 0
The major threshold value for average percent utilization of port resources for all ports by transmitted data as measured in 5-minute intervals.
percent can be configured to any integer value from 0 to 100.

minor percent

Default: 0
The minor threshold value for average percent utilization of port resources for all ports by transmitted data as measured in 5-minute intervals.
percent can be configured to any integer value from 0 to 100.
Usage

Use this command to set the critical, major and minor threshold levels of average percent utilization of port resources for all ports by transmitted data as measured in 5-minute intervals. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well. This command requires a valid product license.

Example

The following command configures a minor threshold level of 25%.

```
congestion-control threshold port-tx-utilization minor 25
```

This setting will remain in configuration unless you specify another minor threshold level in place of 25. The following command returns the critical, major, and minor thresholds levels to their default values:

```
default congestion-control threshold port-tx-utilization
```
congestion-control threshold service-control-cpu-utilization

Configures the congestion thresholds for average percent utilization of CPUs on which a Demux Manager software task instance is running as measured in 10-second intervals.

**Important:** This command applies to MME (version 14.0 and higher) and ePDG (version 14.1 and higher).

**Product**
- MME
- ePDG

**Privilege**
- Security Administrator
- Administrator

**Mode**
- Exec > Global Configuration
- configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
congestion-control threshold service-control-cpu-utilization { critical percent | major percent | minor percent }
```

```
default congestion-control threshold service-control-cpu-utilization
```

Sets all service-control-cpu-utilization thresholds to the default values.

**critical percent**

Default: 80

The critical threshold value for average percent utilization of CPUs on which a Demux Manager software task instance is running as measured in 10-second intervals.

*percent* can be configured to any integer value from 0 to 100.

**major percent**

Default: 0

The major threshold value for average percent utilization of CPUs on which a Demux Manager software task instance is running as measured in 10-second intervals.

*percent* can be configured to any integer value from 0 to 100.

**minor percent**

Default: 0

The minor threshold value for average percent utilization of CPUs on which a Demux Manager software task instance is running as measured in 10-second intervals.

*percent* can be configured to any integer value from 0 to 100.
Usage

Use this command to set the critical, major and minor threshold levels of average percent utilization of CPUs on which a Demux Manager software task instance is running as measured in 10-second intervals. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well. When the service-control-cpu-utilization critical threshold setting is exceeded, ipsecmgrs running in the congested CPU are notified of the congestion. The ipsecmgrs raise traps for service-congestion exceeded and update the NPU so that no new calls are sent to those ipsecmgrs. The NPU does not send any new calls to the congested ipsecmgrs. However, if all ipsecmgrs are congested the action is always drop regardless of the setting for congestion policy action. The packet drops are silently done by the NPU. When ipsecmgrs are congested and an NPU receives a packet whose Security Parameter Index, Initiator (SPIi) in IKE_SA_INIT matches that of a currently established session, the packet is classified as belonging to the existing session. Since congestion action is applied only on new sessions, such IKE_SA_INIT packets are allowed to create sessions. If the IKE_SA_INIT uses an SPIi which does not match any of the existing sessions, it is processed according to the congestion policy action. This command requires a valid product license.

Example

The following command configures a minor threshold level of 25%.

```
congestion-control threshold service-control-cpu-utilization minor 25
```

This setting will remain in configuration unless you specify another minor threshold level in place of 25. The following command returns the critical, major, and minor thresholds levels to their default values:

```
default congestion-control threshold service-control-cpu-utilization
```
congestion-control threshold system-cpu-utilization

Configures the congestion thresholds for average percent CPU utilization of all packet processing cards available to the system as measured in 10-second intervals.

**Important:** This command applies to MME (version 14.0 and higher) and ePDG (version 14.1 and higher).

**Product**
- MME
- ePDG

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
- `configure`

Entering the above command sequence results in the following prompt:

```
[local]hostname(config)#
```

**Syntax**

```
congestion-control threshold system-cpu-utilization { critical percent | major percent | minor percent }
```

```
default congestion-control threshold system-cpu-utilization
```

Sets all system-cpu-utilization thresholds to the default values.

**critical percent**

Default: 80

The critical threshold value for average percent CPU utilization of all packet processing cards available to the system.

`percent` can be configured to any integer value from 0 to 100.

**major percent**

Default: 0

The major threshold value for average percent CPU utilization of all packet processing cards available to the system.

`percent` can be configured to any integer value from 0 to 100.

**minor percent**

Default: 0

The minor threshold value for average percent CPU utilization of all packet processing cards available to the system.

`percent` can be configured to any integer value from 0 to 100.
Use this command to set the critical, major and minor threshold levels of average percent CPU utilization of all packet processing cards available to the system as measured in 10-second intervals. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well.

This command requires a valid product license.

Example

The following command configures a minor threshold level of 25%.

```
congestion-control threshold system-cpu-utilization minor 25
```

This setting will remain in configuration unless you specify another minor threshold level in place of 25. The following command returns the critical, major, and minor thresholds levels to their default values:

```
default congestion-control threshold system-cpu-utilization
```
congestion-control threshold system-memory-utilization

Configures the congestion thresholds for the average percent utilization of all CPU memory available to the system as measured in 10-second intervals.

**Important:** This command applies to MME (version 14.0 and higher) and ePDG (version 14.1 and higher).

**Product**
- MME
- ePDG

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
- configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
congestion-control threshold system-memory-utilization { critical percent | major percent | minor percent }

default congestion-control threshold system-memory-utilization
```

Sets all system-memory-utilization thresholds to the default values.

**critical percent**
Default: 80
The critical threshold value for the average percent utilization of all CPU memory available to the system as measured in 10-second intervals.

**major percent**
Default: 0
The major threshold value for the average percent utilization of all CPU memory available to the system as measured in 10-second intervals.

**minor percent**
Default: 0
The minor threshold value for the average percent utilization of all CPU memory available to the system as measured in 10-second intervals.
Usage

Use this command to set the critical, major and minor threshold levels of average percent utilization of all CPU memory available to the system as measured in 10-second intervals. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well. This command requires a valid product license.

Example

The following command configures a minor threshold level of 25%.

```
congestion-control threshold system-memory-utilization minor 25
```

This setting will remain in configuration unless you specify another minor threshold level in place of 25. The following command returns the critical, major, and minor thresholds levels to their default values:

```
default congestion-control threshold system-memory-utilization
```
congestion-control threshold tolerance

Configures the percentage under a configured threshold value that dictates the point at which the condition is cleared.

**Important:** This command applies to MME (version 14.0 and higher) and ePDG (version 14.1 and higher).

**Product**
- MME
- ePDG

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
  - configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
congestion-control threshold tolerance { critical percent | major percent | minor percent }
```

```
default congestion-control threshold system-cpu-utilization
```

Sets all threshold tolerances to the default values.

- **critical percent**
  - Default: 10
  - The tolerance percentage for critical thresholds. When a critical threshold drops below this level, the condition is cleared.
  - `percent` can be configured to any integer value from 0 to 100.

- **major percent**
  - Default: 0
  - The tolerance percentage for major thresholds. When a major threshold drops below this level, the condition is cleared.
  - `percent` can be configured to any integer value from 0 to 100.

- **minor percent**
  - Default: 0
  - The tolerance percentage for minor thresholds. When a minor threshold drops below this level, the condition is cleared.
  - `percent` can be configured to any integer value from 0 to 100.
Usage

Use this command to set the tolerance limits for critical, major and minor thresholds.
The tolerance parameter establishes the threshold at which the condition is cleared. An SNMP trap
(starCongestionClear) is generated for the clear condition.
This command requires a valid product license.

Example

The following command configures the tolerance level of 5% for minor thresholds.

    congestion-control threshold tolerance minor 5

This setting will remain in configuration unless you specify another tolerance for minor thresholds in place of
5.
The following command returns the critical, major, and minor threshold tolerance levels to their default
values:

    default congestion-control threshold tolerance
**connectedapps**

Enables the configuration of Connected Apps (CA) client communication with the IOS-XR CA server on an ASR 9000. This command sends you to the Connected Apps Configuration mode.

**Product**
SecGW (WSG)

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
```
configure
```
Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**
```
connectedapps
```

**Usage**
Use this command to go to the Connected Apps Configuration mode. In this mode you can set CA client session parameters and ASR 9000 VSM High Availability (HA) chassis and network modes.

**Example**
The following command sends you to the Connected Apps Configuration mode:
```
connectedapps
```
content-filtering category database directory

This command configures the base directory to be used for storing all content-rating databases that are required for Category-based Content Filtering application.

Product
CF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

content-filtering category database directory path  directory_path

default content-filtering category database directory path

default

Specifies the default base directory and directory path for Category-based Content Filtering application.

directory_path

Default: /pcmcia1/cf

Specifies the base directory and its path to store all of the full or incremental content rating databases for the Category-based Content Filtering application.
directory_path must be an alphanumeric string of 1 through 255 characters.

Usage

Use this command to specify the directory and its path to download all full or incremental category-rating databases to be used for the Category-based Content Filtering application.
Merging of incremental database can be done as part of the database upgrade process preformed with upgrade content-filtering category database command in the Executive Mode.

Example

The following command configures the /flash/cf_temp/DB as the base directory to download all full and incremental content-rating databases for content filtering application.

content-filtering category database directory path /flash/cf_temp/DB
content-filtering category database max-versions

This command configures the number of full content-rating databases to maintain/archive in the base directory for category-based content filtering application.

Product
CF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

content-filtering category database max-versions num_archive

default content-filtering category database max-versions

default

Sets the default number of full databases for specified directory path/location.

num_archive

Default: 2
Specifies the maximum number of database to be archived or maintained in the specific location.
num_archive must be an integer from 1 through 3.

Usage

Use this command to set the number of full content-rating database to be maintained in the specified directory path with the base file name specified using the content-filtering database override file command. The specified directory path is the location specified using the content-filtering category database directory path command.

Example

The following command configures the system to maintain 3 full content-rating databases for category-based content filtering application.

content-filtering category database max-versions 3
content-filtering category database override

This command specifies the name of a file to be used by the category-rating database load process for category-based content filtering application.

Product
CF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax
content-filtering category database override file file_name.extension

default content-filtering category database override file

default

Sets the default content rating database file name; for example, optcmd.bin.

file file_name.extension

Specifies the header of the file in the database directory path location to determine the newest full database. file_name must be an alphanumeric string of up to 10 characters with an extension of 3 characters after a period (.) as extension.

Usage
Use this command to configure the category-rating database file name to determine the newest version of full database. A process called "LOAD_DATABASE" invokes during the system startup or the database upgrade process by upgrade content-filtering category database command in Executive Mode. This process examines the header of each of the files in the database folder specified by content-filtering category directory path command in this mode.

Note that by default system examines the header of those files only which begins with the string “OPTCMDB” and having extension “.bin”.

Example
The following command configures the system to examine the header of files that begins with CF_sta.DB only for content filtering application.

content-filtering category database override file CF_sta.DB
context

Enters the Context Configuration mode or is used to add or remove a specified context.

Product

All

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

context name [ -noconfirm ]

no context name

no

Removes the specified context from the configuration.

name

Specifies the name of a context to enter, add, or remove. When creating a new context, the context name must be unique.

Important: When creating a new context, the context name specified must not conflict with the name of any existing context or domain names.

-noconfirm

Indicates that the command is to execute without any additional prompt and confirmation from the user.

Usage

Configure contexts or remove obsolete contexts.

Important: A maximum of 64 contexts may be created.

Example

context sampleContext

no context sampleContext
Global Configuration Mode Commands (A-K)

**crash enable**

Enables or disables the copying of crash data to a specified location.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**configure**
Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
crash enable [ encrypted ] url crash_url [ filename-pattern pattern ] [ restrict mbyte ]
```  

```
no crash enable
```

Removes the specified context from the configuration.

**Important:** System crash information is generated and stored in the crash list even when the no keyword is specified. The information maintained in the crash lists is minimal crash information when the no keyword has been specified.

```
encrypted
```
Indicates that the URL encrypted for security reasons.

```
filename-pattern pattern
```
The filename-pattern is a an alphanumeric string containing any or all of the following variables:
- `%hostname%` - The system hostname.
- `%ip%` - A SPIO IP address
- `%cpu%` - CPU number
- `%card%` - Card number
- `%time%` - POSIX timestamp in hexadecimal notation
- `%filename%` - Alias for `crash-%card%-%cpu%-%time-core%`
- `%%` - A single % sign

If no pattern is specified, the result is the same as the pattern `filename`. Use '/' characters in the filename pattern part to store crashes in per-system subdirectories.
**url crash_url**

Specifies the location to store crash files. *crash_url* may refer to a local or a remote file. *crash_url* must be entered using the following format:

For the ASR 5000:

- `file: /{flash|pcmcia1|hd}/directory/`
- `tftp://host[:port]/{directory}/`
- `ftp: | sftp: //username[:password]@host[:port]/{directory}/`

For the ASR 5500:

- `file: /{flash|usb1|hd}/directory/`
- `tftp://host[:port]/{directory}/`
- `ftp: | sftp: //username[:password]@host[:port]/{directory}/`

**Important:** Use of the SMC hard drive is not supported in this release.

**Important:** Do not use the following characters when entering a string for the field names below: “/” (forward slash), “:” (colon) or “@” (at sign).

- `directory` is the directory name.
- `filename` is the actual file of interest.
- `username` is the user to be authenticated.
- `password` is the password to use for authentication.
- `host` is the IP address or host name of the server.
- `port#` is the logical port number that the communication protocol is to use.

**restrict mbyte**

Specifies a maximum amount of memory (in megabytes) to use for storing crash files as an integer from 1 through 128. Default: 128

The **restrict** keyword is only applicable to local URLs.

**Usage**

Enable crashes if there are systems that are not stable and the crash information will be useful for troubleshooting. The remote storage of the crash file reduces the memory utilized on the chassis.

**Example**

```plaintext
  crash enable ftp://remoteABC/pub/crash.dmp
  crash enable /flash/pub/data/crash.dmp restrict 64
  no crash enable
```
crypto blacklist file

Configures a blacklist (access denied) file to be used by a Wireless Security Gateway (WSG).

Product

All products supporting IPSec blacklisting

**Important**: This command appears in the CLI for this release. However, it has not been qualified for use with any current Cisco StarOS gateway products.

Privilege

Security Administrator

Mode

Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

Syntax

```
crypto blacklist file pathname

no crypto blacklist file
```

**no**

Removes the blacklist file from the system.

**pathname**

Specifies the location of the blacklist file as:

- `[ file: ]{/flash|/usbl|/hd-raid}{/directory}/{filename}
- `tftp://[host[:port]][/directory]/<filename`
- `[ ftp: | sftp: ]//username[:password]@[host][:port][/directory]/<filename`
- `http://<username>:<password>@<host>[:<port>][/<directory>]/<filename`

Usage

Use this command to configure the location of the blacklist file to be used by a WSG. A blacklist is a list or register of entities that are being denied a particular privilege, service, mobility, access or recognition. With blacklisting, any peer is allowed to connect as long as it does not appear in the list. Each entry in the blacklist file should contain the ID type so that the validation is performed for that ID type. In every entry, the ID type and ID value should be separated by a space. Only DOS and UNIX file formatting are supported. For additional information, refer to the *System Administration Guide*. 
**Important:** Either a blacklist, a whitelist or none is configured. Both listing techniques cannot be used simultaneously on the system.

Example

```plaintext
crypto blacklist file ftp://remoteABC/pub/blacklist.txt

crypto blacklist file /flash/pub/data/blacklist.txt
```
crypto remote-secret-list

Specifies the remote secret list for storing remote secrets based on the ID type. This command sends you to the Remote Secret List Configuration mode. Only one active remote-secret-list is supported per system.

Product
All products supporting IPSec remote secrets

**Important:** This command appears in the CLI for this release. However, it has not been qualified for use with any current Cisco StarOS gateway products.

Privilege
Security Administrator

Mode
Exec > Global Configuration

config
Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

crypto remote-secret-list listname

no crypto remote-secret-list listname

no

Deletes the remote-secret-list file from the system.

**Important:** You must unbind the remote-secret-list from any crypto maps or templates before it can be deleted.

listname

Usage

Use this command to specify the remote secret list for storing remote secrets based on the ID type. Only one remote-secret-list can be configured per system. Executing this command places you in the Remote Secret List Configuration mode.

This list of remote pre-shared keys is based on the remote ID type. The remote secret list can contain up to 1000 entries.

For additional information, refer to the Remote Secret List Configuration Commands chapter and the System Administration Guide.

Example

The following command creates a remote-secret-list named rs-list:

```
crypto remote-secret-list rs-list
```
crypto whitelist file

Configures a whitelist (access permitted) file to be used by a Wireless Security Gateway (WSG).

**Product**

All products supporting IPSec whitelisting

---

**Important:** This command appears in the CLI for this release. However, it has not been qualified for use with any current Cisco StarOS gateway products.

**Privilege**

Security Administrator

**Mode**

Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```plaintext
crypto whitelist file pathname [ -noconfirm ]
```

**no crypto whitelist file**

```
no
```

Removes the blacklist file from the system.

**pathname**

Specifies the location of the whitelist file as:

- `[ file: ]{/flash|/usb1|/hd-raid}/[directory]/<filename>`
- `tftp://[host[:port#]]/[directory]/<filename>`
- `[ ftp: | sftp: ]//[username[:password]@] [host][:port#]/[directory]/<filename>`
- `http://[<username>:<password>@]<host>[:<port>]/[<directory>]/<filename>`

**Usage**

Use this command to configure the location of the white file to be used by a WSG. A whitelist is a list or register of entities that are being provided a particular privilege, service, mobility, access or recognition. With whitelisting, no peer is allowed to connect unless it appears in the list. Each entry in the whitelist file should contain the ID type so that the validation is performed for that ID type. In every entry, the ID type and ID value should be separated by a space. Only DOS and UNIX file formatting are supported. For additional information, refer to the *System Administration Guide*.
**Important:** Usually either a blacklist, a whitelist or none is configured. Both listing techniques cannot be used simultaneously on the system.

**Example**

```
crypto whitelist file ftp://remoteABC/pub/whitelist.txt

crypto whitelist file /flash/pub/data/whitelist.txt
```
cs-network

This command creates/removes an HNB-CS network configuration instance for Famed UMTS access over Iu-CS/Iu-Flex interface between Home NodeB Gateway (HNB-GW) service and CS networks elements; i.e. MSC/VLR. This command also configures an existing HNB-CS network instance and enters the HNB-CS Network Configuration mode on a system.

Product
HNB-GW

Privilege
Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local] host_name(config)#

Syntax

`cs-network cs_instance [ -noconfirm ]`

`no cs-network cs_instance`

`no`

Removes the specified HNB-CS network instance from the system.

⚠️ Caution: Removing the HNB-CS network instance is a disruptive operation and it will affect all UEs accessing MSC(s) configured in specific CS core network through the HNB-GW service.

⚠️ Caution: If any HNB-CS Network instance is removed from system all parameters configured in that mode will be deleted and Iu-CS/Iu-Flex interface will be disabled.

`cs_instance`

Specifies the name of the Circuit Switched Core Networks instance which needs to be associated with the HNB Radio Network PLMN via the HNB RN-PLMN Configuration mode. If `cs_instance` does not refer to an existing HNB-PS network instance, the new HNB-CS network instance is created.

`cs_instance` must be an alphanumeric string of 1 through 63 characters.

`-noconfirm`

Indicates that the command is to execute without any additional prompt and confirmation from the user.

Usage

Use this command to enter the HNB-CS Network Configuration mode for an existing CS network instance or for a newly defined HNB-CS network instance. This command is also used to remove an existing HNB-CS network instance.
This configuration enables/disables the Iu-CS/Iu-Flex interface on HNB-GW service with CS core network elements; i.e. MSC/VLR.
A maximum of one HNB-CS network instance per HNB-GW service instance which is further limited to a maximum of 256 services (regardless of type) can be configured per system.

⚠️ Caution: This is a critical configuration. The HNBs cannot access MSC(s) in CS core network without this configuration. Any change to this configuration would lead to disruption in HNB access to CS core network.

Entering this command results in the following prompt:

```plaintext
[context_name]hostname(config-cs-network)#
```

The various parameters available for configuration of an HNB-CS network instance are defined in the HNB-CS Network Configuration Mode Commands chapter.

**Example**

The following command enters the existing HNB-CS Network configuration mode (or creates it if it does not already exist) for the instance named `hnb-cs1`:

```plaintext
cs-network hnb-cs1
```

The following command will remove HNB-CS network instance `hnb-cs1` from the system without any warning to operator:

```plaintext
no cs-network hnb-cs1
```
css acsmgr-selection-attempts

This is a restricted command. In 9.0 and later releases this command is obsolete.
css delivery-sequence

This is a restricted command. In 9.0 and later releases this command is obsolete.
css service

This is a restricted command. In 9.0 and later releases this command is obsolete.
default

Restores the system default values for the specified parameters.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]\host_name(config)#

Syntax

```
default {  aaa { accounting-overload-protection domain-matching | username-format }  |  arp base-reachable-time | autoconfirm | banner [ lawful-intercept | motd | pre-login ] | boot [ delay | interface | nameserver | networkconfig ] | bulkstats historical collection | card-standby-priority | cdr-multi-mode | clock timezone | cli max-sessions | congestion-control [ overload-disconnect | policy | threshold ] | diameter-proxy ramdisk | enforce { imsi-min equivalence | ip optimize-ipid-assignment } | gtpp { compression-processes | ram-disk-limit } | high-availability fault-detection speed | local-user { allow-aaa-authentication | lockout-time | max-failed-logins } | logging { display | filter runtime } | network-overload-protection | operational-mode | pac-standby-priority | qos npu inter-subscriber traffic { bandwidth | priority [ assigned-to dscp { af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | ef } ] } | require { cipher ss1 resource-percentage | demux card | session recovery } | reveal disabled commands | snmp { engine-id | heartbeat | history heartbeat | notif-threshold } | system { contact | description | hostname | location | serial-number } | system-mac | system-priority | task { facility sessmgr start | resource cpu-memory-low } | terminal { all | databits | flowcontrol | parity | speed | stopbits } | threshold { value } | timestamps | upgrade limit [ time ] [ usage ] }

aaa { accounting-overload-protection domain-matching | username-format }

Restores the aaa behavior to its default of disabled for the following options:

*domain-matching*: Restores the default domain matching method.
*username-format*: Restores the use of the default username format for global AAA services

arp base-reachable-time

Restores ARP base-reachable-time to 30 seconds.

autoconfirm

Restores the autoconfirm behavior to its default of disabled.
**banner**

*lawful-intercept* - Restores the system default message of the day for SSH CLI sessions.

*motd* - Restores the system default message of the day banner.

*pre-login* - Restores the CLI login banner to the system default.

**boot [ delay | interface | nameserver | networkconfig ]**

*interface | networkconfig* - Restores the default boot interface and network configuration options. The keywords *interface* and *networkconfig* are used to restore the default option settings for the interface and network configuration options, respectively. Defaulting the network configuration boot option removes the network boot option from the boot.sys file. It does not remove the network config options from the configuration file which is managed separately from the boot.sys file.

*delay* - Removes the boot delay setting (if any). The default for boot delay is “no boot delay”.

*nameserver* - Removes the nameserver IP address.

**card-standby-priority**

Resets the standby priority of the Packet Services Cards.

**cdr-multi-mode**

Restores the default value of this command to Single-CDRMOD mode.

**cli max-sessions**

Restores the default value of this command to *no cli max-sessions* which removes the limit on the number of allowed simultaneous CLI sessions on the system.

**clock-timezone**

Restores the system’s clock timezone to UTC.

**congestion-control [ overload-disconnect | policy | threshold ]**

Restores the system’s congestion-control functionality to its default setting of disabled. You can selectively restore other components to their default values.

**diameter-proxy ram-disk**

Restores the ram-disk size to 32MB.

**enforce { imsi-min equivalence | ip optimize-ipid-assignment }**

Disables the enforcement of either option.

**gtpp { compression-process | ram-disk-limit }**

Restores number of compression processes allowed to 1. Restores the RAM disk size to 32MB.

**high-availability fault-detection speed**

Restores speed to Normal.
local-user { allow-aaa-authentication | lockout-time | max-failed-logins }
Enables aaa-authentication.
Restores lock-time to 60 minutes.
Restores max-failed-logins to 5.

logging {display | filter runtime}
display: sets the default level of detail to display for trace log information to the system default.
fILTER runtime: resets the filtering of logged information to log in real time.

network-overload-protection
For SGSN, disables this attach rate throttle feature that provides network overload protection.

operational-mode
Sets the operational mode of the chassis to the system default.

pac-standby-priority
This parameter has been replaced by the card-standby-priority keyword.

qos npu inter-subscriber traffic {bandwidth | priority [ assigned-to dscp { af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | ef } ] }
Restores the following NPU QoS parameters to their default values:
• bandwidth:
  • gold: 10%
  • silver: 20%
  • bronze: 30%
  • best-effort: 40%
• priority: All DSCP values are mapped to the best-effort priority queue but are not configured.

require { cipher ssl resource-percentage | demux card | session recovery }
Resets the cipher ssl resource-percentage to 0.
Disables the demux capabilities on the demux card.
Disables the session recovery feature.

snmp { engine-id | heartbeat | history heartbeat |notif-threshold }
engine-id: Restores the SNMP engine ID to the system default.
heartbeat: Restores the SNMP heartbeat interval to 60 minutes.
history heartbeat: Reenables the recording of heartbeat notifications in SNMP history.
notif-threshold: Restores the SNMP notification thresholds to the system defaults.

system { contact | description | hostname | location | serial-number }
Sets the following system parameters to their default values:
• contact: Resets to none specified.
• description: Resets to none specified.
• **hostname**: Resets to “asr5000” or asr5500”.
• **location**: Resets to none specified.
• **serial-number**: Resets to factory default.

**system-mac hostname**
Resets the system MAC address to the factory default value.

**system-priority hostname**
Resets the system priority to its default value.

**task { facility sessmgr start | resource cpu-memory-low }**

**facility sessmgr start**: Restores the default session manager start policy to Normal.
**resource cpu-memory-low**: Resets the system so that when a CPU runs very low on memory (below 12MB) the most over-limit task is killed.

**terminal { all | databits | flowcontrol | parity | speed | stopbits }**

**all**: Restores all terminal parameters to their default values.
**databits**: Resets to 8 data bits.
**flowcontrol**: Resets to none.
**parity**: Resets to none.
**speed**: Resets 9600 bits/second.
**stopbits**: Resets to one stop bit.

**threshold { value }**
Restores thresholding values to their default setting. The possible values are:
• **10sec-cpu-utilization**: CPU utilization using a 10 sec average.
• **aaa-acct-archive-queue-size<1..3>**: AAA accounting archive queue threshold settings.
• **aaa-acct-archive-size**: AAA accounting archive size.
• **aaa-acct-failure**: AAA accounting failure threshold settings
• **aaa-acct-failure-rate**: AAA accounting failure rate threshold settings
• **aaa-auth-failure**: AAA authentication failure threshold settings
• **aaa-auth-failure-rate**: AAA authentication failure rate threshold settings
• **aaa-retry-rate**: AAA retry rate threshold settings
• **aamgr-request-queue**: AAA manager internal request queue threshold settings
• **asngw-auth-failure**: ASN-GW Auth Failure related threshold
• **asngw-handoff-denial**: ASN-GW handoff denial threshold
• **asngw-max-eap-retry**: ASN-GW maximum EAP retry threshold
• **asngw-network-entry-denial**: ASN-GW Network entry denial threshold
• **asngw-session-setup-timeout**: ASN-GW session setup timeout threshold
• **asngw-session-timeout**: ASN-GW session timeout threshold
• **asnpc-idle-mode-timeout**: ASN-PC idle mode timeout threshold
• **asnpc-im-entry-denial**: ASN-PC IM entry denial threshold
• asnpc-lu-denial: ASN-PC lu denial threshold
• asnpc-session-setup-timeout: ASN-PC session setup timeout threshold
• bgp-routes: bgp routes threshold
• call-reject-no-resource: Calls rejected due to no resources threshold settings
• call-setup: Calls setup threshold settings
• call-setup-failure: Call setup failure threshold settings
• card-temperature-near-power-off-limit: Threshold for the gap between the current card temperature and the power off limit
• cdr-file-space: CDR file space threshold
• contfilt-block: Content Filtering Blocks threshold settings
• contfilt-rating: Content Filtering Ratings threshold settings
• cpu-available-memory: CPU available memory threshold settings
• cpu-load: PSC/PSC2 CPU load (5-minute average)
• cpu-memory-usage: Percentage of total CPU memory usage
• cpu-orbs-critical: ORBs process CPU usage critical level
• cpu-orbs-warn: PORBs process CPU usage warning level
• cpu-session-throughput: CPU session throughput threshold settings
• cpu-utilization: CPU utilization threshold settings
• dcca-bad-answers: Diameter Bad Answers threshold settings
• dcca-protocol-error: Diameter Protocol Error threshold settings
• dcca-rating-failed: Diameter Rating Failed threshold settings
• dcca-unknown-rating-group: Diameter Unknown Rating Group threshold settings
• diameter: Diameter threshold settings
• dns-learnt-ip-max-entries: DNS IP maximum entries threshold
• dns-lookup-failure: DNS Lookup Failure threshold
• edr-file-space: EDR file space threshold
• edr-udr-dropped-flow-control: EDR-UDRs Dropped due to flow control
• epdg-current-sessions: Current EPDG sessions threshold
• fng-current-active-sessions: Femto Network Gateway (FNG) current active sessions threshold
• fng-current-sessions: FNG current sessions threshold
• fw-deny-rule: Stateful Firewall Deny Rule threshold
• fw-dos-attack: Stateful Firewall Dos-Attacks threshold
• fw-drop-packet: Stateful Firewall Drop Packets threshold
• fw-no-rule: Stateful Firewall No-Rule threshold
• license: Session license threshold settings
• mgmt-cpu-memory-usage: Management (SMC) CPU memory usage threshold
*mgmt-cpu-utilization*: Management (SMC) CPU utilization threshold (most recent 5-minute average)

*mme-attach-failure*: MME Attach Failure related threshold

*mme-auth-failure*: MME Auth Failure related threshold

*model*: Thresholding model settings

*monitoring*: Threshold monitoring configuration settings

*nat-port-chunks-usage*: Port chunk utilization threshold

*npu-utilization*: NPU utilization threshold (most recent 5-minute average)

*packets-filtered-dropped*: Filtered/dropped packet threshold settings

*packets-forwarded-to-cpu*: Forwarded packet threshold settings

*pdg-current-active-sessions*: PDG current active sessions threshold

*pdg-current-sessions*: PDG current sessions threshold

*pdif-current-active-sessions*: Threshold monitoring for only the currently-active PDIF sessions.

*pdif-current-sessions*: Threshold monitoring for all current PDIF sessions.

*per-service-asngw-sessions*: The number of sessions per ASN-GW service

*per-service-ggsn-sessions*: The number of GGSN sessions per GGSN service

*per-service-gprs-pdp-sessions*: The number of PDP contexts per GPRS service

*per-service-gprs-sessions*: The number of GPRS sessions per GPRS service

*per-service-ha-sessions*: The number of HA sessions per HA service

*per-service-lns-sessions*: The number of LNS sessions per LNS service

*per-service-pdsn-sessions*: The number of PDSN sessions per PDSN service

*per-service-sgsn-pdp-sessions*: The number of PDP contexts per SGSN service

*per-service-sgsn-sessions*: The number of SGSN sessions per SGSN service

*phsgw-eapol-auth-failure*: Personal Handy Phone Gateway (PHSGW) EAPOL authentication failure threshold

*phsgw-handoff-denial*: PHSGW handoff denial threshold

*phsgw-max-eap-retry*: PHSGW maximum EAP retry threshold

*phsgw-max-eapol-retry*: PHSGW max EAPOL retry threshold

*phsgw-network-entry-denial*: PHSGW Network entry denial threshold

*phsgw-session-setup-timeout*: PHSGW session setup timeout threshold

*phsgw-session-timeout*: PHSGW session timeout threshold

*phspc-session-setup-timeout*: PHSPC session setup timeout threshold

*phspc-sleep-mode-timeout*: PHSPC sleep mode timeout threshold

*phspc-sm-entry-denial*: PHSPC sm entry denial threshold

*poll*: Threshold polling interval configuration settings

*ppp-setup-fail-rate*: PPP setup failure rate threshold

*rp-setup-fail-rate*: RP setup failure rate threshold
• storage-utilization: Mass storage (flash memory) utilization
• subscriber: subscriber related thresholds
• system-capacity: Percentage usage of system resources
• total-asngw-sessions: Total ASN-GW sessions threshold
• total-ggsn-sessions: Total GGSN sessions for all GGSN services in the system
• total-gprs-pdp-sessions: Total PDP contexts for all GPRS services in the system
• total-gprs-sessions: Total GPRS sessions per for all GPRS services in the system
• total-ha-sessions: Total HA sessions for all HA services in the system
• total-hnbgw-hnb-sessions: Total 3G Home NodeBGateway (HNBGW) HNB sessions for all HNB services in the system
• total-hnbgw-iu-sessions: Total HNBGW Iu sessions in the system
• total-hnbgw-ue-sessions: Total HNBGW UE sessions in the system
• total-hsgw-sessions: Total HRPD Serving Gateway (HSGW) sessions for all HSGW services in the system
• total-lma-sessions: Total Local Mobility Anchor (LMA) sessions for all LMA services in the system
• total-lns-sessions: Total L2TP Network Server (LNS) sessions for all LNS services in the system
• total-mme-sessions: Total Mobility Management Entity (MME) sessions for all MME services in the system
• total-pdsn-sessions: Total PDSN sessions for all PDSN services in the system
• total-pgw-sessions: Total Packet Data Network Gateway (PGW) sessions for all PGW services in the system
• total-saegw-sessions: Total PDP contexts for all SAEGW services in the system
• total-sgsn-pdp-sessions: Total PDP contexts for all SGSN services in the system
• total-sgsn-sessions: Total SGSN sessions for all SGSN services in the system
• total-sgw-sessions: Total Serving gateway (SGW) sessions for all SGW services in the system

timestamps
Resets the inclusion of timestamps in command.

upgrade limit [ time ] [ usage ]
Sets upgrade limit values to the defaults. If the optional keywords are not specified all values are reset to their defaults.
time: Resets the maximum time a session may exist during a software upgrade to the default of 120.
usage: Resets the minimum number of sessions before closing the sessions during a software upgrade to the system default of 100.

Usage
Restore system defaults to aid in trouble shooting or just prior to modifying additional configuration options.

Example
default banner motd
default boot

default logging display

default system hostname

default upgrade limit time
**diameter dynamic-dictionary**

This command allows configuring a Diameter dictionary dynamically at run time, and then loading the dynamic dictionary in to the system.

**Important:** The maximum number of dynamic dictionaries that can be loaded in to the system is 10.

**Product**
- GGSN
- HA
- HSGW
- IPSG
- PDSN
- P-GW
- SAEGW
- S-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
diameter dynamic-dictionary name url
no diameter dynamic-dictionary name
```

**Right Margin**

```
no
Unloads the specified dynamic Diameter dictionary from the system.
```

```
name
Specifies the name of the dynamic Diameter dictionary as an alphanumeric string of 1 through 15 characters.
```

```
url
Specifies the URL of the Diameter dictionary to be loaded in to the system. The input must be an alphanumeric string of 1 through 127 characters.
```
Usage
This command is used to define a new Diameter dictionary on the fly, and load the dynamic dictionary into the system.
To perform this configuration, you should first create a text file in ABNF format and configure all the required Diameter AVPs and command codes in the file. Then, save the file in flash or some URL that will be accessible by the system.
Now, configure a dynamic dictionary with an unique name and map it to the URL of the file to be loaded dynamically into the system at the global configuration level.
When the names of the dynamic dictionaries and their URLs are configured, the corresponding files at the respective URLs are parsed and populated in all SessMgr and AAAMgr facilities as new dictionaries and kept available to be used when these dictionary names are configured under any Diameter application level or AAA group.
When a dynamic dictionary name is configured under an application such as IMS authorization service or in an AAA group, the corresponding dictionary (which is already loaded in SessMgrs and AAAMgrs) entry will be used.
There will be only one instance of a dynamic dictionary loaded into a task for one dynamic dictionary name even if the same dictionary name is configured in multiple AAA groups or multiple application configurations. That is, even if the same dictionary name is configured in several applications or several AAA groups, all these applications and AAA groups will refer to the same dynamic dictionary instance.

Example
The following command configures a Diameter dictionary named *dyn1* and loads this dictionary to the /flash/diameter_custom1.sndd path:

```
diameter dynamic-dictionary dyn1 /flash/diameter_custom1.sndd
```
diameter-host-template

Specifies the name of a Diameter host template and enters the Diameter Host Select mode. A Diameter host template is a table of peer servers that can be shared by multiple services.

Product

GGSN
HA
HSGW
IPSG
PDSN
P-GW
SAEGW
S-GW

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
diameter-host-template name [ -noconfirm ]

no diameter-host-template name
```

no

Removes the specified Diameter host template from the Global Configuration.

name

Specifies the name of the template as an alphanumeric string of 1 through 63 characters.

[-noconfirm ]

Executes the command without prompting for further input from the user.

Usage

Specifies the name of a new or existing Diameter host template and opens the Diameter Host Select mode. You can configure up to 256 templates on the system.

To use the template, Diameter applications must be associated with the template. When an association is made to the template, the system selects the Diameter peer to be contacted based on rows configured in the table and the algorithm configured for selecting rows in the table.
**Important:** Currently, only Gx service can be associated with the template.

If more than one service is using the same set of `peer-select` commands, then it is better to define all the peer selection CLIs in the template and associate the services to the template. Entering this command results in the following prompt:

```
[context_name] hostname (config-host-template) #
```

Diameter host select configuration commands are defined in the *Diameter Host Select Configuration Mode Commands* chapter.

**Example**

The following command specifies a Diameter host template named `diamtemplate`:

```
diameter-host-template diamtemplate
```
diameter-proxy ram-disk

This command configures the amount of extra RAM disk space in MB to be allocated to Diamproxy task when local storage (hard disk) is enabled.

**Product**
- HSGW
- P-GW
- SAEGW
- S-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**
```
diameter-proxy ram-disk mb space_mb
```
```
default diameter-proxy ram-disk mb
```

**Usage**
Specifies the additional storage space to be allocated to Diamproxy for file write, in MB. The specified memory in MB is added to the existing memory allocated to Diamproxy only if HDD storage is enabled. By default, 32 MB is additionally allocated.

**Example**
The following command specifies that 100 MB of additional storage space be allocated to the Diamproxy task:

```
diameter-proxy ram-disk mb 100
```
ecmp-lag hash

This command provides the configuration to select source Boxer Internal Address (SBIA) as the input to the hashing function for ECMP-LAG distribution.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
[no] ecmp-lag hash use-sbia-only
```

- **no**
  
  Disables the hashing function selection and sets the system to use IP Source Address, IP Destination Address, IP Protocol and Source BIA as inputs to the hashing algorithm for ECMP-LAG distribution.

**Usage**

Use this command to allow the operator to change the way hashing works in deciding which link to use for ECMP and Link Aggregation. In the default hashing algorithm the IP Source Address, IP Destination Address, IP Protocol and Source BIA are used in the hashing function. When “use-sbia-only” option is selected, only the Source BIA is used in the hashing function.

⚠️ **Caution:** When using ECMP-LAG on a HNB-GW, this configuration is **mandatory** for standalone HNB-GW deployment and highly recommended in other deployment scenarios where HNB-GW is used in combination with other services.

**Example**

The following command enables the SBIA as input to hash function for ECMP-LAG on the HNB-GW:

```
ecmp-lag hash use-sbia-only
```

The following commands sets the hashing function to use standard inputs for ECMP-LAG on HNB-GW:

```
no ecmp-lag hash use-sbia-only
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Use this command to return to the Exec mode.
enforce imsi-min equivalence

Enables the PDSN/HA to treat IMSI and MIN as the same for identifying the PDSN/HA session.

**Product**
PDSN
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
[ no | default ] enforce imsi-min equivalence
```

- **default**
  
  Returns the command to its default setting of disabled.

- **no**
  
  Disables the PDSN/HA from treating IMSI and MIN as the same for identifying the PDSN/HA session.

**Usage**

Generally on an HA, the IMSI and MIN are treated as different and hence the RRQs with 1x and DO PDSNs are processed as different sessions. You can use this feature to treat the IMSI and MIN with the matching lower 10-digit as the same for identifying a session. The 10-digit MIN and the 15-digit IMSI are treated as equivalent for the purpose of matching sessions if the lower 10 digits are the same. Any handoff from 1x to DO or vice-versa is treated as the same session if the NAI and HoA also match. If the NAI and/or HoA do not match, then the duplicate IMSI session detect and terminate feature is applicable.

Generally on a PDSN, the IMSI and MIN are treated as different and hence RP messages from 1x and DO PDSNs are processed as different sessions. You can use this feature to treat the IMSI and MIN with the matching lower 10-digit as the same for identifying a session. The 10-digit MIN and the 15-digit IMSI are treated as equivalent for the purpose of matching PDSN sessions if the lower 10 digits are the same. Any handoff from 1x to DO or vice-versa is treated as the same session.

**Example**

To monitor or clear subscriber session information filtered by on IMSI/MIN refer to the `show subscribers msid` command.

**Important:** This command must be executed at startup only and will not take effect when reconfigured without rebooting.
**Example**

The following command enables the treatment of the IMSI and MIN as the same for identifying the session:

```
enforce imsi-min equivalence
```

Either of the following commands disables the treatment of the IMSI and MIN as the same for identifying sessions:

```
no enforce imsi-min equivalence
default enforce imsi-min equivalence
```
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**
Use this command to return to the parent configuration mode.
fa-spi-list

Replaces a duplicate Foreign Agent- Security Parameter Index (FA-SPI) remote address list applied to multiple FA services with a list name.

Product
PDSN
FA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
fa-spi-list fa_spi_list
```

```
fa_spi_list

Remote address list name expressed as an alphanumeric string of 1 through 64 characters.
```

Usage
Use this command to Replace duplicate FA-SPI remote address list applied to multiple FA or HA services with a list name.

Example
The following command configures the list FA SPI list to fa-list2:

```
fa-spi-list fa-list2
```
failure-handling-template

This command allows the user to create/modify/delete a Diameter failure handling template at the global configuration level. This command specifies the name of failure handling template and enters the Failure Handling Template mode. The users can define the failure handling configurations within this template.

**Important:** A maximum of 64 templates can be configured on the system.

**Product**
- GGSN
- HA
- HSGW
- IPSG
- PDSN
- P-GW
- SAEGW
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
- `configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
failure-handling-template name [ -noconfirm ]
```

```
no failure-handling-template name
```

- **no**
  - Removes the specified failure handling template from the Global Configuration.

- **name**
  - Specifies the name of the failure handling template as an alphanumeric string of 1 through 63 characters.

- **[ -noconfirm ]**
  - Executes the command without prompting for further input from the user.
Usage

Specifies the name of a new or existing failure handling template and opens the Failure Handling Template mode. Depending on which application is using the failure handling template, some of the syntactically possible configurations within the template are not applicable.

To use the template, Diameter applications must be associated with the template. When an association is made to the template, in the event of a failure, the system takes the action as defined in the failure handling template. Both IMS Authorization (Gx) and Diameter Credit Control Application (DCCA) (Gy) services can be associated with the template.

Entering this command results in the following prompt:

[context_name]hostname(config-fh-template)#

Failure handling template configuration commands are defined in the Diameter Failure Handling Template Configuration Mode Commands chapter.

Example

The following command specifies a failure handling template named FHtemplate:

`failure-handling-template FHtemplate`
get context-list

Generates an XML-formatted list of all currently configured contexts within the system.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
get context list [ | { grep grep_options | more } ]
```

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.

For details on the usage of `grep` and `more`, refer to the Regulating a Command’s Output section of the Command Line Interface Overview chapter.

**Usage**

Generates a list of all currently configured contexts in XML format. The output can be copied and pasted into compatible applications.

**Example**

```
get context-list
```
get ip

Generates an XML-formatted display of IPv4-based information.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

get ip { access-list | arp [vrf name] | bgp neighbors | interface [vrf name] | ospf { interface | neighbor | vrf name | route [vrf name] | vrf } [ | { grep grep_options | more } ]

access-list
Generates an XML-formatted display of all IPv4 Access Control Lists (ACLs).

arp
Generates an XML-formatted display of all Allocation Retention Priorities (ARPs) or the ARPs for the named Virtual Routing and Forwarding (VRF) table.

bgp neighbors
Generates an XML-formatted display of all Border Gateway Protocol (BGP) neighbors.

interface [vrf name]
Generates an XML-formatted display of all interfaces or for only those associated with a specified VRF table (optional).

ospf { interface | neighbor | vrf name }
Generates an XML-formatted display of all Open Shortest Path First (OSPF) routing information.

*interface: Displays interface information for OSPF.
*neighbor: Displays summarized information about all known OSPF neighbors.
*vrf name: Displays information for the named VRF table.

route [vfr name]
Generates an XML-formatted display of all IPv4-based routes or for only those associated with a specified VRF table (optional).
**get ip**

<table>
<thead>
<tr>
<th>vrf</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generates an XML-formatted display of all VRF tables.</td>
</tr>
</tbody>
</table>

`vrf` | \{ grep grep_options | more \}

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.

For details on the usage of *grep* and *more*, refer to the *Regulating a Command’s Output* section of the *Command Line Interface Overview* chapter.

---

**Usage**

Generates a display of IPv4-based information in XML format. The output can be copied and pasted into compatible applications.

**Example**

```
get ip access-list
```
get ipv6

Generates an XML-formatted display of IPv6-based information.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
get ip { access-list | interface [vrf name] | ospf { interface | neighbor } | route [vrf name] } [ | { grep grep_options | more } ]
```

<table>
<thead>
<tr>
<th><strong>access-list</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Generates an XML-formatted display of all IPv6 Access Control Lists (ACLs).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>interface [vrf name]</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Generates an XML-formatted display of all IPv6 interfaces or for only those associated with a specified VRF table (optional).</td>
</tr>
</tbody>
</table>

| **ospf { interface | neighbor }** |
|------------------------------|
| Generates an XML-formatted display of all Open Shortest Path First version 3 (OSPFv3) routing information. |
| *interface*: Displays interface information for OSPFv3. |
| *neighbor*: Displays summarized information about all known OSPFv3 neighbors. |

<table>
<thead>
<tr>
<th><strong>route [vrf name]</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Generates an XML-formatted display of IPv6 routes or for only those associated with a specified VRF table (optional).</td>
</tr>
</tbody>
</table>

| | { grep grep_options | more } |
|-----------------------------|
| Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent. |
| For details on the usage of **grep** and **more**, refer to the Regulating a Command’s Output section of the Command Line Interface Overview chapter. |

**Usage**

Generates a display of IPv6-based information in XML format. The output can be copied and pasted into compatible applications.
Example

```
get ipv6 access-list
```
get port info

Generates an XML-formatted display for all physical ports or a specific port in the system.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

`[local]host_name(config)#`

**Syntax**

```
get port info [slot/port ] [ | { grep grep_options | more } ]
```

- `slot/port`
  Generates an XML-formatted display of information for the port specified by its chassis slot and card port number.

- `| { grep grep_options | more }`
  Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
  For details on the usage of `grep` and `more`, refer to the *Regulating a Command’s Output* section of the *Command Line Interface Overview* chapter.

**Usage**

Generates a display of IP-based information in XML format. The output can be copied and pasted into compatible applications.

**Example**

```
get ip port
```
global-title-translation address-map

Creates an instance of a Global Title Translation (GTT) address-map, a database, for global titles (ISDN-type address) used for SCCP routing. Upon creating the instance, the system enters global title translation address-map configuration mode. For the commands to configure the database, go to the Global Title Translation Address-Map Configuration Mode Commands chapter.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
global-title-translation address-map instance instance

no global-title-translation address-map instance instance
```

no

Removes the specified GTT address-map database from the SCCP portion of the configuration.

```
instance
```

This value uniquely identifies a specific instance of a GTT address-map. `instance` must be an integer from 1 through 4096.

**Usage**

Create a GTT address-map with a unique identifier and enter the GTT address-map configuration mode.

**Example**

```
global-title-translation address-map instance 324
```
global-title-translation association

Creates an instance of a Global Title Translation (GTT) association which defines the rules for handling global title translation. Upon creating the instance, the system enters global title translation association configuration mode. For the commands to configure the rules, go to the Global Title Translation Association Configuration Mode Commands chapter.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
global-title-translation association instance instance

no global-title-translation association instance instance
```

Usage

Removes the specified instance of a GTT association from the SCCP portion of the configuration.

```
instance
```

This value uniquely identifies a specific instance of a GTT association.

`instance` must be an integer from 1 through 16.

Example

Create a GTT association with a unique identifier and enter the GTT association configuration mode.

```
global-title-translation association instance 2
```
gtpp compression-process

This command configures the maximum number of child compression processes that AAA proxy can have.

Product
- GGSN
- SAEGW
- SGSN

Privilege
- Security Administrator, Administrator

Mode
Exec > Global Configuration
```
configure
```
Entering the above command sequence results in the following prompt:
```
[local]host_name(config)#
```

Syntax
```
gtpp compression-process max_number
default gtpp compression-process
```

**default**
Restores the system to the default settings for the number of child compression processes allowed.

**max_number**
Specifies the maximum number of child processes. The default is 1

```
max_number: must be an integer from 1 through 4.
```

Usage
This command configures the maximum number of child compression processes that AAA proxy can have only if hard disk storage is enabled.

Example
```
gtpp compression-process 3
```
**gtpp ram-disk-limit**

This command configures additional storage space to be allocated for writing files.

**Product**
- GGSN
- SAEGW
- SGSN

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
- configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
gtpp ram-disk-limit mb mega_bytes
```

```
default gtpp ram-disk-limit
```

**default**

Restores the system to the default settings of 32 MB of storage.

```
mb mega_bytes
```

Specifies the number of megabytes of storage allocated for files.

`mega_bytes`: must be an integer from 10 through 256. The default is 32 MB.

**Usage**

The memory specified with this command would be added to the existing memory allocated to the AAA proxy only if hard disk storage is enabled.

**Example**

```
gtpp ram-disk-limit mb 256
```
gtpp single-source

Configures the system to reserve a CPU for performing a proxy function for accounting.

**Product**
- GGSN
- SGSN
- P-GW
- SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
gtpp single-source [ centralized-lrsn-creation | private-extensions ]
```

**no gtpp single-source**

```
centralized-lrsn-creation
```
Defines Log Record Sequence Number (LRSN) generation at proxy. The AAA proxy will generate the LRSN for all CDR types generated by either the GGSN or the SGSN. Default: disabled

```
private-extensions
```
This optional keyword enables the proprietary use of customer-specific GTPP extensions. If `private-extensions` is not configured, all customer specific private extensions related to GTPP message transfer with CGF and recovery through GSS are disabled.

**Important:** In order for the customer-specific extensions to work properly, the `gtpp max-pdu-size` command in the Context Configuration Mode should be set to 65400 and the `gtpp server` command’s `max` value should be set to “1”.

```
no
```
Disables GTPP single-sourcing. This is the default setting.

**Caution:** Entering this command while PDP contexts are in process could cause the loss of pending CDRs. The configuration must be saved and the chassis reloaded for this option to take effect.

---

**Note:**
- The `gtpp single-source` command is used to configure the system to reserve a CPU for performing a proxy function for accounting. It is typically used in scenarios where there is a need to monitor and track traffic at the network level, such as in QoS (Quality of Service) applications or traffic management systems.
- The command can be configured with optional parameters like `centralized-lrsn-creation` and `private-extensions` to define specific behaviors for handling CDRs (Call Detail Records).
- The `no` option is used to disable the `gtpp single-source` configuration and revert to the default settings.
- Proper configuration of this command, especially with the `max-pdu-size` parameter, is crucial to avoid any loss of data during network operations.

---

**Product:**
- GGSN: Gateway General Packet Radio Service Node
- SGSN: Serving GPRS Support Node
- P-GW: Packet Data Network Gateway
- SAEGW: Service Access Gateway

**Privilege:**
- Security Administrator
- Administrator

**Mode:**
- Exec > Global Configuration
Usage

When GTPP single-sourcing is enabled, the system’s AAA proxy function generates requests to the accounting server using a single UDP source port number, instead of having each AAA Manager generate independent requests with unique UDP source port numbers. This is accomplished by the AAA Managers forwarding their GTPP PDUs to the AAA Proxy function that runs on a reserved packet processing card CPU. Since a packet processing card CPU is being reserved, fewer Session Managers and AAA Managers will be started on that card.

⚠️ Caution: This command must be entered prior to the configuration of other services. Specifying it later may return an error due to a lack of CPU availability.

Example

The following command enables GTPP single-sourcing with the use of private GTPP extensions:

```
    gtpp single-source private-extensions
```

The following command disables GTPP single-sourcing:

```
    no gtpp single-source
```
**ha-spi-list**

Replaces a duplicate Home Agent-Security Parameters Index (HA-SPI) remote address list applied to multiple HA services with a list name.

**Product**

PDSN

HA

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
ha-spi-list ha_spi_list
```

- **ha_spi_list**

Remote address list name expressed as an alphanumeric string of 1 through 64 characters.

**Usage**

Use this command to Replace duplicate HA-SPI remote address list applied to multiple HA services with a list name.

**Example**

The following command configures the list HA SPI list to `ha-list2`:

```
ha-spi-list ha-list2
```
**hd raid**

Performs RAID management operations on the platform hard disk drives.

### Product

All

### Privilege

Security Administrator, Administrator

### Mode

Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

### Syntax

For the ASR 5000:

```
hd raid { check | create | insert | overwrite | remove select } local1 | remote1 } [ -force ] [ -noconfirm ]
```

For the ASR 5500:

```
hd raid { check | create | insert | overwrite | remove select } hd_num [ -force ] [ -noconfirm ]
```

---

**check**

 Starts a background check on RAID disks unless the RAID is running in degraded mode.

---

**create local1 | remote1**

On the ASR 5000, creates a new RAID that could run in degraded mode on the specified drive:

- `local1`: specifies the RAID is to be established on the primary SMC.
- `remote1`: specifies the RAID is to be established on the backup SMC.

---

**create hd_num**

On the ASR 5500, creates a new RAID that could run in degraded mode on the hard drive array of a specific FSC.

- `hd_num`: specifies the RAID is to be established on the FSC in slot numbers 13 through 18 (hd13, hd14, ..., hd18).

---

**insert local1 | remote1**

On the ASR 5000, inserts the specified disk to the running RAID causing it to recover from degraded mode.

- `local1`: specifies the primary SMC is to be inserted into the RAID.
- `remote1`: specifies the backup SMC is to be inserted into the RAID.
Global Configuration Mode Commands (A-K)

**hd raid**

### insert hd_num

On the ASR 5500, inserts the specified FSC disk array into the running RAID causing it to recover from degraded mode.

**hd_num** specifies the RAID is to be established on the FSC in slot numbers 13 through 18 (hd13, hd14, ..., hd18).

### insert { | local1 | local2 }

On VPC, inserts the specified vHD into the running RAID causing it to recover from degraded mode.

### overwrite local1 | remote1

On the ASR 5000, overwrites the specified disk and adds it to the current running RAID to construct a fully mirrored array.

**local1** specifies the primary SMC is to be added to the current RAID. **remote1** specifies the backup SMC is to be added to the current RAID.

### overwrite hd_num

On the ASR 5500, overwrites the specified FSC disk array and adds it to the current running RAID to construct a fully mirrored array.

**hd_num** specifies the RAID is to be established on the FSC in slot numbers 13 through 18 (hd13, hd14, ..., hd18).

### overwrite { | local1 | local2 }

On VPC, overwrites the specified vHD and adds it to the current running RAID to construct a fully mirrored array.

### remove local1 | remote1

On the ASR 5000, removes the specified disk from the running RAID causing it to run in degraded mode or to fail.

**local1** specifies the primary SMC is to be removed from the RAID. **remote1** specifies the backup SMC is to be removed from the RAID.

### remove hd_num

On the ASR 5500, removes the specified FSC disk array from the running RAID causing it to run in degraded mode or to fail.

**hd_num** specifies the RAID is to be established on the FSC in slot numbers 13 through 18 (hd13, hd14, ..., hd18).

### remove { | local1 | local2 }

On the VPC, removes the specified vHD from the running RAID causing it to run in degraded mode or to fail.

### select local1 | remote1

On the ASR 5000, selects the specified disk to assemble a RAID when two unrelated RAID disks are present in the system. The resulting RAID runs in degraded mode.

**local1** specifies the primary SMC is to assemble the RAID. **remote1** specifies the backup SMC is to assemble the RAID.
**select hd_num**

On the ASR 5500, selects the specified FSC disk array to assemble a RAID when two or more unrelated RAID disks are present in the system. The resulting RAID runs in degraded mode.

*hd_num* specifies the RAID is to be established on the FSC in slot numbers 13 through 18 (hd13, hd14, ..., hd18).

**-noconfirm**

Executes the command without displaying “are you sure” prompts.

**-force**

Executes the command and overrides warnings.

---

**Usage**

All commands need confirmation unless the `--noconfirm` is included in the command. If the result will bring down a running RAID, you have to force the command using `--force`. RAID commands are needed to intervene in the following situations:

- the hard disk controller task can not determine the correct operation,
- administrator action is required by policy
- the administrator wants to wipe out an unused disk.

In an automated system, the policies created with this CLI address the possibility of a manually partitioned disk, a disk resulting from a different version of software, a partially constructed disk, or the case of two unrelated disks in the system.

To reduce administrator intervention, a set of policies can be configured to set the default action using the commands in the HD RAID configuration mode. These commands are described in the *HD Storage Policy Configuration Mode Commands* chapter of this guide.

**Example**

The following instructs the system to setup a RAID on the primary ASR 5000 SMC hard drive.

```bash
hd raid create local1 --force
```
**hd storage-policy**

Provides access to the local hard drive configuration mode in order to manage parameters supporting local storage of records.

**Product**

GGSN
SGSN
HSGW
P-GW
SAEGW
S-GW

**Privilege**

Administrator

**Mode**

Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
[ no ] hd storage-policy name
```

**no**

Removes a configured HD storage policy from the system.

```
storage-policy name
```

Specifies a name for an HD storage policy and then enters the HD Storage Policy Configuration Mode. `name` must be an alphanumeric string of 1 through 63 characters.

**Usage**

Creates a new policy or specifies an existing policy and enters the HD Storage Policy Configuration Mode. Entering this command results in the following prompt:

```
[context_name]hostname(config-hd-storage-policy)#
```

HD Storage Policy Configuration Mode commands are defined in the HD Storage Policy Configuration Mode Commands chapter.

**Example**

The following command creates an HD storage policy named `policy3` and enters the HD Storage Policy Configuration Mode:

```
hd storage-policy policy3
```
high-availability

Configures the speed for detection of packet processing card task failures.

**Product**
- PDSN
- GGSN
- ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
high-availability fault-detection speed { aggressive | normal }

default high-availability fault-detection speed

{ aggressive | normal }

Default: normal

• aggressive: Initiates packet processing card failover without performing additional checks.
• normal: Initiates packet processing card failover after additional checks are performed.
```

**Usage**

Use this command to increase the fault detection speed for faster switchovers after a packet processing card task failure.

Setting fault detection speed to aggressive will trigger packet processing card failover as soon as possible if a potential failure is detected. Aggressive mode will reduce the duration of subscriber outages caused by a failed packet processing card if session recovery is enabled.

Aggressive mode also bypasses most information gathering steps and logs that can be used to determine the root cause of the failure.

In normal mode, additional checks are performed before triggering a packet processing card failover to ensure that the card has actually failed. In aggressive mode these checks are bypassed so that session recovery can start as soon as possible. These additional checks reduce the likelihood of a false positive failure.

**Example**

The following command sets the fault detection speed for packet processing card tasks to **aggressive**:

```
high-availability fault-detection speed aggressive
```
**hybrid-mode**

Enables an ASR 5000 chassis to run a mix of Packet Services Cards (PSCs) and PSC Type A (PSCAs). When enabled, PSCAs will boot and be compatible with the PSCs as long as encryption services are disabled. The default is to run the chassis in non-hybrid mode; PSCAs will not boot when inserted in the chassis.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
[ no ] hybrid-mode [ force ]
```

- `no`
  Returns the chassis to non-hybrid mode. PSCAs will not boot.

- `force`
  Always updates the configuration, even if the encryption services could not be disabled. However, the PSC and PSCA cards will continue to be incompatible until encryption services are manually disabled.

**Usage**

To allow a chassis to run in PSC/PSCA hybrid-mode with encryption services disabled you must configure `hybrid-mode force` once.

To go from hybrid mode to non-hybrid mode, you must enter the `no hybrid-mode force` command. Non-hybrid chassis mode allows encryption services to be started through the appropriate CLI commands. However, all PSCAs in the chassis will be disabled.

For additional information, see the *ASR 5000 Installation Guide*.

**Example**

The following command enables the chassis to run a mix of PSCs and PSCAs without encryption services:

```
hybrid-mode force
```
imei-profile

Creates an instance of an International Mobile Equipment Identity (IMEI) profile.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration  
  configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
[ no ] imei-profile imei_profile_name
```

- **no**
  Deletes the IMEI profile instance from the configuration.

- **imei_profile_name**
  Specifies the name of the IMEI profile as an alphanumeric string of 1 through 64 characters.

**Usage**

Use this command to create an instance of an IMEI profile and to enter the IMEI Profile Configuration mode. An IMEI profile is a template which groups a set of device instructions, such as blacklisting, that may be applicable to one or more calling devices. See the **IMEI Profile Configuration Mode Commands** chapter for information regarding the definition of the rules contained within the profile and the use of the profile.

**Important:** An IMEI profile is a key element of the Operator Policy feature and is only valid when associated with at least one operator policy.

To see what IMEI profiles have already been created, return to the Exec mode and enter the `show imei-profile all` command.

**Example**

The following command creates a configuration instance of an IMEI profile:

```
imei-profile imeiprof1
```
Chapter 141
Global Configuration Mode Commands (L-S)

This section includes the commands license through system.
The Global Configuration Mode is used to configure basic system-wide parameters.

Mode

Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
license

Configures the session license key.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
license key key_value [ -force ] session-limit

no license key key_value [ -force ] session-limit
```

- **no**
  - Removes the license key(s) installed.

- **key key_value**
  - Installs the license key specified by `key_value`. `key_value` is provided by Cisco operations staff.

- **session-limit**
  - Use this keyword to suppress fail-over calls from being rejected if the licensed threshold is crossed.

**Important:** This is a customer-specific command that is available for HA, PDSN, EHA, and PDIF. Please contact your local Cisco sales representative for more information.

- **-force**
  - Sets the license key even if resources are not available. The system supports the dynamic resizing of demultiplexor software tasks based on the licensed session capacity and feature type. When installing a license, the system automatically attempts to resize currently functioning tasks. Warning messages are displayed if there is an issue. Though its use is not recommended, the `-force` keyword can be used to suppress these warning messages.

**Caution:** Use of this option is not recommended.

**Usage**

Install or update system session keys when necessary due to expiration and/or capacity needs.

**Example**

Install or update system session keys when necessary due to expiration and/or capacity needs.
license key sampleKeyValue

no license key
**line**

Enters the terminal display line configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
line
```

**Usage**

Change the terminal display configuration based upon the users own terminal characteristics.
link-aggregation

Configures system MAC address and priority for Link Aggregation. These parameters are usually changed to match the feature requirements of the remote Ethernet switch.

Product
WiMAX
PDSN
HA
FA
GGSN
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

link-aggregation { system-mac { MAC_address | auto } | system-priority priority } [-noconfirm ]

{ default | no } link-aggregation { system-mac | system-priority } [-noconfirm ]

---

default

Resets the configuration to the default.

---

system-mac { MAC_address | auto }

Sets the system MAC address used along with the system priority to form the system ID.
MAC_address is manually entered as six groups of two hexadecimal digits separated by hyphens (for example, 01-23-45-67-89-ab).
Auto is the default and is the MAC address of the LAG master port.

---

system-priority priority

This command sets the system priority used by Link Aggregation Control Protocol (LACP) to form the system ID.
priority is a hexadecimal value from 0x0000 through 0xFFFF. Default is 0x8000 (32768).

---

-noconfirm

Executes the command without additional prompting for command confirmation.
link-aggregation

Usage

The system MAC address (6 bytes) and system priority (2 bytes) combine to form the system ID. A system consists of a packet processing card and its associated QGLC or XGLC traffic ports. The highest system ID priority (the lowest number) handles dynamic changes.

For additional usage and configuration information for the link aggregation feature, refer to the System Administration Guide.

Important: Not supported on all platforms

Example

The following command configures the link aggregation system-priority to 10640 (0x2990):

```
link-aggregation system-priority 0x2990
```
**local-policy-service**

This command enables creating, configuring, or deleting a local QoS policy.

**Product**

P-GW
SAEGW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
local-policy-service name [ -noconfirm ]
no local-policy-service name
```

*no*

Deletes the specified local QoS policy service from the system.

*name*

Specifies name of the local QoS policy service as an alphanumeric string of 1 through 63 characters.

**Important:** The *name* must be unique across all contexts.

If the named local QoS policy service does not exist, it is created, and the CLI mode changes to the Local Policy Service Configuration Mode wherein the local QoS policy service can be configured. If the named local QoS policy service already exists, the CLI mode changes to the Local Policy Service Configuration Mode for that local QoS policy service.

*noconfirm*

Specifies that the command must execute without prompting for confirmation.

**Usage**

Use this command to specify a local QoS policy service name to allow configuration of a local QoS policy service.

**Important:** This feature is license dependent. Please contact your local sales representative for more information.
A local QoS policy service can be used to control different aspects of a session, such as QoS, data usage, subscription profiles, or server usage, by means of locally defined policies. Local QoS policies are triggered when certain events occur and the associated conditions are satisfied. For example, when a new call is initiated, the QoS to be applied for the call could be decided based on the IMSI, MSISDN, and APN.

**Important:** A maximum of 16 local QoS policy services are supported.

Entering this command results in the following prompt:

```
[context_name] hostname(config-local-policy-service)#
```

Local Policy Service Configuration Mode commands are defined in the *Local Policy Service Configuration Mode Commands* chapter.

**Example**

The following command creates a local QoS policy service named `lctest` and enters the Local Policy Service Configuration Mode:

```
local-policy-service lctest
```
local-user allow-aaa-authentication

Enables or disables the use of administrative accounts other than local-user administrative accounts.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
[ default | no ] local-user allow-aaa-authentication
```

- **default**
  Returns this parameter to its default setting of enabled.

- **no**
  Disables administrative user accounts other than local-user accounts.

**Usage**

Local-user administrative accounts are separate from other administrative user accounts configured at the context level (Security Administrator, Administrator, Operator, and Inspector). Context-level administrative users rely on the system’s AAA subsystems for validating user names and passwords during login. This is true for both administrative user accounts configured locally through a configuration file or on an external RADIUS server. Since the T1.276-2003 password security mechanisms are supported only for local-user administrative accounts and not for the AAA-based administrative accounts, this command provides a mechanism for disabling AAA-based administrative accounts.

By default, AAA-based administrative accounts are allowed.

**Example**

The following command forces the system to authenticate local-user accounts based only on the information in the security account file on its CompactFlash:

```
no local-user allow-aaa-authentication
```
local-user lockout-time

Configures the lockout period for local-user administrative accounts.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[[local]host_name(config)#

Syntax

local-user lockout-time time

default local-user lockout-time

default
Restores the parameter to its default setting.

time
Default: 60
Specifies the amount of time (in minutes) that must elapse before a previously locked-out local-user account can attempt to login again. time is an integer from 1 through 10080.

Usage
Local-user administrative accounts can become locked for reasons such as exceeding the configured maximum number of login failures.

Once an account is locked, this parameter specifies the lockout duration. Once the amount of time configured by this parameter has elapsed, the local-user can once again attempt to login.

Example
The following command configures a lockout time of 120 minutes (2 hours):

      local-user lockout-time 120
local-user max-failed-logins

Configures the maximum number of failed login attempts a local-user can have before their account is locked out.

Product  
All

Privilege  
Security Administrator, Administrator

Mode  
Exec > Global Configuration  
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```plaintext
local-user max-failed-logins number
```

| [ default | no ] local-user max-failed-logins |
|-----------------------------|
| no |
| Disables this functionality. |
| default |
| Restores this parameter to its default setting. |
| number |
| Default: 5 |
| Specifies the maximum number of times a local-user could experience a login failure before their account is locked out. `number` is an integer from 2 through 100. |

Usage

This command configures the maximum number of failed login attempts a local-user can have before their account is locked out. For example if, this parameter is configured to “3” then after the third failed login attempt, the account would be locked.

**Important:** Local-user accounts can be configured to either enforce or reject a lockout due to the maximum number of failed login being reached. Refer to the `local-user username` command for more information.

Example

Refer to the `local-user lockout-time` command for more information.

The following command configures a maximum of three login attempts:

```plaintext
local-user max-failed-logins 3
```
local-user password

Configures local-user administrative account password properties.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

local-user password { [ complexity { ansi-t1.276-2003 | none } ] [ history length number ] [ duration days ] [ max-age days ] [ min-change-char number ] [ min-change-interval days ] [ min-length number ] }

no local-user password { [ history ] [ max-age ] [ min-change-interval ] }

default local-user password { [ complexity ] [ history ] [ max-age ] [ min-change-char ] [ min-change-interval ] [ min-length ] }

no
Disables the specified parameter.

default
Restores the specified parameter to its default setting.

[ complexity { ansi-t1.276-2003 | none } ]

Default: ansi-t1.276-2003

Specifies the password strength as one of the following:

ansi-t1.276-2003: If this option is selected, the following rules are enforced:

• Passwords may not contain the username or the reverse of the username
• Passwords may contain no more than three of the same characters used consecutively
• Passwords must contain at least three of the following:
  • uppercase alpha character
  • lowercase alpha character
  • numeric character
  • special character

none: No additional password checks are performed.
[ **Global Configuration Mode Commands (L-S)**](#)

### local-user password

```
[ history length number [ duration days ] ]
```

Default: length is 5
Specifies the number of previous password entries kept in the history list maintained by the system. A password cannot be reused if it is one of the entries kept in the history list unless the time it was last used was more than the number of days specified by the `duration` keyword.

If the `duration` keyword is not used, the only check performed by the system is that it is not in the history list. `number` is the number of entries for each account stored in the history list entered as an integer from 1 through 100. `days` is the number of days during which a password can not be reused entered an integer from 1 through 365.

```
[ max-age days ]
```

Default: 90
Specifies the maximum age for a password. Users logging in with a password older than the specified limit are locked out. Once the lockout period expires, at their next login attempt, they are prompted to change their password before accessing the CLI.

**Important:** Local-user accounts can be configured to either enforce or reject a lockout due to a password’s maximum age being reached. Refer to the `local-user username` command for more information.

`days` is the number of days that passwords remain valid entered as an integer from 1 through 365.

```
[ min-change-char number ]
```

Default: 2
Specifies the minimum number of characters that must be changed (in comparison to the current password) when a user changes their password.

**Important:** Changes in password length are counted as “character” changes. For example: changing a password from “password” to “passwo” is a 2-character change, changing a password from “password” to “password2” is a 1-character change, and changing a password from “password” to “apassword” is a 9-character change.

`number` is the number of characters entered as an integer from 0 through 16.

```
[ min-change-interval days ]
```

Default: 1
Specifies the frequency that passwords can be changed (other than first login).
`days` is the minimum number of days that must pass before a user can change their password. It is an integer from 1 through 365.

**Important:** If the `no local-user password min-change-interval` command is used, users may change their password as often as desired which could allow them to circumvent the password history function.

```
[ min-length number ]
```

Default: 8
Specifies the minimum length allowed for user-defined password.
`number` is the minimum number of alphanumeric characters that the password must contain, entered as an integer from 3 through 32.
Usage
This command is used to set the property requirements for user-defined passwords and system behavior in relation to those passwords. Information pertaining to user passwords, login failures, and password history are stored on the packet processing cards and in the software’s Shared Configuration Task (SCT). The system uses the information in the SCT for runtime operations such as determining password ages and determining if new passwords meet the criteria specified by this command.

Example
The following command configures a minimum password length requirement of 6 characters:

```
local-user password min-length 6
```

The following command configures the system to store the 4 most recently used passwords per user-account in the history list:

```
local-user password history length 4
```
local-user username

Adds or removes local-user administrative accounts.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

local-user username name [ authorization-level { administrator | inspector | operator | security-admin } ] [ ecs | noecs ] [ ftp | noftp ] [ timeout-min-absolute time ] [ no-lockout-login-failure ] [ no-lockout-password-aging ] [ password password | nopassword ] [ timeout-min-idle time ]

no local-user username name

no

Removes a previously configured user.

name

Specifies the name of the user as an alphanumeric string of 3 through 16 characters that is case sensitive.

[ authorization-level { administrator | inspector | operator | security-admin } ]

Default: Operator

Configures the authorization level for the user as one of the following:

• administrator: Administrator users have read-write privileges and can execute any command throughout the CLI except for a few security functions allowed only in the administrator mode. Administrators can configure or modify the system and are able to execute all system commands, including those available to the operator and inspector user. This level corresponds to the both the System Administrator and Application Administrator levels in the T1.276-2003.

• inspector: Inspector users are limited to a small number of read-only Exec Mode commands. The bulk of these are “show” commands giving the inspector the ability to view a variety of statistics and conditions. The Inspector cannot execute show configuration commands and do not have the privilege to enter the Config Mode.

• operator: Operator users have read-only privileges to a larger subset of the Exec Mode commands as depicted in the following figure. Operator users can execute all commands that are part of the inspector mode, plus some system monitoring, statistical, and fault management functions. Operators do not have the ability to enter the Config Mode.
• **security-admin**: Security Administrator users have read-write privileges and can execute any command throughout the CLI. Security Administrators can execute all system commands, including those available to the administrator, operator, and inspector users. This level corresponds to both the System Security Administrator and Application Security Administrator levels in T1.276-2003.

```plaintext
[ ecs | noecs ]
```

Specifies whether or not the user has access to Active Charging Service configuration parameters.
- **ecs**: The user has access.
- **noecs**: The user does not have access.

Default: **ecs**

```plaintext
[ ftp | noftp ]
```

Default: **ftp**

Specifies whether or not the user is allowed to access the system via the File Transfer Protocol (FTP) and/or the Secure File Transfer Protocol (SFTP).
- **ftp**: The user has access.
- **noftp**: The user does not have access.

```plaintext
[ no-lockout-login-failure ]
```

Default: **Disabled**

Specifies that this user will never be locked out due to login attempt failures.

```plaintext
[ no-lockout-password-aging ]
```

Default: **Disabled**

Specifies that this user will never be locked out due to the age of their password.

```plaintext
[ password password | nopassword ]
```

Specifies the initial password for this user. **password** must an alphanumeric string of 6 through 32 characters that is case sensitive.

**Important**: The user is requested to change their password upon their first login.

```plaintext
[ timeout-min-absolute time ]
```

Default: **0**

Specifies the maximum session time (in minutes) for this user. **time** is an integer from 0 through 525600. A value of “0” indicates no limit.

**Important**: This limit applies only to the user’s CLI sessions.

```plaintext
[ timeout-min-idle time ]
```

Default: **0**

Specifies the maximum idle time (in minutes) for this user. **time** is an integer from 0 through 525600. A value of “0” indicates no limit.
**Global Configuration Mode Commands (L-S)**

**local-user username**

- **Usage**
  - The ability to configure administrative local-users is provided in support of the login security mechanisms specified in ANSI T1.276-2003.
  - Like administrative users configured at the context level, local-users can be assigned one of 4 security levels:

<table>
<thead>
<tr>
<th>Local-User Level User</th>
<th>Context Level User</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security Administrator</td>
<td>Administrator</td>
</tr>
<tr>
<td>Administrator</td>
<td>Config-Administrator</td>
</tr>
<tr>
<td>Operator</td>
<td>Operator</td>
</tr>
<tr>
<td>Inspector</td>
<td>Inspector</td>
</tr>
</tbody>
</table>

- Local-user configuration support is handled differently from that provided for administrative users configured at the context level.
  - Context-level administrative users rely on the system’s AAA subsystems for validating user names and passwords during login. This is true for both administrative user accounts configured locally through a configuration file or on an external RADIUS server. Passwords for these user types are assigned once and are accessible in the configuration file.
  - Local-user account information (passwords, password history, lockout states, etc.) is maintained in non-volatile memory and in the software’s Shared Configuration Task (SCT). This information is maintained in a separate file – not in configuration files used by the system. As such, the configured local-user accounts are not visible with the rest of the system configuration.
  - Local-user and context-level administrative accounts can be used in parallel.

- **Example**
  - The following command configures a security-administrator level local-user administrative account for a user named *User672* that has FTP privileges, a temporary password of *abc123*, and that does not lockout due to either login attempt failures or password aging:

    ```
    local-user username User672 authorization-level security-admin ftp no-lockout-login-failure no-lockout-password-aging password abc123
    ```

  - The following command deletes a previously configured local-user administrative account called admin32:

    ```
    no local-user username admin32
    ```

**Important:** This limit applies only to the user’s CLI sessions.
**logging console**

Enables the output of logged events to be displayed on the console terminal.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

**Syntax**

[ no ] logging console

no

Disables the output of events to the console port.

**Usage**

Log console output to allow for offline review during system monitoring and/or trouble shooting.
logging disable

Enables/disables the logging of the specified event ID or range of IDs.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Configure**
Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
logging disable eventid id [ to to_id ]
no logging disable eventid id [ to to_id ]
```

- **no**
  Indicates the event IDs specified are to be enabled for logging.

- **eventid id**
  Specifies the event for which no logging is to occur.
  In 14.1 and earlier releases, *id* is an integer from 1 through 202699.
  In 15.0 and later releases, *id* is an integer from 1 through 204999.

- **to to_id**
  Specifies the end ID of the events when a range of event ID is to be disabled from being logged. *to_id* must be an integer from 1 through 204999. The *to_id* must be equal to or larger than the *id* specified.

**Usage**

Disable common events which may occur with a normal frequency are not of interest in monitoring the system for troubles.

**Example**

The following commands disables the logging of event ID 4580 and the range of events from 4500 through 4599, respectively.

```
logging disable eventid 4580 4580
logging disable eventid 4500 to 4599
```

The following enables the subset of disabled event IDs:

```
no logging disable eventid 4500 to 4549
```
logging display

Configures the level of detail for information to be logged.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```bash
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```bash
logging display event-verbosity evt_level ] [ pdu-data format ] [ pdu-verbosity pdu_level ]
```

- `event-verbosity evt_level`
  Specifies the level of verboseness to use in logging of events as one of:
  - min
  - concise
  - full

- `pdu-data format`
  Specifies output format for packet data units when logged as one of:
  - none: outputs in raw format
  - hex: displays out in hexadecimal format
  - hex-ascii: displays output in hexadecimal and ASCII similar to a main-frame dump

- `pdu-verbosity pdu_level`
  Specifies the level of verboseness to use in logging of packet data units as an integer from 1 through 5, where 5 is the most detailed.

**Usage**

Tune the level of information to be logged so as to avoid flooding a log file with information which is not useful or critical.

**Example**

The following sets the logging display for events to the maximum.

```bash
logging display event-verbosity full
```

The following command sets the logging display level of detail for packet data units to level 3 and sets the output format to the main-frame style hex-ascii:
logging display pdu-data hex-ascii pdu-verbosity 3
logging filter

Configures the logging of events to be performed in real time for the specified facility.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```bash
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```bash
logging filter runtime facility facility level report_level [ critical-info | no-critical-info ]
```

```bash
facility facility
```

Specifies the facility to modify the filtering of logged information. The following list displays the valid facilities for this command:

- **a10**: A10 interface facility
- **a11**: A11 interface facility
- **a11mgr**: A11 Manager facility
- **aaa-client**: Authentication, Authorization and Accounting (AAA) client facility
- **aaamgr**: AAA manager logging facility
- **aaaproxy**: AAA Proxy facility
- **aal2**: ATM Adaptation Layer 2 (AAL2) protocol logging facility
- **acl-log**: Access Control List (ACL) logging facility
- **ascctrl**: Active Charging Service (ACS) Controller facility
- **acsmgr**: ACS Manager facility
- **afctrl**: Fabric Controller facility [ASR 5500 only]
- **afmgr**: Fabric Manager logging facility [ASR 5500 only]
- **alarmctrl**: Alarm Controller facility
- **alcap**: Access Link Control Application Part (ALCAP) protocol logging facility
- **alcapmgr**: ALCAP manager logging facility
- **all**: All facilities
- **asngwmg**: Access Service Network (ASN) Gateway Manager facility
- **asnpcmgr**: ASN Paging Controller Manager facility
- **bfd**: Bidirectional Forwarding Detection (BFD) protocol logging facility
- **bgp**: Border Gateway Protocol (BGP) facility
- **bindmux**: IPCF BindMux-Demux Manager logging facility
- **bngmgr**: Broadband Network Gateway (BNG) Demux Manager logging facility
- **bssap+**: Base Station Sub-system Application Part+ protocol facility for the login interface between the SGSN and the MSC/VLR (2.5G and 3G)
- **bssgp**: Base Station Sub-system GPRS Protocol logging facility handles exchange information between the SGSN and the BSS (2.5G only)
- **callhome**: Call Home application logging facility
- **cap**: CAMEL Application Part (CAP) logging facility for protocol used in prepaid applications (2.5G and 3G)
- **cbsmgr**: Cell Broadcasting Service (CBS) logging facility [HNBGW]
- **cdf**: Charging Data Function (CDF) logging facility
- **cgw**: Converged Access Gateway (CGW) logging facility
- **cli**: Command Line Interface (CLI) logging facility
- **cmp**: Certificate Management Protocol (IPSec) logging facility
- **connectedapps**: SecGW ASR 9000 oneP communication protocol
- **connproxy**: Controller Proxy logging facility
- **credit-control**: Credit Control (CC) facility
- **cscf**: IMS/MMD Call Session Control Function (CSCF)
- **cscfcpmgr**: CSCFCPMGR logging facility
- **cscfmgr**: SIP CSCF Manager facility
- **cscfnpdb**: CSCF Number Portability Database (NPDB) logging facility
- **cscfrtcp**: IMS/MMD CSCF RTCP log facility
- **cscfrtp**: IMS/MMD CSCF RTP log facility
- **cscfttmgr**: SIP CSCF Tunnel and Transport Manager facility
- **csp**: Card/Slot/Port controller facility
- **css**: Content Service Selection (CSS) facility
- **css-sig**: CSS RADIUS Signaling facility
- **cx-diameter**: Cx Diameter Messages facility [CSCF <-> HSS]
- **dcardctrl**: IPSec Daughter Card Controller logging facility
- **dcardmgr**: IPSec Daughter Card Manager logging facility
- **demuxmgr**: Demux Manager API facility
- **dgmnbmgr**: Diameter Gmb Application Manager logging facility
- **dhcp**: Dynamic Host Configuration Protocol (DHCP) logging facility
- **dhcpv6**: DHCPv6
- **dhost**: Distributed Host logging facility
- **diabase**: Diabase messages facility
- **diameter**: Diameter endpoint logging facility
Global Configuration Mode Commands (L-S)

- **diameter-acct**: Diameter Accounting
- **diameter-auth**: Diameter Authentication
- **diameter-dns**: Diameter DNS subsystem
- **diameter-ecs**: ACS Diameter signaling facility
- **diameter-hdd**: Diameter Horizontal Directional Drilling (HDD) Interface facility
- **diameter-svc**: Diameter Service
- **diamproxy**: DiamProxy logging facility
- **dpath**: IPSec Data Path facility
- **drvctrl**: Driver Controller facility
- **doulosuemgr**: Doulos (IMS-IPSec-Tool) user equipment manager
- **eap-diameter**: Extensible Authentication Protocol (EAP) IPSec facility
- **eap-ipsec**: Extensible Authentication Protocol (EAP) IPsec facility
- **eap-sta-s6a-s13-s6b-diameter**: EAP/STA/S6A/S13/S6B Diameter messages facility
- **ecs-ess**: ACSMGR <-> Session Manager Signalling Interface facility
- **egtpc**: eGTP-C logging facility
- **egtpmgr**: enhanced GPRS Tunneling Protocol (eGTP) manager logging facility
- **egtpu**: eGTP-U logging facility
- **epdg**: evolved Packet Data (ePDG) gateway logging facility
- **event-notif**: Event Notification Interface logging facility
- **evlog**: Event log facility
- **famgr**: Foreign Agent manager logging facility
- **firewall**: Firewall logging facility
- **fng**: Femto Network Gateway (FNG) logging facility
- **gbmgr**: SGSN Gb Interface Manager facility
- **gmm**:  
  - For 2.5G: Logs the GPRS Mobility Management (GMM) layer (above LLC layer)  
  - For 3G: Logs the access application layer (above the RANAP layer)
- **gprs-app**: GPRS Application logging facility

• kvstore: Key/Value Store (KVSTORE) Store facility
• l2tp-control: Layer 2 Tunneling Precool (L2TP) control logging facility
• l2tp-data: L2TP data logging facility
• l2tpdemux: L2TP Demux Manager logging facility
• l2tpmgr: L2TP Manager logging facility
• lagmgr: Link Aggregation Group (LAG) manager logging facility
• lcs: Location Services (LCS) logging facility
• **ldap**: Lightweight Directory Access Protocol (LDAP) messages logging facility
• **li**: Refer to the *Lawful Intercept Interface Reference* for a description of this command.
• **linkmgr**: SGSN/BSS SS7 Link Manager logging facility (2.5G only)
• **llc**: Logical Link Control (LLC) Protocol logging facility; for SGSN: logs the LLC layer between the GMM and the BSSGP layers for logical links between the MS and the SGSN
• **local-policy**: Local Policy Service facility
• **location-service**: Location Services facility
• **m3ua**: M3UA Protocol logging facility
• **magmgr**: Mobile Access Gateway manager logging facility
• **map**: Mobile Application Part (MAP) protocol logging facility
• **megadiammgr**: MegaDiameter Manager (SLF Service) logging facility
• **mme-app**: Mobility Management Entity (MME) Application logging facility
• **mme-misc**: MME miscellaneous logging facility
• **mmedemux**: MME Demux Manager logging facility
• **mmemgr**: MME Manager facility
• **mmgr**: Master Manager logging facility
• **mobile-ip**: Mobile IP processes
• **mobile-ip-data**: Mobile IP data facility
• **mobile-ipv6**: Mobile IPv6 logging facility
• **mpls**: Multiprotocol Label Switching (MPLS) protocol logging facility
• **mrme**: Multi Radio Mobility Entity (MRME) logging facility
• **mseg-app**: Mobile Services Edge Gateway (MSEG) application logging facility (This option is not supported in this release.)
• **mseg-gtpc**: MSEG GTP-C application logging facility (This option is not supported in this release.)
• **mseg-gtpu**: MSEG GTP-U application logging facility (This option is not supported in this release.)
• **msegmgr**: MSEG Demux Manager logging facility (This option is not supported in this release.)
• **mtp2**: Message Transfer Part 2 (MTP2) Service logging facility
• **mtp3**: Message Transfer Part 3 (MTP3) Protocol logging facility
• **multicast-proxy**: Multicast Proxy logging facility
• **nas**: Non-Access Stratum (NAS) protocol logging facility [MME 4G]
• **netwstrg**: Network Storage facility
• **npuctrl**: Network Processor Unit Control facility
• **npudrv**: Network Processor Unit Driver facility [ASR 5500 only]
• **npumgr**: Network Processor Unit Manager facility
• **npumgr-acl**: NPUMGR ACL logging facility
• **npumgr-drv**: NPUMGR DRV logging facility
• **npumgr-flow**: NPUMGR FLOW logging facility
- `npumgr-fwd`: NPUMGR FWD logging facility
- `npumgr-init`: NPUMGR INIT logging facility
- `npumgr-lc`: NPUMGR LC logging facility
- `npumgr-port`: NPUMGR PORT logging facility
- `npumgr-recovery`: NPUMGR RECOVERY logging facility
- `npumgr-rri`: NPUMGR RRI (Reverse Route Injection) logging facility
- `npumgr-vpn`: NPUMGR VPN logging facility
- `npusim`: NPUSIM logging facility [ASR 5500 only]
- `ntfy-intf`: Notification Interface logging facility [Release 12.0 and earlier versions only]
- `orbs`: Object Request Broker System logging facility
- `ospf`: OSPF protocol logging facility
- `ospfv3`: OSPFv3 protocol logging facility
- `p2p`: Peer-to-Peer Detection logging facility
- `pagingmgr`: PAGINGMGR logging facility
- `pccegr`: Intelligent Policy Control Function (IPCF) Policy Charging and Control (PCC) Manager library
- `pdg`: Packet Data Gateway (PDG) logging facility
- `pdgdmgr`: PDG Demux Manager logging facility
- `pdif`: Packet Data Interworking Function (PDIF) logging facility
- `pgw`: Packet Data Network Gateway (PGW) logging facility
- `pmm-app`: Packet Mobility Management (PMM) application logging facility
- `ppp`: Point-To-Point Protocol (PPP) link and packet facilities
- `pppoe`: PPP over Ethernet logging facility
- `push`: VPNMGR CDR push logging facility
- `radius-acct`: RADIUS accounting logging facility
- `radius-auth`: RADIUS authentication logging facility
- `radius-coa`: RADIUS change of authorization and radius disconnect
- `ranap`: Radio Access Network Application Part (RANAP) Protocol facility logging info flow between SGSN and RNS (3G)
- `rct`: Recovery Control Task logging facility
- `rdt`: Redirect Task logging facility
- `resmgr`: Resource Manager logging facility
- `rf-diameter`: Diameter Rf interface messages facility
- `rip`: Routing Information Protocol (RIP) logging facility [RIP is not supported at this time.]
- `rlf`: Rate Limiting Function (RLF) logging facility
- `rohc`: Robust Header Compression (RoHC) facility
logging filter

• **rsvp**: Reservation Protocol logging facility
• **rua**: RANAP User Adaptation (RUA) [3G Femto GW - RUA messages] logging facility
• **s1ap**: S1 Application Protocol (S1AP) Protocol logging facility
• **sabp**: Service Area Broadcast Protocol (SABP) logging facility
• **saegw**: System Architecture Evolution (SAE) Gateway facility
• **sccp**: Signalling Connection Control Part (SCCP) Protocol logging (connection-oriented messages between RANAP and TCAP layers).
• **set**: Shared Configuration Task logging facility
• **sctp**: Stream Control Transmission Protocol (SCTP) Protocol logging facility
• **sef ecs**: Severely Errored Frames (SEF) APIs printing facility
• **sess-gr**: SM GR facility
• **sessctrl**: Session Controller logging facility
• **sessmgr**: Session Manager logging facility
• **sesstrc**: session trace logging facility
• **sft**: Switch Fabric Task logging facility
• **sgs**: SGs interface protocol logging facility
• **sgsn-app**: SGSN-APP logging various SGSN “glue” interfaces (for example, between PMM, MAP, GPRS-FSM, SMS).
• **sgsn-failures**: SGSN call failures (attach/activate rejects) logging facility (2.5G)
• **sgsn-gtpc**: SGSN GTP-C Protocol logging control messages between the SGSN and the GGSN
• **sgsn-gtpu**: SGSN GTP-U Protocol logging user data messages between the SGSN and GGSN
• **sgsn-mbms-bearer**: SGSN Multimedia Broadcast/Multicast Service (MBMS) Bearer app (SMGR) logging facility
• **sgsn-misc**: Used by stack manager to log binding and removing between layers
• **sgsn-system**: SGSN System Components logging facility (used infrequently)
• **sgsn-test**: SGSN Tests logging facility; used infrequently
• **sgtpcmgr**: SGSN GTP-C Manager logging information exchange through SGTPC and the GGSN
• **sgw**: Serving Gateway facility
• **sh-diameter**: Sh Diameter messages facility
• **sitmain**: System Initialization Task main logging facility
• **sm-app**: SM Protocol logging facility
• **sms**: Short Message Service (SMS) logging messages between the MS and the SMSC
• **sndep**: Sub Network Dependent Convergence Protocol (SNDCP) logging facility
• **snmp**: SNMP logging facility
• **sprmgr**: IPCF Subscriber Policy Register (SPR) manager logging facility
• **srdb**: Static Rating Database
• **srp**: Service Redundancy Protocol (SRP) logging facility
• **sscfnni**: Service-Specific Coordination Function for Signaling at the Network Node Interface (SSCF-NNI) logging facility
• **sscop**: Service-Specific Connection-Oriented Protocol (SSCOP) logging facility
• **ssh-ipsec**: Secure Shell (SSH) IP Security logging facility
• **ssl**: Secure Socket Layer (SSL) message logging facility
• **stat**: Statistics logging facility
• **supserv**: Supplementary Services logging facility [H.323]
• **system**: System logging facility
• **tacacplus**: TACACS+ Protocol logging facility
• **tcap**: TCAP Protocol logging facility
• **testctrl**: Test Controller logging facility
• **testmgr**: Test Manager logging facility
• **threshold**: threshold logging facility
• **ttg**: Tunnel Termination Gateway (TTG) logging facility
• **tucl**: TCP/UDP Convergence Layer (TUCL) logging facility
• **udr**: User Data Record (UDR) facility (used with the Charging Service)
• **user-data**: User data logging facility
• **user-l3tunnel**: User Layer 3 tunnel logging facility
• **usertcp-stack**: User TCP Stack
• **vim**: Voice Instant Messaging (VIM) logging facility
• **vinfo**: VINFO logging facility
• **vmgctrl**: Virtual Media Gateway (VMG) controller facility
• **vmgctrl**: VMG Content Manager facility
• **vpn**: Virtual Private Network logging facility
• **wimax-data**: WiMAX DATA
• **wimax-r6**: WiMAX R6
• **wsg**: Wireless Security Gateway (ASR 9000 Security Gateway)

```
level report_level [ critical-info | no-critical-info ]
```

**level report_level**: specifies the level of information to be logged, *report_level*, as one of:
• **critical**
• **debug**
• **error**
• **info**
• **trace**
• **unusual**
• **warning**
**logging filter**

**critical-info | no-critical-info**: indicates if critical information is to be displayed or not. The keyword `critical-info` specifies that events with a category attribute of critical information are to be displayed. Examples of these types of events can be seen at bootup when system processes and tasks are being initiated. The `no-critical-info` keyword specifies that events with a category attribute of critical information are not to be displayed.

**Usage**

This command is useful when it is necessary to get real-time output of events. Event output may be cached otherwise which may make it difficult to troubleshoot problems which do not allow the last cache of events to be output prior to system problems.

**Caution:** Issuing this command could negatively impact system performance depending on system loading, the log level, and/or the type of facility(ies) being logged.

**Example**

Set real time output for the point-to-point protocol facility and all facilities, respectively, to avoid logging of excessive information.

```
logging filter runtime facility ppp
logging filter runtime facility all level warning
```
logging monitor

Enables or disables the monitoring of a specified user.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

[ no ] logging monitor { ipaddr ip_address | ipv6addr ipv6_address | msid ms_id | username user_name }

no
Disables the monitoring of the user specified by the options given.

ipaddr ip_address
Specifies the IP address of the user for which the monitoring filter is to be set. ip_address must entered using IPv4 dotted-decimal notation.

ipv6addr ipv6_address
Specifies the IPv6 address of the user for which the monitoring filter is to be set. ipv6_address must be followed by IPv6 address in a xx:yy:zz format .

msid ms_id
msid ms_id: specifies the mobile subscriber ID for which the monitoring filter is to be set. ms_id must be from 7 to 16 digits.
This keyword/option can be used to specify the Mobile Subscriber ISDN (MSISDN) for GGSN calls which enables logging based on MSISDN.

username user_name
username user_name: specifies a user for which the monitoring filter is to be set. user_name must refer to a previously configured user.

Usage

Monitor subscribers which have complaints of service availability or to monitor a test user for system verification.
**Caution:** Issuing this command could negatively impact system performance depending on the number of subscribers for which monitoring is performed and/or the amount of data they’re passing.

**Example**

The following command enables the monitoring of user `user1` and mobile subscriber ID 4441235555, respectively.

```sh
logging monitor username user1
logging monitor msid 4441235555
```

The following disables the monitoring of user `user1`.

```sh
no logging monitor username user1
```
logging runtime

Enables events to be filtered and logged in real time.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

logging runtime buffer store { all-events | filtered-events-only }

buffer store { all-events | filtered-events-only }

Determines which logs are stored in internal logging daemon runtime buffer.

*all-events*: Logging daemon runtime buffer stores all logs that come to it.

*filtered-events-only*: Logging daemon runtime buffer stores only logs that pass the runtime filter.

Usage
Sets the filtering of logged information to log in real time.

Example
The following command enables storage of logs that pass the runtime filter:

 logging runtime buffer store filtered-events-only
**lte-policy**

This command enters the LTE Policy Configuration Mode where LTE policy parameters can be configured.

**Product**
- MME
- SAEGW
- S-GW
- SGSN

**Privilege**
- Administrator

**Mode**
- Exec > Global Configuration
  - `configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
lte-policy
```

**Usage**

Enters the LTE Policy Configuration Mode.

Entering this command results in the following prompt:

```
[context_name] hostname(lte-policy)#
```

LTE Policy Configuration Mode commands are defined in the *LTE Policy Configuration Mode Commands* chapter.
**mediation-device**

This command is obsolete. Even though the CLI accepts the command no function is performed.

**Product**
- GGSN

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
  - `configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
[ no ] mediation-device mode { tcs }
```
mobile-services-edge-gateway

This command is not supported in this release.
network-overload-protection mme-new-connections-per-second

This command configures an attach rate throttle mechanism to control the number of new connections allowed on a per-second basis.

**Product**
MME

**Privilege**
Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```plaintext
network-overload-protection mme-new-connections-per-second #_new_connections action
attach { drop | reject-with-emm-cause { congestion | network-failure | no-suitable-cell-in-tracking-area } } tau { drop | reject-with-emm-cause { congestion | network-failure | no-sec-ctxt-in-nw | no-suitable-cell-in-tracking-area } } fwd-reloc { drop | reject } [ queue-size queue_size ] [ wait-time wait_time ]
```

**default network-overload-protection mme-new-connections-per-second**

- **default**
  Disables the MME attach rate throttle feature.

- **mme-new-connections-per-second #_new_connections**
  Define the number of new connections to be accepted per second.
  `#_new_connections`: Must be an integer from 50 to 5000.

- **action**
  Specifies the action to be taken by the MME when the new connection queue is full. Specific actions can be defined for each of the following connection types:
  - **UE-initiated attaches** (see `attach` keyword).
  - **UE-initiated inter-CN node TAU requests** (see `tau` keyword).
  - **Peer SGSN/MME initiated forward relocation requests** (see `fwd-reloc` keyword).

```plaintext
attach { drop | reject-with-emm-cause { congestion | network-failure | no-suitable-cell-in-tracking-area } }
```

Specifies the action to be taken for all types of UE-initiated initial attaches (IMSI, local GUTI, foreign GUTI, mapped GUTI, etc.). Select one of the following actions:

- **drop**: Drop the new connection request.
**reject-with-cause**: Reject the new connection request. Include one of the following as the cause in the reject message:

- congestion
- network-failure
- no-suitable-cell-in-tracking-area

```
tau { drop | reject-with-emm-cause { congestion | network-failure | no-sec-ctxt-in-nw | no-suitable-cell-in-tracking-area } }
```

Specifies the action to be taken for UE-initiated inter-CN TAU requests requiring context transfer from old MME/SGSN, including TAU requests with foreign GUTI or mapped GUTI. Select one of the following actions:

- **drop**: Drop the new connection request.
- **reject-with-cause**: Reject the new connection request. Include one of the following as the cause in the reject message:
  - congestion
  - network-failure
  - no-sec-ctxt-in-nw
  - no-suitable-cell-in-tracking-area

```
fwd-reloc { drop | reject }
```

Specifies the action to be taken for peer SGSN/MME initiated forward relocation requests via Gn/S10/S3. Select one of the following actions:

- **drop**: Drop the new connection request.
- **reject**: Reject the new connection request. If the inbound forward-relocation requests are rejected, the following cause codes shall be used:
  - GTPv1 - No resources available (199)
  - GTPv2 - No resources available (73)

In the event of an MME failure, the surviving MME in the pool may receive a very large number of IMSI requests, which may overwhelm the IMSI Manager. To avoid congestion, the MME can be configured using this keyword to throttle the IMSI-based DDN requests it receives if the configured #new_connections rate is exceeded. Select one of the following actions:

- **drop**: Drop new IMSI-based DDN requests.
- **reject**: Reject the IMSI-based DDN request. Include one of the following as the cause in the reject message:
  - unable-to-page-ue
  - context-not-found
Global Configuration Mode Commands (L-S)

network-overload-protection mme-new-connections-per-second

queue-size  queue_size
Defines the maximum size of the pacing queue used for buffering the packets. If configured, the queue-size should be greater than or equal to the #_new_connections value and less than or equal to the optimal value (the wait_time * #_new_connections). This validation is done in the CLI.
queue_size Must be an integer from 250 to 25000.
Default: unconfigured. The default value is the #_new_connections * wait-time. This will be the optimal value.

wait-time  wait_time
Defines the maximum life-time (number of seconds) of the packets in the queue beyond which the packets are considered to be “stale” and are dropped.
wait_time Must be an integer from 1 to 15
Default: 5

Usage
Use this command to configure attach rate throttling on the MME.
When enabled, new connections (except emergency requests) are buffered and paced through the queue. Messages in the queue are processed (FIFO) until they age-out when the queued message's lifetime crosses the configured wait-time. The wait-time and the attach rate decide the optimal size of the queue. If the queue is full, packets are rejected or dropped based on the configured action.
This feature functions at a system (chassis) level for all MME services. All MME services on the system are controlled by a single pacing queue. For a combo MME-SGSN node, each type of service shall be controlled by its own queue and its own configuration.
Emergency attaches are not be throttled when this feature is enabled.

Important: This command is available only if a valid license (MME Resiliency) is installed. Contact your Cisco account representative for more information.

Example
Configure the new connections per second rate at 2500, reject all (non-emergency) attaches and TAU requests, and drop forward relocation requests if the new connection rate is exceeded. Rejects will return emm cause code “Congestion”.

    network-overload-protection mme-new-connections-per-second 2500 action
    attach reject-with-emm-cause congestion tau reject-with-emm-cause
    congestion fwd-reloc drop ddn drop wait-time 5

Set the attach rate to 500 per second, the same actions as the previous example, but set the wait time to 5 seconds, and the queue size to be calculated (as follows: wait_time * #_new_connections - i.e., 2500)

    network-overload-protection mme-new-connections-per-second 500 action
    attach reject-with-emm-cause congestion tau reject-with-emm-cause
    congestion fwd-reloc drop ddn drop wait-time 5 5
network-overload-protection sgsn-new-connections-per-second

This command configures an attach rate throttle mechanism to control the number of new connections (attaches or inter-SGSN RAUs), through the SGSN, on a per second basis.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
network-overload-protection sgsn-new-connections-per-second #_new_connections action { drop | reject with cause { congestion | network failure } } [ queue-size queue_size ] [ wait-time wait_time ]

default network-overload-protection sgsn-new-connections-per-second

default
```

Using `default` in the command, disables this attach rate throttle feature that provides network overload protection.

```
sgsn-new-connections-per-second #_new_connections
```

Define the number of new connections to be accepted per second.

`#_new_connections`: Must be an integer from 50 to 5000.

**action**

Specifies the action to be taken by the SGSN when the attach rate exceeds the configured limit on the number of attaches. Select one of the following actions:

- **drop**: Drop the new connection request.
- **reject-with-cause**: Reject the new connection request. Include one of the following as the cause in the reject message:
  - **congestion**
  - **network failure**

**queue-size queue_size**

Defines the maximum size of the pacing queue used for buffering the packets. If configured, the queue-size should be greater than or equal to the `#_new_connections` value and less than or equal to the optimal value (the `wait_time` * `#_new_connections`). This validation is done in the CLI.

`queue_size` Must be an integer from 250 to 25000.
Global Configuration Mode Commands (L-S)

network-overload-protection sgsn-new-connections-per-second

Default: unconfigured. The default value is the \( \# \_new \_connections \times wait \_time \). This will be the optimal value.

**wait-time wait_time**

Defines the maximum life-time (number of seconds) of the packets in the queue beyond which the packets are considered to be "stale".

*wait_time* Must be an integer from 1 to 15

Default: 5

**Usage**

Use this command to configure the rate at which the SGSN must process new connection requests. The rate is the number of new connections to be accepted per second.

With basic network overload protection, the incoming new connection rate is higher than this configured rate. When this occurs, all of the new connection requests cannot be processed. This command can also be used to configure the action to be taken when the rate limit is exceeded. The new connection requests, which cannot be processed, can be either dropped or rejected with a specific reject cause.

The SGSN’s *optimized* network overload protection performs attach-rate throttling to avoid overloading Gr, Gn, and Gf interfaces. This is enabled with queue-size and wait-time keywords so that the IMSIMgr throttles the attach rate to values configured with these keywords.

If the SGSN receives more than the configured number of attaches in a second, then the attaches are buffered in the pacing queue and requests are only dropped when the buffer overflows due to high incoming attach rate. Messages in the queue are processed (FIFO) until they age-out when the queued message's lifetime crosses the configured wait-time. The wait-time and the attach rate decide the optimal size of the queue.

Counters for this feature are available in the `show gmm-sm statistics` command display in the Network Overload Protection portion of the table.

**Example**

Configure the throttle rate or limit to 2500 attaches per second and to drop all requests if the limit is exceeded.

```
network-overload-protection sgsn-new-connections-per-second 2500 action drop
```

Disables the network-overload protection feature and set the default queue size to 1000 and the wait time to 5 seconds:

```
default network-overload-protection sgsn-new-connections-per-second
```

Set the attach rate to 500 per second, the action to drop, the wait time to 5 seconds, and the queue size to be calculated (as follows: `wait_time * \#_new_connections` e.g., 2500)

```
network-overload-protection sgsn-new-connections-per-second 500 action drop wait-time 5
```
network-service-entity

This command creates a new instance of an SGSN network service entity (NSE) for either the IP environment or the Frame Relay environment.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
[ no ] network-service-entity ( ip-local | peer-nsei peer_nsei_number frame-relay )
```

<table>
<thead>
<tr>
<th><strong>no</strong></th>
<th>Deletes the network service entity definition from the system configuration.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ip-local</strong></td>
<td>Configures the local endpoint for NS/IP and enters the NSE-IP configuration mode. The prompt will change to:</td>
</tr>
<tr>
<td><code>no</code></td>
<td><code>[local]&lt;hostname&gt;(nse-ip-local)#</code></td>
</tr>
</tbody>
</table>

| **peer-nsei peer_nsei_number frame-relay** | Configures a peer NSE with frame relay connectivity. This set of keywords also provides access to the NSE-FR Configuration mode. The prompt will change to: |
| `no` | `[local]<hostname>(nse-fr-peer-nsei=<peer_nsei_number>)#` |

**Usage**

Use this command to access the configuration modes for either the IP or Frame Relay network service entities.

**Example**

Enter the NSE for a Frame Relay configuration instance identified as 4554:

```
network-service-entity peer-nsei 4554 frame-relay
```
network-service-entity ip

This command has been deprecated. See the replacement command network-service-entity.
**ntp**

Enters the Network Time Protocol (NTP) configuration mode or disables the use of NTP on the system.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

```console
configure
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
[ no ] ntp
```

- **no**

  Disables the use of NTP for clock synchronization. When omitted, NTP client support is enabled on the chassis. By default NTP synchronization to external servers is disabled.

**Important:** If the use of NTP is disabled the system clock may drift over a period of time. This may require manual updates to the system clock to synchronize the clock with other network elements.

**Usage**

Used when it is necessary to enable or configure NTP settings. For additional information refer to the *NTP Configuration Mode Commands* chapter and the *System Administration Guide*.

**Example**

The following command enters the NTP configuration mode:

```console
ntp
```

The following disables the use of the network timing protocol for system clock synchronization.

```console
no ntp
```
**ntsr pool-id**

Configures a pool ID and pool type (either MME or S4-SGSN) for Network Triggered Service Restoration (NTSR). Once executed, the user is placed in NTSR Pool Configuration Mode.

### Product
S-GW

### Privilege
Administrator, Security Administrator

### Mode
Exec > Global Configuration  
**configure**

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

### Syntax

```
ntsr pool-id number pool-type [ mme | s4-sgsn ]
```

```
no ntsr pool-id
```

```
ntsr pool-idnumber
```

Specifies an ID number for this NTSR pool. Valid entries are from 1 to 65535.

```
pool-type
```

Specifies the type of pool for the pool-id. Options are MME or S4-SGSN.

### Usage

This command is used to configure a pool ID and pool type (either MME or S4-SGSN) for NTSR. Once executed, the operator must configure a peer IP address in NTSR Pool Configuration mode using the **peer-ip-address** command.

### Example

This example configures an NTSR pool ID of 1 and a pool type of mme.

```
ntsr pool-id 1 pool-type mme
```
operator-policy

This command creates an operator policy and enters the operator policy configuration mode. Commands for configuration of the policies are available in the Operator Policy Configuration Mode Commands chapter.

**Product**
- MME
- SGSN
- SAEGW
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
- `configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
operator-policy ( default | name policy_name ) [ -noconfirm ]

no operator-policy ( default | name policy_name )
```

- `-noconfirm`
  Indicates that the command is to execute without any additional prompt and confirmation from the user.

- `no`
  Removes the specified operator policy from the system configuration.

- `default`
  `default`, in this case, is the name of a specific operator policy. This default policy is used when no other defined operator policy matches the incoming IMSI.

**Important:** You should configure this default operator policy to be it available to handle IMSIs that are not matched with other defined policies.

- `name policy_name`
  Specifies the unique name of an operator policy. `policy_name` is entered as an alphanumeric string of 1 through 64 characters.
Usage

Use this command to create an operator policy and to enter the operator policy configuration mode to define or modify policies.

An operator policy associates APNs, APN profiles, IMEI ranges, IMEI profiles, an APN remap table and a call-control profile to ranges of IMSIs. These profiles and tables are created and defined within their own configuration modes to generate sets of rules and instructions that can be reused and assigned to multiple policies. In this manner, an operator policy manages the application of rules governing the services, facilities and privileges available to subscribers. These policies can override standard behaviors and provide mechanisms for an operator to get around the limitations of other infrastructure elements such as DNS servers and HLRs.

The system supports up to 1,000 operator policies, including the default operator policy.

Important: An operator policy is the key element of the Operator Policy feature. After defining an instance of an operator policy, you must go to the SGSN Global Configuration Mode (from the Global Configuration mode) to define the IMSI range(s). This requirement does not hold if you are using a default operator policy.

To see what operator policies have already been created, return to the Exec mode and enter the show operator-policy all command.

Example

The following command accesses the default operator policy and enters the operator policy configuration mode to view or modify the specified policy:

```
operator-policy default
```
orbem

Enters the Object Request Broker Element Manager (ORBEM) Configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
orbem
```

**Usage**
Set the configuration mode to allow modification of the ORBEM configuration data.
pac-standby-priority

This command has been renamed to card-standby-priority. Please refer to that command for details. Note that for backwards compatibility, the system accepts this command as valid.
peer-profile

This command creates a peer profile based on service type and interface and enters the Peer-Profile Configuration mode. Commands for configuration of the policies are available in the Peer Profile Configuration Mode Commands chapter.

Product

GGSN
P-GW
SAEGW
S-GW

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

peer-profile service-type { ggsn-access | pgw-access | sgw-access | sgw-network } { default | name peer_profile_name } [ -noconfirm ]

no peer-profile service-type { ggsn-access | pgw-access | sgw-access | sgw-network } name peer_profile_name

[ -noconfirm ]

Indicates that the command is to execute without any additional prompt and confirmation from the user.

no

Removes the specified peer profile for specific service type from the system configuration.

service-type

Specifies service type for which peer profile is being configured.

\textbf{ggsn-access} configure profile for peer nodes of GGSN.

\textbf{pgw-access} configures profile for peer nodes of P-GW.

\textbf{sgw-access} configures profile for peer nodes of S-GW toward S4/S11 interfaces.

\textbf{sgw-network} configures profile for peer nodes of S-GW toward S5/S8 interfaces.

name peer_profile_name

Specifies the unique name of a peer profile for specific service type.

\textit{peer_profile_name} is entered as an alphanumeric string of 1 through 64 characters.
default

`default`, in this case, is the name of a specific peer profile. This default profile is used when no other defined peer profile matches.

**Important:** When there is no association of peer-map in any of the services, then “default” peer profile of the corresponding service-interface type shall be applied, except for GTP-C parameters. In addition, GTP-C parameter configuration shall be applied from eGTP service-level configuration for P-GW/S-GW service and GGSN service-level configuration for GGSN.

### Usage

Use this command to create a peer profile for specific service type and to enter the service specific Peer Profile configuration mode to define or modify the peer profile parameters.

The peer profile feature allows flexible profile-based configuration to accommodate growing requirements of customizable parameters with default values and actions for peer nodes of GGSN/P-GW/S-GW. With this feature, configuration of GTP-C echo parameters and disabling/enabling of Lawful intercept per MCC/MNC or IP address based on rules can be managed.

Before StarOS Release 15.0, the GGSN service allowed operator to configure list of SGSNs. Using this configuration, operator can also control some parameters associated with the configured SGSN, such as RAT type. This would be taken from configuration if CPC request does not have RAT type.

**Important:** The system supports up to 64 peer profiles configured for each of the peer profile types; there can be up to 1024 peer map rules configured, including all the peer maps.

### Example

The following command accesses the default peer profile for GGSN service and enters the GGSN Peer Profile configuration mode to view or modify the specified profile:

```
peer-profile service-type ggsn-access default
```
**plugin**

Specifies a previously installed software plugin module and enters the Plugin Configuration Mode. This function is associated with the patch process for dynamic software upgrades. A plugin module is a loadable dynamic link library (DLL) of shared objects.

**Product**
ADC

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
plugin module_name
```

*module_name*

Specifies the name of an existing plugin module that you want to downgrade as an alphanumeric string of 1 through 16 characters. If the named module is not known to the system, an error message is displayed.

**Usage**

Specify a previously loaded software plugin module that you wish to configure. The specified module must have been previously copied onto the system and unpacked/verified via the `patch plugin` and `install patch plugin` commands.

For additional information, refer to the `Plugin Configuration Mode Commands` chapter.

**Example**

To specify the plugin module named `p2p_odyssey` enter the following command:

```
plugin p2p_odyssey
```
**port atm**

Identifies a physical port on a line card that supports ATM signaling and then enters the configuration mode for the specific interface-type. For the commands to configure the port interface, see the CLI chapter ATM Port Configuration Mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

*configure*

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
port atm slot/port
```

- **atm**
  Indicates the port identified is an ATM interface port.

- **slot/port**
  To determine valid ATM slot and port numbers, use the Exec mode’s command `show port table slot`.

  - **slot**: Identifies the chassis slot holding the line card that supplies ATM ports. The slot ID number can be an integer from 17 through 48.
  - **port**: Identifies the physical port that is to be configured to support ATM signaling. The ID number can be an integer from 1 through 4.

**Usage**

Change the current configuration mode to Ethernet Port Configuration mode.

**Important**: This command is not supported on all platforms.

**Example**

The following enters the ATM port configuration mode for ATM port 1 on the card in slot 19:

```
port atm 19/1
```
**port bits**

Enters the Building Integrated Timing Supply (BITS) port configuration mode by identifying the BITS port on the active or standby SPIO.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**

```plaintext
port bits slot/port
```

**Usage**
Change the current configuration mode to BITS port configuration mode.

**Important:** This command is not supported on all platforms.

**Example**
The following enters the BITS port configuration mode for the active SPIO:

```plaintext
port bits 24/4
```
port channelized

Identifies a physical port on a Channelized Line Card (CLC) that supports Frame Relay signaling and creates a Frame Relay interface. This command enters the configuration mode for the commands that configure the Frame Relay interface and the channelized port interface. For additional information, see the Channelized Port Configuration Mode Commands chapter.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
port channelized slot/port
```

channelized
Selects the channelized frame relay interface for the selected line card and port.

```
slot/port
```

To determine valid slots and port numbers, use the Exec mode’s command `show port table` to find the channelized line card.

- `slot`: Identifies the chassis slot holding the Channelized Line Card that sources Frame Relay ports. The slot ID number can be an integer from 17 through 48.
- `port`: Identifies the physical port that is to be configured to support Frame Relay signaling. The ID number can only be 1.

Usage

Change the current configuration mode to Channelized Port configuration mode.

Example

The following enters the Channelized port configuration mode for port 1 on the card in slot 20:

```
port channelized 20/1
```
port ethernet

Enters the Ethernet Port Configuration mode for the identified port.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```
Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
port ethernet slot/port
```

- **ethernet**
  Indicates the port identified is an Ethernet interface port.

- **slot/port**
  Specifies the slot and port for which Ethernet Port Configuration mode is being entered. The slot and port must refer to an installed card and port.

**Usage**

Change the current configuration mode to Ethernet Port Configuration mode.

**Example**

The following command enters the Ethernet Port Configuration mode for ethernet port 1 in slot 17 (ASR 5000):

```
port ethernet 17/1
```

The following command enters the Ethernet Port Configuration mode for ethernet port 11 in slot 5 (ASR 5500):

```
port ethernet 5/11
```
port mac-address virtual-base-address

This command defines a block of 256 consecutive media access control (MAC) addresses and enables virtual MAC addressing for Ethernet line card ports. Not available for the XT2 platform.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

port mac-address virtual-base-address MAC_Address

no port mac-address virtual-base-address

no

Disables virtual MAC addressing for Ethernet line card ports. The block of virtual MAC addresses is not saved.

MAC_Address

Specifies the beginning address of a block of 256 MAC addresses that are used for virtual MAC addressing.

Usage

Use this command to disregard the MAC addresses assigned and stored in card firmware and assign MAC addresses for all Ethernet ports from the specified block of virtual MAC addresses. This command does not affect the MAC addresses on SPIO cards.
There are 65536 MAC addresses (00:05:47:FF:00:00 - 00:05:47:FF:FF:FF) reserved for use by customers. This range allows for the creation of 256 address blocks each containing 256 MAC addresses (for example, 00:05:47:FF:00:00, 00:05:47:FF:01:00, 00:05:47:FF:02:00, 00:05:47:FF:03:00, 00:05:47:FF:04:00, etc.).

⚠️ Caution: This configuration requires the configuration of a valid block of unique MAC addresses that are not used anywhere else. Use of non-unique MAC addresses can degrade and impair the operation of your network.

❗ Important: This command is not supported on all platforms.

Example

To enable virtual MAC addressing for Ethernet ports on all Ethernet line cards in the system using a block of MAC addresses starting at 00:05:47:FF:00:00, enter the following command:
port mac-address virtual-base-address 00:05:47:FF:00:00
port rs232

Enters the RS-232 Port Configuration mode for the RS-232 console port on the specified SPIO card. Not available on the XT2 platform.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
port rs232 slot 3
```

<table>
<thead>
<tr>
<th>rs232</th>
</tr>
</thead>
<tbody>
<tr>
<td>Indicates the port identified is an RS-232 port on a SPIO card.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>slot 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the slot of the SPIO for which RS-232 Port Configuration mode is being entered. The slot must refer to an installed SPIO card. The specified port must always be 3 for an RS-232 port. The value for <code>slot</code> must be either 24 or 25.</td>
</tr>
</tbody>
</table>

**Usage**
Change the current configuration mode to RS-232 Port Configuration mode.

**Example**
The following command enters the RS-232 Port Configuration mode for the SPIO in slot 24;

```
port rs232 24 3
```
profile-id-qci-mapping

Creates a Qos Class-Identifier-Radio Access Network (QCI-RAN) ID mapping table or specifies an existing table and enters the QCI Mapping Configuration mode for the system.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

[ no ] profile-id-qci-mapping name [ -noconfirm ]

- no
  Removes the specified mapping table from the system

- name
  Creates a new or enters an existing mapping table configuration. name must be an alphanumeric string of 1 through 63 alphanumeric.

- -noconfirm
  Indicates that the command is to execute without any additional prompt and confirmation from the user.

Usage

Enters the QCI-RAN ID mapping configuration mode for an existing table or for a newly defined table. This command is also used to remove an existing table.

Entering this command results in the following prompt:

[context_name]hostname(config-hsgw-association-table)#

QCI Mapping Configuration Mode commands are defined in the QCI Mapping Configuration Mode Commands chapter.
Use this command when configuring the HSGW eHRPD component.

Important: This command creates a mapping table available to any HSGW context configured on the system.

Example

The following command enters the existing QCI mapping configuration mode (or creates it if it doesn’t already exist) for a mapping table named qci_table1:
profile-id-qci-mapping qci_table1

The following command will remove qci_table1 from the system:

no profile-id-qci-mapping qci_table1
ps-network

This command creates/removes an HNB-PS network configuration instance for Femto UMTS access over Iu-PS/Iu-Flex interface between Home NodeB Gateway (HNB-GW) service and PS networks elements; i.e. SGSN. This command also configures an existing HNB-CS network instance and enters the HNB-CS Network Configuration mode on a system.

Product
HNB-GW

Privilege
Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:
[local]host_name(config)#

Syntax

[ no ] ps-network ps_instance [ -noconfirm ]

no ps-network ps_instance

no

Removes the specified HNB-PS network instance from the system.

⚠️ Caution: Removing the HNB-PS network instance is a disruptive operation and it will affect all UEs accessing SGSN(s) in specific PS core network through the HNB-GW service.

⚠️ Caution: If any HNB-PS Network instance is removed from the system, all parameters configured in that mode will be deleted and Iu-PS/Iu-Flex interface will be disabled.

ps_instance

Specifies the name of the Packet Switched Core Networks instance which needs to be associated with HNB Radio Network PLMN in HNB RN-PLMN configuration mode. If ps_instance does not refer to an existing HNB-PS instance, the new HNB-PS network instance is created.

ps_instance must be an alphanumeric string of 1 through 63 characters.

-noconfirm

Indicates that the command is to execute without any additional prompt and confirmation from the user.

Usage

Use this command to enter the HNB-PS Network Configuration mode for an existing PS network instance or for a newly defined HNB-PS network instance. This command is also used to remove an existing HNB-PS network instance.
This configuration enables the Iu-PS/Iu-Flex interface on HNB-GW service with CS core network elements; i.e. MSC/VLR.
A maximum of 1 HNB-PS networks instance which is further limited to a maximum of 256 services (regardless of type) can be configured per system.

⚠️ **Caution:** This is a critical configuration. The HNBs can not access SGSNs in PS core network without this configuration. Any change to this configuration would lead to disruption in HNB access to PS core network.

Entering this command results in the following prompt:

```
[context_name]hostname(config-ps-network)#
```

The various parameters available for configuration of an HNB-PS network instance are defined in the *HNB-PS Network Configuration Mode Commands* chapter.

**Example**

The following command enters the existing HNB-PS Network configuration mode (or creates it if it doesn’t already exist) for the instance named `hnb-ps1`:

```
ps-network hnb-ps1
```

The following command will remove HNB-PS network instance `hnb-ps1` from the system without any prompt to user:

```
no ps-network hnb-ps1
```
qci-qos-mapping

Global QCI-QoS mapping tables are used to map QoS Class Identifier (QCI) values to appropriate Quality of Service (QoS) parameters.

Product
- ePDG
- GGSN
- HSGW
- P-GW
- SAEGW
- S-GW

Privilege
- Administrator

Mode
- Exec > Global Configuration
  - configure
  Entering the above command sequence results in the following prompt:

  [local]host_name(config)#

Syntax

qci-qos-mapping name [ -noconfirm ]

no qci-qos-mapping name

no
- Removes the specified mapping configuration from the system

name
- Creates a new or enters an existing mapping configuration. name must be an alphanumeric string of 1 through 63 characters.

-noconfirm
- Indicates that the command is to execute without any additional prompt and confirmation from the user.

Usage

Enter the QCI-QoS mapping configuration mode for an existing table or for a newly defined table. This command is also used to remove an existing table.

Entering this command results in the following prompt:

[context_name]host_name(config-qci-qos-mapping)#
QCI - QoS Mapping Configuration Mode commands are defined in the *QCI - QoS Mapping Configuration Mode Commands* chapter.
Use this command when configuring the following eHRPD component: HSGW, P-GW, SAEGW, S-GW.

**Important:** This command creates a mapping configuration available to any GGSN, HSGW, P-GW, SAEGW, S-GW context configured on the system.

**Example**

The following command enters the existing QCI - QoS mapping configuration mode (or creates it if it doesn’t already exist) for a mapping configuration named `qci-qos3`:

```
qci-qos-mapping qci-qos3
```
**qci**

Defines QCI value.

**Product**
ePDG
HSGW
P-GW
SAEGW
S-GW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > qci-qos-mapping

`configure > qci-qos-mapping mapping_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpu-service)#
```

**Syntax**

```
quci num [ delay-class delay-class-value [ precedence-class precedence-class-value [ reliability-class reliability-class-value ] ] ] [ downlink [ 802.1p-value value ] [ encaps-header { copy-inner | dscp-marking dscp-marking-value } ] [ gbr ] [ max-packet-delay max-packet-delay-value max-error-rate max-error-rate ] [ non-gbr ] [ traffic-policing interval value ] [ uplink [ 802.1p-value value ] [ encaps-header { copy-inner | dscp-marking dscp-marking-value } ] [ mpls-exp-value value ] [ user-datagram dscp-marking dscp-marking-value ] ]
```

```
no | default qci num
```

| no | Removes the specified QCI value. |
| default | Sets the default QCI value. |

```
quci num
```

`num` must be an integer from 1 through 256.

```
delay-class delay-class-value
```

Defines Pre Release 8 value for configuring packet delay.

`delay-class delay-class-value:` Defines Pre Release 8 value for configuring packet delay as an integer from 1 through 9.
**precedence-class** *precedence-class-value*
Defines Pre Release 8 value for configuring packet precedence.
`precedence-class` *precedence-class-value*: Defines Pre Release 8 value for configuring packet precedence as an integer from 1 through 32.

**reliability-class** *reliability-class-value*
Defines Pre Release 8 value for configuring packet reliability.
`reliability-class` *reliability-class-value*: Defines Pre Release 8 value for configuring packet reliability as an integer from 1 through 32.

downlink
Configures for downlink traffic.

**802.1p-value** *value*
`802.1p-value` *value*: Configures for downlink traffic 802.1p-value as an integer from 1 through 7.

caps-header { copy-inner | dscp-marking dscp-marking-value }
`caps-header`: Defines the DSCP value to be applied to caps header.
`copy-inner`: Copy inner DSCP to outer.
`dscp-marking` *dscp-marking-value*: Defines the DSCP value to be applied to packets with this QCI.
`dscp-marking-value`: A Hexadecimal number between 0x0 and 0x3F.

gbr
Sets the type of the QCI to GBR.

**max-packet-delay** *max-packet-delay-value*
Defines the maximum packet delay in ms for the data with the QCI as an integer from 10 through 1000.

**max-error-rate** *max-error-rate*
Defines the maximum error rate that the data stream can handle in power of 10 as an integer from 1 through 6.

**non-gbr**
Sets the type of the QCI to non GBR.

**traffic-policing interval** *value*
Sets the parameters for traffic policing interval in seconds as an integer from 1 through 100.

uplink
Configures for uplink traffic.

**mpls-exp-value** *value*
Configures for uplink traffic mpls-exp-value as an integer from 1 through 7.
user-datagram
Defines DSCP value to be applied to user data gram.

Usage
Use this command to define QCI value in qci-qos-mapping.

Example
The following command defines QCI value as 56:

```
qci 56
```
qos npu inter-subscriber traffic bandwidth

Configures NPU QoS bandwidth allocations for the system.

Product
PDSN
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

qos npu inter-subscriber traffic bandwidth gold percent silver percent bronze percent best-effort percent

no qos npu inter-subscriber traffic bandwidth

no

Removes a previous bandwidth allocation.

gold percent

Default: 10%
Specifies the maximum percentage of bandwidth to be allocated to the gold queue priority. percent can be configured to an integer from 0 through 100.

silver percent

Default: 20%
Specifies the maximum percentage of bandwidth to be allocated to the silver queue priority. percent can be configured to an integer from 0 through 100.

bronze percent

Default: 30%
Specifies the maximum percentage of bandwidth to be allocated to the bronze queue priority. percent can be configured to an integer from 0 through 100.

best-effort percent

Default: 40%
Specifies the maximum percentage of bandwidth to be allocated to the best-effort queue priority. percent can be configured to an integer from 0 through 100.
Usage

The bandwidth of a subscriber queue is maintained by rate limiting functions which implement packet-rate
limiting at the first level and bit-rate limiting at the next level.
The packet-rate limit of a queue is defined by the number of packets-per-second (PPS) permitted for queuing.
Before queuing a packet on a subscriber queue, the NPU ensures that the packet falls within the limit. If the
packet to be queued exceeds the packet rate limit, it is dropped.
Each subscriber queue is configured with a bit rate limit, measured in megabits-per-second (Mbps), referred
to as CP-BPS (bit-per-second to CP). The CP-BPS is available as the total bandwidth for the subscriber traffic
that a CP can sustain. Each subscriber queue receives an allocation of a certain percentage of the CP-BPS.
The following maximum CP-BPS values are supported:
• Lead CP (CP0) = 128 Mbps
• Remaining CPs (CP1, CP2, CP3) = 256 Mbps
For additional information on the NPU QoS functionality, refer to the System Administration and
Configuration Guide.

Important: This functionality is not supported for use with the PDSN at this time.

Example

The following command configures bandwidth allocations of 20, 30, 40, and 50% for the gold, silver, bronze,
and best-effort queues respectively:

```
qos npu inter-subscriber traffic bandwidth gold 20 silver 30 bronze 40 best-effort 50
```

Upon executing this command, the priority queues will have the following packet processing card CP
bandwidth allocations based on the maximum CP bandwidth specifications:

<table>
<thead>
<tr>
<th>Priority</th>
<th>Lead CP (CP 0) Bandwidth (Mbps)</th>
<th>CP 1 through CP 3 Bandwidth (Mbps)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gold</td>
<td>25.6</td>
<td>51.2</td>
</tr>
<tr>
<td>Silver</td>
<td>38.4</td>
<td>76.8</td>
</tr>
<tr>
<td>Bronze</td>
<td>51.2</td>
<td>102.4</td>
</tr>
<tr>
<td>Best-effort</td>
<td>64</td>
<td>128</td>
</tr>
</tbody>
</table>
**qos npu inter-subscriber traffic bandwidth-sharing**

Configures NPU QoS bandwidth sharing properties for the system.

**Product**
- PDSN
- GGSN

**Privilege**
Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
qos npu inter-subscriber traffic bandwidth-sharing { { enable | disable } { all | slot slot_num cpu cpu_num } }
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>Enables bandwidth sharing for the specified criteria.</td>
</tr>
<tr>
<td>disable</td>
<td>Disables bandwidth sharing for the specified criteria.</td>
</tr>
<tr>
<td>all</td>
<td>Specifies that the bandwidth action is to be applied to all packet processing cards and every CPU on each packet processing card.</td>
</tr>
<tr>
<td>slot slot_num</td>
<td>Specifies that the bandwidth action is to be applied to a packet processing card in a specific chassis slot number.</td>
</tr>
<tr>
<td>cpu cpu_num</td>
<td>Specifies a specific control processor (CP) on a packet processing card for which to perform the bandwidth action.</td>
</tr>
</tbody>
</table>

**Usage**

The available bandwidth of a subscriber queue can be shared equally among the other subscriber queues. Any unutilized bandwidth of a queue can be shared with the other queues equally. For example, if only one DSCP
is configured and it is mapped to best-effort, that DSCP would get the bandwidth allocated to the best-effort in addition to the rest of the bandwidth allocated to the gold, silver, and bronze. By default, the system enables sharing for all packet processing cards and their CPs. For additional information on the NPU QoS functionality, refer to the System Administration Guide.

**Important:** This functionality is not supported for use with the PDSN at this time.

**Example**

The following command disables bandwidth sharing for the fourth CP (CP 3) on a packet processing card installed in chassis slot 3:

```
qos npu inter-subscriber traffic bandwidth-sharing disable slot 4 cpu 3
```
**qos npu inter-subscriber traffic priority**

Configures the DSCP-to-Priority assignments for the system.

**Product**

- PDSN
- GGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
qos npu inter-subscriber traffic priority { best-effort | bronze | gold | silver }
assigned-to dscp { af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | ef | dscp_num }
```

```
no qos npu inter-subscriber traffic priority [ assigned-to dscp { af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | ef } ]
```

---

**best-effort**

Specifies the best-effort queue priority.

---

**bronze**

Specifies the bronze queue priority.

---

**gold**

Specifies the gold queue priority.

---

**silver**

Specifies the silver queue priority.

---

**afXX**

Assigns the Assured Forwarding XX PHB (per-hop behavior) DSCP.

Each Assured Forwarding PHB has a corresponding DSCP value as follows:

- af11 through af13: DSCP values 5 through 7 respectively
- af21 through af23: DSCP values 9 through 11 respectively
- af31 through af33: DSCP values 13 through 15 respectively
- af41 through af43: DSCP values 17 through 19 respectively
**qos npu inter-subscriber traffic priority**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>be</strong></td>
<td>Assigns the Best Effort forwarding PHB which has a corresponding DSCP value of 0.</td>
</tr>
<tr>
<td><strong>ef</strong></td>
<td>Assigns the Expedited Forwarding PHB which has a corresponding DSCP value of 23.</td>
</tr>
<tr>
<td><strong>dscp_num</strong></td>
<td>Specifies a specific DSCP value as an integer from 0 through 31.</td>
</tr>
</tbody>
</table>

**Usage**

The differentiated services (DS) field of a packet contains six bits (0-5) that represent the differentiated service code point (DSCP) value. Five of the bits (1-5) represent the DSCP. Therefore, up to 32 (2^5) DSCPs can be assigned to the various priorities. By default, they're all assigned to the lowest priority (best-effort). For additional information on the NPU QoS functionality, refer to the System Administration Guide.

**Important:** This functionality is not supported for use with the PDSN at this time.

**Example**

The following command maps the ef DSCP to the gold priority queue:

```
qos npu inter-subscriber traffic priority gold assigned-to dscp ef
```
ran-peer-map

Creates a Radio Access Network (RAN) Peer Map and enters the RAN Peer Map Configuration Mode.

Product
ASN-GW
PHSGW

Privilege
Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

[ no ] ran-peer-map name [ -noconfirm ]

no
Removes the RAN Peer Map from the system.

name
Specifies the name of the RAN Peer Map. name must be an alphanumeric string of 1 through 31 characters.

Usage
Use this command to create a new RAN Peer Map or edit an existing one. RAN peer maps reconcile base station MAC addresses received in R6 protocol messages to the base station’s IP address. Entering this command results in the following prompt:

[context_name]hostname(config-ran-peer-map)#

RAN Peer Map Configuration Mode commands are defined in the ASN RAN Peer Map Configuration Mode Commands chapter in this guide.

Example
The following command creates a RAN peer map named ran12:

   ran-peer-map ran12
**require active-charging**

This command enables/disables Active Charging Service (ACS) with or without the Category-based Content Filtering application.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

`[local]host_name(config)#`

**Syntax**

```
require active-charging [ isolated-mode ] [ content-filtering category [ static-and-dynamic ] ] [ optimized-mode ]
```

no require active-charging

```
no
```

Disables ACS on the system.

```
isolated-mode
```

Enables ACS and separates ACS-related resources from other sub-system resource sharing.

**Important:** In 8.1 and later releases, this keyword is not supported.

```
optimized-mode
```

Enables ACS in Optimized mode, wherein ACS functionality is managed by SessMgrs.

**Important:** In 8.0 and earlier releases and in 9.0 and later releases, this keyword is not supported.

**Important:** In Release 8.1, ACS must be configured in the Optimized mode.

**Important:** In Release 8.1, if the active-charging mode is changed from the default (non-optimized) mode to the Optimized mode, or vice-versa, the system must be rebooted for the change to take effect.

**Important:** In Release 8.3, this keyword is obsolete. With or without this keyword ACS is always enabled in the Optimized mode.
Use the `require active-charging` command to enable ACS in the non-optimized mode. Wherein, ACS Managers will spawn to support ACS.

Use the `require active-charging optimized-mode` command to enable ACS in the Optimized mode. Wherein, ACS is enabled as part of Session Managers.

```
content-filtering category [ static-and-dynamic ]
```

Enables the Category-based Content Filtering application with ACS support and creates the necessary Static Rating Database (SRDB) tasks to utilize the internal database of static/dynamic URLs.

For Dynamic Content Filtering support, the `static-and-dynamic` keyword must be configured to specify that the Dynamic Rater Package (model and feature files) must be distributed to rating modules on startup, recovery, etc. If not configured, by default, the static-only mode is enabled.

---

**Usage**

Use this command to enable/disable ACS with or without Category-based Content Filtering application on the chassis.

---

**Important:** This command triggers the resource subsystem to switch to ACS-enabled mode and start ACS-related tasks. This CLI command must be configured before any services are configured, so that the resource subsystem can appropriately reserve adequate memory for the ACS-related tasks. After configuring this command, the configuration must be saved and the system rebooted in order to allocate the resources for ACS upon system startup.

In 8.0 and 8.1 releases, this command must be configured before configuring any services. This is to ensure that the resource subsystem can appropriately reserve adequate memory for ACS Manager tasks. If this command is configured after all the Session Manager tasks are already active, the ACS Manager tasks will not be started even if additional cards are added to the chassis—instead, the chassis must be rebooted.

---

**Example**

In Release 8.0, the following command enables resource subsystem to configure ACS in isolated mode:

```
require active-charging isolated-mode
```

In Release 8.1, the following command enables ACS in Optimized mode:

```
require active-charging optimized-mode
```

In Release 8.3, the following command enables ACS in Optimized mode:

```
require active-charging
```
**require cipher ssl resource-percentage**

Assigns the 8 processing cores on the PSC2 card and splits the hardware acceleration resources between SSL protocol and IPSec protocol processing.

**Product**
SCM (P-CSCF, A-BG)

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```sh
configure
```

Entering the above command sequence results in the following prompt:

```sh
[local]host_name(config)#
```

**Syntax**

```sh
require cipher ssl resource-percentage percentage_value
```

**default require cipher ssl resource-percentage**

`percentage_value`

The system converts the specified resource percentage value to the nearest number of processing cores assigned to SSL processing. The system assigns the remaining processing cores to IPSec processing. This value can be within the range of 0 to 100.

For example, if 20% of the hardware acceleration resources are assigned to SSL processing, the system translates this value to INT((20*8+50)/100) = 2 processing cores assigned to SSL processing, and (8-2) = 6 processing cores assigned to IPSec processing.

**default**

Sets the default percentage value to 0%, assigning all 8 processing cores to IPSec processing.

**Usage**

Use this command to split the 8 processing cores on the PSC2 card between SSL protocol and IPSec protocol processing.

**Example**

The following command assigns 20% of the hardware acceleration resources on the PSC2 card (2 processing cores) to SSL processing, and 80% of the hardware acceleration resources (6 processing cores) to IPSec processing:

```sh
require cipher ssl resource-percentage 20
```
require cscf-connection-proxy

Configures one Diameter proxy per card (multiple) or one proxy per system (single).

**Product**
SCM (P-CSCF, A-BG)

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
   configure
Entering the above command sequence results in the following prompt:

   [local]host_name(config)#

**Syntax**

   require cscf-connection-proxy { multiple | single }

   { multiple | single }
   Configures one Diameter proxy per card (support for multiple proxies) or one CSCF proxy per system.

**Usage**
Use this command to establish a single Diameter proxy per system or multiple Diameter proxies (one per card). For additional information refer to the **CSCF Proxy-CSCF Configuration Mode Commands** chapter.

**Example**
The following command allows one Diameter proxy per system:

   require cscf-connection-proxy single
require demux

Enables or disables demux capabilities on an ASR 5x00 system. On an ASR 5500 when demux tasks are enabled on a management card, the Active and Standby MIOs will host and migrate all demux tasks.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
[ default | no ] require demux { card | management-card | processing-card }
```

- **default**
  Demux functions will be run on a processing card.

- **no**
  Disables the demux capabilities except when session recovery is enabled.

**Important:** On a system with session recovery licensed and enabled, a processing or management card must be designated to run demux functions.

**Usage**

Use this command to configure the system to direct demux task placement.

The following restrictions apply when enabling an MIO/UMIO as a demux card:

- The `require demux management-card` command must be configured before any service or contexts have been created on the system. The command will not execute after a mode of operation has been selected for the chassis.

- Only the following services currently support the designation of an MIO/UMIO card for demux functions: GGSN, SGW, PGW, HA and SAE-GW.

- Ex-GW, L2TP, MME, NEMO and SGSN are not supported.
After the ASR 5500 has booted with demux functions running on an MIO/UMIO, you cannot configure non-supported services. A maximum of eight Demux Managers are supported. Any attempt to add more than eight Demux Managers will be blocked.

Service/products requiring a large number of VPN Managers, VRFs and/or Demux Managers must not enable demux functions on an MIO.

With demux functions running on an MIO, the ASR 5500 supports a maximum of 10 contexts, 15 interfaces per context, with a maximum of 64 interfaces and 250 VRFs per system.

Implementation of this feature assumes that CEPS (Call Events Per Second) and the number of subscribers will remain constant, and only the data rate will increase. This ensures that the CPU demand will not increase on the MIO/UMIO.

**Caution:** Enabling the Demux on MIO/UMIO feature changes resource allocations within the system. This directly impacts an upgrade or downgrade between StarOS versions in ICSR configurations. Contact Cisco TAC for procedural assistance prior to upgrading or downgrading your ICSR deployment.

**Important:** Contact Cisco TAC for additional assistance when assessing the impact to system configurations when enabling the Demux on MIO/UMIO feature.

**Example**

For releases prior to 15.0, to configure a DPC/UDPC as a demux card enter the following CLI commands:

```plaintext
require demux card
```

For release 15.0+, to configure a DPC/UDPC as a demux card enter the following CLI commands:

```plaintext
require demux processing-card
```

To configure an MIO/UMIO as a demux card enter the following CLI commands:

```plaintext
require demux management-card
```
require detailed-rohc-stats

Enables or disables context-specific Robust Header Compression (RoHC) statistics.

**Product**
- HSGW
- PDSN

**Privilege**
- Administrator

**Mode**
- Exec > Global Configuration
- `configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
[ no ] require detailed-rohc-stats
```

- `no`
  Disables statistics for RoHC calls. This is the default condition.

**Usage**

Enables context-specific statistics for RoHC calls.

**Example**

Enter the following command to enable context specific statistics for RoHC calls:

```
require detailed-rohc-stats
```
require diameter-proxy

This command enables or disables Diameter Proxy mode.

Product
IPCFC

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

require diameter-proxy { master-slave | multiple | single }

no require diameter-proxy

no
Disables Diameter Proxy mode. This is the default configuration.

master-slave
Sets the Diameter-Proxy to Master-Slave mode.
In Master-Slave mode, multiple Diameter proxies are running, one on each packet processing card. One proxy serves as the Master and the other proxies are Slaves. The Master proxy relays the traffic across multiple Slave Diameter proxies.

multiple
Configures one Diameter proxy for each active packet processing card.

single
Configures one Diameter proxy for the entire chassis.

Usage
When the Diameter Proxy mode is enabled, each proxy process is a Diameter host, instead of requiring every Diameter application user (such as, every ACSMgr and/or every SessMgr, depending on the application) to be a host.
In Master-Slave mode, multiple Diameter proxies are running, one on each packet processing card. One proxy serves as the Master and the other proxies are Slaves. The Master relays the traffic from an incoming connection to a specific Slave Diameter proxy.

Example
The following command configures a Diameter proxy for each active packet processing card:

require diameter-proxy multiple
The following command configures a single Diameter proxy for the entire chassis:

```
require diameter-proxy single
```
**require ecs credit-control**

This command configures the Diameter Credit-Control Application (DCCA) to work in per subscriber-PDN level Gy mode.

**Product**
- GGSN
- HA
- IPSG
- PDSN
- P-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
- `configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

**In 14.0 and earlier releases:**

```
[ no ] require ecs credit-control subscriber-mode
```

**In 14.1 and later releases:**

```
[ no ] require ecs credit-control session-mode per-subscriber
```

**Usage**

**In 14.0 and earlier releases:**

This command is applicable to all products using the Gy interface. Use this command to configure DCCA/Gy to work in per subscriber-PDN level Gy mode, wherein one Diameter session is created per subscriber PDN rather than per bearer, and only one DCCA/Gy session is created for multi-bearer PDNs. If this command is not configured, or the `no require ecs credit-control subscriber-mode` command is configured, DCCA/Gy sessions are created per bearer/PDP-context, and as a result when there are multiple PDP contexts or multiple bearers in a PDN as many DCCA/Gy sessions are created.

**Important:** This command will take effect only when the system is booted/rebooted. When configured after the system comes up, the command will be accepted but will not be applied until after the system is rebooted with the saved configuration.
**Important:** This command is independent of the `require active-charging` command. The `ecs` keyword in this command is license dependent.

**In 14.1 and later releases:**
This CLI command is made configurable on the fly, that means, the credit control mode can be seamlessly changed from subscriber (PDN) to sub-session and vice-versa without requiring a system reboot.

This change is done to align with the new CLI commands “`credit-control-client override session-mode { per-sub-session | per-subscriber }`” introduced in APN and Subscriber Group configuration modes.

This will be the default mode for all subscribers unless overwritten by APN/Subscriber configuration mode CLI commands.

Releases prior to 14.1, subscriber mode Gy and bearer mode Gy were implemented based on the configuration of CLI command `require ecs credit-control subscriber-mode`. This CLI is used as a chassis level configuration which mandates that all subscribers anchored to this chassis should always be running in only one of these two modes. Enabling and disabling the CLI requires system reboot. ICSR switchover between two chassis running in two different modes will not work.

Release 14.1 and later, the Subscriber/Bearer mode Gy is selected based on APN/Subscriber mode instead of chassis wide configuration. This will provide the following:

- Flexibility to configure different modes for different subscriber.
- Flexibility to switch between modes without system reboot.
- Flexibility to switchover between two chassis working in different modes.
require session recovery

Enables session recovery when hardware or software fault occurs within system.

Product
- ePDG
- GGSN
- ASN-GW
- HA
- HSGW
- LNS
- MME
- PDG/TTG
- PDIF
- PDSN
- P-GW
- SAEGW
- SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

[ no ] require session recovery

no

Disables session recovery feature after configuration file is saved and system is restarted.

Usage

When this feature is enabled, the system attempts to recover any home agent-based Mobile IP sessions that would normally be lost due to a hardware or software fault within the system. This functionality is available for the following call types:

- ASN-GW services supporting simple IP, Mobile IP, and Proxy Mobile IP
- PDSN services supporting simple IP, Mobile IP, and Proxy Mobile IP
- HA services supporting Mobile IP and/or Proxy Mobile IP session types with or without per-user Layer 3 tunnels
require session recovery

- GGSN services for IPv4 and PPP PDP contexts
- SGSN services for all attached and/or activated subscribers
- LNS session types
- PDIF services supporting Simple-IP, Mobile-IP and Proxy Mobile-P
- MME services

The default setting for this command is disabled.
The no option of this command disables this feature.
This command only works when the Session Recovery feature is enabled through a valid Session and Feature Use License Key.

**Important:** After entering this command, you must restart the system for the command takes effect. Remember to save the configuration file before issuing the **reload** command.
reveal disabled commands

Enables the input of commands for features that do not have license keys installed. The output of the command `show cli` indicates when this is enabled. This command effects all future CLI sessions. This is disabled by default.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
[ no ] reveal disabled commands
```

- **no**
  
  Do not show disabled commands.

**Usage**

When this is enabled and a disabled command is entered, a message is displayed that informs you that the required feature is not enabled and also lists the name of the feature that you need to support the command. When this is disabled and a disabled command is entered, the CLI does not acknowledge the existence of the command and displays a message that the keyword is unrecognized.

**Example**

Set the CLI to accept disabled commands and display the required feature for all future CLI sessions with the following command:

```
reveal disabled commands
```

Set the CLI to reject disabled commands and return an error message for all future CLI sessions:

```
no reveal disabled commands
```
**rlf-template**

This command enters the Rate Limiting Function (RLF) Template Configuration Mode. This mode is used to configure the RLF template to control the throttling parameters.

**Important:** RLF template cannot be deleted if it is bound to any application (peers/endpoints).

**Product**

- GGSN
- P-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
[ no ] rlf-template rlf_template_name
```

- **no**
  
  Remove the specified RLF template from global configuration.

- **rlf_template_name**

  The name of the RLF template to create or remove. `rlf_template_name` must be an alphanumeric string of 1 through 127 characters.

**Usage**

Use this command to enter the RLF Template Configuration mode. The users can define the rate limiting configurations within this template.

**Important:** Rate Limiting Function (RLF) is a license-controlled feature. A valid feature license must be installed prior to configuring this feature. Contact your Cisco account representative for more information.

This feature implements a generic framework that can be used by multiple interfaces and products for rate-limiting/throttling outgoing messages like Diameter messages on Gx, Gy interface towards PCRF. When applications send messages to peers at a high rate, (e.g. when a large number of sessions goes down at the same time, accounting stop messages for all the sessions are generated at the same time) the peer may not be able to handle the messages at such high rates. To overcome this situation, the Rate Limiting Function (RLF) framework is developed so that the application sends messages at an optimal rate such that peer is capable of receiving all the messages and does not enter an overload condition.
When RLF feature is enabled, all the messages from the application are pushed to the RLF module for throttling and rate control, and depending on the message-rate configured the RLF module sends the messages to the peer. Once the rate or a threshold value is reached, the RLF module notifies the application to slow down or stop sending messages. RLF module also notifies the application when it is capable of accepting more messages to be sent to the peer. RLF module typically uses a Token Bucket Algorithm to achieve rate limiting.

Currently in the deployment of the Diameter applications (Gx, Gy, etc.), many operators make use of “max-outstanding <number>” as a means of achieving some rate-limiting on the outgoing control traffic. With RLF in place, this is no longer required since RLF takes care of rate-limiting in all cases. If RLF is used and max-outstanding is also used, there might be undesirable results.

**Important:** If RLF is being used with an "diameter endpoint", then set the max-outstanding value of the peer to be 255.

To use the template, Diameter or any other applications must be associated with the template. The RLF provides only the framework to perform the rate limiting at the configured Transactions Per Second (TPS). The applications (like Diameter) should perform the configuration specific to each application.

Entering this command results in the following prompt:

```
[context_name]host_name(cfg-rlf-template)#
```

RLF Template Configuration Mode commands are defined in the *RLF Template Configuration Mode Commands* chapter.

**Example**

The following command creates an RLF template named `rlf_1` and enters the RLF Template Configuration mode:

```
rlf-template rlf_1
```
**rohc-profile**

This command allows you to create an RoHC (Robust Header Compression) profile and enter the RoHC Profile Configuration Mode. This mode is used to configure RoHC Compressor and Decompressor parameters. RoHC profiles can then be assigned to specific subscriber sessions when RoHC header compression is configured.

**Product**

HSGW

PDSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

**Syntax**

```
rohc-profile profile-name name [ -noconfirm ] [ common-options | compression-options | decompression-options ]
```

```
no rohc-profile profile-name name
```

---

**common-options**

Configures common parameters for compressor and decompressor.

**compression-options**

Configures ROHC compression options.

**decompression-options**

Configures ROHC decompression options.

**no**

Remove the specified RoHC profile.

**name**

The name of the RoHC profile to create or remove. *name* must be an alphanumeric string of 1 through 63 characters.

**-noconfirm**

Do not prompt for additional verification when executing this command.
Usage

Use this command to enter the RoHC Profile Configuration mode. Entering this command results in the following prompt:

```
[context_name]host(config-rohcprofile-<profile_name>)#
```

RoHC Profile Configuration Mode commands are defined in the RoHC Profile Configuration Mode Commands chapter.

Example

Enter the following command to create an RoHC profile named HomeUsers and enter the RoHC Configuration mode without prompting for verification:

```
rohc-profile profile-name HomeUsers
```

The following command removes the RoHC profile named HomeUsers:

```
no rohc-profile profile-name HomeUsers
```
**sccp-network**

This command creates or removes a Signaling Connection Control Part (SCCP) network instance which is used to define the SS7 end-to-end routing in a UMTS network. As well, this command enters the SCCP network configuration mode. The SGSN supports up to 12 SCCP network instances at one time.

**Product**
SGSN  
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
sccp-network sccp_net_id [ -noconfirm ]
```

```
no sccp-network sccp_net_id
```

- **no**
  Remove the SCCP network configuration with the specified index number from the system configuration.

- **sccp_net_id**
  This number identifies a specific SCCP network configuration.

  - **sccp_net_id**: must be an integer from 1 through 12.

- **-noconfirm**
  Indicates that the command is to execute without any additional prompt and confirmation from the user.

**Usage**

Use this command to create or modify an SCCP network and enter the SCCP network configuration mode. The SCCP network is not a standard SS7 or UMTS concept - this concept is specific to this platform. For details about the commands and parameters needed to create and edit the SCCP Network configuration, check the **SCCP Network Configuration Mode** chapter.

**Example**

The following command creates an SCCP network with the index number of 1:

```
sccp-network 1
```

The following command creates an SCCP network with the index number of 2 to associate with HNB-GW service for HNB access network users without any prompt:
sccp-network 2 -noconfirm
sctp-param-template

This command allows you to create an SCTP parameter template and enter the SCTP Parameter Template Configuration Mode. This mode is used to configure parameters for SCTP associations.

**Product**
MME

**Privilege**
Administrator

**Mode**
Exec > Global Configuration
   *configure*
Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
[ no ] sctp-param-template name
```

- **no**
  Removes the specified SCTP parameter template from the system.

- **name**
  Specifies the name of the SCTP parameter template being created or accessed. *name* must be an alphanumeric string of 1 through 63 characters.

**Usage**
Use this command to enter the SCTP Parameter Template Configuration mode.
Entering this command results in the following prompt:

```
[context_name] host(sctp-param-template) #
```

SCTP Parameter Template Configuration Mode commands are defined in the *SCTP Parameter Template Configuration Mode Commands* chapter.

**Example**
The following command creates a new SCTP parameter template or enters an existing template named *sctp-tmpl2*:

```
sctp-param-template sctp-tmpl2
```
**session trace**

This command configures the type of network elements, file transfer protocol, and Trace collection entity mode to be used for the transportation of trace files collected for the subscriber session tracing on the UMTS/EPC network element(s) along with network connection parameters and timers.

**Product**
- GGSN
- MME
- P-GW
- SAEGW
- S-GW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```plaintext
session trace network-element { all | mme | pgw | sgw | ggsn | saegw } [ collection-timer sec ] [ file-type { a-type | b-type } ] [ tce-mode { none | push transport sftp path string username name { encrypted password enc_pw | password password } } ]
```

**no session trace network-element { all | mme | pgw | sgw | ggsn saegw }

**no**

Removes the entire session trace configuration from the system or a specific network element trace configuration.

**Important:** To modify the session trace network-element configuration, you must first enter the `no session trace network-element` form of the command to remove the session trace configuration and then enter an entirely new configuration.

```plaintext
network-element { all | mme | pgw | sgw | ggsn saegw }
```

Identifies the type of service to the session trace application in order to determine the applicable interfaces.
- **all:** Specifies that all network elements and their associated interfaces are to be made available to the session trace application.
- **ggsn:** Specifies that the GGSN and its associated interfaces is to be made available to the session trace application.
- **mme:** Specifies that the MME and its associated interfaces is to be made available to the session trace application.
pgw: Specifies that the P-GW and its associated interfaces is to be made available to the session trace application.

sgw: Specifies that the S-GW and its associated interfaces is to be made available to the session trace application.

saegw: Specifies that the SAEGW and its associated interfaces is to be made available to the session trace application.

collection-timer sec

Specifies the amount of time (in seconds) to wait from initial activation/data collection before data is reported to the Trace Collection Entity (TCE). sec must be an integer from 0 through 255.

tce-mode none

Specifies that session trace files are to be stored locally and must be pulled by the TCE.

tce-mode push transport sftp path string username name { encrypted password enc_pw | password password }

Specifies that session trace files are to be pushed to the Trace Collection Entity (TCE).
sftp: Specifies that Secure FTP is used to push session trace files to the TCE.
path string: Specifies the directory path on the TCE where files will be placed.
username name: Specifies the username to be used when pushing files to the TCE.
encrypted password enc_pw: Specifies the encrypted password to be used when pushing files to the TCE.
password password: Specifies the password to be used when pushing files to the TCE.

Usage

Use this command to configure the file transfer methods and modes for subscriber session trace functionality and to how and where session trace files are sent after collection. This configuration contains collection timer, UMTS/EPC network element, type of file transfer, and user credentials setting to send the collected trace files to the TCE.

Example

The following command configures the collection time for session traces to 30 seconds, identifies the network element as all elements (GGSN, MME, S-GW, SAEGW, and P-GW), and pushes session trace files to a TCE via SFTP into a directory named /trace/agw using a username admin and a password of pw123:

```
session trace network-element all collection-timer 30 tce-mode push transport sftp path /trace/agw username admin password pw123
```

The following command configures the collection time for session traces to 30 seconds, identifies the network element as an MME, and pushes session trace files to a TCE via SFTP into a directory named /trace/sgw using a username admin and a password of pw123:

```
session trace network-element mme collection-timer 30 tce-mode push transport sftp path /trace/mme username admin password pw123
```

The following command configures the collection time for session traces to 30 seconds, identifies the network element as GGSN, and pushes session trace files to a TCE via SFTP into a directory named /trace/ggsn using a username admin and a password of pw123:

```
session trace network-element ggsn collection-timer 30 tce-mode push transport sftp path /trace/ggsn username admin password pw123
```
sgsn-global

This command gives access to the SGSN Global configuration mode to set parameters relevant to the SGSN and HNB-GW as a whole.

Product
SGSN
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

sgsn-global

Usage
Using this command moves into SGSN Global Configuration mode. In this mode, you can set system-wide parameters on SGSN and HNB-GW to perform the following tasks:
On SGSN:
• monitoring and managing TLLIs in the BSSGP layer.
• defining IMSI ranges used as filters in the operator policy selection process.
On HNB-GW:
• setting system-wide IPC message aggregation parameters

Example
Enter the SGSN Global configuration mode with the following:

sgsn-global
snmp authentication-failure-trap

Enables or disables the SNMP traps for authentication failures.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```bash
configure
```
Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
[ no ] snmp authentication-failure-trap
```

---

**no**

Disables SNMP traps for authentication failures. When omitted, SNMP traps for authentication failures will be generated.

---

**Usage**

Disables authentication failure traps if they are not of interest. At this time the option may be changed to support trouble shooting.

By default SNMP authentication failure traps are disabled.
**snmp community**

Configures the SNMP v1 and v2 community strings.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

In StarOS 12.3 and later releases:

```
snmp community [ encrypted ] name string [ context context_name | read-only | read-write | view view_name ]
```

```
no snmp community [ encrypted ] name string
```

In StarOS 12.2:

```
snmp community [ encrypted ] name string | read-only | read-write ]
```

```
no snmp community [ encrypted ] name string
```

In StarOS 12.1 and earlier releases:

```
snmp community string [ read-only | read-write ]
```

```
no snmp community string
```

**no**

The specified community string is removed from the configuration.

**encrypted**

Specifies the use of an encrypted string when entering the community name. Without the encrypted option, the plain-text community name must be provided.

**name string**

Specifies a community string whose options are to be modified. An unencrypted string must be an alphanumeric string of 1 through 31 characters. An encrypted string is an alphanumeric string of 1 through 80 characters.
context context_name
Default: community string applies to all contexts.
Specifies a the context to which the community string shall be applied. context_name must be an alphanumeric string of 1 through 31 characters.

read-only | read-write
Default: read-only
Specifies if access rights for the community string.
read-only: the configuration may only be viewed.
read-write: the configuration may be viewed and edited.

view view_name
Default: community string applies to all views.
Specifies the view to which the community string shall be applied. view_name must be an alphanumeric string of 1 through 31 characters.

Usage
The community strings define the privileges of SNMP users. It may be desirable to give read-only access to front line operators.

Example

snmp community name plain_text_string
snmp community encrypted name encrypted_string
snmp community name plain_text_string context sampleContext
snmp community name plain_text_string context sampleContext view sampleView
snmp community name plain_text_string read-write view sampleView
no snmp community plain_text_string
snmp discard-snmpv3-pdu

Configures the system to discard all SNMPv3 protocol data units (PDUs) received.

**Product**
All

**Privilege**
Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
snmp discard-snmpv3-pdu

no snmp discard-snmpv3-pdu
```

**Usage**

Use this command to configure the system to discard all SNMPv3 messages received. By default, the system processes SNMPv3 PDUs.

**Example**

The following command configures the system to discard all SNMPv3 messages received.

```
snmp discard-snmpv3-pdu arg1
```
**snmp engine-id**

Configures the SNMP engine to use for SNMP requests when SNMPv3 agents are utilized.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
snmp engine-id local id
```

- **id**

  Specifies the SNMPv3 engine to employ. *id* must be an alphanumerical string of 1 through 31 characters.

**Usage**

When SNMPv3 is used for SNMP access to the chassis the engine ID can be used to quickly change which schema is used for SNMP access.

**Important:** The system can send either SNMPv1, SNMPv2c, or SNMPv3 traps to numerous target devices. However, the Web Element Manager can only process SNMP version 1 (SNMPv1) and SNMP version 2c (SNMPv2c) traps. If the SNMP target being configured is Web Element Manager application, then you must not configure this command to use.

**Example**

```
snmp engine-id local id
```
snmp heartbeat

Enables the sending of periodic “heartbeat” notifications (traps).

Product
All

Privilege
Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
snmp heartbeat { interval [ minutes ] | second-interval [ seconds ] }
[ default | no ] snmp heartbeat
```

- **default**
  Returns the command to its default setting of disabled.

- **no**
  Disables the feature.

- **interval [ minutes ]**
  Default: 60
  Specifies the interval time (in minutes) between notifications. minutes must be an integer from 1 through 1440.

- **second-interval [ seconds ]**
  Default: 30
  Specifies the secondary interval time, in seconds, between notifications. seconds must be an integer from 10 through 50.

Usage

Use this command to enable the sending of a heartbeat notification periodically to confirm a system is up and communicating.

Example

The following command sets the SNMP heartbeat notification interval to 2 hours, 15 minutes and 30 seconds:

```
snmp heartbeat interval 135 second-interval 30
```
**snmp history heartbeat**

Enables the recording of heartbeat notifications in SNMP history.

**Product**
All

**Privilege**
Administrator

**Mode**
Exec > Global Configuration
  - `configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
[ default | no ] snmp history heartbeat
```

- **default**
  Returns the command to the default setting of enabled.

- **no**
  Disables the history recording feature.

**Usage**

Use this command to enable the recording of SNMP heartbeat notifications in SNMP history files.
**snmp mib**

Enables or disables a specified SNMP Management Information Base (MIB).

**Product**
All

**Privilege**
Administrator

**Mode**
Exec > Global Configuration

**Syntax**
```
[ no ] snmp mib mib_name
```

*no*
Disables the specified MIB.

*mib_name*
 Specifies a MIB by its name. You can find the currently supported MIBs by running the Exec mode `show snmp server` command. Enter the MIB name as a text string exactly as displayed under “SNMP Agent Mib Configuration”. By default the STARENT-MIB is enabled.

**Usage**

Use this command to enable or disable system support for an SNMP MIB.

**Example**
The following command enables the SNMP MIB entitled “CISCO-MOBILE-WIRELESS-SERVICE-MIB”.

```
snmp mib CISCO-MOBILE-WIRELESS-SERVICE-MIB
```
**snmp notif-threshold**

Configures the number of SNMP notification that need to be generated for a given event before it is propagated to the SNMP users.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
*configure*

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
snmp notif-threshold count [ low low_count ] [ period seconds ]
```

```
no snmp notif-threshold
```

- **count**
  - Default: 100
  - The traps creation rate will be monitored periodically (as configured by the period field). If the number of traps created over one period cycle exceeds the count value configured, then the trap creation will be disabled. count must be an integer from 1 through 10000.

- **low low_count**
  - Default: 20
  - The traps creation rate will be monitored periodically (as configured by the period field). The trap creation will be enabled again only if the number of trap creation drops below the low_count value configured. Otherwise, trap creation remains disabled. low_count must be an integer from 1 through 10000.

- **period seconds**
  - Default: 300
  - Specifies the number of seconds of the monitoring window size before any subsequent notification may be broadcast to users. seconds must be an integer from 10 through 3600.

**Usage**

Set the notification threshold to avoid a flood of events which may be the result of a single failure or maintenance activity.

**Example**
snmp notif-threshold 100

snmp notif-threshold 100 period 30
snmp server

 Enables the SNMP server as well the configuration of the SNMP server port.

 **Product**
 All

 **Privilege**
 Security Administrator, Administrator

 **Mode**
 Exec > Global Configuration

 configure
 Entering the above command sequence results in the following prompt:

 [local]host_name(config)#

 **Syntax**

 snmp server [ port number ]

 no snmp server

  no
  Restores the default SNMP port assignment.

  port number
  Default: 161
  Specifies the port number to use for SNMP communications. *number* must be an integer from 1 to 65535.

 **Usage**
 Set the SNMP port for communications when SNMP is enabled.

 **Important:** This will result in restarting the SNMP agent when the **no** keyword is omitted. SNMP queries as well as notifications/traps will be blocked until the agent has restarted.

 **Example**

 snmp server port 100

 no snmp server
snmp target

Configures remote receivers for SNMP notifications.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
snmp target name ip_address [ port number ] [ non-default ] [ security-name string ] [ version { 1 | 2c | 3 | view } [ security-level { noauth | { auth | priv-auth privacy [ encrypted ] des privpassword } authentication [ encrypted ] { md5 | sha } authpassword } } [ informs | traps ]
```

```
no snmp target name
```

- **no**
  Removes the specified target as a receiver of unsolicited SNMP messages (traps).

- **authentication** { md5 | sha } authpassword
  Reads the authentication type and password if the security level of the SNMP messages is set to auth or priv-auth. Authentication types are:
  - **md5**: Configures the hash-algorithm to implement MD5 per RFC 1321.
  - **sha**: Specifies that the hash protocol is Secure Hash Algorithm.

- **security-level** { noauth | { auth | priv-auth privacy [ encrypted ] des privpassword } }
  Sets the security level of the SNMPv3 messages, as follows:
  - **noauth**: No authentication and encryption is used.
  - **auth**: Only authentication will be used.
  - **priv-auth**: Both authentication and encryption will be used.
  - **privacy des privpassword**: Reads the privacy type and password.

- **name**
  Specifies a logical name to use to refer to the remote receiver. *name* must be an alphanumeric string of 1 through 31 characters.
**ip_address**

Specifies the IP address of the receiver. *ip_address* must be specified using IPv4 dotted-decimal notation.

**non-default**

Specifies that this destination is only used for SNMP traps which have been specifically identified.

**port number**

Default: 162

Specifies the port which is to be used in communicating with the remote receivers. *number* must be an integer from 0 through 65535.

**security-name string**

Default: no community string included

Specifies the community string to use in the unsolicited messages. *string* must be an alphanumeric string of 1 through 31 characters.

**version { 1 | 2c | 3 } | view**

Default: 1

Specifies the SNMP version the target supports and consequently the version of the SNMP protocol to use for communications.

**Important:** The system can send either SNMPv1, SNMPv2c, or SNMPv3 traps to numerous target devices. However, the Web Element Manager can only process SNMP version 1 (SNMPv1) and SNMP version 2c (SNMPv2c) traps. If the SNMP target being configured is Web Element Manager application, then you must configure this command to use version 1 or version 2c.

**informs | traps**

Default: traps

Specifies the type of SNMP event to use to send notifications to SNPM targets. *traps* are unacknowledged (fire and forget) whereas *informs* require a response from the SNMP target.

If the notification type is set to *informs*, the notification is resent if no response is received within 5 seconds. The notification is resent at most two times.

**Usage**

The target manages the list of remote receivers to which unsolicited messages are sent. Use this command to add/remove a monitoring system to/from a network.

**Example**

```
snmp target sampleReceiver 1.2.3.4 security-name sampleComm

snmp target sampleReceiver 1.2.5.6 port 100

snmp target sampleReceiver 1.2.7.8 version 2c traps

no snmp target sampleReceiver
```
**snmp trap**

This command enables or disables generation of specific or all SNMP traps.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
snmp trap { enable | suppress } [ trap_name1 trap_name2 ... trap_nameN | all ]
```

<table>
<thead>
<tr>
<th>enable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enables or allows the generation of one or more SNMP traps by the system.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>suppress</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disables the generation of one or more SNMP traps by the system.</td>
</tr>
</tbody>
</table>

```
trap_name1 trap_name2 ... trap_nameN
```

The name of the specific SNMP trap to enable or disable. Multiple traps can be listed for a single instance of this command.

**Important:** The system disregards character case (case insensitive) when entering trap names.

```
all
```

Default: Enable All

Specifies that all SNMP traps will be affected by the specified operation (enable or suppress).

**Usage**

SNMP traps are used by the system to indicate that certain events have occurred. A complete listing of the traps supported by the system and their descriptions can be found in the *SNMP MIB Reference*. Additionally, a trap listing can be viewed using the following command:

```
snmp trap { enable | suppress } ?
```

By default, the system enables the generation of all traps. However, individual traps can be disabled allowing only traps of a certain type or alarm level to be generated. This command can be used to disable un-desired traps and/or re-enable previously suppressed traps.

**Example**

The following command suppresses the LogMessage trap:
snmp trap suppress logmessage

The following command suppresses the CLISessEnd and CLISessStart:

```
snmp trap suppress clisessend clisessstart
```
snmp trap-timestamps

Adds an additional system-time varbind to generated traps.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

[ no ] snmp trap-timestamps

  no

  Disables the adding of timestamps to generated traps.

Usage

The timestamp added to the generated trap reflects the current system time. The timestamp is proprietary. This functionality is disabled by default.

Important: If the Web Element Manager application is used as your alarm server, the application relies on the timestamp provided by enabling this command to identify duplicate traps. As a result, it is recommended that this parameter be enabled for this case.

Example

The following command enables the inclusion of a timestamp with each generated trap:

    snmp trap-timestamps
snmp user

Configures an SNMPv3 user for SNMP access.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
snmp user user_name [ [ encrypted ] password password ] | engine id | group grp_name | security-model model auth [ [ encrypted ] password password ] ]

no snmp user user_name
```

**no snmp user user_name**

Removes the specified user from the list of valid SNMPv3 users.

**user_name**

Specifies the user which is to use SNMPv3 interfaces to the system. *user_name* must be an alphanumeric string of 1 through 31 characters.

**engine id**

The SNMP engine ID. *id* must be an alphanumeric string of 1 through 31 characters.

**group grp_name**

Default: undefined (not a member of any group)

Specifies the user SNMPv3 group the into which user will be added. *grp_name* must be an alphanumeric string of 1 to 1023 characters.

**security-model model auth**

Default: USM

Specifies the security model used to authenticate the user. *model* must be configured to the following:

- usm: User Security Model

**[ encrypted ] password password**

Default: undefined

Specifies the password for authenticating the user when the security model is set to User-based Security Model (USM).
The encrypted keyword indicates the password will be received in an encrypted form. password must be an alphanumeric string of 8 through 31 characters.
The encrypted keyword is intended only for use by the chassis while saving configuration scripts. The system displays the encrypted keyword in the configuration file as a flag that the variable following the password keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file.

Usage
Add and remove SNMPv3 users as operations staff or automated systems are updated. The security model will be user dependant based upon the support the user's system provides.

Important: The system can send either SNMPv1, SNMPv2c, or SNMPv3 traps to numerous target devices. However, the Web Element Manager can only process SNMP version 1 (SNMPv1) and SNMP version 2c (SNMPv2c) traps. If the SNMP target being configured is the Web Element Manager application, then you must not configure this command to use.

Example

```
snmp user user1
snmp user user1 security-model 2c auth
snmp user user1 group user1 group sampleGroup security-model usm auth
no snmp user user1
```
ss7-routing-domain

This command creates an SS7 routing domain instance and enters the SS7 Routing Domain Configuration mode.

**Product**

SGSN
HNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
ss7-routing-domain rd_id variant v_type [ -noconfirm ]
no ss7-routing-domain rd_id
```

**no**

Removes the specified SS7 routing domain from the system configuration.

**rd_id**

Identifies a specific SS7 routing domain. Once it has been created, it can be accessed for further configuration and modification by entering the `rd_id` without entering the variant.

`rd_id` must be an integer from 1 through 12.

**variant v_type**

Identifies the national standard to be used for call setup, routing and control, signaling. Select one of the following:

- **ansi**: American National Standards Institute (U.S.A.)
- **bici**: Broadband Intercarrier Interface standard
- **china**: Chinese standard
- **itu**: International Telecommunication Union (ITU-T) Telecommunication Standardization Sector
- **ntt**: Japanese standard
- **ttc**: Japanese standard

**-noconfirm**

Indicates that the command is to execute without any additional prompt and confirmation from the user.
Usage

Use this command to create an SS7 routing domain configuration instance or to enter the SS7 routing domain configuration mode to edit the configuration.

A routing domain groups configuration items to facilitate the management of the SS7 connection resources for an SGSN service. An Access Gateway supports up to 12 configured SS7 routing domains at one time.

After entering this command, the prompt appears as:

[context_name]<hostname>(config-ss7-routing-domain-routing_domain_id)#

For details about the commands and parameters used to define or edit an SS7 routing domain, refer SS7 Routing Domain Configuration Mode chapter.

Example

The following creates an SS7 routing domain with an index of 1 and the variant selection of Broadcast Intercarrier Interface (bici):

```
ss7-routing-domain 1 variant bici
```

The following command creates an SS7 routing domain instance with an index of 2 and the variant selection of Broadcast Intercarrier Interface (bici) to be associated with HNB RN-PLMN in an HNB access network:

```
ss7-routing-domain 2 variant bici
```
statistics-backup-interval

This command defines the time between backups of the service’s key KPI statistics.

Product
MME
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

statistics-backup-interval minutes

no statistics-backup-interval

no

Disables the interval configuration.

minutes

Enter an integer from 1 to 60 to define the number of minutes for the interval between each backup.

Usage

This interval should only be defined after the statistics-backup command has been entered to configure the MME or SGSN to enable backup of statistics. For details on the feature, refer to the Backup and Recovery of Key KPI Statistics feature chapter in either the MME Administration Guide or the SGSN Administration Guide.

Example

Set the interval between backups to 30 minutes with the following command:

statistics-backup-interval 30
support collection

Modifies and/or enables the Support Data Collector (SDC) process. If record collection has been previously disabled, this command enables the collection activity. If the record collection is currently enabled, this command may be used to modify the sleep-duration interval and/or the maximum number of Support Data Records (SDRs) that can be collected and stored.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

support collection sleep-duration { hours | minutes } value max-records number_records

no support collection

default support collection

---

no

Removes the settings for support collection and effectively disables the SDC.

---

default

Resets the sleep duration and maximum number of records to their default values.

---

support collection

Enables the SDC.

---

sleep-duration { hours | minutes } value

Specifies the hours and/or minutes between record collection activity. value must be an integer from 1 through 1000. The default setting is one hour (60 minutes).

---

**Important:** The period between SDRs is equal to the configured sleep-duration interval + the time taken to collect the previous record.

---

max-records number_records

Specifies the maximum number of records to maintain within the record collection. number_records must be an integer from 1 through 1000. When this value is exceeded, a new SDR overwrites the oldest SDR. Default is 168.
**Usage**

Use this command to control the amount of support information that is collected by the Support Data Collector. Increasing the sleep interval for data collection and reducing the number of records to be collected frees system resources for processing calls and storing other data records. For additional information, refer to the *System Administration Guide*.

**Example**

The following command sets the collection sleep interval to 30 minutes with a maximum of 100 records being stored:

```
support collection sleep-duration minutes 30 max-records 100
```
support record

Specifies the `show` commands that will be collected and output by the Support Data Collector (SDC) process in the specified record section(s). The order in which the record section commands are specified defines the order in which the collected support data record sections are saved.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
support record section section_name command "command_string" [ section section_name command "command_string" ] ...

do support record { all | section section_name }

default support record section { all | section section_name }
```

- `no support record { all | section section_name }`
  Removes the specified record section or all sections from the output of the SDC. This effectively disables the support data collector mechanism.

- `default support record section { all | section section_name }`
  Resets all support record sections or the specified section to the default command listing.

- `section section_name`
  Identifies the record section as an alphanumeric string of 1 through 64 characters.

- `command "command_string"`
  Identifies a CLI `show` command to be included in the record section as an alphanumeric string of 1 through 256 characters enclosed in double quotation marks.

---

**Important:** Refer to the *System Administration Guide* for a comprehensive list of command strings that can be entered via this keyword.

You can add command strings to the record section by repeating the `section section_name command "command_string"` keywords.
Usage

Use this command to tune the output of the Support Data Collector to meet specific site requirements. Refer to the System Administration Guide for a complete description of the SDC feature.

**Important:** If the support record section command is not explicitly configured by the user, a default set of record section commands are used. These default record section commands are displayed when you run the show configuration verbose command. If support record section commands are explicitly configured, they replace the default commands.

Example

The following command creates a record section named show_ip_vrf containing the CLI command show ip vrf:

```
support record section vrf command "show ip vrf"
```
suspend local-user

Suspends a local-user administrative account.

Product
All

Privilege
Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

[ no ] suspend local-user name

no
Removes the suspended status for the specified local-user account.

name
The name of the local-user account expressed as an alphanumeric string of 3 through 16 characters that is case sensitive.

Usage

This command allows a security administrator to suspend local-user administrative accounts. A “suspended” user cannot login to the system. The user’s account information (passwords, password history, etc.), however, is preserved.

Example

The following command suspends a local-user account called Inspector1:

    suspend local-user Inspector1

The following command removes the suspension from a local-user account called Admin300:

    no suspend local-user Admin300
**system**

Configures system information which is accessible via SNMP.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
system { carrier-id mcc mcc_id mnc mnc_id | contact who | description string | hostname host_name | location text | serial-number ser_number | sysdesc-sysoid-style [ default | new ] }

default system { contact | location }

default
```

Removes the configured `system contact` and `system location` form the system.

```
carrier-id mcc mcc_id mnc mnc_id
```

**Important:** This carrier ID is not used by the GGSN.

Specifies a carrier-id that is a unique identifier for the carrier that has installed the system. When the carrier ID values are set, the carrier-id and gmt_offset attributes are included in access-request and accounting packets when using the following RADIUS dictionaries:

- 3gpp2
- 3gpp2-835
- starent
- starent-835
- starent-vsa1
- starent-vsa1-835
- custom9

**mcc mcc_id:** The mobile country code. This must be specified as a 3-digit string from 001 through 999.

**mnc mnc_id:** The mobile network code. This must be specified as a 2- or 3-digit string from 01 through 999.

```
contact who
```

Default: No contact specified.
contact who: specifies the contact information for the chassis. who must be an alphanumeric string of 0 through 255 characters. The string must be embedded in double quotes () if spaces and special punctuation is to be used.

description string

Allows a user to describe the system for identification purposes. The system description can be comprised of a mix of alphanumeric characters, as follows:

- %version% - software version.
- %build% - software build number
- %chassis% - chassis type (ST16, ASR 5000, or ASR 5500)
- %staros% - OS type
- %hostname% - system name
- %release% - release number
- %kerver% - kernel version
- %machine% - machine hardware name
- string - an alphanumeric string of 1 through 255 characters.

hostname host_name

hostname host_name: configures the chassis host name where host_name must be an alphanumeric string of 1 through 63 characters.

Important: Please note that changing the chassis host name results in the command prompt changing as well to reflect the new name. This may affect any previously scripted interfaces from an OSS or maintenance facility.

location text

Default: No location specified.

location text: specifies the system location expressed as an alphanumeric string of 0 through 255 characters. The text specified must be embedded in double quotes (") if spaces are to be used.

serial-number ser_number

Default: None.

Specifies a system identifier as an alphanumeric string of 1 through 11 characters.

sysdesc-sysoid-style [ default | new ]

Allows the user to select the SNMP return for the objects sysDescr and sysOid.

- default - SNMP returns old style system description and old style system OID string.
- new - SNMP returns Cisco style system description and Cisco style OID string.

Usage

Specify system basic information which is useful back at a network operations center which uses the SNMP interfaces for management.

Example
The following commands configure the contact information, system host name, and location text, or remove configured location and system respectively.

```
  system contact user1@company.com
  system hostname system16
  system location "Clark Street Closet\nBasement Rack 4"
```

The following commands remove the configured contact and location from system respectively

```
  default system contact
  default system location
```
Chapter 142
Global Configuration Mode Commands (T-threshold phspc)

This section includes the commands `tacacs mode` through `threshold phspc-sm-entry-denial`.
The Global Configuration Mode is used to configure basic system-wide parameters.

Mode

Exec > Global Configuration
`configure`

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
tacacs mode

Enters the TACACS+ (Terminal Access Controller Access Control System+) configuration mode. Use this mode to configure up to three TACACS+ servers for use in authenticating administrative users via the TACACS+ protocol.

Product
- All

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration
  - configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

tacacs mode

Usage
Enter TACACS Configuration Mode to configure up to three TACACS+ servers for use in authenticating administrative users via the TACACS+ protocol. For additional information, see the TACACS+ Configuration Mode Commands chapter.

Example
Use the following command to enter TACACS mode:

  tacacs mode
task facility acsmgr

This command configures ACSMgr task settings.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

task facility acsmgr start [ aggressive | normal ]

no task facility acsmgr start

Usage
This command provides option for the resource subsystem to start maximum possible ACSMgr tasks based on the license configured and the available system configuration.

Example
The following command starts the maximum possible ACSMgr tasks:

    task facility acsmgr start aggressive
task facility imsimgr

This command is used to configure the IMSI Manager parameters.

Product
SGSN
MME

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
task facility imsimgr { avoid-sessmgr-broadcast | required-sessmgr no_sess_mgrs |
sessmgr-sessions-threshold high-watermark <high_value> low-watermark <low_value> }

no task facility imsimgr [ avoid-sessmgr-broadcast | required-sessmgr ]

default task facility imsimgr sessmgr-sessions-threshold
```

**no**

Disables the selected parameter’s functionality in the configuration.

**default**

This prefix is only used with the `sessmgr-sessions-threshold` parameter. By default, the threshold levels are set to the maximum allowed sessions per Session Manager based on the card type. Both high and low watermarks are set to “100”% by default to ensure backward compatibility.

**avoid-sessmgr-broadcast**

This keyword configures the IMSIMgr to avoid or disable broadcast requests to all SessMgrs when the IMSIMgr finds a particular IMSI is unknown. With this keyword, broadcasting can be disabled ‘on the fly’ if CPU usage is too high due to a large number of broadcast messages.

By default, broadcasting is enabled.

**required-sessmgr**

SGSN only.

This keyword configures the required number of Session Manager instances at the IMSI Manager. By default, this parameter is disabled to ensure backward compatibility.

`no_sess_mgrs`: The number of required Session Managers can be an integer value from “1” through “384”.

Global Configuration Mode Commands (T-threshold phspc)

**sessmgr-sessions-threshold**

This option is used to configure the threshold high and low watermarks, in terms of percentage, for the sessions per Session Manager. The actual session limits are derived based on the card type.

- **high-watermark** `high_value`: The high-watermark value can be a percentage value from “70” through “100”. The default percentage value is “100”.
- **low-watermark** `low_value`: The low-watermark value can be a percentage value from “50” through “100”. The default percentage value is “100”.

**Usage**

For the MME:

Typically, the `avoid-sessmgr-broadcast` and `sessmgr-sessions-threshold` keywords are available for configuration but not used.

For the SGSN:

This command configures the number of Session Manager instances required at the IMSI Manager before forwarding any calls from the Gb Manager or Link Manager, as well, it configures the high watermark and low watermark threshold levels per Session Manager.

If the required number of Session Managers are configured through this command, once the Link Manager or Gb Manager comes up, it sends a query to the IMSI Manager to verify if the IMSI Manager has learnt the configured number of Session Manager instances. IMSI Manager readiness status is determined based on the number of Session Manager instances present in the list maintained. Once the IMSI Manager has completed learning about all the required number Session Manager instances, it informs the Link Manager and Gb Manager. Runtime enabling and modification of Session Manager instance is disabled except disabling this configuration. Disabling of this configuration does not affect the call forwarding to the IMSI Manager as the default behavior is to always forward the calls to the IMSI Manager. This configuration is used to avoid the session imbalance across Session Manager instances due to call forwarding to the same Session Manager instance during or after re-load, if the IMSI Manager has learnt only few Session Manager instances. By default, this feature is disabled and Gb Manager or Link Manager start forwarding calls immediately during or after re-load to the IMSI Manager which in turn forwards the request to the available Session Manager instances. It is recommended to have this configuration before re-load. This option is available only under a SGSN license.

The high and low watermark limits allow the IMSI Manager to decide and select the Session Manager for processing new calls and eliminate the chances of it receiving a “call reject” in instances where the Session Manager has reached its maximum allowed session limits and the IMSI Manager is not aware of the same.

The IMSI Manager converts the high and low watermark percentage to the maximum session allowed for the configured percentage based on the card type. It uses the calculated session values for both high and low watermark to decide and select the Session Manager for processing new calls. Once the Session Manager active session count reaches the calculated high watermark sessions the IMSI Manager stops forwarding the new calls to the Session Manager until the active session count becomes less than the calculated low watermark value. This option is available only under SGSN and MME licenses.

**Example**

Use the following command to configure the required session manager count to be learnt by IMSI Manager for processing new calls to “28”:

```
task facility imsimgr required-sessmgr 28
```

Use the following command to configure the threshold for the sessions per Session Manager:

```
task facility imsimgr sessmgr-sessions-threshold high-watermark 95 low-watermark 85
```
task facility ipsecmgr

Configures IPSec manager settings.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
task facility ipsecmgr { ikev1 { task-count { increased | normal } } | task-count { increased | normal } }
```

ikev1 { task-count { increased | normal } }

Default: normal
Adjusts the IPSec manager task count to support EHA for IKEv1. See task-count below.

```
task-count { increased | normal }
```

Default: normal
Adjusts the IPSec manager task count to support EHA.

increased: Starts additional IPSec manager tasks operating on the packet processing cards. In increased mode, they run on all but demux packet processing cards. Also, all the IPSec managers start at the same time when an active non-demux card is detected and IPSec is configured.

normal: Uses the standard algorithm for allocating memory for IPSec manager tasks. In normal mode, IPSec managers do not run on session packet processing cards.

⚠️ Caution: If task-count is set to normal and session recovery is enabled, IPSec manager tasks are not allowed to start on most packet processing cards. Because the resources are not reserved, IPSec managers in normal mode only run on demux packet processing cards.

Usage
Sets IPSec manager parameters for all IPSec managers in the system.

Example
Use the following command to set the IPSec manager task count to increased mode:

```
task facility ipsecmgr task-count increased
```
task facility linkmgr

This command controls the maximum number of Link Managers that can be configured for an SGSN.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator.

**Mode**
Exec > Global Configuration

```configure```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
task facility linkmgr max max_linkmgrs
```

```default```

default task facility linkmgr max

```default```

Resets the value to 4.

```max max_linkmgrs```

Sets the maximum number of LinkMgrs configurable for the SGSN.

`max_linkmgrs` is an integer from 1 to 4. With Release 15.0, the range is from 1 to 12.

**Usage**

By default, 4 LinkMgrs will be started in the system when an SGSN service configuration is present. Use this command to change the maximum number of LinkMgrs to be started in the system.

**Important:** If a change to the default is needed, this command must be used before configuring any SGSN service-related configuration, including SS7 Routing Domain and SCCP Network configurations.

The number of LinkMgrs configurable impacts the following SS7 routing domain components:

- The number of Application Server Process (ASP) instances that can be configured (maximum of 12).
- The number of peer-servers that can be configured across all SS7RDs (maximum of 512).
- The number of peer-servers that can be configured per SS7RD (maximum of 256).
- The number of Peer-Server Process (PSP) instances that can be configured per SS7 Peer (maximum of 12).
**Important:** This command cannot be set dynamically. If the LinkMgr count is modified dynamically, the system must be rebooted for the change to take effect.

**Example**

Change the maximum number of LinkMgrs that can be configured for an SGSN from 4 to 8:

```
task facility linkmgr max 8
```
**task facility mmedemux**

Configures wait-time and percentage parameters related to the MMEDEMUX. The MMEDEMUX distributes the incoming traffic to the associated MMEMGRs based on the percentage value and wait-time configured in this command.

**Product**
MME.

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
task facility mmedemux mmemgr-startup-percentage percent_value [ mmemgr-startup-wait-time wait_time ]
[ default | no ] task facility mmedemux mmemgr-startup-percentage mmemgr-startup-wait-time
```

Either of these command filters disables the operator defined configuration and replaces the configuration with default values.

---

**mmemgr-startup-percentage percent_value**

The percentage parameter allows the operator to configure the percentage of MMEMGRs to be associated with the MMEDEMUX.

*percent_value* must be an integer from 1 to 100. Default is 90%.

---

**mmemgr-startup-wait-time wait_time**

This parameter enables the operator to configure the time (in seconds) that the MMEDEMUX waits for MMEMGRs to start before processing incoming traffic.

*wait_time* must be an integer from 300 to 3600. Default is 600 (10 minutes).

---

**Usage**

This command gives operators some control over the MMEDEMUX system. It allows operators to configure the percentage of MMEMGRs to be associated with the MMEDEMUX. It also assigns the waiting time before processing the incoming traffic. Incoming traffic is distributed to the MMEMGRs based on a combination of the configured values of the two parameters.

By default, the MME waits for ten minutes to check if 90% of the MMEMGRs have started.

---

**Example**

...
The following configures the MMEDEMUX to distribute incoming traffic after a minimum of 5 minutes after the MME starts and as soon as 75% of the MMEMGRs are up and running:

```
task facility mmedemux mmemgr-startup-percentage 75 mmemgr-startup-wait-time 5
```
**task facility sessmgr**

Configures system information which is accessible via SNMP.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```configure```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```task { facility sessmgr start { aggressive | normal }```

---

```facility sessmgr start { aggressive | normal }
Default: Normal
Specifies the facility options for the session manager.
aggressive: specifies the maximum number of session manager processes are started immediately.

---

⚠️ **Caution:** The **task facility sessmgr start aggressive** command should only be used if the system will reach capacity (for the existing configuration) during the first few minutes of service.

⚠️ **Caution:** This command must only be executed last during configuration (or appended to the end of the configuration file) to ensure the availability of memory resources to contexts and services.

**Usage**

Set the session manager start policy to aggressive on heavily utilized systems to avoid undue delays in processing subscriber sessions.

**Example**

```task facility sessmgr start aggressive

task facility sessmgr start normal```
task resource cpu-memory-low

Configures the system action for SNMP trap generation and logging whenever CPU memory.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

**Syntax**

```plaintext
task resource cpu-memory-low { kill | warn }
```

Default: kill

Sets the action for the Resource Manager to take when the amount of free memory on a CPU falls below 12MB. An SNMP TRAP and CORBA notification are generated and the event is logged. Once the free memory threshold is crossed, The Resource Manager examines all tasks on that cpu and finds the most over limit task and kills it. If there are no over limit tasks nothing happens. Resource Manager takes preference on killing a non-sessmgr task over a sessmgr task.

**Example**

Set the CPU memory low action to only log CPU low memory events.

```plaintext
task resource cpu-memory-low warn
```
**tech-support test-commands password**

Configures the password that protects access to the `cli test-commands` mode in the Exec mode and Global Configuration mode. This command is only visible to a user logged in as a Security Administrator.

**Product**
All

**Privilege**
Security Administrator

**Caution:** The `cli test-commands` are for use by or under the supervision of Cisco TAC.

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
tech-support test-commands [encrypted] password password

no tech-support test-commands password
```

- **no**
  Disables the use of a test-commands password. All subsequent attempts to execute `cli test-commands` in Exec or Global Configuration modes will fail.
  Default: no password, access disabled

- **[encrypted]**
  If this optional keyword is specified, the `<password>` argument is interpreted as an encrypted string containing the password value. If the encrypted keyword is not specified, then the `<password>` argument is interpreted as the actual plain text value. In the output of `show configuration` and `save configuration` commands, only the encrypted option of this command syntax appears.

- **password**
  Specifies the password to be used when executing the `cli test-commands` command in Exec or Global Configuration modes. For a plain text password, `password` is an alphanumeric string of 1 through 64 characters. For an encrypted password, `password` is an alphanumeric string of 1 through 524 characters.
  If a password is not entered via this command, the `cli test-commands` command remains disabled in the Exec and Global Configuration modes.
  Default: no password, access disabled

**Important:** An SNMP trap is generated when an administrator enters or edits a password via this command (`starTechSupportPasswordChanged`). Refer to the `SNMP MIB Reference` for additional information.
Usage
Sets the password required to execute the `cli test-commands` command in the Exec and Global Configuration mode.

**Important:** Access to the `cli test-commands` command also requires that a Security Administrator or Administrator enabled the Global Configuration mode `cli hidden` command.

Example
The following command sets the password for `cli test-commands` to `testCommander`.

```
tech-support test-commands password testCommander
```
**terminal**

Configures the console port on the SPIO.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
terminal [ carrierdetect { off | on } | databits { 7 | 8 } | flowcontrol { hardware { off | on } | none } | parity { even | none | odd } | speed { 115200 | 19200 | 38400 | 57600 | 9600 } | stopbits { 1 | 2 } ]
```

- **carrierdetect { off | on }**
  Specifies whether or not the console port is to use Data Carrier Detect (DCD) when connecting to a terminal.
  Default: off
  - off: Do not use DCD.
  - on: Use DCD.

- **databits { 7 | 8 }**
  Specifies the number of data bits used to transmit and receive characters.
  Default: 8
  - 7: Use 7 databits to transmit and receive characters.
  - 8: Use 8 databits to transmit and receive characters.

- **flowcontrol { hardware { off | on } | none }**
  Specifies how the flow of data is controlled between the SPIO and a terminal.
  Default: none
  - hardware: Enables or disables the use of hardware-based flow control
  - off: Disables the use of Ready to Send (RTS) and Clear to Send (CTS).
  - on: Enables the use of Ready to Send (RTS) and Clear to Send (CTS).
  - none: Disables the use of DCD, RTS and CTS.

- **parity { even | none | odd }**
  Specifies the type of error checking used on the port.
  Default: none
  - even: Enables error checking by setting the parity bit to 1 (if needed) making the number of 1s in the data bits even.
  - none: Disables error checking.
**odd** - Enables error checking by setting the parity bit to 1 (if needed) making the number of 1s in the data bits odd.

**speed** { 115200 | 19200 | 38400 | 57600 | 9600 }

Specifies the flow of data in bits per second between the console port and terminal.
Default: 9600

**stopbits** { 1 | 2 }

Specifies the number of stop bits between each transmitted character.
Default: 1
1: Use one stop bit between each transmitted character.
2: Use two stop bits between each transmitted character.

**Usage**

Sets the SPIO’s console port parameters for communication with the terminal device.

**Example**

The following command sets the SPIO’s console port. The terminal must support these values.

```
terminal carrierdetect off databits 7 flowcontrol hardware on parity even speed 115200 stopbits 1
```
threshold 10sec-cpu-utilization

Configures alarm or alert thresholds that measure a 10-second average of CPU utilization. Its polling interval can be set down to 30 seconds.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```bash
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold 10sec-cpu-utilization percent [ clear percent ]
```

- **percent**
  Default: 0
  Configures Specifies the high threshold for 10-second average cpu-utilization. If the monitored CPU utilization is greater than or equal to the specified percentage an alert is sent. Regardless of the length of the polling interval, only one sample at the end of the polling interval is tested.

- **clear percent**
  Default: 0
  This is a low watermark value that sets the alarm clearing threshold value. If not specified it is taken from the first value.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to set a threshold that sends an alert when CPU utilization over a 10-second average exceeds the limit set.

Alerts or alarms are triggered for 10-second sample of CPU utilization based on the following rules:

- **Enter condition:** 10-second average percentage of CPU utilization is greater than or equal to the high threshold.
- **Clear condition:** 10-second average percentage of CPU utilization is less than the low threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.
Global Configuration Mode Commands (T-threshold phspc)

threshold 10sec-cpu-utilization

**Important:** This command is not supported on all platforms.

Example

The following command generates an alert when the 10-second average CPU utilization reaches 45 percent:

```
threshold 10sec-cpu-utilization 45
```
threshold aaa-acct-archive-queue-size

Configures AAA accounting archive, alarm or alert thresholds based on the maximum values of session manager and ACS manager archive queue size.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold aaa-acct-archive-queue-size1 percent [ clear percent ]
default threshold aaa-acct-archive-queue-size1 percent [ clear percent ]
threshold aaa-acct-archive-queue-size2 percent [ clear percent ]
default threshold aaa-acct-archive-queue-size2 percent [ clear percent ]
threshold aaa-acct-archive-queue-size3 percent [ clear percent ]
default threshold aaa-acct-archive-queue-size3 percent [ clear percent ]

percent

Configures Specifies the high threshold for monitoring the accounting message archive queue length. If the queue length is greater than or equal to the specified percentage an alarm is sent.
Default value for aaa-acct-archive-queue-size1: 25%
Default value for aaa-acct-archive-queue-size2: 50%
Default value for aaa-acct-archive-queue-size3: 90%

clear percent

This is a low watermark value that sets the alarm clearing threshold value. If not specified it is taken from the first value.
Default value for aaa-acct-archive-queue-size1: 25%
Default value for aaa-acct-archive-queue-size2: 50%
Default value for aaa-acct-archive-queue-size3: 90%

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.
Usage

In the event that the system cannot communicate with configured AAA accounting servers (RADIUS or CGFs), either due to the server being busy or loss of network connectivity, the system buffers, or archives, the accounting messages.

Accounting message archive queue size thresholds generate alerts or alarms based on the queue length of AAA accounting messages buffered in the archive during the specified polling interval. Accounting requests are counted for all AAA accounting servers that the system is configured to communicate with.

Alerts or alarms are triggered for accounting message archive queue size thresholds based on the following rules:

- **Enter condition:** Actual number of archived messages is greater than or equal to the high threshold.
- **Clear condition:** Actual number of archived messages less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

Example

The following command generates an alarm when 70% of the AAA accounting message archive buffer is filled, and clears the alarm when the buffer size is reduced to 30%:

```
threshold aaa-acct-archive-queue-size1 70 clear 30
```
threshold aaa-acct-archive-size

Configures accounting message archive size, alarm or alert thresholds.

**Product**
- PDSN
- GGSN
- HA
- ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
   `configure`

Entering the above command sequence results in the following prompt:
```
[local]host_name(config)#
```

**Syntax**
```
threshold aaa-acct-archive-size high_thresh [ clear low_thresh ]

default threshold aaa-acct-archive-size
```

### high_thresh

Default: 1
Specifies the high threshold number of archived accounting messages that must be met or exceeded within the polling interval to generate an alert or alarm. `high_thresh` is an integer from 0 through 1044000.

### clear low_thresh

Default: 1
Specifies the low threshold number of archived accounting messages that maintains a previously generated alarm condition. If the number of failures falls beneath the low threshold within the polling interval, a clear alarm will be generated. `low_thresh` is an integer from 0 through 1044000.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**
In the event that the system cannot communicate with configured AAA accounting servers (RADIUS or CGFs), either due to the server being busy or loss of network connectivity, the system buffers, or archives, the accounting messages.
Accounting message archive size thresholds generate alerts or alarms based on the number of AAA accounting messages buffered in the archive during the specified polling interval. Accounting requests are counted for all AAA accounting servers that the system is configured to communicate with.
Alerts or alarms are triggered for accounting failures based on the following rules:

- **Enter condition**: Actual number of archived messages that is greater than or equal to the high threshold.

- **Clear condition**: Actual number of archived messages that is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 250 AAA accounting archived messages and low threshold of 100 for a system using the Alarm thresholding model:

```
threshold aaa-acct-archive-size 250 clear 100
```
threshold aaa-acct-failure

Configures accounting failure, alarm or alert thresholds for the system.

Product

- PDSN
- GGSN
- HA
- ASN-GW

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold aaa-acct-failure high_thres [ clear low_thres ]

default threshold aaa-acct-failure

- **high_thres**
  - Default: 0
  - Specifies the high threshold number of accounting failures that must be met or exceeded within the polling interval to generate an alert or alarm. *high_thres* is an integer from 0 through 10000000. A value of 0 disables the threshold.

- **clear low_thres**
  - Default: 0
  - Specifies the low threshold number of accounting failures that maintains a previously generated alarm condition. If the number of failures falls beneath the low threshold within the polling interval, a clear alarm will be generated. *low_thres* is an integer from 0 through 10000000. A value of 0 disables the threshold.

**Important**: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Accounting failure thresholds generate alerts or alarms based on the number of failed AAA accounting message requests that occur during the specified polling interval. Accounting requests are counted for all AAA accounting servers that the system is configured to communicate with. Alerts or alarms are triggered for accounting failures based on the following rules:

- **Enter condition**: Actual number of failures is greater than or equal to the high threshold.
• **Clear condition:** Actual number of failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 100 AAA accounting failures and low threshold of 25 for a system using the Alarm thresholding model:

```
threshold aaa-acct-failure 100 clear 25
```
threshold aaa-acct-failure-rate

Configures accounting failure rate, alarm or alert thresholds for the system.

Product
PDSN
GGSN
HA
ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold aaa-acct-failure-rate high_thresh [ clear low_thresh ]

default threshold aaa-acct-failure-rate

**high_thresh**

Default: 1
Specifies the high threshold percent of accounting failures that must be met or exceeded within the polling interval to generate an alert or alarm. high_thresh is an integer from 0 and 100.

**clear low_thresh**

Default: 1
Specifies the low threshold percent of accounting failures that maintains a previously generated alarm condition. If the percentage of failures falls beneath the low threshold within the polling interval, a clear alarm will be generated. low_thresh is an integer from 0 through 100.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Accounting failure rate thresholds generate alerts or alarms based on the percentage of AAA accounting message requests that failed during the specified polling interval. Accounting requests are counted for all AAA accounting servers that the system is configured to communicate with.

Alerts or alarms are triggered for accounting failure rates based on the following rules:

- **Enter condition:** Actual failure percentage is greater than or equal to the high threshold.
- **Clear condition:** Actual failure percentage is less than the low threshold.
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

Example

The following command configures a AAA accounting failure rate high threshold percentage of `30` and a low threshold percentage of `10` for a system using the Alarm thresholding model:

```
threshold aaa-acct-failure-rate 30 clear 10
```
threshold aaa-auth-failure

Configures authentication failure, alarm or alert thresholds for the system.

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold aaa-auth-failure high_thresh [ clear low_thresh ]

default threshold aaa-auth-failure

<table>
<thead>
<tr>
<th>high_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0</td>
</tr>
<tr>
<td>Specifies the high threshold number of authentication failures that must be met or exceeded within the polling interval to generate an alert or alarm. high_thresh is an integer from 0 through 10000000. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>clear low_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0</td>
</tr>
<tr>
<td>Specifies the low threshold number of authentication failures that maintains a previously generated alarm condition. If the number of failures falls beneath the low threshold within the polling interval, a clear alarm will be generated. low_thresh is an integer from 0 through 10000000. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Authentication failure thresholds generate alerts or alarms based on the number of failed AAA authentication message requests that occur during the specified polling interval. Authentication requests are counted for all AAA authentication servers that the system is configured to communicate with. Alerts or alarms are triggered for authentication failures based on the following rules:
- **Enter condition:** Actual number of failures is greater than or equal to the high threshold.
- **Clear condition:** Actual number of failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 100 AAA authentication failures for a system using the Alert thresholding model:

```
threshold aaa-auth-failure 100
```
threshold aaa-auth-failure-rate

Configures authentication failure rate, alarm or alert thresholds for the system.

Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold aaa-auth-failure-rate high_thresh [ clear low_thresh ]
default threshold aaa-auth-failure-rate

| high_thresh
| Default: 5
| Specifies the high threshold percent of authentication failures that must be met or exceeded within the polling interval to generate an alert or alarm. high_thresh is an integer from 0 through 100.

| clear
| Allows the configuration of Specifies the low threshold.

| low_thresh
| Default: 5
| Specifies the low threshold percent of authentication failures that maintains a previously generated alarm condition. If the percentage of failures falls beneath the low threshold within the polling interval, a clear alarm will be generated. low_thresh is an integer from 0 through 100.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.
Usage

Authentication failure rate thresholds generate alerts or alarms based on the percentage of AAA authentication message requests that failed during the specified polling interval. Authentication requests are counted for all AAA authentication servers that the system is configured to communicate with. Alerts or alarms are triggered for authentication failures based on the following rules:

- **Enter condition**: Actual failure percentage is greater than or equal to the high threshold.
- **Clear condition**: Actual failure percentage is less than the low threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

Example

The following command configures a AAA authentication failure rate high threshold percentage of 30 for a system using the Alert thresholding model:

```
threshold aaa-auth-failure-rate 30
```
threshold aaa-retry-rate

Configures AAA retry rate, alarm or alert thresholds for the system.

Product
PDSN
GGSN
HA
ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold aaa-retry-rate high_thresh [ clear low_thresh ]

default threshold aaa-retry-rate

high_thresh
Default: 5
Specifies the high threshold percent of AAA request message retries that must be met or exceeded within the polling interval to generate an alert or alarm. high_thresh is an integer from 0 through 100.

clear low_thresh
Default: 5
Specifies the low threshold percent of AAA request message retries that maintains a previously generated alarm condition. If the percentage of retries falls beneath the low threshold within the polling interval, a clear alarm will be generated. low_thresh is an integer from 0 through 100.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

AAA request message retry rate thresholds generate alerts or alarms based on the percentage of request messages (both authentication and accounting) that were retried during the specified polling interval. The percentage is based on a message count taken for all AAA authentication and accounting servers that the system is configured to communicate with.
Alerts or alarms are triggered for request message retries based on the following rules:

● Enter condition: Actual retry percentage is greater than or equal to the high threshold.
• **Clear condition:** Actual retry percentage is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a AAA message retry rate high threshold percentage of 25 and a low threshold percentage of 10 for a system using the Alarm thresholding model:

```
threshold aaa-retry-rate 25 clear 10
```
threshold aaamgr-request-queue

Configures the AAA Manager internal request queue, alarm or alert thresholds.

**Product**
- PDSN
- GGSN
- HA
- ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configured

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold aaamgr-request-queue high_thresh [ clear low_thresh ]
```

default threshold aaamgr-request-queue

```
high_thresh
Default: 0
Specifies the high threshold number of AAA Manager Requests that must be met or exceeded within the polling interval to generate an alert or alarm. high_thresh is an integer from 1 through 100.
```

```
clear
Allows the configuration of Specifies the low threshold.
```

```
low_thresh
Default: 5
Specifies the low threshold number of AAA Manager Requests that maintains a previously generated alarm condition. If the percentage of failures falls beneath the low threshold within the polling interval, a clear alarm is generated. low_thresh is an integer from 0 through 100.
```

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

AAA Manager Request thresholds generate alerts or alarms based on the number of AAA Manager Requests for an AAA manager process during the specified polling interval.

Alerts or alarms are triggered for AAA Manager Requests based on the following rules:
- Enter condition: Actual number of AAA Manager Requests per AAA manager is greater than or equal to the high threshold.

- Clear condition: Actual number of AAA Manager Requests per AAA manager process is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm is not generated until the end of the polling interval. Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

Example

The following command configures a AAA authentication failure rate high threshold percentage of 30 for a system using the Alert thresholding model:

```
threshold aaamgr-request-queue 30
```
threshold asngw-auth-failure

Configures authentication failure, alarm or alert thresholds for the ASN-GW system.

Product
ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold asngw-auth-failure high_thresh [ clear low_thresh ]

default threshold asngw-auth-failure

| high_thresh  
| Default: 0  
| Specifies the high threshold number of authentication failures that must be met or exceeded within the polling interval to generate an alert or alarm.  
| *high_thresh* is an integer from 0 through 10000000. A value of 0 disables the threshold. |

| clear low_thresh  
| Default: 0  
| Specifies the low threshold number of authentication failures that maintains a previously generated alarm condition. If the number of failures falls beneath the low threshold within the polling interval, a clear alarm will be generated.  
| *low_thresh* is an integer from 0 through 10000000. A value of 0 disables the threshold. |

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to configure threshold limits to generate alerts or alarms based on the number of failed ASN-GW authentication message requests that occur during the specified polling interval. Authentication requests are counted for all ASN Gateway authentication servers with which the system is configured to communicate. Alerts or alarms are triggered for authentication failures based on the following rules:

- **Enter condition:** Actual number of failures is greater than or equal to the high threshold.
- **Clear condition:** Actual number of failures is less than the low threshold.
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 100 authentication failures for an ASN-GW using the Alert thresholding model:

```
  threshold asngw-auth-failure 100
```
threshold asngw-handoff-denial

Configures alarm or alert thresholds for hand-off denials within the ASN-GW service.

Product
ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```plaintext
threshold asngw-handoff-denial high_thresh [ clear low_thresh ]

default threshold asngw-handoff-denial
```

**high_thresh**

Default: 0
Specifies the high threshold number of hand-off denials that must be met or exceeded within the polling interval to generate an alert or alarm.

*high_thresh* is an integer from 0 through 10000000. A value of 0 disables the threshold.

**clear low_thresh**

Default: 0
Specifies the low threshold number of hand-off denials that maintains a previously generated alarm condition. If the number of hand-off denials falls beneath the low threshold within the polling interval, a clear alarm will be generated.

*low_thresh* is an integer from 0 through 10000000. A value of 0 disables the threshold.

⚠️ Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set threshold limits to generate alerts or alarms based on the number of denied hand-off that occurred during the specified polling interval. Hand-off denial messages are counted for all ASN Gateways that the system is configured to communicate with.

Alerts or alarms are triggered for hand-off denials based on the following rules:

- **Enter condition:** Actual number of failures is greater than or equal to the high threshold.
- **Clear condition:** Actual number of failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

Example

The following command configures a high threshold count of 100 hand-off denials using the Alert thresholding model:

```
threshold asngw-handoff-denial 100
```
**threshold asngw-max-eap-retry**

Configures alarm or alert thresholds for maximum retries for Extensible Authentication Protocol (EAP) authentication within an ASN-GW service.

**Product**
ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold asngw-max-eap-retry high_thresh [ clear low_thresh ]
```

**default threshold asngw-max-eap-retry**

- `high_thresh`
  Default: 0
  Specifies the high threshold number of retries for EAP authentication that must be met or exceeded within the polling interval to generate an alert or alarm.
  `high_thresh` is an integer from 0 through 10000000. A value of 0 disables the threshold.

- `clear low_thresh`
  Default: 0
  Specifies the low threshold number of retries for EAP authentication that maintains a previously generated alarm condition. If the number of retries falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  `low_thresh` is an integer from 0 through 10000000. A value of 0 disables the threshold.

---

**Important**: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

---

**Usage**

Use this command to set threshold limits to generate alerts or alarms based on the number of retries for EAP authentication that occur during the specified polling interval.

Alerts or alarms are triggered for maximum number of retries for EAP authentication based on the following rules:

- **Enter condition**: Actual number of failures is greater than or equal to the high threshold.
- **Clear condition**: Actual number of failures is less than the low threshold.
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 100 alerts or alarms generated on maximum number of retries for EAP authentication for an ASN Gateway using the Alert thresholding model:

```
threshold asngw-max-eap-retry 100
```
threshold asngw-network-entry-denial

Configures alarm or alert thresholds for denials of network entry to an MS within the ASN-GW service.

Product
ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold asngw-network-entry-denial high_thresh [ clear low_thresh ]

default threshold asngw-network-entry-denial

| high_thresh |
| Default: 0 |
| Specifies the high threshold number of denial of network entry to an MS that must be met or exceeded within the polling interval to generate an alert or alarm. high_thresh is an integer from 0 through 10000000. A value of 0 disables the threshold. |

| clear low_thresh |
| Default: 0 |
| Specifies the low threshold number of denial of network entry to an MS that maintains a previously generated alarm condition. If the number of denials falls beneath the low threshold within the polling interval, a clear alarm will be generated. low_thresh is an integer from 0 through 10000000. A value of 0 disables the threshold. |

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set threshold limits to generate alerts or alarms based on the number of network entry denials that occurred during the specified polling interval. Network denial messages are counted for an MS with which the system is configured to communicate. Alerts or alarms are triggered for network entry denials based on the following rules:

- **Enter condition:** Actual number of failures is greater than or equal to the high threshold.
- **Clear condition:** Actual number of failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 100 network entry denials for an MS using the Alert thresholding model:

```
threshold asngw-network-entry-denial 100
```
threshold asngw-session-setup-timeout

Configures alarm or alert thresholds for session setup timeouts in an ASN-GW service.

Product
ASN-GW

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set threshold limits to generate alerts or alarms based on the number of timeouts during session setup that occurred during the specified polling interval.

Alerts or alarms are triggered for session setup timeouts based on the following rules:

- **Enter condition:** Actual number of failures is greater than or equal to the high threshold.
- **Clear condition:** Actual number of failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 100 timeouts during session setup using the Alert thresholding model:

```
threshold asngw-session-setup-timeout 100
```
threshold asngw-session-timeout

Configures alarm or alert thresholds for session timeouts in an ASN-GW service.

Product
ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold asngw-session-timeout high_thresh [ clear low_thresh ]

default threshold asngw-session-timeout

- **high_thresh**
  
  Default: 0
  
  Specifies the high threshold number of timeouts during session that must be met or exceeded within the polling interval to generate an alert or alarm.
  
  **high_thresh** is an integer from 0 through 10000000. A value of 0 disables the threshold.

- **clear low_thresh**
  
  Default: 0
  
  Specifies the low threshold number of timeouts during session that maintains a previously generated alarm condition. If the number of session timeouts falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  
  **low_thresh** is an integer from 0 through 10000000. A value of 0 disables the threshold.

⚠️ **Important**: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set threshold limits to generate alerts or alarms based on the number of timeouts during a session that occurred during the specified polling interval.

Alerts or alarms are triggered for session timeouts based on the following rules:

- **Enter condition**: Actual number of failures is greater than or equal to the high threshold.
- **Clear condition**: Actual number of failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 100 timeouts during a session using the Alert thresholding model:

```
threshold asngw-session-timeout 100
```
threshold asnpc-idle-mode-timeout

Configures alarm or alert thresholds for ASNPC Instant Messenger idle mode timeouts.

**Product**
ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold asnpc-idle-mode-timeout high_thresh [ clear low_thresh ]
```

**high_thresh**
Default: 0
Specifies the high threshold number of ASNPC idle mode timeouts that must be met or exceeded within the polling interval to generate an alert or alarm.

**clear low_thresh**
Default: 0
Specifies the low threshold number of ASNPC idle mode timeouts during session that maintains a previously generated alarm condition. If the number of session timeouts falls beneath the low threshold within the polling interval, a clear alarm will be generated.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**
Set the maximum number of idle mode timeouts allowed in the ASNPC service. Alerts or alarms are triggered for session timeouts based on the following rules:

- **Enter condition:** Actual number of timeouts is greater than or equal to the high threshold.
- **Clear condition:** Actual number of timeouts is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

**Example**
The following command configures the high threshold for ASNPC idle mode timeouts at 10000:

```
threshold asnpc-idle-mode-timeout 10000
```
threshold asnpc-idle-mode-timeout 10000
threshold asnpc-im-entry-denial

Configures the ASNPC Instant Messenger (IM) entry denial, alarm or alert thresholds.

Product
ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:
[local]host_name(config)#

Syntax

```
threshold asnpc-im-entry-denial high_thresh [ clear low_thresh ]
```

- **high_thresh**
  Default: 0
  Specifies the high threshold number of IM entry denials during session that must be met or exceeded within the polling interval to generate an alert or alarm.
  high_thresh is an integer from 0 through 10000000. A value of 0 disables the threshold.

- **clear low_thresh**
  Default: 0
  Specifies the low threshold number of IM entry denials during session that maintains a previously generated alarm condition. If the number of session timeouts falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  low_thresh is an integer from 0 through 10000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Set the maximum number of IM session denials allowed in the ASNPC service. Alerts or alarms are triggered for session timeouts based on the following rules:
- **Enter condition:** Actual number of failures is greater than or equal to the high threshold.
- **Clear condition:** Actual number of failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

Example

The following command configures the high threshold for IM session counts at 10000:

```
threshold asnpc-im-entry-denial 10000
```
threshold asnpc -im -entry -denial 10000
threshold asnpc-lu-denial

Configures the alarm or alert thresholds for Location Update (LU) denials.

Product
ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold asnpc-lu-denial high_thresh [ clear low_thresh ]

- **high_thresh**
  - Default: 0
  - Specifies the high threshold number of LU denials during session that must be met or exceeded within the polling interval to generate an alert or alarm.
  - **high_thresh** is an integer from 0 through 10000000. A value of 0 disables the threshold.

- **clear low_thresh**
  - Default: 0
  - Specifies the low threshold number of LU denials during session that maintains a previously generated alarm condition. If the number of session timeouts falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - **low_thresh** is an integer from 0 through 10000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
Set the maximum number of Location Update denials allowed in the ASNPC service.

Example
The following command configures high threshold of 10000 LU denials:

threshold asnpc-lu-denial 10000
threshold asnpc-session-setup-timeout

Configures alarm or alert thresholds for ASNPC session setup timeouts in an ASN-GW service.

**Product**
ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```plaintext
threshold asnpc-session-setup-timeout value

default threshold asnpc-session-setup-timeout

value

value is an integer from 1 through 1000000.
```

**Usage**

Use this command to set threshold limits to generate alerts or alarms based on the number of timeouts during session setup that occurred during the specified polling interval.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 100 timeouts during session setup using the Alert thresholding model:

```plaintext
threshold asnpc-session-setup-timeout 100
```
threshold call-reject-no-resource

Configures alarm or alert thresholds on the system for calls rejected due to insufficient resources.

Product  
All

Privilege  
Security Administrator, Administrator

Mode  
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold call-reject-no-resource high_thresh [ clear low_thresh ]

high_thresh

Default: 0
Specifies the high threshold number of no-resource call rejects issued by the system that must be met or exceeded within the polling interval to generate an alert or alarm.
The number is an integer from 0 through 100000. A value of 0 disables the threshold.

clear low_thresh

Default: 0
Specifies the low threshold number of no-resource call rejects issued by the system that maintains a previously generated alarm condition. If the number of rejections falls beneath the low threshold within the polling interval, a clear alarm will be generated.
The number is an integer from 0 through 100000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

No resource call reject thresholds generate alerts or alarms based on the total number of calls that were rejected by the system due to insufficient or no resources (memory and/or session licenses) during the specified polling interval.
Alerts or alarms are triggered for no-resource-rejected calls based on the following rules:

- **Enter condition:** Actual number of calls rejected due to no resources is greater than or equal to the high threshold.

- **Clear condition:** Actual number of calls rejected due to no resources is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

Example

The following command configures a high threshold count for the number of calls rejected by the system due to insufficient or no resources to 100 and allow threshold of 40 for a system using the Alarm thresholding model:

```
threshold call-reject-no-resource 100 clear 40
```
threshold call-setup

Configures call setup, alarm or alert thresholds for the system.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold call-setup high_thresh [ clear low_thresh ]

high_thresh
Default: 0
Specifies the high threshold number of calls setup by the system that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh is an integer from 0 through 100000. A value of 0 disables the threshold.

clear low_thresh
Default: 0
Specifies the low threshold number of calls setup by the system that maintains a previously generated alarm condition. If the number of setups falls beneath the low threshold within the polling interval, a clear alarm will be generated.

low_thresh is an integer from 0 through 100000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Call setup thresholds generate alerts or alarms based on the total number of calls setup by the system during the specified polling interval.

Alerts or alarms are triggered for call setups based on the following rules:

• Enter condition: Actual number of call setups is greater than or equal to the high threshold.

• Clear condition: Actual number of call setups is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

Example
The following command configures a high threshold count of 100 calls setup for a system using the Alert thresholding model:

```
threshold call-setup 100
```
threshold call-setup-failure

Configures call setup failure, alarm or alert thresholds for the system.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold call-setup-failure high_thresh [ clear low_thresh ]
```

- `high_thresh`
  Default: 0
  Specifies the high threshold number of call setup failures experienced by the system that must be met or exceeded within the polling interval to generate an alert or alarm.
  `high_thresh` is an integer from 0 through 100000. A value of 0 disables the threshold.

- `clear low_thresh`
  Default: 0
  Specifies the low threshold number of call setup failures experienced by the system that maintains a previously generated alarm condition. If the number of setup failures falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  `low_thresh` is an integer from 0 through 100000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Call setup failure thresholds generate alerts or alarms based on the total number of call setup failures experienced by the system during the specified polling interval.

Alerts or alarms are triggered for call setup failures based on the following rules:

- **Enter condition:** Actual number of call setup failures is greater than or equal to the high threshold.
- **Clear condition:** Actual number of call setup failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**
The following command configures a high threshold count of 100 call setup failures and a low threshold of 80 for a system using the Alarm thresholding model:

```
threshold call-setup-failure 100 clear 80
```
**threshold card-temperature-near-power-off-limit**

Configures alarm or alert thresholds for triggering and clearing high card temperature alarms.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold card-temperature-near-power-off-limit high_temp [ clear low_temp ]
```

- **high_thresh**
  Default: 0
  Specifies the high card temperature (in degrees Celsius) that must be met or exceeded within the polling interval to generate an alert or alarm.
  **high_thresh** is an integer from 0 through 100. A value of 0 disables the threshold.

- **clear low_thresh**
  Default: 0
  Specifies the low card temperature (in degrees Celsius) before a high temperature alarm is cleared.
  **low_thresh** is an integer from 0 through 100. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**
Set the high and low temperatures in degrees Celsius that generate and clear alarms.

**Example**
The following command configures sets the high and low temperatures to 40 and 35 degrees:

```
threshold card-temperature-near-power-off-limit 40 clear 35
```
threshold cdr-file-space

Configures, alarm or alert thresholds for monitoring the percentage of total file space allocated for Charging Data Records (CDRs) used during the polling interval.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold cdr-file-space high_thresh [ clear low_thresh ]
```

**default threshold cdr-file-space**

```
default
```

Configures this command with the default threshold settings.

```
high_thresh
```

Specifies the high threshold for percentage of total allocated CDR file space used that must be met or exceeded at the end of the polling interval to generate an alert or alarm.

*high_thresh* is measured in percentage of total allocated CDR file space used and is an integer from 0 through 100. A value of 0 disables the threshold.

Default: 90

```
clear low_thresh
```

Specifies the low threshold for percentage of total allocated CDR file space used that maintains a previously generated alarm condition. If the space usage falls below *low_thresh* within the polling interval, a clear alarm is generated.

*low_thresh* is measured in percentage of total allocated CDR file space used and is an integer from 0 through 100. A value of 0 disables the threshold.

Default: 0

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to *low_thresh*.

**Usage**

CDR file space usage generate alerts or alarms based on the percentage of total allocated CDR file space used during the polling interval.
Alerts or alarms are triggered for CDR file space usage session based on the following rules:

- **Enter condition:** Actual percentage of allocated CDR file space usage is greater than or equal to the specified percentage of total CDR file space.

- **Clear condition:** Actual CDR file space used is less than the specified clear percentage of total allocated CDR file space usage.

If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a threshold of 65 percent of total allocated CDR file space usage and a clear threshold of 35 percent:

```
threshold cdr-file-space 65 clear 35
```
threshold contfilt-block

Configures, alarm or alert thresholds for Content Filtering rating operations blocked during a polling interval at which the threshold are raised or cleared.

Product
CF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold contfilt-block high_thresh_value [ clear low_thresh_value ]

default threshold contfilt-block

default
Configures this command with the default threshold settings.

high_thresh
Specifies the high threshold for number of rating operations blocked for content filtering service that must be met or exceeded at the end of the polling interval to generate an alert or alarm.

high_thresh is measured in numbers of total rating operations blocked and is an integer from 0 through 1000000. A value of 0 disables the threshold.

clear low_thresh
Specifies the low threshold for the total number of rating operations blocked for a content filtering service that maintains a previously generated alarm condition. If the threshold falls below specifies the low threshold within the polling interval, a clear alarm is generated.

low_thresh is measured in numbers of total rating operations blocked and is an integer from 0 through 1000000. A value of 0 disables the threshold.
Default: 0

Usage
Use this command to configure the threshold for a content filtering service to generates alerts or alarms based on the number of rating operations blocked for a content filtering service during the polling interval. If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the threshold poll contfilt-block command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

Example
The following command configures a threshold of 65000 rating operations blocked and a clear threshold of 35000 operations:

```
threshold contfilt-block 65000 clear 35000
```
threshold contfilt-rating

Configures, alarm or alert thresholds for Content Filtering rating operations performed during a polling interval at which the threshold are raised or cleared.

Product
CF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold contfilt-rating high_thresh_value [ clear low_thresh_value ]

default threshold contfilt-rating

default

Configures this command with the default threshold settings.

high_thresh

Specifies the high threshold for number of rating operations performed for content filtering service that must be met or exceeded at the end of the polling interval to generate an alert or alarm.

high_thresh is measured in numbers of total rating operations performed and is an integer from 0 through 1000000. A value of 0 disables the threshold.

clear low_thresh

Specifies the low threshold for the total number of rating operations performed for a content filtering service that maintains a previously generated alarm condition. If the threshold falls below

low_thresh is measured in number of total rating operations performed and is an integer from 0 through 1000000. A value of 0 disables the threshold.

Default: 0

Usage

Use this command to configure the threshold for a content filtering service to generates alerts or alarms based on the number of rating operations performed for a content filtering service during the polling interval.

If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the threshold poll contfilt-rating command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

Example
The following command configures a threshold of 65000 percent of total rating operations performed and a clear threshold of 35000 percent:

`threshold contfilt-rating 65000 clear 35000`
threshold cpu-available-memory

Configures alarm or alert thresholds for available CPU memory in the system.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config) #

Syntax

threshold cpu-available-memory low_thresh [ clear high_thresh ]

<table>
<thead>
<tr>
<th>low_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 32</td>
</tr>
<tr>
<td>Specifies the low threshold amount of CPU memory that must be met or exceeded at the polling time to generate an alert or alarm.</td>
</tr>
<tr>
<td>low_thresh is measured in megabytes (MB) and is an integer from 0 through 2048.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>clear high_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 32</td>
</tr>
<tr>
<td>Specifies the high threshold amount of CPU memory that maintains a previously generated alarm condition.</td>
</tr>
<tr>
<td>If the memory amount rises above the high threshold within the polling interval, a clear alarm will be generated.</td>
</tr>
<tr>
<td>high_thresh is measured in megabytes (MB) and is an integer from 0 through 2048.</td>
</tr>
</tbody>
</table>

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

Usage

CPU available memory thresholds generate alerts or alarms based on the amount of available memory for each packet processing card CPU at the polling time. Although, a single threshold is configured for all CPUs, separate alerts or alarms can be generated for each CPU.

Alerts or alarms are triggered for available CPU memory based on the following rules:

- **Enter condition**: Average measured amount of memory/CPU for the last 5 minutes is less than or equal to the low threshold.

- **Clear condition**: Average measured amount of memory/CPU for the last 5 minutes is greater than the high threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Important:** This command is not supported on all platforms.

**Example**

The following command configures a low threshold count of 50 MB CPU memory available and a high threshold of 112 MB for a system using the Alarm thresholding model:

```
threshold cpu-available-memory 50 clear 112
```
threshold cpu-load

Configures alarm or alert thresholds for monitoring packet processing card CPU loads using a 5-minute average measurement. The threshold is enabled by enabling CPU resource monitoring.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold cpu-load high_thresh [ clear low_thresh ]
```

* `high_thresh`
  Default: 0
  If the monitored CPU load is greater than or equal to the specified number an alert is sent. `high_thresh` must be an integer from 0 through 15.

* `clear low_thresh`
  Default: 0
  This is a low watermark value that sets the alarm clearing threshold value. If not present it is taken from the first value. `low_thresh` must be an integer from 0 through 15.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to Specifies the low threshold.

**Usage**

Use this command to set an alert when the card’s CPU load is equal to or greater than the number specified. Alerts or alarms are triggered for CPU load based on the following rules:

* **Enter condition:** Actual CPU load is greater than or equal to the high threshold.
* **Clear condition:** Actual CPU load is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Important:** This command is not supported on all platforms.
Example

To set an alert when the packet processing card CPU load is over 10 and set an alert clear when the CPU load drops down equal or less than 7, enter the following command:

```bash
threshold cpu-load 10 clear 7
```
threshold cpu-memory-usage

Configures, alarm or alert thresholds for monitoring the percentage of total CPU memory used during the polling interval.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold cpu-memory-usage high_thresh [ clear low_thresh ]

| high_thresh |
| Default: 0 |
| Specifies the high threshold for percentage of total memory used that must be met or exceeded at the end of the polling interval to generate an alert or alarm. |
| high_thresh is measured as a percentage of total CPU memory used and is an integer from 0 and 100. A value of 0 disables the threshold. |

| clear low_thresh |
| Default: 0 |
| Specifies the low threshold for percentage of total CPU memory used that maintains a previously generated alarm condition. If the memory usage falls below the low threshold within the polling interval, a clear alarm is generated. |
| low_thresh is measured as a percentage of total CPU memory used and is an integer from 0 and 100. A value of 0 disables the threshold. |

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to Specifies the low threshold.

Usage

CPU memory usage generate alerts or alarms based on the percentage of total CPU memory used during the polling interval.

Alerts or alarms are triggered for CPU memory usage session based on the following rules:

- **Enter condition**: Actual percentage of CPU memory usage is greater than or equal to the specified percentage of total CPU memory.

- **Clear condition**: Actual CPU memory usage is less than the specified clear percentage of total CPU memory usage.
If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

Example

The following command configures a threshold of 65 percent of total packet processing card CPU memory usage and a clear threshold of 35 percent:

```
threshold cpu-memory_usage 65 clear 35
```
threshold cpu-orbs-crit

Configures thresholds for generating critical-level alerts or alarms based on the percentage of CPU utilization by the Object Request Broker System (ORBS) software task.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

```
threshold cpu-orbs-crit high_thresh [ clear low_thresh ]
[ default ] threshold cpu-orbs-crit
```

- **default**
  Restores this parameter to its default setting.

- **high_thresh**
  Default: 60
  Specifies the high threshold percent of CPU utilization by the ORB software task that must be exceeded as measured at the time of polling to generate a critical-level alert or alarm. `high_thresh` is measured in percentage of total CPU utilization and is an integer from 0 through 100. A value of 0 disables the threshold.

- **clear low_thresh**
  Default: 60
  Specifies the low threshold percent of CPU utilization by the ORB software task that maintains a previously generated alarm condition. If the percentage is measured as less than or equal to `low_thresh` at the time of polling, a clear alarm will be generated. `low_thresh` is measured in percentage of total CPU utilization and is an integer from 0 through 100. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to `low_thresh`.

**Usage**

Object Request Broker (ORB) software task CPU utilization thresholds generate critical-level alerts or alarms based on the percentage of packet processing card CPU resources it is consuming at the time of polling.
Critical-level alerts or alarms are triggered for CPU usage by the ORBs software task based on the following rules:

- **Enter condition:** Actual CPU usage percentage is greater than the high threshold.
- **Clear condition:** Actual CPU usage percentage is less than or equal to the low threshold.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a critical-level alarm threshold of 35 percent of CPU utilization by the ORBS task and a clear threshold of 30 percent:

```
threshold cpu-orbs-crit 35 clear 30
```
threshold cpu-orbs-warn

Configures thresholds for generating warning-level alerts or alarms based on the percentage of CPU utilization by the Object Request Broker System (ORBS) software task.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold cpu-orbs-warn high_thresh [ clear low_thresh ]
[ default ] threshold cpu-orbs-warn

default
Restores this parameter to its default setting.

high_thresh
Default: 50
Specifies the high threshold percent of CPU utilization by the ORBS software task that must be exceeded as measured at the time of polling to generate a warning-level alert or alarm. high_thresh is measured in percentage of total CPU utilization and is an integer from 0 through 100. A value of 0 disables the threshold.

clear low_thresh
Default: 50
Specifies the low threshold percent of CPU utilization by the ORBS software task that maintains a previously generated alarm condition. If the percentage is measured as less than or equal to low_thresh at the time of polling, a clear alarm will be generated.
low_thresh is measured in percentage of total CPU utilization and is an integer from 0 through 100. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to Specifies the low threshold.
Usage
Object Request Broker (ORB) software task CPU utilization thresholds generate warning-level alerts or alarms based on the percentage of packet processing card CPU resources it is consuming at the time of polling. Warning-level alerts or alarms are triggered for CPU usage by the ORBS software task based on the following rules:

- **Enter condition:** Actual CPU usage percentage is greater than the high threshold.
- **Clear condition:** Actual CPU usage percentage is less than or equal to the low threshold.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

Example
The following command configures a warning-level alarm threshold of 25 percent of CPU utilization by the ORBS task and a clear threshold of 20 percent:

```
threshold cpu-orbs-warn 25 clear 20
```
threshold cpu-session-throughput

Configures alarm or alert thresholds for CPU session throughput within the system.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config) #

Syntax

threshold cpu-session-throughput high_thresh [ clear low_thresh ]

high_thresh
Default: 0
Specifies the high threshold session throughput that must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is measured in kilobytes per second (Kbps) and is an integer from 0 through 1000000000. A value of 0 disables the threshold.

clear low_thresh
Default: 0
Specifies the low threshold session thereabout that maintains a previously generated alarm condition. If the throughput falls below Specifies the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is measured in kilobytes per second (Kbps) and is an integer from 0 through 1000000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

CPU session throughput thresholds generate alerts or alarms based on total throughput for all Session Manager tasks running on each packet processing card CPU during the polling interval. Although, a single threshold is configured for all CPUs, separate alerts or alarms can be generated for each CPU. Alerts or alarms are triggered for CPU session throughput based on the following rules:

- Enter condition: Actual CPU session throughput is greater than or equal to the high threshold.

- Clear condition: Actual CPU session throughput is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Important:** This command is not supported on all platforms.

**Example**

The following command configures a high threshold count of 900 Kbps session throughput and a low threshold of 500 KBps for a system using the Alarm thresholding model:

```
threshold cpu-session-throughput 900 clear 500
```
threshold cpu-utilization

Configures alarm or alert thresholds for CPU utilization within the system.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config) #

Syntax

threshold cpu-utilization high_thres [ clear low_thres ]

high_thres
Default: 85
Specifies the high threshold CPU utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm.
high_thres is an integer from 0 through 100.

clear low_thres
Default: 85
Specifies the low threshold CPU utilization percentage that maintains a previously generated alarm condition. If the utilization percentage falls below the low threshold within the polling interval, a clear alarm will be generated.
low_thres is an integer from 0 through 100.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

CPU utilization thresholds generate alerts or alarms based on the utilization percentage of each packet processing card CPU during the specified polling interval. Although, a single threshold is configured for all CPUs, separate alerts or alarms can be generated for each CPU.

Alerts or alarms are triggered for CPU utilization based on the following rules:

- **Enter condition**: Average measured CPU utilization for the last 5 minutes
- **Clear condition**: Average measured CPU utilization for the last 5 minutes is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Important:** This command is not supported on all platforms.

**Example**

The following command configures a high threshold CPU utilization percentage of 90 for a system using the Alert thresholding model:

```
threshold cpu-utilization 90
```
threshold dcca-bad-answers

Configures alarm or alert thresholds for invalid or bad responses to the system from Diameter servers.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```plaintext
threshold dcca-bad-answers high_thresh [ clear low_thresh ]
default threshold dcca-bad-answers
```

**default**
Disables the threshold for configured alarm and sets the `high_thresh` and `low_thresh` values to 0.

**high_thresh**
Default: 0
Specifies the high threshold number of invalid messages or responses that must be met or exceeded within the polling interval to generate an alert or alarm.

`high_thresh` is an integer from 0 through 1000000.

**clear low_thresh**
Default: 0
Specifies the low threshold number of invalid messages/responses that maintains a previously generated alarm condition. If the number of failures falls beneath the low threshold within the polling interval, a clear alarm will be generated.

`low_thresh` is an integer from 0 through 1000000.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

In the event that the system receives invalid message or response from Diameter server `dcca-bad-answers` is generated.
DCCA bad answer messages size threshold generates alerts or alarms based on the number of invalid response or messages received during the specified polling interval.
Alerts or alarms are triggered for DCCA bad answers based on the following rules:
• **Enter condition:** Actual number of DCCA bad answer messages is greater than or equal to the high threshold.

• **Clear condition:** Actual number of DCCA bad answer messages is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

**Example**

The following command configures a high threshold count of 250 DCCA bad answer messages and low threshold of 100 for a system using the Alarm thresholding model:

```
threshold dcca-bad-answers 250 clear 100
```
threshold dcca-protocol-error

Configures alarm or alert thresholds for Diameter Credit Control Application (DCCA) protocol errors from the Diameter server.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold dcca-protocol-error high_thresh [ clear low_thresh ]

default threshold dcca-protocol-error

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>

<tr>
<td>Specifies the low threshold number of protocol error received from Diameter server that maintains a previously generated alarm condition. If the number of errors falls beneath the low threshold within the polling interval, a clear alarm will be generated.</td>
</tr>
<tr>
<td>low_thresh is an integer from 0 through 1000000.</td>
</tr>
</tbody>
</table>

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

In the event that the system receives the protocol errors from Diameter server, dcca-protocol-error is generated.

DCCA protocol error threshold generates alerts or alarms based on the number of protocol error messages received from Diameter server during the specified polling interval.
Alerts or alarms are triggered for DCCA protocol error based on the following rules:

- **Enter condition:** Actual number of DCCA protocol error is greater than or equal to the high threshold.
- **Clear condition:** Actual number of DCCA protocol errors is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

**Example**

The following command configures a high threshold count of 250 protocol errors and low threshold of 100 for a system using the Alarm thresholding model:

```
threshold dcca-protocol-error 250 clear 100
```
threshold dcca-rating-failed

Configures Diameter Credit Control Application (DCCA) Rating Group (content-id) request reject, alarm or alert thresholds.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config) #

Syntax

threshold dcca-rating-failed high_thresh [ clear low_thresh ]

default threshold dcca-rating-failed

default

Disables the threshold for configured alarm and sets the high_thresh and low_thresh values to 0.

high_thresh

Default: 0
Specifies the high threshold number of requests for a block of credits due to invalid Rating Group (content-id), rejected from the Diameter server that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh is an integer from 0 through 1000000.

clear low_thresh

Default: 0
Specifies the low threshold number of requests for a block of credits due to invalid Rating Group (content-id), rejected from the Diameter server that maintains a previously generated alarm condition. If the number of errors falls beneath the low threshold within the polling interval, a clear alarm will be generated.

low_thresh is an integer from 0 through 1000000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

In the event that the Diameter server rejects the system request for a block of credits due to invalid Rating Group, defined as content-id, dcca-rating-failed message is generated.
Rating Group failed threshold generates alerts or alarms based on the number of requests rejected from Diameter server during the specified polling interval. Alerts or alarms are triggered for Rating Group failed based on the following rules:

- **Enter condition:** Actual number of DCCA Rating Group failed is greater than or equal to the high threshold.

- **Clear condition:** Actual number of DCCA Rating Group failed is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

**Example**

The following command configures a high threshold count of 250 requests rejected and low threshold of 100 for a system using the Alarm thresholding model:

```
threshold dcca-rating-failed 250 clear 100
```
threshold dcca-unknown-rating-group

Configures alarm or alert thresholds for the unknown Diameter Credit Control Application (DCCA) Rating Group (content-id) messages returned by Diameter servers.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

threshold dcca-unknown-rating-group high_thresh [ clear low_thresh ]

default threshold dcca-unknown-rating-group

**default**

Disables the threshold for configured alarm and sets the high_thresh and low_thresh values to 0.

**high_thresh**

Default: 0
Specifies the high threshold number of unknown Rating Group (content-id) messages sent by the Diameter server that must be met or exceeded within the polling interval to generate an alert or alarm. 
high_thresh is an integer from 0 through 1000000.

**clear low_thresh**

Default: 0
Specifies the low threshold number of unknown Rating Group (content-id) sent by Diameter server and received by system that maintains a previously generated alarm condition. If the number of errors falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 through 1000000.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

In the event that the Diameter server sends invalid Rating Groups, content-ids to the system, dcca-unk-
rating-group message is generated.
Unknown Rating Group threshold generates alerts or alarms based on the number of unknown Rating Groups received by the system from Diameter server during the specified polling interval.
Alerts or alarms are triggered for unknown rating groups based on the following rules:

- **Enter condition**: Actual number of unknown rating groups is greater than or equal to the high threshold.
- **Clear condition**: Actual number of unknown rating groups is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

**Example**

The following command configures a high threshold count of 250 unknown rating groups and low threshold of 100 for a system using the Alarm thresholding model:

```bash
threshold dcca-unknown-rating-group 250 clear 100
```
threshold diameter diameter-retry-rate

Configures Diameter Retry Rate, alarm or alert thresholds based on the percentage of Diameter requests that were retried during the polling interval.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
`configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold diameter diameter-retry-rate high_thresh [ clear low_thresh ]
```

**default**

```
threshold diameter diameter-retry-rate
```

- **default**
  Configures this command with the default threshold settings.
  Default: 0—disabled

- **high_thresh**
  Specifies the high threshold. If, within the polling interval, the percentage of Diameter requests retried equals or exceeds `high_thresh` an alert or alarm is generated. `high_thresh` is an integer from 0 through 100.
  Default: 0

- **clear low_thresh**
  Specifies the low threshold. If, within the polling interval, the percentage of Diameter requests retried falls below `low_thresh`, a clear alarm is generated. `low_thresh` is an integer from 0 through 100.
  Default: 0

**Important:** This value is applicable for the Alarm mode, and ignored for the Alert mode. In addition, if this value is not configured for the Alarm mode, the system assumes it is identical to the high threshold.

**Usage**

Diameter Retry Rate threshold generates alerts or alarms based on the percentage of Diameter requests that were retried during the specified polling interval.
Alerts or alarms are triggered based on the following rules:
- **Enter condition:** Percentage of Diameter requests retried is greater than or equal to the high threshold.
- **Clear condition:** Percentage of Diameter requests retried is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

**Example**

The following command configures a high threshold of 75 percent, and a low threshold of 50 percent for a system using the Alarm thresholding model:

```
threshold diameter diameter-retry-rate 75 clear 50
```
threshold dns-learnt-ip-max-entries

Configures alarm or alert thresholds for the percentage of total DNS-learnt IP entries in relation to the ACS DNS Snooping feature.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config)#

Syntax

threshold dns-learnt-ip-max-entries high_thresh [ clear low_thresh ]

default threshold dns-learnt-ip-max-entries

default

Configures this command with the default threshold setting.
Default: 90 percent. It is the same for both high and low thresholds.

high_thresh

Default: 90 percent

Specifies the high threshold for percentage of total DNS-learnt IP entries. When the percentage of total DNS-learnt IP entries meets or exceeds the high threshold at the end of the polling interval, an alert or alarm is generated.

When the percentage of total DNS-learnt IPv4 entries meets or exceeds the high threshold, the ECSTotalDNSLearntIPv4Threshold trap is generated.
When the percentage of total DNS-learnt IPv6 entries meets or exceeds the high threshold, the ECSTotalDNSLearntIPv6Threshold trap is generated.

high thresh is an integer value from 0 through 100. When configured to 0 the threshold is disabled.

clear low_thresh

Default: 90 percent

 Specifies the low threshold for percentage of total DNS-learnt IP entries. When the percentage of total DNS-learnt IP entries goes below the low threshold within the polling interval, a clear alarm is generated.
When the percentage of total DNS-learnt IPv4 entries goes below the low threshold, the ECSTotalDNSLearntIPv4ThresholdClear trap is generated.
When the percentage of total DNS-learnt IPv6 entries goes below the low threshold, the ECSTotalDNSLearntIPv6ThresholdClear trap is generated.

low_thresh is an integer value from 0 through 100. When configured to 0 the threshold is disabled.
Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

Usage
Use this command to configure thresholds for the percentage of total DNS-learnt IP entries in relation to the ACS DNS Snooping feature. Note that this threshold applies to both IPv4 and IPv6 DNS entries. Alerts or alarms are triggered based on the following rules:

- **Enter condition:** Actual percentage of total DNS-learnt IP entries is greater than or equal to the specified percentage of total DNS-learnt IP entries.

- **Clear condition:** Actual of total DNS-learnt IP entries is less than the specified clear percentage of total DNS-learnt IP entries.

If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval, and the `threshold monitoring` command to enable thresholding for this value.

Example
The following command configures a high threshold of 65 percent and a clear threshold of 35 percent for total DNS-learnt IP entries:

```
threshold dns-learnt-ip-max-entries 65 clear 35
```
threshold dns-lookup-failure

Configures alarm or alert thresholds based on the percentage of total DNS lookup failures.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

\[threshold dns-lookup-failure\]

**default**

Configures this command with the default threshold setting.
Default: 90 percent. It is the same for both high and low thresholds.

**high_thresh**

Default: 90 percent
Specifies the high threshold for percentage of total DNS lookup failures. When the percentage of total failures meets or exceeds the high threshold at the end of the polling interval, an alert or alarm is generated.
\[high_thresh\] is an integer value from 0 through 100. When configured to 0 the threshold is disabled.

**clear low_thresh**

Default: 90 percent
Specifies the low threshold for percentage of total DNS lookup failures. When the percentage of total failures goes below the low threshold within the polling interval, a clear alarm is generated.
\[low_thresh\] is an integer value from 0 through 100. When configured to 0 the threshold is disabled.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

**Usage**

Use this command to configure thresholds for the percentage of total DNS lookup failures. Note that this threshold applies to both IPv4 and IPv6 DNS entries.
Alerts or alarms are triggered based on the following rules:

- **Enter condition:** Actual percentage of total DNS lookup failures is greater than or equal to the specified percentage of total DNS lookup failures.
• **Clear condition**: Actual of total DNS lookup failures is less than the specified clear percentage of total DNS lookup failures.

If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval, and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold of 65 percent and a clear threshold of 35 percent for total DNS lookup failures:

```
threshold dns-lookup-failure 65 clear 35
```
threshold edr-file-space

Configures alarm or alert thresholds for monitoring the percentage of total file space allocated for Event Data Records (EDRs) used during the polling interval.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
[ default ] threshold edr-file-space high_thresh [ clear low_thresh ]
```

**high_thresh**

Default: 90
Specifies the high threshold for percentage of total allocated EDR file space used that must be met or exceeded at the end of the polling interval to generate an alert or alarm.

*high_thresh* is measured in percentage of total allocated EDR file space used and is an integer from 0 through 100. A value of 0 disables the threshold.

**clear low_thresh**

Default: 0
Specifies the low threshold for percentage of total allocated EDR file space used that maintains a previously generated alarm condition. If the space usage falls below the low threshold within the polling interval, a clear alarm is generated.

*low_thresh* is measured in percentage of total allocated EDR file space used and is an integer from 0 through 100. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

**Usage**

EDR file space usage generate alerts or alarms based on the percentage of total allocated EDR file space used during the polling interval.

Alerts or alarms are triggered for EDR file space usage session based on the following rules:

- **Enter condition:** Actual percentage of allocated EDR file space usage is greater than or equal to the specified percentage of total EDR file space.

- **Clear condition:** Actual EDR file space used is less than the specified clear percentage of total allocated EDR file space usage.
If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold of 65 percent and a clear threshold of 35 percent for total allocated EDR file space usage:

```
threshold edr-file-space 65 clear 35
```
threshold edr-udr-dropped flow control

Configures alarm or alert thresholds to monitor the total number of Event Data Records (EDRs) and Usage Data Records (UDRs) discarded due to flow control.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold edr-udr-dropped-flow-control high_thresh [ clear low_thresh ]

default threshold edr-udr-dropped-flow-control

  default
  Configures this command with the default threshold settings.
  Default: High threshold: 90; Low threshold: 10

  high_thresh
  Specifies the high threshold for total number of EDRs + UDRs dropped due to flow control, which must be
  met or exceeded within the polling interval to generate an alert or alarm.
  high_thresh must be an integer from 0 through 100000.
  A value of 0 disables the threshold.
  Default: 90

  clear low_thresh
  Specifies the low threshold for total number of EDRs + UDRs dropped that maintains a previously generated
  alarm condition. If the total number of EDRs + UDRs dropped falls below Specifies the low threshold within
  the polling interval, a clear alarm is generated.
  low_thresh must be an integer from 0 through 100000 that must be lower than high_thresh.
  A value of 0 disables the threshold.
  Default: 10

**Usage**

Use this command to configure thresholds to monitor the total number of EDRs + UDRs discarded due to
flow control. Alerts or alarms are generated based on the total number of EDRs + UDRs dropped during
polling interval.

Alerts or alarms are triggered for EDR file space usage session based on the following rules:
• **Enter condition:** Actual number of EDRs + UDRs dropped greater than or equal to the specified number of EDRs + UDRs dropped.

• **Clear condition:** Actual number of EDR + UDRs dropped is less than the specified clear number of EDRs + UDRs dropped.

If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold of **90** and a clear threshold of **45** to monitor EDRs + UDRs dropped due to flow control:

```
threshold edr-udr-dropped-flow-control 90 clear 45
```
threshold epdg-current-sessions

Configures alarm or alert thresholds for the number of subscribers currently in Evolved Packet Date Gateway (ePDG) sessions.

**Product**
ePDG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold epdg-current-sessions

default threshold epdg-current-sessions
```

**default**

Disables the threshold for configured alarm and sets the `high_thresh` and `low_thresh` values to 0.

```
high_thresh
```

Default: 0
Specifies the high threshold number of the total number of ePDG subscriber sessions that must be met or exceeded within the polling interval to generate an alert or alarm. `high_thresh` is an integer from 0 through 1000000.

```
clear low_thresh
```

Default: 0
Specifies the low threshold number of the total number of ePDG subscriber sessions that maintains a previously generated alarm condition. If the number of errors falls beneath the low threshold within the polling interval, a clear alarm will be generated. `low_thresh` is an integer from 0 through 1000000.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Sets the upper and power thresholds for the total number of ePDG subscriber sessions that will generate and clear alerts or alarms. Alerts or alarms are triggered based on the following rules:
Global Configuration Mode Commands (T-threshold phspc)

threshold epdg-current-sessions

- **Enter condition:** Actual number of ePDG subscriber sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual number of ePDG subscriber sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

**Example**

The following command configures sets the upper threshold of ePDG subscriber sessions at 100000 and the lower threshold at 90000:

```
threshold epdg-current-sessions 100000 clear 90000
```
threshold fng-current-active-sessions

Configures alarm or alert thresholds for the number of subscribers currently active Femto Network Gateway (FNG) sessions.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold fng-current-active-sessions

default threshold fng-current-active-sessions

default
Disables the threshold for configured alarm and sets the high_thresh and low_thresh values to 0.

high_thresh
Default: 0
Specifies the high threshold number of the total number of active FNG subscriber sessions that must be met or exceeded within the polling interval to generate an alert or alarm. high_thresh is an integer from 0 through 1000000.

clear low_thresh
Default: 0
Specifies the low threshold number of the total number of active FNG subscriber sessions that maintains a previously generated alarm condition. If the number of errors falls beneath the low threshold within the polling interval, a clear alarm will be generated. low_thresh is an integer from 0 through 1000000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
Sets the upper and power thresholds for the total number of active FNG subscriber sessions that will generate and clear alerts or alarms.
Alerts or alarms are triggered based on the following rules:
• **Enter condition**: Actual number of active FNG subscriber sessions is greater than or equal to the high threshold.

• **Clear condition**: Actual number of active FNG subscriber sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

**Example**

The following command configures sets the upper threshold of active FNG subscriber sessions at 100000 and the lower threshold at 90000:

```
threshold fng-current-active-sessions 100000 clear 90000
```
threshold fng-current-sessions

Configures alarm or alert thresholds for the number of subscribers currently in Femto Network Gateway (FNG) sessions, including inactive sessions.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold fng-current-sessions

default threshold fng-current-sessions

default

Configures this command with the default threshold settings.
Default: High threshold: 90; Low threshold: 10

high_thresh

Default: 0
Specifies the high threshold number of the total number of FNG subscriber sessions that must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 1000000.

clear low_thresh

Default: 0
Specifies the low threshold number of the total number of FNG subscriber sessions that maintains a previously generated alarm condition. If the number of errors falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 through 1000000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Sets the upper and power thresholds for the total number of FNG subscriber sessions that will generate and clear alerts or alarms.
Alerts or alarms are triggered based on the following rules:
- **Enter condition**: Actual number of FNG subscriber sessions is greater than or equal to the high threshold.
- **Clear condition**: Actual number of FNG subscriber sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

**Example** The following command configures sets the upper threshold of FNG subscriber sessions at 200000 and the lower threshold at 190000:

```
threshold fng-current-sessions 200000 clear 190000
```
threshold fw-deny-rule

Configures alarm or alert thresholds for the Stateful Firewall Deny Rule.

**Product**
PSF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config) #
```

**Syntax**

```
threshold fw-deny-rule high_thresh [ clear low_thresh ]
default threshold fw-deny-rule
```

**default threshold fw-deny-rule**

```
default
Confides this command with the default threshold settings.
Default: 0—disabled
```

```
high_thresh
Specifies the Stateful Firewall Deny-Rule threshold value, which if met or exceeded generates an alert or alarm.
high_thresh must be an integer from 0 through 1000000.
Default: 0
```

```
clear low_thresh
Specifies the Stateful Firewall Deny-Rule alarm clear threshold value. If, in the same polling interval, the threshold falls below low_thresh a clear alarm is generated.
low_thresh must be an integer from 0 through 1000000.
Default: 0
```

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

**Usage**

When the number of Deny-Rule instances exceeds a given value, an alarm or alert is raised; it is cleared when the number of Deny-Rule instances falls below a value within the polling interval.

Refer to the **threshold poll** command to configure the polling interval, and the **threshold monitoring** command to enable thresholding for this value.

**Example**
The following command configures a Stateful Firewall Deny Rule high threshold of 1000 and a low threshold of 900 for a system using the Alarm Thresholding model:

```
threshold fw-deny-rule 1000 clear 900
```
threshold fw-dos-attack

Configures alarm or alert thresholds for Stateful Firewall Denial-of-Service (DoS) attacks.

Product
PSF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

text

Syntax

threshold fw-dos-attack high_thresh [ clear low_thresh ]

default threshold fw-dos-attack

  default
  Configures this command with the default threshold settings.
  Default: 0—disabled

  high_thresh
  Specifies the Stateful Firewall DoS attacks threshold value, which if met or exceeded generates an alert or
  alarm.
  high_thresh must be an integer from 0 through 1000000.
  Default: 0

  clear low_thresh
  Specifies the Stateful Firewall DoS attacks clear threshold value. If, in the same polling interval, the threshold
  falls below low_thresh a clear alarm is generated.
  low_thresh must be an integer from 0 through 1000000.
  Default: 0

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm
model, the system assumes it is identical to the low threshold.

Usage

When the number of DoS attacks exceed a given value, a threshold is raised and it is cleared when the
number of DoS attacks fall below a value within the polling interval.
Refer to the threshold poll command to configure the polling interval and the threshold monitoring
command to enable thresholding for this value.

Example
The following command configures a Stateful Firewall DoS attacks high threshold of 1000 and a low threshold of 100 for a system using the Alarm Thresholding model:

```
threshold fw-dos-attack 1000 clear 100
```
**threshold fw-drop-packet**

Configures alarm or alert thresholds for Stateful Firewall dropped packets.

**Product**
PSF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold fw-drop-packet high_thresh [ clear low_thresh ]
default threshold fw-drop-packet
```

**default threshold fw-drop-packet**

```
default
Configures this command with the default threshold settings.
Default: 0—disabled
```

```
high_thresh
Specifies the Stateful Firewall dropped packets threshold value, which if met or exceeded generates an alert
or alarm.
high_thresh must be an integer from 0 through 1000000.
Default: 0
```

```
clear low_thresh
Specifies the Stateful Firewall dropped packets clear threshold value. If, in the same polling interval, the
threshold falls below low_thresh a clear alarm is generated.
low_thresh must be an integer from 0 through 1000000.
Default: 0
```

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm
model, the system assumes it is identical to the low threshold.

**Usage**

When the number of dropped packets exceed a given value, a threshold is raised and it is cleared when the
number of dropped packets fall below a value within the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring`
command to enable thresholding for this value.

**Example**
The following command configures a Stateful Firewall dropped packets high threshold of 1000 and a low threshold of 900 for a system using the Alarm thresholding model:

```
threshold fw-drop-packet 1000 clear 900
```
threshold fw-no-rule

Configures alarm or alert thresholds for Stateful Firewall no rule occurrences.

Product
PSF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure
Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold fw-no-rule high_thresh [ clear low_thresh ]

default threshold fw-no-rule

---

default

Configures this command with the default threshold settings.
Default: 0—disabled

high_thresh

Specifies the Stateful Firewall no rules threshold value, which if met or exceeded generates an alert or alarm.
high_thresh must be an integer from 0 through 1000000.
Default: 0

clear low_thresh

Specifies the Stateful Firewall no rules clear threshold value. If, in the same polling interval, the threshold falls below low_thresh a clear alarm is generated.
low_thresh must be an integer from 0 through 1000000.
Default: 0

---

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

---

Usage

When the number of no rule occurrences exceeds a given value, a threshold is raised and it is cleared when the number of no rules fall below a value within the polling interval.
Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

---

Example
The following command configures a Stateful Firewall no rule high threshold of 1000 and a low threshold of 900 for a system using the Alarm Thresholding model:

```
threshold fw-no-rule 1000 clear 900
```
threshold license remaining-sessions

Configures alarm or alert thresholds for the percentage of session license utilization by the system.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

[ no ] threshold license remaining-sessions low_thresh clear high_thresh

no low_thresh
Disables threshold session license utilization alerts or alarms.

remaining-sessions low_thresh
Default: 10
Specifies the low threshold session license utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm.
low_thresh is an integer from 0 through 100.

clear high_thresh
Default: 10
Specifies the high threshold session license utilization percentage that maintains a previously generated alarm condition. If the utilization percentage rises above the high threshold within the polling interval, a clear alarm will be generated.
high_thresh is an integer from 0 through 100.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to Specifies the low threshold.

Usage
Session license utilization thresholds generate alerts or alarms based on the utilization percentage of all session capacity licenses during the specified polling interval.
The system uses session capacity license to dictate the maximum number of simultaneous sessions that can be supported. There are multiple session types that require licenses. Although, a single threshold is configured for all session types, alerts or alarms can be generated for each type.
Alerts or alarms are triggered for session license utilization based on the following rules:
**Enter condition:** Actual session license utilization percentage per session type is greater than or equal to the low threshold.

**Clear condition:** Actual session license utilization percentage per session type is greater than the high threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a session license low threshold percentage of 10 and a high threshold of 35 for a system using the Alarm thresholding model:

```
threshold license remaining-sessions 10 clear 35
```
threshold mgmt-cpu-memory-usage

Configures alarm or alert thresholds for the percentage of CPU memory usage on management cards.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

threshold mgmt-cpu-memory-usage high_thresh [ clear low_thresh ]

**high_thresh**

Default: 0
Specifies the high threshold percent of CPU memory usage that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh is measured in percentage of total memory used and can be configured to an integer from 0 through 100. A value of 0 disables the threshold.

**clear low_thresh**

Specifies the low threshold percent of CPU memory usage that maintains a previously generated alarm condition. If the percentage falls beneath the low threshold within the polling interval, a clear alarm will be generated.

low_thresh is measured in percentage of total memory used and can be configured to an integer from 0 through 100. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

CPU memory usage thresholds generate alerts or alarms based on memory usage for the SPC, SMC, or MIO CPU during the polling interval. A single threshold enables CPU monitoring for both the active and standby SPCs, SMCs, or MIOs allowing for alerts or alarms to be generated for each CPU.

Alerts or alarms are triggered for SPC, SMC, or MIO CPU memory usage based on the following rules:

- **Enter condition:** Actual CPU memory usage is greater than or equal to the high threshold
  - **Clear condition:** Actual CPU memory usage is less than the low threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Important:** This command is not supported on all platforms.

**Example**

The following command configures a threshold of 65 percent of total SPC, SMC, or MIO CPU memory usage and a clear threshold of 35 percent:

```
threshold mgmt-cpu-memory-usage 65 clear 35
```
threshold mgmt-cpu-utilization

Configures alarm or alert thresholds for the percentage of CPU utilization on management cards.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

*configure*

Entering the above command sequence results in the following prompt:

```
threshold mgmt-cpu-utilization
```

**Syntax**

```
threshold mgmt-cpu-utilization high_thresh [ clear low_thresh ]
```

**high_thresh**

Default: 0

Specifies the high threshold CPU utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm.

*high_thresh* is an integer from 0 through 100.

**clear low_thresh**

Specifies the low threshold CPU utilization percentage that maintains a previously generated alarm condition. If the utilization percentage falls beneath the low threshold within the polling interval, a clear alarm will be generated.

*low_thresh* is an integer from 0 through 100.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

CPU utilization thresholds generate alerts or alarms based on the utilization percentage of each SPC, SMC, or MIOCPU during the specified polling interval. Although, a single threshold is configured for both SPC, SMC, or MIO CPUs, separate alerts or alarms can be generated for each CPU.

Alerts or alarms are triggered for SPC, SMC, or MIO CPU utilization based on the following rules:

- **Enter condition:** Average measured CPU utilization for the last 5 minutes is greater than or equal to the high threshold.

- **Clear condition:** Average measured CPU utilization for the last 5 minutes is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Important:** This command is not supported on all platforms.

**Example**

The following command configures a high threshold SPC, SMC, or MIO CPU utilization percentage of 90 for a system using the Alert thresholding model:

```
threshold mgmt-cpu-utilization 90
```
threshold mme-attach-failure

Configures alarm or alert thresholds for the total number of MME Attach Failure messages across all the MME services in the system.

**Product**
MME

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
threshold total-mme-attach-failure high_thresh [ clear low_thresh ]
```

**high_thresh**
Default: 0 (Disabled)
Specifies the high threshold number of total MME Attach Failure messages across all services on a system that must be met or exceeded within the polling interval to generate an alert or alarm.
*high_thresh* can be configured to an integer from 0 through 100000. A value of 0 disables the threshold.

**clear low_thresh**
Default: 0 (Disabled)
Specifies the low threshold number of total MME Attach Failure messages across all services on a system that maintains a previously generated alarm condition. If the number of MME Attach Failure messages across all the services in a system, falls beneath the low threshold within the polling interval, a clear alarm will be generated.
*low_thresh* is an integer from 0 through 100000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to monitor and set alarms or alerts when the total number of MME Attach Failure message across all the MME services in the system is equal to or greater than the set limit.
Alerts or alarms are triggered for the total number of MME Attach Failure message based on the following rules:

- **Enter condition:** Actual total number of MME Attach Failure messages is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of MME Attach Failure messages is less than the low threshold.
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the `threshold poll mme-attach-failure` command to configure the polling interval and the `threshold monitoring mme-service` command to enable thresholding for this value.

**Example**

The following command configures the limit of MME Attach Failure high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold mme-attach-failure 10000
```
threshold mme-auth-failure

Configures alarm or alert thresholds for the total number of MME Auth Failure messages across all the MME services.

Product
MME

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

\texttt{threshold total-mme-auth-failure \texttt{high\_thresh} [ \texttt{clear \ low\_thresh} ]}

\texttt{high\_thresh}

Default: 0 (Disabled)
Specifies the high threshold number of total MME Auth Failure messages across all MMM services on a system that must be met or exceeded within the polling interval to generate an alert or alarm.

\texttt{high\_thresh} can be configured to an integer from 0 through 100000. A value of 0 disables the threshold.

\texttt{clear \ low\_thresh}

Default: 0 (Disabled)
Specifies the low threshold number of total MME Auth Failure messages across all services on a system that maintains a previously generated alarm condition. If the number of MME Attach Failure messages across all the services in a system, falls beneath the low threshold within the polling interval, a clear alarm will be generated.

\texttt{low\_thresh} is an integer from 0 through 100000. A value of 0 disables the threshold.

\textbf{Important:} This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to monitor and set alarms or alerts when the total number of MME Auth Failure messages across all the MME services in the system is equal to or greater than the set limit. Alerts or alarms are triggered for the total number of MME Auth Failure messages based on the following rules:

\begin{itemize}
  \item \textbf{Enter condition:} Actual total number of MME Auth Failure messages is greater than or equal to the high threshold.
  \item \textbf{Clear condition:} Actual total number of MME Auth Failure messages is less than the low threshold.
\end{itemize}

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll mme-auth-failure` command to configure the polling interval and the `threshold monitoring mme-service` command to enable thresholding for this value.

**Example**

The following command configures a total MME Auth Failure high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold mme-auth-failure 10000
```
threshold model

Configures the thresholding model, alarm or alert, for the system to use.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**

```plaintext
threshold model { alarm | alert }
```

**alarm**
Selects the alarm thresholding model as described in the *Usage* section for this command.

**alert**
Selects the alert thresholding model as described in the *Usage* section for this command.

**Usage**
The system supports the following thresholding models:

- **Alert**: A value is monitored and an alert condition occurs when the value reaches or exceeds the configured high threshold within the specified polling interval. The alert is generated then generated and/or sent at the end of the polling interval.

In the example shown in the figure below, this model generates alerts during period 2, 3, and 5 at the point where the count exceeded the high threshold.

- **Alarm**: Both high and low threshold are defined for a value. An alarm condition occurs when the value reaches or exceeds the configured high threshold within the specified polling interval. The alert is generated then generated and/or sent at the end of the polling interval.

The alarm is cleared at the end of the first interval where the measured value is below the low threshold. In the example shown in the figure below, this model generates an alarm during period 2 when the count exceeds the high threshold. A second alarm is generated in period 6 when the count falls beneath low threshold. The second alarm indicates a “clear” condition.
**Important:** For certain values the alert or alarm serves to warn of low quantities (such as, memory, session licenses, etc.). In these cases, the low threshold is the condition that must be met or exceeded within the polling interval to generate the alert or alarm. When the high threshold is exceeded during an interval, the low quantity condition is cleared.

Refer to the `threshold monitoring` command for additional information on thresholding.

**Example**

The following command configures the system to support the Alarm thresholding model:

```
threshold model alarm
```
threshold monitoring

Enables threshold monitoring for the selected value.

**Product**
All

**Privilege**
Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
```

- **no**
  Disables threshold monitoring for the specified value.

- **default**
  Sets or restores the default value assigned to the specified parameter.

- **aaa-acct-archive-queue**
  Enables threshold monitoring for the AAA accounting archive message queue size.
  Refer to the `threshold aaa-acct-archive-queue-size` command for additional information on these values.

- **aaa-acct-archive-size**
  Enables threshold monitoring for the size of the AAA accounting record archive.

- **aaa-acct-failure**
  Enables threshold monitoring for AAA accounting failures and AAA accounting failure rate values.
  Refer to the `threshold aaa-acct-failure` and `threshold aaa-acct-failure-rate` commands for additional information on these values.

- **aaa-auth-failure**
  Enables threshold monitoring for AAA authentication failures and AAA authentication failure rate values.
Refer to the `threshold aaa-auth-failure` and `threshold aaa-auth-failure-rate` commands for additional information on these values.

aaa-retry-rate
Enables threshold monitoring for the AAA retry rate value.
Refer to the `threshold aaa-retry-rate` command for additional information on this value.

aaamgr-request-queue
Enables threshold monitoring for AAA Manager Requests for each AAA manager process. Refer to the `threshold aaamgr-request-queue` command for additional information on these values.

asngw
Enables the threshold monitoring for ASN-GW services.

call-setup
Enables threshold monitoring for the call setup, call setup failures, and no-resource rejected call values.
Refer to the `threshold call-setup`, `threshold call-setup-failure`, `threshold ppp-setup-fail-rate`, `threshold rp-setup-fail-rate`, and `threshold call-reject-no-resource` commands for additional information on these values.

cpu-resource
Enables threshold monitoring for CPU thresholds.

cpu-session-throughput
Enables threshold monitoring for the CPU session throughput value.
Refer to the `threshold cpu-session-throughput` command for additional information on this value.

content-filtering
Enables threshold monitoring for the Content Filtering in-line service.

diameter
Enables threshold monitoring for Diameter.

ecs
Enables threshold monitoring for the Active Charging Service (ACS)/Enhanced Charging Service (ECS).

epdg-service
Enables threshold monitoring for Evolved Packet Data Gateway (ePDG) service.
Refer to the `threshold epdg-current-sessions` command for additional information on this value.
fa-service
Enables threshold monitoring for Registration Reply errors for each FA service.
Refer to the threshold reg-reply-error FA Service Configuration Mode command for additional information on this value.

fw-and-nat
Enables threshold monitoring for the Firewall and NAT in-line service.
Default: Disabled
Refer to the threshold fw-deny-rule, threshold fw-dos-attack, threshold fw-drop
packet, threshold fw-no-rule, threshold nat-pkt-drop, and threshold nat-port
chunks-usage commands for additional information on this value.

ha-service
Enables threshold monitoring for Registration Reply errors, re-registration reply errors, deregistration reply errors, and average calls setup per second for each HA service and average calls setup per second at the context level.
Refer to the threshold init-rrq-rcvd-rate, threshold reg-reply-error, threshold
rereg-reply-error, and threshold dereg-reply-error HA Service Configuration Mode commands and the threshold ha-service init-rrq-rcvd-rate Context Configuration mode command for additional information on this value.

hnbgw-service
Enables threshold monitoring for HeNB-GW service.

Important: This keyword is required to activate the threshold alarm/alert for HeNB-GW service to use
threshold hnbgw-paging-messages, threshold total-hnbgw-hnb-sessions, and threshold
total-hnbgw-ue-sessions commands for threshold values.

hnbgw-service
Enables threshold monitoring for HNB-GW sessions including Iu-CS and Iu-PS sessions for HNB-GW services on a system at the system level.

Important: This keyword is required to activate the threshold alarm/alert for HNB-GW service to use
threshold total-hnbgw-hnb-sessions, threshold total-hnbgw-ue-sessions, and threshold
total-hnbgw-ue-sessions command for threshold values.

hsgw-service
Enables threshold monitoring for HSGW services.
Refer to the threshold total-hsgw-sessions for more information on HSGW thresholds.

ipsec
Enables monitoring of IPSec thresholds.
Refer to the HA-Service Configuration Mode chapter of the Command Line Interface Reference for information on the IPSec thresholds.
license
Enables threshold monitoring for the session license value.
Refer to the threshold license command for additional information on this value.

lma-service
Enables threshold monitoring for LMA services.
Refer to the threshold total-lma-sessions command for more information on LMA thresholds.

mme-service
Default: Disabled.
Enables threshold monitoring for the MME services.
Refer to the threshold total-mme-sessions command for additional information on this value.

npu-resource
Enables threshold monitoring for the Network Processor Unit (NPU) resources, including NPU utilization.
Refer to the threshold npu-utilization command for additional information on this value.

packets-filtered-dropped
Enables threshold monitoring for the filtered/dropped packet value.
Refer to the threshold packets-filtered-dropped command for additional information on this value.

packets-forwarded-to-cpu
Enables threshold monitoring for the forwarded packet value.
Refer to the threshold packets-forwarded-to-cpu command for additional information on this value.

pdg-service
Enables threshold monitoring for PDG service.
Threshold monitoring for PDG service is disabled by default.

pdif-service
Enables threshold monitoring for PDIF service.

pdsn-service
Enables threshold monitoring for average calls setup per second for contexts and for PDSN services, A11 Request.
Refer to the threshold packets-forwarded-to-cpu command for additional information on this value.

pgw-service
Enables threshold monitoring for P-GW services.
Refer to the threshold total-pgw-sessions for more information on P-GW thresholds.

route-service
Enables threshold monitoring for BGP/VRF route services.
Refer to the ip maximum-routes command in Context configuration mode and threshold route-service bgp-routes in this mode for more information on route thresholds.
**saegw-service**

Enables threshold monitoring for SAEGW services.
Refer to the `threshold total-saegw-sessions` for more information on SAEGW thresholds.

**sess-flow-count**

Enables threshold monitoring for Session Flow Count.
Default: 90%
Refer to the `threshold sess-flow-count` for more information on Session Flow Count Thresholds

**sgw-service**

Enables threshold monitoring for S-GW services.
Refer to the `threshold total-sgw-sessions` for more information on S-GW thresholds.

**subscriber**

Enables threshold monitoring for the subscriber and session values.
Refer to the `threshold subscriber active, threshold subscriber total, threshold total-ggsn-sessions, threshold total-gprs-sessions, threshold total-gprs-pdp-sessions, threshold total-ha-sessions, threshold total-lns-sessions, threshold total-pdsn-sessions, threshold total-pgw-sessions, threshold total-sgw-sessions, threshold total-saegw-sessions, threshold total-sgsn-sessions, threshold total-sgsn-pdp-sessions, threshold per-service-ggsn-sessions, threshold per-service-ha-sessions, threshold per-service-lns-sessions, and threshold per-service-pdsn-sessions` commands for additional information on these values.

**system**

Enables system (chassis) thresholds monitoring.

**tpo**

**Important:** The Traffic Performance Optimization (TPO) in-line service is not supported in this release.

**Usage**

Thresholding on the system is used to monitor the system for conditions that could potentially cause errors or outage. Typically, these conditions are temporary (i.e. high CPU utilization, or packet collisions on a network) and are quickly resolved. However, continuous or large numbers of these error conditions within a specific time interval may be indicative of larger, more severe issues. The purpose of thresholding is to help identify potentially severe conditions so that immediate action can be taken to minimize and/or avoid system downtime.

Thresholding reports conditions using one of the following mechanisms:

- **SNMP traps:** SNMP traps have been created that indicate the condition (high threshold crossing and/or clear) of each of the monitored values. Complete descriptions and other information pertaining to these traps is located in the starentMIB(8164).starentTraps(2) section of the SNMP MIB Reference.

The generation of specific traps can be enabled or disabled on the system allowing you to view only those traps that are most important to you.
• **Logs:** The system provides a facility called threshold for which active and event logs can be generated. As with other system facilities, logs are generated Log messages pertaining to the condition of a monitored value are generated with a severity level of WARNING.

• **Alarm System:** High threshold alarms generated within the specified polling interval are considered “outstanding” until the condition no longer exists and/or a condition clear alarm is generated. “Outstanding” alarms are reported to through the system’s alarm subsystem and are viewable through the CLI.

The following table indicates the reporting mechanisms supported by each of the above models.

**Table 29. ASR 5000 Thresholding Reporting Mechanisms by Model**

<table>
<thead>
<tr>
<th>Model</th>

</table>

In addition to the values that can be enabled by this command, the system supports the enabling of threshold monitoring for IP pool address availability (refer to the `ip pool` and `threshold` commands in this reference) and port utilization (refer to the `threshold` commands in this chapter).

**Example**

The following command enables thresholding for subscriber totals:

```
threshold monitoring subscriber
```
threshold nat-port-chunks-usage

Configures alarm or alert thresholds for the percentage of Network Address Translation (NAT) port chunk utilization.

**Important:** This command is only available in 8.3 and later releases.

**Product**
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold nat-port-chunks-usage high_thresh [ clear low_thresh ]

default threshold nat-port-chunks-usage
```

**default**

Configures this command with the default threshold settings.

Default: 0—disabled

**high_thresh**

Specifies the high NAT-port-chunks-usage percentage threshold that must be met or exceeded within the polling interval to generate an alert or alarm.

*high_thresh* must be an integer from 0 through 100. A value of 0 disables the threshold.

Default: 0

**clear low_thresh**

Specifies the low nat-port-chunks-usage percentage threshold that must be met within the polling interval for a clear alarm to be generated.

*low_thresh* must be an integer from 0 through 100. A value of 0 disables the threshold. If not set, the *high_thresh* will be the high and low threshold setting.

Default: 0

**Usage**

Use this command to configure the NAT port chunk utilization threshold settings.

**Example**

The following command sets the NAT port chunk utilization threshold settings to a high of 75% and a low of 15%:

```
threshold nat-port-chunks-usage 75 clear 15
threshold npu-utilization

Configures alarm or alert thresholds for the percentage of network processing unit (NPU) utilization.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**configure**
Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```plaintext
threshold npu-utilization high_thresh clear low_thresh
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>default</strong></td>
<td>Configures this command with the default threshold settings. Default: 0—disabled</td>
</tr>
<tr>
<td><strong>high_thresh</strong></td>
<td>Specifies the high percentage threshold for NPU utilization that must be met or exceeded within the polling interval to generate an alert or alarm. <code>high_thresh</code> must be an integer from 0 through 100. A value of 0 disables the threshold. Default: 0</td>
</tr>
<tr>
<td><strong>clear low_thresh</strong></td>
<td>Specifies the low percentage threshold for NPU utilization that must be met within the polling interval for a clear alarm to be generated. <code>low_thresh</code> must be an integer from 0 through 100. A value of 0 disables the threshold. If not set, the <code>high_thresh</code> will be the high and low threshold setting. Default: 0</td>
</tr>
</tbody>
</table>

**Usage**
Use this command to configure the NPU utilization threshold settings.

**Example**
The following command sets the NPU utilization threshold settings to a high of 90% and a low of 75%:

```
threshold npu-utilization 90 clear 75
```
**threshold packets-filtered-dropped**

Configures alarm or alert thresholds for filtered or dropped packets within the system.

**Product**
- PDSN
- GGSN
- HA
- P-GW
- SAEGW
- SGSN
- ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**

```
threshold packets-filtered-dropped high_thresh [ clear low_thresh ]
```

- `high_thresh`
  - Default: 0
  - Specifies the high threshold number of filtered/dropped packets experienced by the system resulting from access control list (ACL) rules that must be met or exceeded within the polling interval to generate an alert or alarm.
  - `high_thresh` is an integer from 0 through 100000000. A value of 0 disables the threshold.

- `clear low_thresh`
  - Default: 0
  - Specifies the low threshold number of filtered/dropped packets experienced by the system resulting from ACL rules that maintains a previously generated alarm condition. If the number of packets falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - `low_thresh` is an integer from 0 through 100000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.
Filtered/dropped packet thresholds generate alerts or alarms based on the total number of packets that were filtered or dropped by the system as a result of ACL rules during the specified polling interval. Alerts or alarms are triggered for filtered/dropped packets based on the following rules:

- **Enter condition:** Actual number of filtered/dropped packets is greater than or equal to the high threshold.
- **Clear condition:** Actual number of filtered/dropped packets is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value. In addition, refer to information on ACLs in this reference.

**Example**

The following command configures a filtered/dropped packet high threshold count of 150000 for a system using the Alert thresholding model:

```
threshold packets-filtered-dropped 150000
```
threshold packets-forwarded-to-cpu

Configures alarm or alert thresholds for packets forwarded to active system CPUs in the system.

**Product**
- PDSN
- GGSN
- HA
- P-GW
- SAEGW
- SGSN
- ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold packets-forwarded-to-cpu high_thresh  [ clear low_thresh ]
```

**high_thresh**

Default: 0
Specifies the high threshold number of packets forwarded to CPUs that must be met or exceeded within the polling interval to generate an alert or alarm.
`high_thresh` is an integer from 0 through 1000000000. A value of 0 disables the threshold.

**clear low_thresh**

Default: 0
Specifies the low threshold number of packets forwarded to CPUs that maintains a previously generated alarm condition. If the number of packets falls beneath the low threshold within the polling interval, a clear alarm will be generated.
`low_thresh` is an integer from 0 through 1000000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.
Global Configuration Mode Commands (T-threshold phspc)

Usage

Forwarded packet thresholds generate alerts or alarms based on the total number of packets that were forwarded to active system CPU(s) during the specified polling interval. Packets are forwarded to active system CPUs when the NPUs do not have adequate information to properly route them.

**Important:** Ping and/or traceroute packets are intentionally forwarded to system CPUs for processing. These packet types are included in the packet count for this threshold.

Alerts or alarms are triggered for forwarded packets based on the following rules:

- **Enter condition:** Actual number of forwarded packets is greater than or equal to the high threshold
- **Clear condition:** Actual number of forwarded packets is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

Example

The following command configures a forwarded packet high threshold count of **100000** for a system using the Alert thresholding model:

```
threshold packets-forwarded-to-cpu 100000
```
threshold pdg-current-active-sessions

Configures alarm or alert thresholds for monitoring the total number of currently active Packet Data Gateway/Tunnel Termination Gateway (PDG/TTG) sessions.

Product
PDG/TTG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold pdg-current-active-sessions high_thresh [ clear low_thresh ]

/configure

high_thresh

Configures the total number of active PDG sessions to be monitored on a chassis. high_thresh is an integer from 0 through 1000000. There is no default, but 0 means that there is no threshold monitoring.

clear low_thresh

Clears the number of sessions being monitored using the high_thresh variable defined above. low_thresh is an integer from 0 through 1000000.

Usage

Thresholds are provided for monitoring the overall PDG usage on a chassis. This command is used to monitor the total number of active PDG sessions for an entire chassis.

Example

The following command configures a monitoring threshold of 300000 and a clearing threshold of 100000 active PDG sessions on a chassis:

threshold pdg-current-active-sessions 300000 clear 100000
threshold pdg-current-sessions

Configures alarm or alert thresholds for monitoring the total number of current Packet Data Gateway/Tunnel Termination Gateway (PDG/TTG) sessions, including inactive sessions.

Product
PDG/TTG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold pdg-current-sessions high_thresh [ clear low_thresh ]

*high_thresh*

Configures the total number of PDG sessions on a chassis, both active and inactive. *high_thresh* is any integer from 0 through 1000000. There is no default, but 0 means that there is no threshold monitoring.

*clear low_thresh*

Clears any number of sessions being monitored using the *high_thresh* variable defined above. *low_thresh* is any integer from 0 through 1000000.

Usage

Thresholds are provided for monitoring the overall PDG usage on a chassis. This command is used to monitor the total number of PDG sessions, both active and inactive, for an entire chassis.

Example

The following command configures a monitoring threshold of 300000 and a clearing threshold of 100000 active and inactive PDG sessions on a chassis:

```
threshold pdg-current-sessions 300000 clear 100000
```
threshold pdif-current-active-sessions

Configures alarm or alert thresholds for monitoring the total number of currently active Packet Data Interworking Function (PDIF) sessions.

Product
PDIF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold pdif-current-active sessions high_thresh [ clear low_thresh ]

**high_thresh**

Configures the total number of active PDIF sessions to be monitored on a chassis. *high_thresh* is any integer from 0 through 1000000. There is no default, but 0 means that there is no threshold monitoring.

**clear low_thresh**

Clears the specified number of sessions being monitored using the *high_thresh* variable defined above. *low_thresh* is any integer from 0 through 1000000.

Usage

Thresholds are provided for monitoring the overall PDIF usage on a chassis. This command is used to monitor the total number of active PDIF sessions for an entire chassis.

Example

The following command configures a monitoring threshold of 300000 and a clearing threshold of 100000 active PDIF sessions on a chassis:

```
threshold pdif-current-active-sessions 300000 clear 100000
```
threshold pdif-current-sessions

Configures alarm or alert thresholds for monitoring the total number of current Packet Data Interworking Function (PDIF) sessions, including inactive sessions.

**Product**
PDIF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold pdif-current-sessions high_thresh [ clear low_thresh ]
```

- **high_thresh**
  Configures the total number of PDIF sessions on a chassis, both active and inactive. `high_thresh` is an integer from 0 through 1000000. There is no default, but 0 means that there is no threshold monitoring.

- **clear low_thresh**
  Clears the specified number of sessions being monitored using the `high_thresh` variable defined above. `low_thresh` is an integer from 0 through 1000000.

**Usage**

Thresholds are provided for monitoring the overall PDIF usage on a chassis. This command is used to monitor the total number of PDIF sessions, both active and inactive, for an entire chassis.

**Example**

The following command configures a monitoring threshold of 300000 and a clearing threshold of 100000 active and inactive PDIF sessions on a chassis:

```
threshold pdif-current-sessions 300000 clear 100000
```
threshold per-service-asngw-sessions

Configures alarm or alert thresholds for the number of sessions per ASN-GW service in the system.

Product
ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold per-service-asngw-sessions high_thresh [ clear low_thresh ]

| **high_thresh**
Default: 0
Specifies the high threshold number of PDP contexts for any one ASN-GW service that must be met or exceeded within the polling interval to generate an alert or alarm.
| **low_thresh** is an integer from 0 through 2500000. A value of 0 disables the threshold.

| **clear low_thresh**
Default: 0
Specifies the low threshold number of PDP contexts for any one ASN-GW service that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
| **low_thresh** is an integer from 0 through 2500000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the number of PDP contexts for any ASN-GW service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for PDP contexts based on the following rules:

- **Enter condition:** Actual number of PDP contexts for any ASN-GW service is greater than or equal to the high threshold
- **Clear condition:** Actual number of PDP contexts is less than the low threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.
Example

The following command configures a high threshold count of 10000 subscriber attaches per GGSN service for the Alert thresholding model:

```
threshold per-service-asngw-sessions 10000
```
threshold per-service-ggsn-sessions

Configures alarm or alert thresholds for the number of PDP contexts per GGSN service in the system.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
threshold per-service-ggsn-sessions high_thresh [ clear low_thresh ]
```

- **high_thresh**
  - Default: 0
  - Specifies the high threshold number of PDP contexts for any one GGSN service that must be met or exceeded within the polling interval to generate an alert or alarm.
  - `high_thresh` is an integer from 0 through 4000000. A value of 0 disables the threshold.

- **clear low_thresh**
  - Default: 0
  - Specifies the low threshold number of PDP contexts for any one GGSN service that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - `low_thresh` is an integer from 0 through 4000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the number of PDP contexts for any GGSN service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for PDP contexts based on the following rules:

- **Enter condition:** Actual number of PDP contexts for any GGSN service is greater than or equal to the high threshold
- **Clear condition:** Actual number of PDP contexts is less than the low threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.
Example

The following command configures a high threshold count of 10000 subscriber attaches per GGSN service for the Alert thresholding model:

```
threshold per-service-ggsn-sessions 10000
```
threshold per-service-gprs-pdp-sessions

Configures alarm or alert thresholds for the number of 2G-activated PDP contexts per GPRS service.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
   configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
threshold per-service-gprs-pdp-sessions high_thresh [ clear low_thresh ]
```

---

### high_thresh

Default: 0
Specifies the high threshold number of 2G-activated PDP contexts for any one GPRS service. This number must be met or exceeded within the polling interval to generate an alert or alarm.

*high_thresh* is an integer from 0 through 4000000. A value of 0 disables the threshold.

---

### clear low_thresh

Default: 0
Specifies the low threshold number of 2G-activated PDP contexts for any one GPRS service. This number or higher maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, then a clear alarm will be generated.

*low_thresh* is an integer from 0 through 4000000. A value of 0 disables the threshold.

---

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

---

**Usage**

Monitor and set alarms or alerts when the number of 2G-activated PDP contexts for any GPRS service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for PDP contexts based on the following rules:

- **Enter condition:** Actual number of PDP contexts for any GPRS service is greater than or equal to the high threshold.

- **Clear condition:** Actual number of PDP contexts is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.
Example

The following command configures a high threshold count of 10000 2G-activated PDP contexts per GPRS service for the Alert thresholding model:

```
threshold per-service-gprs-sessions 10000
```
threshold per-service-gprs-sessions

Configures alarm or alert thresholds for the number of 2G-attached subscribers per GPRS service.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold per-service-gprs-sessions high_thresh [ clear low_thresh ]

high_thresh

Default: 0

Specifies the high threshold number of 2G-attached subscribers for any one GPRS service. This threshold number must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh is an integer from 0 through 2000000. A value of 0 disables the threshold.

clear low_thresh

Default: 0

Specifies the low threshold number of 2G-attached subscribers for any one GPRS service. The number of subscribers must remain above this threshold in order to maintain a previously generated alarm condition. If the number of 2G subscribers falls beneath the low threshold within the polling interval, then a clear alarm will be generated.

low_thresh is an integer from 0 through 2000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the number of 2G-attached subscribers for any GPRS service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for PDP contexts based on the following rules:

• Enter condition: Actual number of 2G-attached subscribers for any GPRS service is greater than or equal to the high threshold.

• Clear condition: Actual number of 2G-attached subscribers is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of **10000** 2G-attaches per GPRS service for the Alert thresholding model:

```
threshold per-service-gprs-sessions 10000
```
threshold per-service-ha-sessions

Configures alarm or alert thresholds for the number of HA sessions per Home Agent (HA) service in the system.

Product

HA

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold per-service-ha-sessions high_thresh [ clear low_thresh ]

- **high_thresh**
  - Default: 0
  - Specifies the high threshold number of HA sessions for any one HA service that must be met or exceeded within the polling interval to generate an alert or alarm.
  - *high_thresh* is an integer from 0 through 4000000. A value of 0 disables the threshold.

- **clear low_thresh**
  - Default: 0
  - Specifies the low threshold number of HA sessions for any one HA service that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - *low_thresh* is an integer from 0 through 4000000. A value of 0 disables the threshold.

- **Important**: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the number of HA sessions for any HA service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for HA sessions based on the following rules:

- **Enter condition**: Actual number of HA sessions for any HA service is greater than or equal to the high threshold.

- **Clear condition**: Actual number of HA sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.
Example

The following command configures a HA session per service high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold per-service-ha-sessions 10000
```
threshold per-service-lns-sessions

Configures alarm or alert thresholds for the number of L2TP Network Server (LNS) sessions per LNS service in the system.

Product
PDSN
GGSN
HA
ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
threshold per-service-lns-sessions high_thresh [ clear low_thresh ]
```

high_thresh
Default: 0
Specifies the high threshold number of LNS sessions for any one LNS service that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh is an integer from 0 through 2500000. A value of 0 disables the threshold.

clear low_thresh
Default: 0
Specifies the low threshold number of LNS sessions for any one LNS service that maintains a previously generated alarm condition. If the number of LNS sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

low_thresh is an integer from 0 through 2500000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
Monitor and set alarms or alerts when the number of LNS sessions for any LNS service in the system is equal to or greater than the set limit.
Alerts or alarms are triggered for LNS sessions based on the following rules:

- **Enter condition:** Actual number of LNS sessions for any LNS service is greater than or equal to the high threshold.
**Clear condition:** Actual number of LNS sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a LNS session per service high threshold count of **10000** for a system using the Alert thresholding model:

```
threshold per-service-Ins-sessions 10000
```
threshold per-service-pdg-sessions

Configures alarm or alert thresholds for the number of Packet Data Gateway (PDG) sessions per PDG service in the system.

**Product**
PDG/TTG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold per-service-pdg-sessions high_thresh [ clear low_thresh ]
```

**high_thresh**
Default: 0
Specifies the high threshold number of PDG sessions for any one PDG service that must be met or exceeded within the polling interval to generate an alert or alarm.

*high_thresh* is an integer from 0 through 1000000. A value of 0 disables the threshold.

**clear low_thresh**
Default: 0
Specifies the low threshold number of PDG sessions for any one PDG service that maintains a previously generated alarm condition. If the number of PDG sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

*low_thresh* is an integer from 0 through 1000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**
Monitor and set alarms or alerts when the number of PDG sessions for any PDG service in the system is equal to or greater than the set limit.
Alerts or alarms are triggered for PDSN sessions based on the following rules:

- **Enter condition:** Actual number of PDG sessions for any PDG service is greater than or equal to the high threshold.

- **Clear condition:** Actual number of PDSN sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

Example

The following command configures a PDG session per service high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold per-service-pdg-sessions 10000
```
threshold per-service-pdsn-sessions

Configures alarm or alert thresholds for the number of Packet Data Serving Node (PDSN) sessions per PDSN service in the system.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold per-service-pdsn-sessions high_thresh [ clear low_thresh ]
```

**high_thresh**

Default: 0
Specifies the high threshold number of PDSN sessions for any one PDSN service that must be met or exceeded within the polling interval to generate an alert or alarm.

*high_thresh* is an integer from 0 through 2500000. A value of 0 disables the threshold.

**clear low_thresh**

Default: 0
Specifies the low threshold number of PDSN sessions for any one PDSN service that maintains a previously generated alarm condition. If the number of PDSN sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

*low_thresh* is an integer from 0 through 2500000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Monitor and set alarms or alerts when the number of PDSN sessions for any PDSN service in the system is equal to or greater than the set limit.
Alerts or alarms are triggered for PDSN sessions based on the following rules:

- **Enter condition:** Actual number of PDSN sessions for any PDSN service is greater than or equal to the high threshold.
- **Clear condition:** Actual number of PDSN sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a PDSN session per service high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold per-service-pdsn-sessions 10000
```
threshold per-service-sgsn-pdp-sessions

Configures alarm or alert thresholds for the number of 3G-activated PDP contexts per SGSN service on the system.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**
```plaintext
threshold per-service-sgsn-pdp-sessions high_thresh [ clear low_thresh ]
```

| high_thresh |
| Default: 0 |
| Specifies the high threshold number of 3G-activated PDP contexts for any one SGSN service. This number must be met or exceeded within the polling interval to generate an alert or alarm. |
| high_thresh is an integer from 0 through 4000000. A value of 0 disables the threshold. |

| clear low_thresh |
| Default: 0 |
| Specifies the low threshold number of 3G-activated PDP contexts for any one SGSN service. This number or higher maintains a previously generated alarm condition. If the number of 3G-activated PDP contexts falls beneath the low threshold within the polling interval, a clear alarm will be generated. |
| low_thresh is an integer from 0 through 2400000. A value of 0 disables the threshold. |

---

**Important**: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**
Monitor and set alarms or alerts when the number of 3G-activated PDP contexts for any SGSN service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for PDP contexts based on the following rules:

- **Enter condition**: Actual number of 3G-activated PDP contexts for any SGSN service is greater than or equal to the high threshold.

- **Clear condition**: Actual number of 3G-activated PDP contexts is less than the low threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.
Example

The following command configures a high threshold count of 10000 3G-activated PDP contexts per SGSN service for the system’s Alert thresholding model:

```
threshold per-service-sgsn-sessions 10000
```
threshold per-service-sgsn-sessions

Configures alarm or alert thresholds for the number of 3G-attached subscribers per SGSN service in the system.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:
[local]host_name(config)#

Syntax

threshold per-service-sgsn-sessions high_thresh [ clear low_thresh ]

high_thresh
Default: 0
Specifies the high threshold number of 3G-attached subscribers for any one SGSN service. This number must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 2000000. A value of 0 disables the threshold.

clear low_thresh
Default: 0
Specifies the low threshold number of 3G-attached subscribers for any one SGSN service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 through 2000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
Monitor and set alarms or alerts when the number of 3G-attached subscribers for any one SGSN service in the system is equal to or greater than the set limit.
Alerts or alarms are triggered for PDP contexts based on the following rules:

- **Enter condition**: Actual number of 3G-attached subscribers for any single SGSN service is greater than or equal to the high threshold.
- **Clear condition**: Actual number of 3G-attached subscribers for any single SGSN service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 10000 3G-attached subscribers per SGSN service for a system using the Alert thresholding model:

```
threshold per-service-sgsn-sessions 10000
```
threshold phsgw-auth-failure

Configures alarm or alert thresholds for the number of authentication failures in Personal Handyphone Service Gateway (PHSGW) service.

Product
PHSGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold phsgw-auth-failure high_thresh [ clear low_thresh ]

#### high_thresh

Default: 0
Specifies the high threshold number for PHSGW authentication failures in any one PHSGW service. This number must be met or exceeded within the polling interval to generate an alert or alarm.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

#### clear low_thresh

Default: 0
Specifies the low threshold number of PHSGW authentication failures in any one PHSGW service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Set the monitoring and clearing thresholds for PHSGW authentication failures.

Alerts or alarms are triggered for authentication failures based on the following rules:

- **Enter condition:** Actual number of PHSGW authentication failures in any one PHSGW service is greater than or equal to the high threshold.

- **Clear condition:** Actual number of PHSGW authentication failures in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the *threshold poll* command to configure the polling interval and the *threshold monitoring* command to enable thresholding for this value.

**Example**

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSGW auth failures:

```
threshold phsgw-auth-failure 100000 clear 50000
```
threshold phsgw-eapol-auth-failure

Configures alarm or alert thresholds for authentication failures for a PHSGW service using Extensible Authentication Protocol Over LAN (EAPOL).

Product
PHSGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold phsgw-eapol-auth-failure high_thresh [ clear low_thresh ]

- **high_thresh**
  Default: 0
  Specifies the high threshold number for PHSGW EAPOL failures in any one PHSGW service. This number must be met or exceeded within the polling interval to generate an alert or alarm.
  **high_thresh** is an integer from 0 through 1000000. A value of 0 disables the threshold.

- **clear low_thresh**
  Default: 0
  Specifies the low threshold number of PHSGW EAPOL failures in any one PHSGW service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  **low_thresh** is an integer from 0 through 1000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Set the monitoring and clearing thresholds for PHSGW EAPOL failures. Alerts or alarms are triggered for EAPOL failures based on the following rules:

- **Enter condition:** Actual number of PHSGW EAPOL failures in any one PHSGW service is greater than or equal to the high threshold.
- **Clear condition:** Actual number of PHSGW EAPOL failures in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSGW EAPOL failures:

```
threshold phsgw-eapol-auth-failure 100000 clear 50000
```
**threshold phsgw-handoff-denial**

Configures alarm or alert thresholds for handoff denials in PHSGW.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold phsgw-handoff-denial high_thresh [ clear low_thresh ]
```

```
high_thresh
Default: 0
Specifies the high threshold number of handoff denials for any one PHSGW service. This number must be met or exceeded within the polling interval to generate an alert or alarm.
`high_thresh` is an integer from 0 through 1000000. A value of 0 disables the threshold.
```

```
clear low_thresh
Default: 0
Specifies the low threshold number of handoff denials for any one PHSGW service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.
`low_thresh` is an integer from 0 through 1000000. A value of 0 disables the threshold.
```

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Set the monitoring and clearing thresholds for PHSGW handoff denials.

Alerts or alarms are triggered for handoff denials based on the following rules:

- **Enter condition:** Actual number of PHSGW handoff denials in any one PHSGW service is greater than or equal to the high threshold.
- **Clear condition:** Actual number of PHSGW handoff denials in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.
Example

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSGW handoff denials:

```
threshold phsgw-handoff-denial 100000 clear 50000
```
threshold phsgw-max-eap-retry

Configures alarm or alert thresholds for the maximum number of Extensible Authentication Protocol (EAP) retries in PHSGW.

Product

PHSGW

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold phsgw-max-eap-retry high_thresh [ clear low_thresh ]

| high_thresh

Default: 0
Specifies the high threshold number of EAP retries for any one PHSGW service. This number must be met or exceeded within the polling interval to generate an alert or alarm.

| low_thresh

Default: 0
Specifies the low threshold number of EAP retries for any one PHSGW service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Set the monitoring and clearing thresholds for PHSGW EAP retries.
Alerts or alarms are triggered for handoff denials based on the following rules:

- **Enter condition:** Actual number of PHSGW EAP retries in any one PHSGW service is greater than or equal to the high threshold.

- **Clear condition:** Actual number of PHSGW EAP retries in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSGW EAP retries:

```
threshold phsgw-max-eap-retry 100000 clear 50000
```
threshold phsgw-max-eapol-retry

Configures alarm or alert thresholds for the maximum number of Extensible Authentication Protocol over LAN (EAPOL) retries in PHSGW.

Product
PHSGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold phsgw-max-eapol-retry high_thresh [ clear low_thresh ]

- **high_thresh**
  - Default: 0
  - Specifies the high threshold number of EAPOL retries for any one PHSGW service. This number must be met or exceeded within the polling interval to generate an alert or alarm.
  - *high_thresh* is an integer from 0 through 1000000. A value of 0 disables the threshold.

- **clear low_thresh**
  - Default: 0
  - Specifies the low threshold number of EAPOL retries for any one PHSGW service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - *low_thresh* is an integer from 0 through 1000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Set the monitoring and clearing thresholds for PHSGW EAPOL retries.
Alerts or alarms are triggered for handoff denials based on the following rules:

- **Enter condition:** Actual number of PHSGW EAPOL retries in any one PHSGW service is greater than or equal to the high threshold.

- **Clear condition:** Actual number of PHSGW EAPOL retries in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSGW EAPOL retries:

```
threshold phsgw-max-eapol-retry 100000 clear 50000
```
threshold phsgw-network-entry-denial

Configures, alarm or alert thresholds for the number of network entry denials in PHSGW.

Product
PHSGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
threshold phsgw-max-network-entry-denial high_thresh [ clear low_thresh ]
```

**high_thresh**

Default: 0

Specifies the high threshold number of network entry denials for any one PHSGW service. This number must be met or exceeded within the polling interval to generate an alert or alarm.

*high_thresh* is an integer from 0 through 1000000. A value of 0 disables the threshold.

**clear low_thresh**

Default: 0

Specifies the low threshold number of network entry denials for any one PHSGW service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.

*low_thresh* is an integer from 0 through 1000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Set the monitoring and clearing thresholds for PHSGW network entry denials. Alerts or alarms are triggered for handoff denials based on the following rules:

- **Enter condition:** Actual number of PHSGW network entry denials in any one PHSGW service is greater than or equal to the high threshold.

- **Clear condition:** Actual number of PHSGW network entry denials in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.
Example

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSGW network entry denials:

```
threshold phsgw-network-entry-denial 100000 clear 50000
```
threshold phsgw-session-setup-timeout

Configures alarm or alert thresholds for the number of PHSGW sessions that timed out during setup.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold phsgw-session-setup-timeout high_thresh [ clear low_thresh ]
```

- **high_thresh**
  Default: 0
  Specifies the high threshold number of session setup timeouts for any one PHSGW service. This number must be met or exceeded within the polling interval to generate an alert or alarm.
  `high_thresh` is an integer from 0 through 1000000. A value of 0 disables the threshold.

- **clear low_thresh**
  Default: 0
  Specifies the low threshold number of session setup timeouts for any one PHSGW service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  `low_thresh` is an integer from 0 through 1000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Set the monitoring and clearing thresholds for PHSGW session setup timeouts.
Alerts or alarms are triggered for handoff denials based on the following rules:

- **Enter condition:** Actual number of PHSGW session setup timeouts in any one PHSGW service is greater than or equal to the high threshold.
- **Clear condition:** Actual number of PHSGW session setup timeouts in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.
Example

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSGW session setup timeouts:

```
threshold phsgw-session-setup-timeout 100000 clear 50000
```
threshold phsgw-session-timeout

Configures alarm or alert thresholds for the number of PHSGW sessions that timed out.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
*configure*

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold phsgw-session-timeout high_thresh [ clear low_thresh ]
```

- **high_thresh**
  
  Default: 0
  
  Specifies the high threshold number of session timeouts for any one PHSGW service. This number must be met or exceeded within the polling interval to generate an alert or alarm.
  
  high_thresh is an integer from 0 through 1000000. A value of 0 disables the threshold.

- **clear low_thresh**

  Default: 0
  
  Specifies the low threshold number of session timeouts for any one PHSGW service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  
  low_thresh is an integer from 0 through 1000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Set the monitoring and clearing thresholds for PHSGW session timeouts.

Alerts or alarms are triggered for handoff denials based on the following rules:

- **Enter condition:** Actual number of PHSGW session timeouts in any one PHSGW service is greater than or equal to the high threshold.

- **Clear condition:** Actual number of PHSGW session timeouts in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.
Example

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSGW session timeouts:

```
threshold phsgw-session-timeout 100000 clear 50000
```
### threshold phspc-session-setup-timeout

Configures alarm or alert thresholds for the number of Personal Handyphone System - Personal Computer (PHSPC) sessions that timed out during setup.

**Product**
- PHSGW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
  ```
  configure
  ```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold phspc-session-setup-timeout high_thresh  [ clear low_thresh ]
```

- **high_thresh**
  
  Default: 0
  
  Specifies the high threshold number of session setup timeouts for any one PHSPC service. This number must be met or exceeded within the polling interval to generate an alert or alarm.
  
  `high_thresh` is an integer from 0 through 1000000. A value of 0 disables the threshold.

- **clear low_thresh**
  
  Default: 0
  
  Specifies the low threshold number of session setup timeouts for any one PHSPC service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  
  `low_thresh` is an integer from 0 through 1000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Set the monitoring and clearing thresholds for PHSPC session setup timeouts.

Alerts or alarms are triggered for handoff denials based on the following rules:

- **Enter condition:** Actual number of PHSPC session setup timeouts in any one PHSGW service is greater than or equal to the high threshold.
  
  - **Clear condition:** Actual number of PHSPC session setup timeouts in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

Example

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSPC session setup timeouts:

```
threshold phspc-session-setup-timeout 100000 clear 50000
```
threshold phspc-sleep-mode-timeout

Configures alarm or alert thresholds for the number of PHSPC sessions that timed out when the personal computer went into sleep mode.

**Product**

PHSGW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

**Syntax**

```
threshold phspc-sleep-mode-timeout high_thresh [ clear low_thresh ]
```

- **high_thresh**
  
  Default: 0
  
  Specifies the high threshold number of sleep mode timeouts for any one PHSPC service. This number must be met or exceeded within the polling interval to generate an alert or alarm. `high_thresh` is an integer from 0 through 1000000. A value of 0 disables the threshold.

- **clear low_thresh**
  
  Default: 0
  
  Specifies the low threshold number of sleep mode timeouts for any one PHSPC service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated. `low_thresh` is an integer from 0 through 1000000. A value of 0 disables the threshold.

- **Important**: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Set the monitoring and clearing thresholds for PHSPC sleep mode timeouts. Alerts or alarms are triggered for handoff denials based on the following rules:

- **Enter condition**: Actual number of PHSPC sleep mode timeouts in any one PHSGW service is greater than or equal to the high threshold.

- **Clear condition**: Actual number of PHSPC sleep mode timeouts in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSPC sleep mode timeouts:

```
threshold phspc-sleep-mode-timeout 100000 clear 50000
```
threshold phspc-sm-entry-denial

Configures alarm or alert thresholds for the number of denied PHSPC short message (SM) sessions.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold phspc-sm-entry-denial high_thresh [ clear low_thresh ]
```

- **high_thresh**
  - Default: 0
  - Specifies the high threshold number of SM entry denials for any one PHSPC service. This number must be met or exceeded within the polling interval to generate an alert or alarm.
  - *high_thresh* is an integer from 0 through 1000000. A value of 0 disables the threshold.

- **clear low_thresh**
  - Default: 0
  - Specifies the low threshold number of SM entry denials for any one PHSPC service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - *low_thresh* is an integer from 0 through 1000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**
Set the monitoring and clearing thresholds for PHSPC SM entry denials.
Alerts or alarms are triggered for handoff denials based on the following rules:

- **Enter condition:** Actual number of PHSPC SM entry denials in any one PHSPC service is greater than or equal to the high threshold.
- **Clear condition:** Actual number of PHSPC SM entry denials in any one PHSPC service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the *threshold poll* command to configure the polling interval and the *threshold monitoring* command to enable thresholding for this value.
Example

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSPC SM entry denials:

```
threshold phsgw-sm-entry-denial 100000 clear 50000
```
Chapter 143
Global Configuration Mode Commands (threshold poll commands A - N)

This section includes the commands threshold poll 10sec-cpu-utilization interval through threshold poll npu-utilization interval.

The Global Configuration Mode is used to configure basic system-wide parameters.

Mode

Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
threshold poll 10sec-cpu-utilization interval

Configures the polling interval over which to measure a 10-second average of CPU utilization.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config) #

Syntax

threshold poll 10sec-cpu-utilization interval duration

default threshold poll 10sec-cpu-utilization interval

default
Restores the specified parameter to its default value 300 seconds.

interval duration
Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration is an integer from 30 through 60000 in multiples of 30.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshCPUUtilization10Sec command in this mode.

Example

The following command configures the polling interval to 600 seconds for the 10-second CPU utilization threshold:

threshold poll 10sec-cpu-utilization 600
threshold poll a11-ppp-send-discard interval

Configures the polling interval for PDSN service over which to count the number of packets that the PPP protocol processing layer internally discarded on transmit for any reason.

Product
PDSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
threshold poll a11-ppp-send-discard interval duration
```

default threshold poll a11-ppp-send-discard interval

default
Restores the specified parameter to its default value 0 seconds.

```
interval duration
```
Default: 0 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
`duration` is an integer from 60 through 900 in multiples of 30.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPDSNSvcA11PPPSendDiscard` command in this mode.

Example
The following command configures the polling interval to 600 seconds for the A11 PPP send discard threshold:
threshold poll all-ppp-send-discard interval 600
threshold poll a11-rac-msg-discard interval

Configures the polling interval for PDSN service over which to count the number of Discarded A11 Registration Acknowledgements.

**Product**

PDSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

**Syntax**

```
threshold poll a11-rac-msg-discard interval duration
default threshold poll a11-rac-msg-discard interval
```

**Default**

Restores the specified parameter to its default value 0 seconds.

```
default
```

**interval duration**

Default: 0 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval. duration is an integer from 60 through 900 in multiples of 30.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable** **ThreshPDSNSvcA11RACMsgDiscard** command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the A11 RAC message discard threshold:
threshold poll all-rac-msg-discard interval 600
threshold poll aa11-rrp-failure interval

Configures the polling interval for PDSN service over which to count A11 Registration Response failures.

**Product**  
PDSN

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > Global Configuration  
```bash
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll all-rrp-failure interval duration

default threshold poll all-rrp-failure interval
```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPDSNSvcAllRRPFailure` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the A11 RRP failure threshold:

```
threshold poll all-rrp-failure interval 600
```
threshold poll a11-rrq-msg-discard interval

Configures the polling interval for PDSN service over which to count how many A11 Registration Request messages are discarded.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll a11-rrq-msg-discard interval duration

default threshold poll a11-rrq-msg-discard interval

default

Restores the specified parameter to its default value 0 seconds.

interval duration

Default: 0 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration is an integer from 60 through 900 in multiples of 30.
```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPDSNSvcAllRRQMsgDiscard` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the A11 RRQ message discard threshold:
threshold poll all-rrq-msg-discard interval 600
threshold poll aaa-acct-archive-queue-size interval

Configures the polling interval over which to measure AAA accounting archive message queue size.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

threshold poll aaa-acct-archive-queue-size1 interval duration
default threshold poll aaa-acct-archive-queue-size1 interval
threshold poll aaa-acct-archive-queue-size2 interval duration
default threshold poll aaa-acct-archive-queue-size2 interval
threshold poll aaa-acct-archive-queue-size3 interval duration
default threshold poll aaa-acct-archive-queue-size3 interval

default
Restores the specified parameter to its default value 900 seconds.

interval duration
Default: 900 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration is an integer from 60 through 60000 in multiples of 30.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.
**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshAAAAcctArchiveQueue-<1-3>` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the AAA accounting archive queue size 1 threshold:

```
threshold poll aaa-acct-archive-queue-size1 interval 600
```
threshold poll aaa-acct-archive-size interval

Configures the polling interval over which to count archived AAA accounting messages.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll aaa-acct-archive-size interval duration

default threshold poll aaa-acct-archive-size interval

default
Restores the specified parameter to its default value 300 seconds.

interval duration
Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration is an integer from 60 through 60000 in multiples of 30.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Example

The following command configures the polling interval to 600 seconds for the AAA accounting archive size threshold:

threshold poll aaa-acct-archive-size interval 600
threshold poll aaa-acct-failure interval

Configures the polling interval over which to count failed AAA accounting requests.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll aaa-acct-failure interval duration

default threshold poll aaa-acct-failure interval
```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshAAAACacctFail` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the AAA accounting failure threshold:

```
threshold poll aaa-acct-failure interval 600
```
threshold poll aaa-acct-failure-rate interval

Configures the polling interval over which to measure the percentage of AAA accounting failures.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll aaa-acct-failure-rate interval duration

default threshold poll aaa-acct-failure-rate interval

default

Restores the specified parameter to its default value 300 seconds.

interval duration

Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration is an integer from 60 through 60000 in multiples of 30.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshAAAAcctFailRate command in this mode.

Example

The following command configures the polling interval to 600 seconds for the AAA accounting failure rate threshold:

threshold poll aaa-acct-failure-rate interval 600
threshold poll aaa-auth-failure interval

Configures the polling interval over which to count failed authentication requests.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll aaa-auth-failure interval duration

default threshold poll aaa-auth-failure interval

default
Restores the specified parameter to its default value 300 seconds.

interval duration
Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration is an integer from 60 through 60000 in multiples of 30.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshAAAAuthFail command in this mode.

Example
The following command configures the polling interval to 600 seconds for the AAA authentication failure threshold:

threshold poll aaa-auth-failure interval 600
threshold poll aaa-auth-failure-rate interval

Configures the polling interval over which to measure the percentage of AAA authentication failures.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

**Syntax**

`threshold poll aaa-auth-failure-rate interval duration`

`default threshold poll aaa-auth-failure-rate interval`

**default**

Restores the specified parameter to its default value 300 seconds.

`interval duration`

Default: 300 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

`duration` is an integer from 60 through 60000 in multiples of 30.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshAAAAuthFailRate` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the AAA authentication failure rate threshold:

`threshold poll aaa-auth-failure-rate interval 600`
threshold poll aaa-retry-rate interval

Configures the polling interval over which to measure the percent of AAA request message retries.

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

threshold poll aaa-retry-rate interval duration

default threshold poll aaa-retry-rate interval

default
Restores the specified parameter to its default value 300 seconds.

interval duration
Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration is an integer from 60 through 60000 in multiples of 30.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshAAARetryRate command in this mode.

Example

The following command configures the polling interval to 600 seconds for the AAA retry rate threshold:

threshold poll aaa-retry-rate interval 600
threshold poll aaamgr-request-queue interval

Configures the polling interval over which to count the number of AAA Manager Requests for each AAA manager process.

default threshold poll active-subscriber interval
```

```
default
Restores the specified parameter to its default value 300 seconds.
```

```
interval duration
Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration is an integer from 60 through 60000 in multiples of 30.
```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable ThreshSubscriberActive** command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the active subscriber threshold:

```
threshold poll active-subscriber interval 600
```
threshold poll asngw-auth-failure interval

Configures the polling interval over which to count or measure the thresholding value for ASN Gateway authentication failure.

**Product**
ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**

```
threshold poll asngw-auth-failure interval dur
```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

---
**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the *threshold monitoring* and other threshold commands for additional information on the system’s support for thresholds in this chapter.

---
**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThresholdASNGWAuthFail` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the ASN Gateway authentication failure threshold:
threshold poll asngw-auth-failure interval 600
threshold poll asngw-handoff-denial interval

Configures the polling interval over which to count or measure the thresholding value for ASN Gateway hand-off denial.

Usage

This command configures the polling interval for CDR File Space Usage threshold.

⚠️ Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

⚠️ Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshCDRFileSpace command in this mode.

Example

The following command configures the polling interval to 600 seconds for the CDR file space usage threshold:

threshold poll cdr-file-space interval 600
threshold poll contfilt-block interval

Configures the polling interval Content Filtering Block threshold.

**Product**
CF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll contfilt-block interval duration
default threshold poll contfilt-block interval
```

- `default`
  Uses the default threshold polling interval.
  Default: 300 seconds

```
interval duration
```

- Specifies the polling interval (in seconds) for the Content Filtering Block threshold.
- `duration` must be an integer from 60 through 60000.

**Usage**

This command configures the polling interval Content Filtering Block threshold.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshContFiltBlock` command in this mode.

**Example**

The following command configures the polling interval to **600** seconds for the content filtering blocking threshold:

```
threshold poll contfilt-block interval 600
```
threshold poll contfilt-rating interval

Configures the polling interval for the Content Filtering Rating threshold.

</thead>
<tbody>
<tr>
<td>Specifies the polling interval (in seconds) for the Content Filtering Rating threshold.</td>
</tr>
<tr>
<td>duration must be an integer from 60 through 60000.</td>
</tr>
</tbody>
</table>

Usage

This command configures the polling interval for the Content Filtering Rating threshold.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshContFiltRating` command in this mode.

Example

The following command configures the polling interval to 600 seconds for the content filtering rating processing threshold:

```
threshold poll contfilt-rating interval 600
```
threshold poll cpu-available-memory interval

Configures the polling interval over which to measure the percentage of total packet processing card CPU memory used.

**Product**

<tr>
<td>Specifies the amount of time (in seconds) that comprises the polling interval.</td>
</tr>
<tr>
<td>duration must be an integer from 30 through 60000.</td>
</tr>
</tbody>
</table>

**Usage**
This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshCPU Memory` command in this mode.

**Example**
The following command configures the polling interval to 600 seconds for the CPU available memory threshold:

```
threshold poll cpu-available-memory interval 600
```
threshold poll cpu-load interval

Configures the polling interval over which to monitor packet processing card CPU loads using a 5-minute average measurement.

default threshold poll cscf-service-route-failures interval

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshCSCFSvcRouteFailures` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the CSCF service route failures threshold:

```
threshold poll cscf-service-route-failures interval 600
```
threshold poll dcca-bad-answers interval

Configures the polling interval for DCCA Bad Answers threshold—invalid or bad response to the system from the Diameter server.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**

```plaintext
threshold poll dcca-bad-answers interval duration

default threshold poll dcca-bad-answers interval
```

- **default**
  
  Uses the default threshold polling interval.
  
  Default: 900 seconds

- **interval duration**
  
  Specifies the polling interval (in seconds) for the DCCA Bad Answers threshold.
  
  `duration` must be an integer from 60 through 60000.

**Usage**

This command configures the polling interval for DCCA Bad Answers threshold.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholding in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshDCCABadAnswers` command in this mode.

**Example**

The following command configures the polling interval to **600** seconds for invalid or bad response threshold to the system from Diameter server:
threshold poll dcca-bad-answers interval

threshold poll dcca-rating-failed interval 600
threshold poll dcca-protocol-error interval

Configures the polling interval for Diameter Credit-Control Application (DCCA) Protocol Error threshold.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

threshold poll dcca-protocol-error interval duration

default threshold poll dcca-protocol-error interval

- **default**
  - Uses the default threshold polling interval.
  - Default: 900 seconds

- **interval duration**
  - Specifies the polling interval (in seconds) for the DCCA Protocol Error threshold.
  - duration must be an integer from 60 through 60000.

Usage

Use this the polling interval for DCCA Protocol Error threshold.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholding in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThresholdDCCAProtocolError` command in this mode.

Example

The following command configures the polling interval to 600 seconds for the DCCA protocol error threshold:

```
threshold poll dcca-protocol-error interval 600
```
threshold poll dccarating-failed interval

This command configures the polling interval for Diameter Credit-Control Application (DCCA) Rating Failed threshold.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold poll dccarating-failed interval duration

default threshold poll dccarating-failed interval
```

**Usage**

This command configures the polling interval for DCCA Rating Failed threshold.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholding in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable ThreshDCCARatingFailed** command in this mode.

**Example**

The following command configures the polling interval to **600 seconds** for the Diameter Credit Control Application (DCCA) Rating Group (content-id) request reject thresholds:

```
threshold poll dccarating-failed interval 600
```
threshold poll dcca-unknown-rating-group interval

Configures the polling interval for Diameter Credit-Control Application (DCCA) Unknown Rating Group threshold.

**Product**

ACS

**Privilege**

Security Administrator, Administrator

```

```
default threshold poll dcca-unknown-rating-group interval
```

```
default
```

Uses the default polling interval.
Default: 900 seconds

```
interval duration
```

Specifies the polling interval (in seconds) for the DCCA Unknown Rating Group threshold.

`duration` must be an integer from 60 through 60000.

**Usage**

This command configures the polling interval for DCCA Unknown Rating Group threshold.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholding in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshDCCAUnknownRatingGroup` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds to threshold for the unknown DCCA Rating Group (content-id) returned by Diameter to system:

```
threshold poll dcca-unknown-rating-group interval 600
```
threshold poll dereg-reply-error interval

Configures the polling interval to count the number of de-registration reply errors per HA service.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll dereg-reply-error interval duration

default threshold poll dereg-reply-error interval
```

**default**

Uses the default polling interval.
Default: 300 seconds

```
interval duration
```

Specifies the amount of time (in seconds) that comprises the polling interval.
`duration` must be an integer from 60 through 60000. The input will be rounded up to the closest multiple of 30.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands in this chapter for additional information on the system’s support for thresholding.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshHASvcDeregReplyError` command in this mode.

**Example**

The following command configures the HA de-registration reply error threshold polling interval to 600 seconds:

```
```
threshold poll dereg-reply-error interval 600
threshold poll diameter-retry-rate interval

Configures the polling interval for the Diameter Credit-Control Application (DCCA) Diameter Retry Rate threshold.

Usage
This command specifies the polling interval for Diameter Retry Rate threshold.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands in this chapter for additional information on the system’s support for thresholding.

Important: To enable an SNMP trap for monitoring this threshold use the **snmp trap enable** command in this mode.

Example
The following command configures the Diameter Retry Rate threshold polling interval to 600 seconds:

```
threshold poll diameter-retry-rate interval 600
```
threshold poll edr-file-space interval

Command configures the polling interval for Event Data Record (EDR) File Space Usage threshold.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold poll edr-file-space interval duration
```

### interval duration

Default: 300 seconds.

Specifies the polling interval (in seconds) for the EDR File Space Usage threshold.

*duration* must be an integer from 60 through 60000.

**Usage**

This command configures the polling interval for EDR File Space Usage threshold.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshEDRFileSpace` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the EDR file space usage threshold:

```
threshold poll edr-file-space interval 600
```
threshold poll edr-udr-dropped-flow-control interval

Configures the polling interval to count the total number of Event Data Records (EDRs) and Usage Data Records (UDRs) discarded due to ACSMGR flow control.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll edr-udr-dropped-flow-control interval duration

interval duration

Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 60 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Example

The following command configures the polling interval to 600 seconds for the EDR/UDR drops due to flow control threshold:

threshold poll edr-udr-dropped-flow-control interval 600
threshold poll epdg-current-sessions interval

Configures the polling interval to count the total number of subscribers currently in Evolved Packet Date Gateway (ePDG) sessions.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold poll epdg-current-sessions interval duration
```

**interval duration**

Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
```
duration
```
must be an integer from 60 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThresholdEPDGCurrSess` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the ePDG sessions threshold:

```
threshold poll epdg-current-sessions interval 600
```
threshold poll error-no-resource interval

Configures the polling interval in seconds over which to count CSCF No Resource Errors.

**Product**
SCM

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```conf
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll error-no-resource interval duration
```

- `interval duration`
  - Default: 300 seconds.
  - Specifies the amount of time (in seconds) that comprises the polling interval.
  - `duration` must be an integer from 60 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshCSCFSvcErrorNoResource` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the CSCF No Resource Errors threshold:

```
threshold poll error-no-resource interval 600
```
threshold poll error-presence interval

Configures the polling interval in seconds over which to count CSCF Presence Errors.

**Product**

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config) #

**Syntax**

```
threshold poll error-presence interval duration
```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshCSCFSvcErrorPresence` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the CSCF Presence Errors threshold:

```
threshold poll error-presence interval 600
```
threshold poll error-reg-auth interval

Configures the polling interval in seconds over which to count CSCF Reg-Auth Errors.

Product

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll error-reg-auth interval duration

interval duration

Default: 300 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

duration must be an integer from 60 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshCSCFSvcErrorRegAuth command in this mode.

Example

The following command configures the polling interval to 600 seconds for the CSCF Reg-Auth Errors threshold:

threshold poll error-reg-auth interval 600
threshold poll error-tcp interval

Configures the polling interval in seconds over which to count CSCF TCP Errors.

configure
Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

threshold poll error-tcp interval duration

interval duration
Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 60 through 60000.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

⚠️ Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

⚠️ Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshCSCFSvcErrorTcp command in this mode.

Example

The following command configures the polling interval to 600 seconds for the CSCF TCP Errors threshold:

threshold poll error-tcp interval 600
threshold poll fa-reg-reply-error interval

Configures the polling interval over which to measure the number of registration reply errors for Foreign Agent (FA) services.

Product
FA

Privilege
Security Administrator, Administrator

Mode

*configure*

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll fng-current-active-sessions interval duration
```

*interval duration*

Default: 0 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

*duration* must be an integer from 60 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the *snmp trap enable ThreshFNGCurrActSess* command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the FNG current active sessions threshold:

```
threshold poll fng-current-active-sessions interval 600
```
threshold poll fng-current-sessions interval

Configures the polling interval in seconds over which to count Femto Network Gateway (FNG) current sessions, including inactive sessions.

**Product**
FNG

**Privilege**
Security Administrator, Administrator

**Mode**

```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable ThreshLicense** command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the utilization of session licenses:

```
threshold poll license-remaining-session interval 600
```
threshold poll mgmt-cpu-memory-usage interval

Configures the polling interval over which to measure management card CPU memory usage.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll mgmt-cpu-memory-usage interval duration

interval duration
Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 60000.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Example
The following command configures the polling interval to 600 seconds for management card CPU memory usage:

threshold poll mgmt-cpu-memory-usage interval 600
threshold poll mgmt-cpu-utilization interval

Configures the polling interval over which to measure management card CPU utilization.

**Product**

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll mgmt-cpu-utilization interval duration
```

**interval duration**

Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
*duration* must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the *threshold monitoring* and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Example**

The following command configures the polling interval to 600 seconds for management card CPU memory usage:

```
threshold poll mgmt-cpu-utilization interval 600
```
threshold poll mme-attach-failure interval

Configures the polling interval to count the MME Attach Failure messages across all MME services in the system.

Product
MME

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

threshold poll mme-attach-failure interval dur

default threshold poll mme-attach-failure interval

default
Restores the polling interval value to its default value of 900 seconds.

interval dur
Default: 900 seconds.
Specifies the polling interval (in seconds) for counting MME Attach Failure messages across all MME services in the system.
dur must be an integer from 30 through 60000 in multiples of 30.

Usage
Use this command to configure the polling interval to count the MME Attach Failure messages across all MME services in the system to generate threshold value.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring mme-service and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshMMEAttachFail command in this mode.

Example

The following command configures the polling interval of 600 seconds to count the MME Attach Failure messages for threshold limit:
threshold poll mme-attach-failure interval 600
threshold poll mme-auth-failure interval

Configures the polling interval to count the MME Authentication Failure messages across all MME services in the system.

Product
MME

Privilege
Security Administrator, Administrator

Mode
 Exec > Global Configuration
 configure

Entering the above command sequence results in the following prompt:

[local]host_name(config) #

Syntax

threshold poll mme-auth-failure interval dur

default threshold poll mme-auth-failure interval

default
Restores the specified poll interval value to its default value of 900 seconds.

interval dur
Default: 900 seconds.
Specifies the polling interval (in seconds) for counting MME Authentication Failure messages across all MME services in the system.
dur must be an integer from 30 through 60000 in multiples of 30.

Usage
Use this command to configure the polling interval to count the MME Auth Failure messages across all MME services in the system to generate threshold value.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring mme-service and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshMMEAuthFail command in this mode.

Example
The following command configures the polling interval of 600 seconds to count the MME Auth Failure messages for threshold limit:

```
threshold poll mme-auth-failure interval 600
```
threshold poll nat-port-chunks-usage interval

Configures the polling interval over which to measure the percentage of Network Address Translation (NAT) port chunk utilization.

**Product**
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
```
configure
```
Entering the above command sequence results in the following prompt:

```

**Syntax**

```
threshold poll nat-port-chunks-usage interval duration
```

```
default threshold poll nat-port-chunks-usage interval
```

```
default
```
Restores the specified poll interval value to its default value of 900 seconds.

```
interval duration
```
Specifies the amount of time (in seconds) that comprises the polling interval.
```
duration must be an integer from 30 through 60000.
```
Default: 900 seconds.

**Usage**
This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshNATPortChunksUsage` command in this mode.

**Example**
The following command configures the polling interval to 600 seconds for (NAT) port chunk utilization:
```
threshold poll nat-port-chunks-usage interval 600
```
threshold poll npu-utilization interval

Configures the polling interval over which to measure the percentage of network processing unit (NPU) utilization.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll npu-utilization interval duration
```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshNPUUtilization` command in this mode.

**Example**

The following command configures the polling interval to **600** seconds for NPU utilization:

```
threshold poll npu-utilization interval 600
```
Chapter 144
Global Configuration Mode Commands (threshold poll commands O - Z)

This section includes the commands `threshold poll packets-filtered-dropped interval` through `threshold poll tpo-rto-timeout`.

The Global Configuration Mode is used to configure basic system-wide parameters.

**Mode**

`Exec > Global Configuration`

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config) #
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
threshold poll packets-filtered-dropped interval

Configures the polling interval over which to count the filtered/dropped packets.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
`configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold poll packets-filtered-dropped interval duration
```

**Usage**
This command sets the time period over which to monitor the specified value for threshold crossing.

---
**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

---
**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable` ThreshPacketsFilteredDropped command in this mode.

**Example**
The following command configures the polling interval to 600 seconds for filtered/dropped packets:

```
threshold poll packets-filtered-dropped interval 600
```
threshold poll packets-forwarded-to-cpu interval

Configures the polling interval over which to count packets forwarded to active system CPUs in the system.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll packets-forwarded-to-cpu interval duration

interval duration
Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 60000.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshPacketsForwarded command in this mode.

Example
The following command configures the polling interval to 600 seconds for packets forwarded to active system CPUs in the system:

threshold poll packets-forwarded-to-cpu interval 600
threshold poll pdg-current-active-sessions interval

Configures the polling interval over which to count the total number of currently active Packet Data Gateway/Tunnel Termination Gateway (PDG/TTG) sessions.

Product
PDG
TTG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config)#

Syntax

threshold poll pdg-current-active-sessions interval duration

interval duration
Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 60000.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThresholdPDGCCurrActSess` command in this mode.

Example

The following command configures the polling interval to 600 seconds for PDG/TTG sessions:

```
threshold poll pdg-current-active-sessions interval 600
```
threshold poll pdg-current-sessions interval

Configures the polling interval over which to count the total number of current Packet Data Gateway/Tunnel Termination Gateway (PDG/TTG) sessions, including inactive sessions.

Product

PDG/TTG

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll pdg-current-sessions interval duration

interval duration

Default: 300 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

duration must be an integer from 30 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshPDGCurrSess command in this mode.

Example

The following command configures the polling interval to 600 seconds for PDG/TTG sessions:

threshold poll pdg-current-sessions interval 600
threshold poll pdif-current-active-sessions interval

Configures the polling interval over which to count the total number of currently active Packet Data Interworking Function (PDIF) sessions.

**Product**
PDIF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold poll pdif-current-active-sessions interval duration
```

**interval duration**

Default: 300 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

*duration* must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPDIFCurrActSess` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PDIF sessions:

```
threshold poll pdif-current-active-sessions interval 600
```
threshold poll pdif-current-sessions interval

Configures the polling interval over which to count the total number of current Packet Data Interworking Function (PDIF) sessions, including inactive sessions.

Product
PDIF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll pdif-current-sessions interval duration

interval duration
Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 60000.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system's support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshPDIFCurrSess command in this mode.

Example

The following command configures the polling interval to 600 seconds for PDIF sessions:

threshold poll pdif-current-sessions interval 600
threshold poll pdsn-init-rrq-rcvd-rate interval

Configures the polling interval over which to count the total number of current Packet Data Serving Node (PDSN) sessions, including inactive sessions.

Product
PDSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config) #

Syntax

threshold poll pdsn-init-rrq-rcvd-rate interval duration

  interval duration

Default: 0 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 60 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshPDSNCallSetupRate command in this mode.

Example

The following command configures the polling interval to 600 seconds for PDSN sessions:

    threshold poll pdsn-init-rrq-rcvd-rate interval 600
threshold poll pdsn-svc-init-rrq-rcvd-rate interval

Configures the polling interval over which to count the total number of current Packet Data Serving Node (PDSN) sessions, including inactive sessions.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll pdsn-svc-init-rrq-rcvd-rate interval duration
```

- `interval duration`
  - Default: 300 seconds.
  - Specifies the amount of time (in seconds) that comprises the polling interval.
  - `duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPDSNSvcCallSetupRate` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PDSN sessions:

```
threshold poll pdsn-svc-init-rrq-rcvd-rate interval 600
```
threshold poll per-service-asngw-sessions interval

Configures the polling interval in seconds over which to count the number of PDP contexts per ASN-GW service in the system.

Product
ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll per-service-asngw-sessions interval duration

interval duration

Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshPerServiceASNGWSessions command in this mode.

Example

The following command configures the polling interval to 600 seconds for ASN-GW sessions:

    threshold poll per-service-asngw-sessions interval 600
threshold poll per-service-ggsn-sessions interval

Configures the polling interval in seconds over which to count the number of PDP contexts per GGSN service in the system.

Product: GGSN

Privilege: Security Administrator, Administrator

Mode: Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax:

threshold poll per-service-ggsn-sessions interval duration

- interval duration

Default: 300 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval. duration must be an integer from 30 through 60000.

Usage:

This command sets the time period over which to monitor the specified value for threshold crossing.

⚠️ Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

⚠️ Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshPerServiceGGSNSessions command in this mode.

Example:

The following command configures the polling interval to 600 seconds for GGSN sessions:

threshold poll per-service-ggsn-sessions interval 600
threshold poll per-service-gprs-pdp-sessions interval

Configures the polling interval in seconds over which to count the number of 2G-activated PDP contexts per GPRS service.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold poll per-service-gprs-pdp-sessions interval duration
```

`interval duration`

Default: 300 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.
`duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPerServiceGPRSPDPSessions` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for 2G PDP contexts:

```
threshold poll per-service-gprs-pdp-sessions interval 600
```
threshold poll per-service-gprs-sessions interval

Configures the polling interval in seconds over which to count the number of 2G-attached subscribers per GPRS service.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll per-service-gprs-sessions interval duration
```

```
interval duration
```

Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
```
duration must be an integer from 30 through 60000.
```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPerServiceGPRSSessions` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for 2G GPRS sessions:

```
threshold poll per-service-gprs-sessions interval 600
```
threshold poll per-service-ha-sessions interval

Configures the polling interval in seconds over which to count the number of HA sessions per Home Agent (HA) service in the system.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name (config) #

Syntax

threshold poll per-service-ha-sessions interval duration

interval duration

Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshPerServiceHASSessions command in this mode.

Example

The following command configures the polling interval to 600 seconds for HA sessions:

threshold poll per-service-ha-sessions interval 600
threshold poll per-service-Ins-sessions interval

Configures the polling interval in seconds over which to count the number of L2TP Network Server (LNS) sessions per LNS service in the system.

Product: LNS
Privilege: Security Administrator, Administrator
Mode: Exec > Global Configuration configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll per-service-Ins-sessions interval duration

interval duration
Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval. duration must be an integer from 30 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshPerServiceLNSSessions command in this mode.

Example

The following command configures the polling interval to 600 seconds for LNS sessions:

threshold poll per-service-Ins-sessions interval 600
threshold poll per-service-pdg-sessions interval

Configures the polling interval in seconds over which to count the number of Packet Data Gateway (PDG) sessions per PDG/TTG service in the system.

Product

[local]host_name(config)#

Syntax

```
threshold poll per-service-pdg-sessions interval duration
```

```
interval duration
Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 60000.
```

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThresholdPerServicePDGSessions` command in this mode.

Example

The following command configures the polling interval to 600 seconds for PDG/TTG sessions:

```
threshold poll per-service-pdg-sessions interval 600
```
threshold poll per-service-pdsn-sessions interval

Configures the polling interval in seconds over which to count the number of Packet Data Serving Node (PDSN) sessions per PDSN service in the system.

**Product**

PDSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll per-service-pdsn-sessions interval duration
```

**interval** duration

Default: 300 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

*duration* must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable ThreshPerServicePDNSessions** command in this mode.

**Example**

The following command configures the polling interval to *600* seconds for PDSN sessions:

```
threshold poll per-service-pdsn-sessions interval 600
```
threshold poll per-service-sgsn-pdp-sessions interval

Configures the polling interval in seconds over which to count the number of 3G-activated PDP contexts per SGSN service on the system.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll per-service-sgsn-pdp-sessions interval duration
```

*interval duration*

Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
*duration* must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPerServiceSGSNPDPSessions` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for 3G PDP contexts:

```
threshold poll per-service-sgsn-pdp-sessions interval 600
```
threshold poll per-service-sgsn-sessions interval

Configures the polling interval in seconds over which to count the number of 3G-attached subscribers per SGSN service in the system.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
threshold poll per-service-sgsn-sessions interval duration
```

**interval duration**
Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
`duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPerServiceSGSNSessions` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for SGSN sessions:

```
threshold poll per-service-sgsn-sessions interval 600
```
threshold poll phsgw-auth-failure interval

Configures the polling interval in seconds over which to count the number of Personal Handyphone System Gateway (PHSGW) authentication failures.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold poll phsgw-auth-failure interval duration
```

- **interval duration**
  - Default: 0 seconds.
  - Specifies the amount of time (in seconds) that comprises the polling interval.
  - `duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable` `ThreshPHSGWAuthFail` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PHSGW authentication failures:

```
threshold poll phsgw-auth-failure interval 600
```
threshold poll phsgw-eapol-auth-failure interval

Configures the polling interval in seconds over which to count the number of authentication failures for a PHSGW service using Extensible Authentication Protocol Over LAN (EAPOL).

Product
PHSGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll phsgw-eapol-auth-failure interval duration

interval duration
Default: 0 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 60000.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshPHSGWEAPOLAuthFailure command in this mode.

Example
The following command configures the polling interval to 600 seconds for PHSGW EAPOL failures:

threshold poll phsgw-eapol-auth-failure interval 600
threshold poll phsgw-handoff-denial interval

Configures the polling interval in seconds over which to count the number of handoff denials in PHSGW.

Product
PHSGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:
[local] host_name(config) #

Syntax

```
threshold poll phsgw-handoff-denial interval duration

interval duration
Default: 0 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 60000.
```

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPHSGWMaxEAPOLRetry` command in this mode.

Example

The following command configures the polling interval to 600 seconds for PHSGW handoff denials:

```
threshold poll phsgw-handoff-denial interval 600
```
threshold poll phsgw-max-eap-retry interval

Configures the polling interval in seconds over which to count the maximum number of Extensible Authentication Protocol (EAP) retries in PHSGW.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**

```
threshold poll phsgw-max-eap-retry interval duration
```

*interval duration*

Default: 0 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

*duration* must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPHSGWMaxEAPRetry` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PHSGW EAP retries:

```
threshold poll phsgw-max-eap-retry interval 600
```
threshold poll phsgw-max-eapol-retry interval

Configures the polling interval in seconds over which to count the maximum number of Extensible Authentication Protocol Over LAN (EAPOL) retries in PHSGW.

Product

configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

threshold poll phsgw-max-eapol-retry interval duration

interval duration
Default: 0 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 60000.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshPHSGWMaxEAPOLRetry command in this mode.

Example
The following command configures the polling interval to 600 seconds for PHSGW EAPOL retries:

threshold poll phsgw-max-eapol-retry interval 600
threshold poll phsgw-network-entry-denial interval

Configures the polling interval in seconds over which to count the number of network entry denials in PHSGW.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll phsgw-network-entry-denial interval duration
```

- **interval duration**
  - Default: 0 seconds.
  - Specifies the amount of time (in seconds) that comprises the polling interval.
  - *duration* must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable ThreshPHSGWNWEntryDenial** command in this mode.

**Example**

The following command configures the polling interval to *600* seconds for PHSGW network entry denials:

```
threshold poll phsgw-network-entry-denial interval 600
```
threshold poll phsgw-session-setup-timeout interval

Configures the polling interval in seconds over which to count the number of PHSGW sessions that timed out during setup.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

*configure*

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold poll phsgw-session-setup-timeout interval duration
```

**interval duration**

Default: 0 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

*duration* must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the *snmp trap enable ThreshPHSGWSessSetupTimeout* command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PHSGW session setup timeouts:

```
threshold poll phsgw-session-setup-timeout interval 600
```
threshold poll phsgw-session-timeout interval

Configures the polling interval in seconds over which to count the number of PHSGW sessions that timed out.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll phsgw-session-timeout interval duration
```

```
interval duration
```

Default: 0 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
`duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPHSGWSessTimeout` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PHSGW session timeouts:

```
threshold poll phsgw-session-timeout interval 600
```
threshold poll phspc-session-setup-timeout interval

Configures the polling interval in seconds over which to count the number of Personal Handyphone System - Personal Computer (PHSPC) sessions that timed out during setup.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local] host_name (config) #
```

**Syntax**

```
threshold poll phspc-session-setup-timeout interval duration
```

*interval duration*

Default: 0 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable ThreshPHSPCSessionSetupTimeout** command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PHSPC session setup timeouts:

```
threshold poll phspc-session-setup-timeout interval 600
```
threshold poll phspc-sleep-mode-timeout interval

Configures the polling interval in seconds over which to count the number of PHSPC sessions that timed out when the personal computer went into sleep mode.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

`[local]host_name(config)#`

**Syntax**

```
threshold poll phspc-sleep-mode-timeout interval duration
```

`interval duration`

Default: 0 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
`duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPHSPCSleepModeTimeout` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PHSPC sleep mode timeouts:

```
threshold poll phspc-sleep-mode-timeout interval 600```
threshold poll phspc-sm-entry-denial interval

Configures the polling interval in seconds over which to count the number of denied PHSPC short message (SM) sessions.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll phspc-sm-entry-denial interval duration
```

- **interval duration**
  - Default: 0 seconds.
  - Specifies the amount of time (in seconds) that comprises the polling interval.
  - `duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable` **ThreshPHSPCSmEntryDenial** command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PHSPC SM session denials:

```
threshold poll phspc-sm-entry-denial interval 600
```
threshold poll port-high-activity interval

Configures the polling interval in seconds over which to measure the overall percentage of port utilization.

Product
All

Privilege
Administrator Security Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll port-high-activity interval seconds

intervals seconds

Configures the threshold polling interval in multiples of 30 seconds. seconds is an integer from 30 through 60000. Default is 300 seconds.

Usage

High port activity thresholds generate alerts or alarms based on the peak utilization percentage of each configured port during the specified polling interval. This threshold is configured on a per-port basis. Alerts or alarms are triggered for high port activity based on the following rules:
Enter condition: Actual percent peak utilization of a port is greater than or equal to the high threshold.
Clear condition: Actual percent peak utilization of a port is less than the low threshold.
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. This threshold is configured on a per-port basis configured using the port port-type slot#/port# command syntax.

Important: This command is not available on all platforms

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshPortHighActivity command in this mode.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshPortHighActivity command in this mode.

Example

Use the following example to configure the polling interval over which to measure for high port activity to 300 seconds:
threshold poll port-high-activity interval

threshold poll port-high-activity interval 300
threshold poll port-rx-utilization interval

Configures the polling interval in seconds over which to measure the overall percentage of incoming traffic received over system ports.

Product
All

Privilege
Administrator Security Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll port-rx-utilization interval seconds

**interval seconds**

Configures the threshold polling interval in multiples of 30 seconds. **seconds** is an integer from 30 to 60000. Default is 300 seconds.

Usage

Receive port utilization thresholds generate alerts or alarms based on the utilization percentage of each configured port in relation to data received during the specified polling interval. This threshold is configured on a per-port basis configured using the **port port-type slot#/port#** command syntax.

**Important:** This command is not available on all platforms

**Important:** Ports configured for half-duplex do not differentiate between data received and data transmitted. (The transmitted and received percentages are combined.) Therefore, to avoid redundant alarms, it is recommended that only the receive or transmit utilization threshold be configured.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable ThreshPortRxUtil** command in this mode.

Example

Use the following example to configure a threshold poll interval of 300 seconds (5 minutes)

threshold poll port-rx-utilization interval 300
threshold poll port-tx-utilization

Configures the polling interval in seconds over which to measure the overall percentage of outgoing traffic sent over system ports.

**Product**
All

**Privilege**
Administrator Security Administrator

**Mode**
Exec > Global Configuration
`configure`
Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold poll port-tx-utilization interval seconds
```

- **interval seconds**
  Configures the threshold polling interval in multiples of 30 seconds. `seconds` is an integer from 30 through 60000. Default is 300 seconds.

**Usage**
Transmit port utilization thresholds generate alerts or alarms based on the utilization percentage of each configured port in relation to data transmitted during the specified polling interval. This threshold is configured on a per-port basis configured using the `port port-type slot#/port#` command syntax.

**Important**: This command is not available on all platforms

**Important**: Ports configured for half-duplex do not differentiate between data received and data transmitted. (The transmitted and received percentages are combined.) Therefore, to avoid redundant alarms, it is recommended that only the receive or transmit utilization threshold be configured.

**Important**: To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPortTxUtil` command in this mode.

**Example**

Use the following example to configure a threshold poll interval of **300** seconds (5 minutes)

```
threshold poll port-tx-utilization interval 300
```
threshold poll ppp-setup-fail-rate interval

Configures the polling interval in seconds over which to measure for the percentage of point-to-point protocol (PPP) setup failures.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll ppp-setup-fail-rate interval duration

interval duration
Default: 900 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 60000.
```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPPPSetupFailRate` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PPP setup failures:

```
threshold poll ppp-setup-fail-rate interval 600
```
threshold poll reg-reply-error interval

Configures the polling interval over which to measure number of registration reply errors for Home Agent (HA) services.

Product

Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll storage-utilization interval dur

default threshold poll route-service interval

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Restores the threshold poll interval value to its default value of 900 seconds.</td>
</tr>
<tr>
<td>interval time</td>
<td>Default: 900 seconds</td>
</tr>
<tr>
<td></td>
<td>Specifies the amount of time (in seconds) that comprises the polling interval.</td>
</tr>
<tr>
<td></td>
<td><em>dur</em> is any integer from 30 through 60000.</td>
</tr>
</tbody>
</table>

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold model** and **threshold monitoring** commands for additional information on the system’s support for thresholding.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable** ThreshStorageUtilization command in this mode.

Example

The following command configures the polling interval for flash memory utilization polling duration value to 600 seconds (10 minutes):

threshold poll storage-utilization interval 600
threshold poll system-capacity interval

Configures the polling interval over which to measure the percentage of current system capacity.

Product
All

Privilege
Administrator Security Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll system-capacity interval dur

default threshold poll route-service interval

default

Restores the threshold poll interval value to its default value of 900 seconds.

interval time

Default: 900 seconds

Specifies the amount of time (in seconds) that comprises the polling interval.

dur is any integer from 30 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold model and threshold monitoring commands for additional information on the system’s support for thresholding.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshSystemCapacity command in this mode.

Example

The following command configures the polling interval for flash memory utilization polling duration value to 600 seconds (10 minutes):

threshold poll system-capacity interval 600
**threshold poll total-asngw-sessions interval**

Configures the polling interval over which to count or measure the thresholding value for the total number of sessions across all the ASN-GW services on a system to trigger an alert or alarm.

**Product**
ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll total-asngw-sessions interval time
```

```
default threshold poll total-asngw-sessions interval
```

**Default threshold poll total-asngw-sessions interval**

```
default
```

Restores the threshold polling interval value to its default value of 300 seconds.

```
interval time
```

Default: 300 seconds

Specifies the amount of time (in seconds) that comprises the polling interval.

`time` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold model** and **threshold monitoring** commands for additional information on the system’s support for thresholding.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable** **ThreshASNGWSessions** command in this mode.

**Example**

The following command configures the polling interval for counting the total number of ASN-GW sessions across all the ASN-GW services on a system, to 600 seconds (10 minutes):
threshold poll total-asngw-sessions interval 600
threshold poll total-ggsn-sessions interval

Configures the polling interval over which to count or measure the thresholding value for the total number of sessions across all the GGSN services on a system to trigger an alert or alarm.

Product

```

**Syntax**

```
threshold poll total-lns-sessions interval time
default threshold poll total-lns-sessions interval
```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold model` and `threshold monitoring` commands for additional information on the system’s support for thresholding.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshLNSSessions` command in this mode.

**Example**
The following command configures the polling interval for the total number of LNS sessions across all the LNS sessions on a system, to 600 seconds (10 minutes):

```
threshold poll total-Ins-sessions interval 600```

threshold poll total-mme-sessions

Configures the polling interval over which to count or measure the thresholding value for MME sessions on the system.

Product
MME

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll total-mme-sessions interval time

default threshold poll total-mme-sessions interval

default
Restores the threshold poll interval value to its default value of 900 seconds.

interval time
Default: 900 seconds
Specifies the polling interval (in seconds) for counting the total number of MME sessions on the system.
time must be any integer from 30 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold model and threshold monitoring commands for additional information on the system’s support for thresholding.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThresholdMMESessions command in this mode.

Example

The following command configures the polling interval for the total MME session threshold polling duration value to 600 seconds (10 minutes):

threshold poll total-mme-sessions interval 600
threshold poll total-pdsn-sessions interval

Configures the polling interval over which to count the total number of Packet Data Serving Node (PDSN) sessions in the system.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Mode**

```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold model** and **threshold monitoring** commands for additional information on the system’s support for thresholding.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable** **ThreshSGSNSessions** command in this mode.

**Example**

The following command configures the polling interval for the total number of SGSN sessions on a system, to 600 seconds (10 minutes):

```
threshold poll total-sgsn-sessions interval 600
```
threshold poll total-sgw-sessions interval

Configures the polling interval over which to count the total number of Serving Gateway (S-GW) sessions across all services in the system.

Product
S-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll total-sgw-sessions interval time

default threshold poll total-sgw-sessions interval

default
Restores the threshold poll interval value to its default value of 300 seconds.

interval time

Default: 300 seconds
Specifies the amount of time (in seconds) that comprises the polling interval.
time must be an integer from 30 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold model and threshold monitoring commands for additional information on the system’s support for thresholding.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshSGWSessions command in this mode.

Example
The following command configures the polling interval for the total number of S-GW sessions on a system, to 600 seconds (10 minutes):

```
threshold poll total-sgw-sessions interval 600
```
**threshold poll total-subscriber interval**

Configures the polling interval over which to count the total number of subscriber sessions across all services in the system.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration  
```
configure
```
Entering the above command sequence results in the following prompt:
```
[local]host_name(config)#
```

**Syntax**

```
threshold poll total-subscriber interval time
```

**default threshold poll total-subscriber interval**

```
default
```
Restores the threshold poll interval value to its default value of 300 seconds.

```
interval time
```
Default: 300 seconds  
Specifies the amount of time (in seconds) that comprises the polling interval.  
*time* must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the *threshold model* and *threshold monitoring* commands for additional information on the system’s support for thresholding.

**Important:** To enable an SNMP trap for monitoring this threshold use the *snmp trap enable* ThreshSubscriberTotal command in this mode.

**Example**

The following command configures the polling interval for the total number of subscribers on a system, to 600 seconds (10 minutes):
threshold poll total-subscriber interval 600
threshold poll tpo-dns-failure

The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
threshold poll tpo-low-compression-gain

The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
threshold poll tpo-rto-timeout

The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
This section includes the commands `threshold ppp-setup-fail-rate` through `url-blacklisting database`. The Global Configuration Mode is used to configure basic system-wide parameters.

**Mode**

Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**threshold ppp-setup-fail-rate**

Configures alarm or alert thresholds for the percentage of point-to-point protocol (PPP) setup failures.

**Product**
- PDSN
- GGSN

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
  - configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold ppp-setup-fail-rate high_thresh [ clear low_thresh ]
```

- **high_thresh**
  - Default: 0
  - Specifies the high threshold rate percentage for PPP setup failures experienced by the system that must be met or exceeded within the polling interval to generate an alert or alarm.
  - `high_thresh` is an integer from 0 through 100. A value of 0 disables the threshold.

- **clear low_thresh**
  - Default: 0
  - Specifies the low threshold rate percentage for PPP setup failures experienced by the system that maintains a previously generated alarm condition. If the number of setup failures falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - `low_thresh` is an integer from 0 through 100. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

PPP setup failure rate thresholds generate alerts or alarms based on the rate of call setup failures experienced by the system during the specified polling interval. The failure rate is the percentage of failures as determined by number of PPP setup failures divided by the total number of PPP sessions initiated.

Alerts or alarms are triggered for PPP setup failure rates based on the following rules:

- **Enter condition:** Actual number of call setup failures is greater than or equal to the high threshold.

- **Clear condition:** Actual number of call setup failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a PPP setup failure rate high percentage threshold of 50 percent and a clear threshold of 45 percent:

```
threshold ppp-setup-fail-rate 50 clear 45
```
threshold route-service bgp-routes

Configures alarm or alert thresholds for the percentage of route services to BGP routes.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:
[local]host_name(config)#

Syntax

threshold route-service bgp-routes high_thresh [ clear low_thresh ]

high_thresh
Default: 0
Specifies the high threshold rate percentage for BGP routes on the system that must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 100. A value of 0 disables the threshold.

clear low_thresh
Default: 0
Specifies the low threshold rate percentage for BGP routes on the system that maintains a previously generated alarm condition. If the number of setup failures falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 through 100. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to configure a threshold in percentage of maximum BGP routes allowed. If the percentage of the number of BGP routes in a context (including all VRFs) reaches high_thresh, a notification is generated. Optionally, if the threshold subsystem is configured in ‘alarm’ mode, a Threshold_Clear notification is generated when the percentage of the number of BGP routes in a context (including all VRFs) goes below low_thresh. The maximum number of BGP routes is also sent by BGP task when getting the statistics.
Alerts or alarms are triggered for BGP routes based on the following rules:
• Enter condition: Actual number of call setup failures is greater than the high threshold.
• Clear condition: Actual number of call setup failures is less than the low threshold.
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures system for high threshold of 50 percent and a clear threshold of 45 percent:

```
threshold route-service bgp-routes 50 clear 45
```
threshold rp-setup-fail-rate

Configures alarm or alert thresholds for the percentage of RAN PDSN (RP) setup failures.

Product
PDSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold rp-setup-fail-rate high_thresh [ clear low_thresh ]

high_thresh
Default: 0
Specifies the high threshold rate percentage for RP setup failures experienced by the system that must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 100. A value of 0 disables the threshold.

clear low_thresh
Default: 0
Specifies the low threshold rate percentage for RP setup failures experienced by the system that maintains a previously generated alarm condition. If the number of setup failures falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 through 100. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
RP setup failure rate thresholds generate alerts or alarms based on the rate of call setup failures experienced by the system during the specified polling interval. The failure rate is the percentage of failures as determined by number of Registration Request Messages rejected divided by the total number of Registration Request Messages received.
Alerts or alarms are triggered for RP setup failure rates based on the following rules:

• Enter condition: Actual number of call setup failures is greater than or equal to the high threshold.

• Clear condition: Actual number of call setup failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a RP setup failure rate high threshold of 50 percent and a clear threshold of 45 percent:

```
threshold rp-setup-fail-rate 50 clear 45
```
threshold sess-flow-count

Configures alarm or alert thresholds for the percentage of session manager flow count.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure
Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold sess-flow-count flow_count_thresh [ clear clear_thresh ]

flow_count_percent

Default: 90
Specifies the high threshold rate percentage for session manager flow count to generate an alert or alarm. flow_count_thresh is an integer from 1 through 100.

clear clear_thresh

Specifies the low threshold rate percentage for session manager flow count. If the number of session manager flow count falls beneath the low threshold, a clear alarm will be generated. clear_thresh is an integer from 1 through 100. The value chosen for the clear_thresh must always be lesser than the flow_count_thresh.

Usage
Use this command to configure thresholds for monitoring the session flow count. Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

Example
The following command configures a session flow count high threshold of 50 percent and a clear threshold of 45 percent:

threshold sess-flow-count 50 clear 45
threshold spc-cpu-memory-usage

This command has been renamed to threshold mgmt-cpu-memory-usage. Please refer to that command for details. Note that for backwards compatibility, the system accepts this command as valid.

⚠️ Important: This command is not supported on all platforms.
threshold spc-cpu-utilization

This command has been renamed to `threshold mgmt-cpu-utilization`. Please refer to that command for details. Note that for backwards compatibility, the system accepts this command as valid.
threshold storage-utilization

Configures alarm or alert thresholds for the percentage of management card flash memory utilization.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold storage-utilization high_thresh [ clear low_thresh ]

high_thresh

Default: 90
Specifies the high threshold storage utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh is an integer from 0 through 100. A value of 0 disables the threshold.

clear low_thresh

Default: 90
Specifies the low threshold storage utilization percentage that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

low_thresh is an integer from 0 through 100. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Flash memory utilization thresholds generate alerts or alarms based on the utilization percentage of storage available to the system.
Alerts or alarms are triggered for storage utilization based on the following rules:

- Enter condition: Actual percentage storage utilization is greater than or equal to the high threshold.
- Clear condition: Actual percentage storage utilization is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.
Example

The following command configures a high threshold for storage utilization percentage of 85 for a system using the Alert thresholding model:

```
threshold storage-utilization 85
```
threshold subscriber active

Configures alarm or alert thresholds for the number of active subscribers in the system.

Product
PDSL
GGSN
SGSN
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold subscriber active high_thresh [ clear low_thresh ]

high_thresh
Default: 0
Specifies the high threshold number of active subscriber sessions facilitated by the system that must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 4000000. A value of 0 disables the threshold.

clear low_thresh
Default: 0
Specifies the low threshold number of active subscriber sessions facilitated by the system that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 and 4000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
Active subscriber thresholds generate alerts or alarms based on the total number of active subscriber sessions facilitated by the system during the specified polling interval.
Alerts or alarms are triggered for active subscriber totals based on the following rules:

• Enter condition: Actual total number of active subscriber sessions is greater than or equal to the high threshold.

• Clear condition: Actual total number of active subscriber sessions is less than the low threshold.
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures an active subscriber high threshold count of **150000** and a low threshold of **100000** for a system using the Alarm thresholding model:

```
threshold subscriber active 150000 clear 100000
```
threshold subscriber total

Configures alarm or alert thresholds for the total number of active and inactive subscribers in the system.

**Product**
PDSN
GGSN
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold subscriber total high_thresh [ clear low_thresh ]
```

**high_thresh**

Default: 0
Specifies the high threshold number of subscriber sessions (active and dormant) facilitated by the system that must be met or exceeded within the polling interval to generate an alert or alarm. The high threshold is an integer from 0 through 4000000. A value of 0 disables the threshold.

**clear low_thresh**

Default: 0
Specifies the low threshold number of subscriber sessions (active and dormant) facilitated by the system that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated. The low threshold is an integer from 0 and 4000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Total subscriber thresholds generate alerts or alarms based on the total number of subscriber sessions (active and dormant) facilitated by the system during the specified polling interval. Alerts or alarms are triggered for subscriber totals based on the following rules:

- **Enter condition:** Actual total number of subscriber sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of subscriber sessions is less than the low threshold.
Global Configuration Mode Commands (threshold ppp - url-blacklisting)

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures an active subscriber high threshold count of **450000** and a low threshold of **250000** for a system using the Alarm thresholding model:

```
threshold subscriber total 450000 clear 250000
```
threshold system-capacity

Configures alarm or alert thresholds based on the percentage of current system capacity.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold system high_thresh [ clear low_thresh ]
```

- `high_thresh`
  Default: 90
  Specifies the high threshold system capacity percentage that must be met or exceeded within the polling interval to generate an alert or alarm.
  `high_thresh` is an integer from 0 through 100. A value of 0 disables the threshold.

- `clear low_thresh`
  Default: 90
  Specifies the low threshold system capacity percentage that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  `low_thresh` is an integer from 0 through 100. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Flash memory utilization thresholds generate alerts or alarms based on the system utilization. Alerts or alarms are triggered for system capacity based on the following rules:

- **Enter condition:** Actual percentage of system capacity is greater than or equal to the high threshold.
- **Clear condition:** Actual percentage of system capacity is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**
The following command configures a high threshold for system capacity percentage of 95 for a system using the Alert thresholding model:

```
threshold system-capacity 95
```
threshold total-asngw-sessions

Configures alarm or alert thresholds for the total number of ASN-GW sessions across all the services in the system.

Product
ANS-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold total-asngw-sessions high_thresh [ clear low_thresh ]

**high_thresh**
Default: 0 (Disabled)
Specifies the high threshold number of total ASN-GW sessions across all the sessions in the system that must be met or exceeded within the polling interval to generate an alert or alarm.

*high_thresh* is an integer from 0 through 4000000. A value of 0 disables the threshold.

**clear low_thresh**
Default: 0 (Disabled)
Specifies the low threshold number of total ASN-GW sessions that maintains a previously generated alarm condition. If the number of ASN-GW sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

*low_thresh* is an integer from 0 and 4000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of ASN-GW sessions across all the services in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for the total number of ASN-GW sessions based on the following rules:

- **Enter condition:** Actual total number of ASN-GW sessions is greater than or equal to the high threshold.

- **Clear condition:** Actual total number of ASN-GW sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.
Example

The following command configures a total ASN-GW session high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-asngw-sessions 10000
```
threshold total-ggsn-sessions

Configures alarm or alert thresholds for the total number of GGSN sessions across all the services in the system.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold total-ggsn-sessions high_thresh [ clear low_thresh ]

high_thresh
Default: 0 (Disabled)
Specifies the high threshold number of total GGSN sessions across all the sessions in the system that must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 4000000. A value of 0 disables the threshold.

clear low_thresh
Default: 0 (Disabled)
Specifies the low threshold number of total GGSN sessions that maintains a previously generated alarm condition. If the number of GGSN sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 and 4000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of GGSN sessions across all the services in the system is equal to or greater than the set limit.
Alerts or alarms are triggered for the total number of GGSN sessions based on the following rules:
- **Enter condition:** Actual total number of GGSN sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of GGSN sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

Example
The following command configures a total GGSN session high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-ggsn-sessions 10000
```
threshold total-gprs-pdp-sessions

Configures alarm or alert thresholds for the total number of PDP contexts per GPRS sessions in the system.

Product
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold total-gprs-pdp-sessions high_thresh [ clear low_thresh ]

high_thresh

Default: 0
Specifies the high threshold number of total PDP contexts per GPRS session for all GPRS services that must be met or exceeded within the polling interval to generate an alert or alarm.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

low_thresh is an integer from 1 through 2000000. A value of 0 disables the threshold.

clear low_thresh

Default: 0
Specifies the low threshold number of total PDP contexts per GPRS session for all GPRS services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

low_thresh is an integer from 0 and 2000000. A value of 0 disables the threshold.

Usage

Monitor and set alarms or alerts when the total number of GPRS sessions in the system is equal to or greater than the set limit.
Alerts or alarms are triggered for GPRS sessions based on the following rules:

- **Enter condition**: Actual total number of PDP Contexts is greater than or equal to the high threshold.
- **Clear condition**: Actual total number of PDP contexts is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

Example

Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.
The following command configures a total number of PDP contexts per GPRS session high threshold count of 10000 for a system using the Alert thresholding model:

```bash
threshold total-gprs-pdp-sessions 10000
```
threshold total-gprs-sessions

Configures alarm or alert thresholds for the total number of GPRS sessions in the system.

Product
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

Syntax

threshold total-gprs-sessions high_thresh [ clear low_thresh ]

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>high_thresh</td>
<td>Specifies the high threshold number of total GPRS sessions for all GPRS services that must be met or exceeded within the polling interval to generate an alert or alarm. high_thresh is an integer from 1 through 2000000. A value of 0 disables the threshold.</td>
</tr>
<tr>
<td>clear low_thresh</td>
<td>Specifies the low threshold number of total GPRS sessions for all GPRS services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated. low_thresh is an integer from 0 and 2000000. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of GPRS sessions in the system is equal to or greater than the set limit.
Alerts or alarms are triggered for GPRS sessions based on the following rules:

- **Enter condition:** Actual total number of GPRS sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of GPRS sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

Example
The following command configures a total number of GPRS sessions high threshold count of 10000 for a system using the Alert thresholding model:

```plaintext
threshold total-gprs-sessions 10000
```
threshold total-ha-sessions

Configures alarm or alert thresholds for the total number of Home Agent (HA) sessions across all services in the system.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold total-ha-sessions high_thresh [ clear low_thresh ]

high_thresh
Default: 0
Specifies the high threshold number of HA sessions for all HA services that must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 4000000. A value of 0 disables the threshold.

clear low_thresh
Default: 0
Specifies the low threshold number of HA sessions for all HA services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 and 4000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of HA sessions in the system is equal to or greater than the set limit.
Alerts or alarms are triggered for HA sessions based on the following rules:
• Enter condition: Actual total number of HA sessions is greater than or equal to the high threshold.
• Clear condition: Actual total number of HA sessions is less than the low threshold.
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

Example
The following command configures a total number of HA sessions high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-ha-sessions 10000
```
threshold total-hnb-gw-hnb-sessions

Configures alarm or alert thresholds for the total number of Home NodeB (HNB) sessions across all the HNB Gateway (HNB-GW) services in the system.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
threshold total-hnb-gw-hnb-sessions high_thresh [ clear low_thresh ]
```

<table>
<thead>
<tr>
<th>high_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0 (Disabled)</td>
</tr>
<tr>
<td>Specifies the high threshold for the total number of HNB-HNB-GW sessions on IuH interfaces across all HNB-GW services on a system that must be met or exceeded within the polling interval to generate an alert or alarm.</td>
</tr>
<tr>
<td>high_thresh is an integer from 0 through 1000000. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>clear low_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0 (Disabled)</td>
</tr>
<tr>
<td>Specifies the low threshold for the total number of HNB-HNB-GW sessions on IuH interfaces across all services on a system that maintains a previously generated alarm condition. If the number of HNB-HNB-GW sessions in a system falls beneath the low threshold within the polling interval, a clear alarm will be generated.</td>
</tr>
<tr>
<td>low_thresh is an integer from 0 through 1000000. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

⚠️ Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to monitor and set alarms or alerts when the total number of HNB-HNB-GW sessions on IuH interface across all HNB-GW services in the system is equal to or greater than the set limit. Alerts or alarms are triggered for the total number of HNB-HNB-GW sessions on IuH interface based on the following rules:

- **Enter condition:** Actual total number of HNB-HNB-GW sessions on IuH interface is greater than the high threshold.
threshold total-hnbgw-hnb-sessions

- **Clear condition:** Actual total number of HNB-HNB-GW sessions on IuH interfaces is less than the low threshold.

  If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

  Refer to the `threshold poll total-hnbgw-hnb-sessions` command to configure the polling interval and the `threshold monitoring hnbgw-service` command to enable thresholding for this value.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshTotalHNBGWHnbSess` command in this mode.

**Example**

The following command configures the total number of HNB-GW-HNB sessions on IuH interfaces to a high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-hnbgw-hnb-sessions 10000
```
threshold total-hnbgw-iu-sessions

Configures alarm or alert thresholds for the total number of subscriber sessions towards the Core Networks (CN) across all HNB-GW services over Iu interfaces (Iu-CS/Iu-PS interface) on a system.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold total-hnbgw-iu-sessions high_thresh [ clear low_thresh ]
```

- **high_thresh**
  Default: 0 (Disabled)
  Specifies the high threshold for the total number of subscriber sessions towards CN across all HNB-GW services on a system that must be met or exceeded within the polling interval to generate an alert or alarm.
  `high_thresh` is an integer from 0 through 3000000. A value of 0 disables the threshold.

- **clear low_thresh**
  Default: 0 (Disabled)
  Specifies the low threshold for the total number of subscriber sessions towards CN across all services on a system that maintains a previously generated alarm condition. If the number of subscriber sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  `low_thresh` is an integer from 0 through 3000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to monitor and set alarms or alerts when the total number of subscriber sessions towards CN across all HNB-GW services in the system is equal to or greater than the set limit. Alerts or alarms are triggered for the total number of subscriber sessions towards CN across all HNB-GW service on a system based on the following rules:

- **Enter condition:** Actual total number of subscriber sessions across all HNB-GW service on a system is greater than the high threshold.
- **Clear condition:** Actual total number of subscriber sessions across all HNB-GW service on a system is less than the low threshold.
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the `threshold poll total-hnbgw-iu-sessions` command to configure the polling interval and the `threshold monitoring hnbgw-service` command to enable thresholding for this value.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshTotalHNBGWIuSess` command in this mode.

**Example**

The following command configures the total number of subscriber sessions towards CN across all HNB-GW services to a high threshold count of 30000 for a system using the Alert thresholding model:

```
threshold total-hnbgw-iu-sessions 30000
```
threshold total-hnbgw-ue-sessions

Configures alarm or alert thresholds for the total number of UEs connected to an HNB-GW service across all the HNB-GW services in the system.

Product: HNB-GW
Privilege: Security Administrator, Administrator
Mode: Exec > Global Configuration configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
threshold total-hnbgw-ue-sessions high_thresh [ clear low_thresh ]
```

**high_thresh**

Default: 0 (Disabled)
Specifies the high threshold for the total number of UEs connected across all HNB-GW services on a system that must be met or exceeded within the polling interval to generate an alert or alarm. `high_thresh` is an integer from 0 through 4000000. A value of 0 disables the threshold.

**clear low_thresh**

Default: 0 (Disabled)
Specifies the low threshold for the total number of UEs connected to HNB-GW service across all HNB-GW services that maintains a previously generated alarm condition. If the number of UE sessions across all the services in a system, falls beneath the low threshold within the polling interval, a clear alarm will be generated.
`low_thresh` is an integer from 0 and 4000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to monitor and set alarms or alerts when the total number of UEs connected to HNB-GW service across all HNB-GW services in the system is equal to or greater than the set limit. Alerts or alarms are triggered for the total number of UEs connected across all HNB-GW service on a system based on the following rules:

- **Enter condition:** Actual total number of UEs connected to HNB-GW service across all HNB-GW services on a system is greater than the high threshold.

- **Clear condition:** Actual total number of UEs connected to HNB-GW service across all HNB-GW services on a system is less than the low threshold.
Global Configuration Mode Commands (threshold ppp - url-blacklisting)

threshold total-hnbgw-ue-sessions

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the `threshold poll total-hnbgw-ue-sessions` command to configure the polling interval and the `threshold monitoring hnbgw-service` command to enable thresholding for this value.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshTotalHNBGWUeSess` command in this mode.

**Example**

The following command configures the total number of UEs connected to HNB-GW service across all HNB-GW services to a high threshold count of 40000 for a system using the Alert thresholding model:

```
threshold total-hnbgw-ue-sessions 40000
```
threshold total-hsgw-sessions

Configures alarm or alert thresholds for the total number of HRPD Serving Gateway (HSGW) sessions across all services in the system.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold total-hsgw-sessions high_thresh [ clear low_thresh ]

high_thresh
Default: 0
Specifies the high threshold for the number of HSGW sessions for all HSGW services that must be met or exceeded within the polling interval to generate an alert or alarm. high_thresh is an integer from 1 through 2500000. A value of 0 disables the threshold.

clear low_thresh
Default: 0
Specifies the low threshold for the number of HSGW sessions for all HSGW services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated. low_thresh is an integer from 0 and 2500000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of HSGW sessions in the system is equal to or greater than the set limit. Alerts or alarms are triggered for HSGW sessions based on the following rules:

- **Enter condition:** Actual total number of HSGW sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of HSGW sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.
Example

The following command configures a total number of HSGW sessions high threshold count of \textit{500000} for a system using the Alert thresholding model:

\begin{verbatim}
threshold total-hsgw-sessions 500000
\end{verbatim}
threshold total-lma-sessions

Configures alarm or alert thresholds for the total number of Local Mobility Anchor (LMA) sessions across all services in the system.

Product
P-GW
SAEGW

Privilege
Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
threshold total-lma-sessions high_thresh [ clear low_thresh ]
```

- **high_thresh**
  Default: 0
  Specifies the high threshold number of LMA sessions for all LMA services that must be met or exceeded within the polling interval to generate an alert or alarm.
  `high_thresh` is an integer from 1 through 1500000. A value of 0 disables the threshold.

- **clear low_thresh**
  Default: 0
  Specifies the low threshold number of LMA sessions for all LMA services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  `low_thresh` is an integer from 0 through 1500000. A value of 0 disables the threshold.

- **Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of LMA sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for LMA sessions based on the following rules:

- **Enter condition:** Actual total number of LMA sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of LMA sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a total number of LMA sessions high threshold count of 500000 for a system using the Alert thresholding model:

```
threshold total-lma-sessions 500000
```
threshold total-lns-sessions

Configures alarm or alert thresholds for the total number of L2TP Network Server (LNS) sessions in the system.

Product
PDSN
GGSN
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
threshold total-lns-sessions high_thresh [ clear low_thresh ]
```

**high_thresh**

Default: 0
Specifies the high threshold number of total LNS sessions that must be met or exceeded within the polling interval to generate an alert or alarm.
`high_thresh` is an integer value from 0 through 4000000. A value of 0 disables the threshold.

**clear low_thresh**

Default: 0
Specifies the low threshold number of total LNS sessions that maintains a previously generated alarm condition. If the number of LNS sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
`low_thresh` is an integer from 0 and 4000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of LNS sessions in the system is equal to or greater than the set limit.
Alerts or alarms are triggered for the total number of LNS sessions based on the following rules:

- **Enter condition:** Actual total number of LNS sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of LNS sessions is less than the low threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a total LNS session high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-Ins-sessions 10000
```
threshold total-mme-sessions

Configures alarm or alert thresholds for the total number of Mobility Management Entity (MME) sessions across all the MME services in the system.

**Product**
MME

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold total-mme-sessions high_thresh [ clear low_thresh ]
```

- **`high_thresh`**
  - Default: 0 (Disabled)
  - Specifies the high threshold number of total MME sessions that must be met or exceeded within the polling interval to generate an alert or alarm.
  - `high_thresh` is an integer value from 0 through 2500000. A value of 0 disables the threshold.

- **`clear low_thresh`**
  - Default: 0 (Disabled)
  - Specifies the low threshold number of total MME sessions that maintains a previously generated alarm condition. If the number of MME sessions, across all the services in a system, falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - `low_thresh` is an integer from 0 and 2500000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to monitor and set alarms or alerts when the total number of MME sessions across all the MME services in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for the total number of MME sessions based on the following rules:

- **Enter condition:** Actual total number of MME sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of MME sessions is less than the low threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll total-mme-sessions` command to configure the polling interval and the `threshold monitoring mme-service` command to enable thresholding for this value.
Example

The following command configures a total MME session high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-mme-sessions 10000
```
threshold total-pdsn-sessions

Configures alarm or alert thresholds for the total number of Packet Data Serving Node (PDSN) sessions in the system.

**Product**

PDSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config) #
```

**Syntax**

```
threshold total-pdsn-sessions high_thresh [ clear low_thresh ]
```

- **high_thresh**
  - Default: 0
  - Specifies the high threshold number of total PDSN sessions that must be met or exceeded within the polling interval to generate an alert or alarm.
  - `high_thresh` is an integer from 0 through 2500000. A value of 0 disables the threshold.

- **clear**
  - **low_thresh**
  - Default: 0
  - Specifies the low threshold number of total PDSN sessions that maintains a previously generated alarm condition. If the number of PDSN sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - `low_thresh` is an integer from 0 and 2500000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Monitor and set alarms or alerts when the total number of PDSN sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for the total number of PDSN sessions based on the following rules:

- **Enter condition:** Actual total number of PDSN sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of PDSN sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**
The following command configures a total PDSN session high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-pdsn-sessions 10000
```
threshold total-pgw-sessions

Configures alarm or alert thresholds for the total number of Packet Data Network Gateway (P-GW) sessions across all services in the system.

**Product**
P-GW
SAEGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold total-pgw-sessions high_thresh [ clear low_thresh ]
```

<table>
<thead>
<tr>
<th>high_thresh</th>
</tr>

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Monitor and set alarms or alerts when the total number of P-GW sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for P-GW sessions based on the following rules:

- **Enter condition:** Actual total number of P-GW sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of P-GW sessions is less than the low threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

**Example**

The following command configures a total number of P-GW sessions high threshold count of 500000 for a system using the Alert thresholding model:

```
threshold total-pgw-sessions 500000
```
threshold total-saegw-sessions

Configures alarm or alert thresholds for the total number of System Architecture Evolution Gateway (SAEGW) sessions across all services in the system.

Product
SAEGW

Privilege
Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold total-saegw-sessions high_thresh [ clear low_thresh ]

high_thresh

Default: 0

Specifies the high threshold number of SAEGW sessions for all SAEGW services that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh is an integer from 1 through 3000000. A value of 0 disables the threshold.

clear low_thresh

Default: 0

Specifies the low threshold number of SAEGW sessions for all SAEGW services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

low_thresh is an integer from 0 through 3000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of SAEGW sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for SAEGW sessions based on the following rules:

- **Enter condition:** Actual total number of SAEGW sessions is greater than or equal to the high threshold.

- **Clear condition:** Actual total number of SAEGW sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a total number of SAEGW sessions high threshold count of 500000 for a system using the Alert thresholding model:

```
threshold total-saegw-sessions 500000
```
threshold total-sgsn-pdp-sessions

Configures alarm or alert thresholds for the total number of PDP contexts for all Serving GPRS Support Node (SGSN) sessions in the system.

Product
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:
[local]\host_name(config)#

Syntax

threshold total-sgsn-pdp-sessions high_thresh [ clear low_thresh ]

| high_thresh
Default: 0
Specifies the high threshold number of total PDP contexts per SGSN session for all SGSN services that must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 1 through 4000000. A value of 0 disables the threshold.

| clear low_thresh
Default: 0
Specifies the low threshold number of total PDP contexts per SGSN session for all SGSN services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 through 4000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of SGSN sessions in the system is equal to or greater than the set limit.
Alerts or alarms are triggered for SGSN sessions based on the following rules:
• Enter condition: Actual total number of PDP contexts is greater than or equal to the high threshold.
• Clear condition: Actual total number of PDP contexts is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.
Example

The following command configures a total number of PDP contexts per SGSN session high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-sgsn-pdp-sessions 10000
```
threshold total-sgsn-sessions

Configures alarm or alert thresholds for the total number of SGSN sessions in the system.

Product
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold total-sgsn-sessions high_thresh [ clear low_thresh ]

**high_thresh**

Default: 0
Specifies the high threshold number of total SGSN sessions for all SGSN services that must be met or exceeded within the polling interval to generate an alert or alarm.

**low_thresh** is an integer from 1 through 2000000. A value of 0 disables the threshold.

**clear low_thresh**

Default: 0
Specifies the low threshold number of total SGSN sessions for all SGSN services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

**low_thresh** is an integer from 0 through 2000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of SGSN sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for SGSN sessions based on the following rules:

- **Enter condition:** Actual total number of SGSN sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of SGSN sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

Example
The following command configures a total number of SGSN sessions high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-sgsn-sessions 10000
```
**threshold total-sgw-sessions**

Configures alarm or alert thresholds for the total number of Serving Gateway (S-GW) sessions across all services in the system.

**Product**
S-GW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold total-sgw-sessions high_thresh [ clear low_thresh ]
```

- **high_thresh**
  
  Default: 0
  
  Specifies the high threshold number of S-GW sessions for all S-GW services that must be met or exceeded within the polling interval to generate an alert or alarm. 
  
  `high_thresh` is an integer from 1 through 3000000. A value of 0 disables the threshold.

- **clear low_thresh**

  Default: 0
  
  Specifies the low threshold number of S-GW sessions for all S-GW services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  
  `low_thresh` is an integer from 0 through 3000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Monitor and set alarms or alerts when the total number of S-GW sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for S-GW sessions based on the following rules:

- **Enter condition:** Actual total number of S-GW sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of S-GW sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.
Example

The following command configures a total number of S-GW sessions high threshold count of 500000 for a system using the Alert thresholding model:

```
threshold total-sgw-sessions 500000
```
threshold tpo-dns-failure

The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
threshold tpo-low-compression-gain

The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
threshold tpo-rto-timeout

The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
**timestamps**

Enables or disables the generation of a timestamp in response to each commands entered. The timestamp does not appear in any logs as it is a CLI output only. This command affects all future CLI sessions. Use the `timestamps` command in the Exec Mode to change the behavior for the current CLI session only.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
timestamps
```

```
no timestamps
```

Disables generation of timestamps for each command entered. When omitted, the output of a timestamp for each entered command is enabled.

**Usage**

Enable the timestamps when logging a CLI session on a remote terminal such that each command will have a line of text indicating the time when the command was entered.

**Example**

```
timestamps
```

```
no timestamps
```
**upgrade limit**

Configures upgrade session limits that trigger when the system may execute the software upgrade.

**Product**

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
upgrade limit [ time session_life ] [ usage session_num ]
```

- **upgrade limit**
  This command issued with no keywords sets all parameters to their defaults.

- **time session_life**
  Default: 120
  Defines the maximum number of minutes that a session may exist on the system undergoing a software upgrade, before it is terminated by the system. As individual user sessions reach this lifetime limit, the system terminates the individual session(s). The lifetime limit must be an integer ranging from 1 through 1440.

- **usage session_num**
  Default: 100
  This keyword defines a low threshold limit of sessions running either on a packet processing card or system-wide. When a software upgrade is invoked, this parameter applies to the entire system. When the threshold is crossed (when the number of sessions on the packet processing card or system is less than this value), the remaining sessions on the card or system are terminated allowing the upgrade to begin. The remaining sessions on the packet processing card or system are terminated regardless of their session life. The session limit must be an integer from 0 through 6000.

**Usage**

Use this command to configure upgrade session limits that trigger the system to begin executing the software upgrade.

**Important:** This command is not supported on all platforms.

**Important:** Software Patch Upgrades are not supported in this release.
Example

The following command sets the number of minutes a session can exist to 200, and the minimum number of sessions that may exist before terminating them to 50:

```
upgrade limit time 200 usage 50
```
url-blacklisting database

This command configures URL Blacklisting database directory parameters.

Product
CF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

url-blacklisting database { directory path path | max-versions max_versions | override file file_name }

default url-blacklisting database { directory path | max-versions | override file }

- **default**
  Configures this command with the default settings.

- **directory path path**
  Specifies the path to the directory to be used for storing URL Blacklisting databases.
  *path* must be an alphanumeric string of 1 through 255 characters.
  Default: /flash/bl

- **max-versions max_versions**
  Specifies the maximum number of URL Blacklisting database versions to be maintained in the URL Blacklisting database directory path with the base file name specified by the URL Blacklisting database override file.
  *max_versions* must be an integer from 0 through 3.
  Default: 0

- **override file file_name**
  Specifies the URL Blacklisting database override file name.
  *file_name* must be in *name.extension* format. For example, *abc.bin*.
  And, must be an alphanumeric string of 1 through 10 characters.
  Default: optblk.bin

Usage

Use this command to configure URL Blacklisting database directory parameters.

Example
The following command configures the maximum number of URL Blacklisting database versions to be maintained to 3:

```
url-blacklisting database max-versions 3
```
### wsg-lookup

Enters the WSG lookup priority list configuration mode for site-to-site tunnels.

**Product**

WSG

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
wsg-lookup
```

**Usage**

Use this command to enter the WSG lookup priority list configuration mode for site-to-site tunnels.

**Examples**

```
wsg-lookup
```
Chapter 146
GPRS Service Configuration Mode Commands

The GPRS Service Configuration Mode is used within the context configuration mode to define the criteria the SGSN needs to operate within a GPRS network. The GPRS Service works with other services, such as SGSN GPRS Tunneling Protocol (see SGTP Service Configuration Mode Commands) and Mobile Application Part (see MAP Service Configuration Mode Commands), to handle communication parameters required to work with other network entities such as the base station subsystem (BSS).

Exec > Global Configuration > Context Configuration > GPRS Service Configuration

configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gprs-service)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
accounting

Defines the accounting context name and enables/disables specific types of CDR generation for the accounting in the GPRS service.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gprs-service)#

Syntax

accounting { cdr-types { mcdr | scdr | sms { mo-cdr | mt-cdr } | lcs { mt-cdr | mo-cdr } | smbmscdr } + | context cntx_name }

default accounting cdr-types

no accounting { cdr-types | context }

default

Returns the system to default CDR generation which includes:

• M-CDR
• S-CDR
• SMS CDRs
• LCS CDRs
• SMBMS CDR

no

Disables all CDR types.

cdr-types { mcdr | scdr | sms { mo-cdr | mt-cdr } | lcs { mt-cdr | mo-cdr } | smbmscdr }

Default: all types enabled.

Defines the types of CDRs to be generated within the specified GPRS service for accounting:

• mcdr: Enables generation of M-CDRs.
• scdr: Enables generation of S-CDRs.
• sms: Enables generation of SMS-type CDRs based on one of the following:
  • mo-cdr: SMS CDRs originates from the mobile.
• mt-cdr: SMS CDRs terminates at the mobile.
• smbmscdr: This CDR type is currently under development and should not be included in configuration for this release.
• lcs: Enables the generation of LCS CDRs, based on:
  • mt-cdr: Mobile terminated location request CDR
  • mo-cdr: Mobile originated location request CDR

This symbol indicates that more than one keyword can be used and repeated. This enables you to include more than one type of CDR selection in a single command.

context cntx_name

Specifies an accounting context to be associated with the GPRS service.
cntx_name: Define a string of 1 to 79 alphanumeric characters.

Usage

Use this command to define the type of CDRs to generate for GPRS service. By default all types of CDRs are generated. Note that change of this configuration will be applied to new calls and/or to new PDP contexts only.
By default, the generation of all CDR types is enabled.

Example

The following command configures the system to generate only M-CDRs for accounting in the current GPRS service:

```
accounting cdr-types mcdr
```
admin-disconnect-behavior

This command defines some of the actions the SGSN will take during an Admin-Disconnect procedure.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GPRS Service Configuration
configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gprs-service)#

Syntax

admin-disconnect-behavior { clear-subscription | detach-type { reattach-not-required | reattach-required } }

default admin-disconnect-behavior { clear-subscription | detach-type }

clear-subscription

Including this keyword in the configuration instructs the SGSN to clear subscriber contexts and the subscription data database whenever the clear subscribers all command is issued (from the Exec mode) for attached subscribers. As well, the SGSN will issue an appropriate Map-Purge-MS-Req to the HLR if needed.
Default: disabled

detach-type

Including this keyword defines which type of detach instruction to include in the Detach-Request message during an Admin-Disconnect procedure. One of the following options must be included when this command is entered:

• reattach-not-required
• reattach-required

Default: reattach-required

default

Including the default keyword in the command, instructs the SGSN to use the default value for the specified parameter.

no

Returns the SGSN to the default where this clear function is disabled
Usage

Using the `clear subscribers all` command (in the Exec Mode) will clear subscriber contexts and the subscription data database, and if needed, issue an appropriate Map-Purge-MS-Req to the HLR. Include the `clear-subscription` keyword with this command configuration to ensure that more than attached MM-context and active PDP-contexts are cleared when the clear `subscribers all` command is issued for attached subscribers.

To clear subscription data for detached subscribers, refer to the `sgsn clear-detached-subscriptions` command described in the Exec mode chapter.

Including the `detach-type` keyword with this command instructs the SGSN to include either a ‘reattach-required’ or a ‘reattach-no-required’ instruction in the Detach-Request message.

Example

Enable the clearing function so that subscription data is cleared from the HLR database:

```
admin-disconnect-behavior clear-subscription
```
associate

Associates or disassociates supportive services and policies, such as an Evolved GPRS Tunnelling Protocol (eGTP) service or a DSCP marking template with this GPRS service configuration.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
associate { { camel-service service_name [ context context_name ] | dscp-template downlink dscp_template_name | egtp-service egtp_svc_name [ context context_name ] | gs-service gs_svc_name [ context context_name ] | hss-peer-service hss_svc_name [ context context_name ] | location-service loc_name [ context context_name ] | map-service map_svc_name [ context context_name ] | network-global-mme-id-mgmt-db | sgtp-service sgtp_svc_name [ context context_name ] | tai-mgmt-db database_name }

no associate { camel-service | dscp-template downlink | egtp-service | gs-service | hss-peer-service | location-service | map-service | network-global-mme-id-mgmt-db | sgtp-service | tai-mgmt-db }
```

**no**

Disassociates a previously associated service, DSCP marking template or management database with this GPRS service.

```
context ctx_name
```

Identifies an existing context name in which the named service is configured. If this keyword is omitted, the named service must exist in the same context as the GPRS service.

**camel-service camel_svc_name**

Associates a CAMEL service with this GPRS service.

**camel_svc_name** specifies the name for a configured CAMEL service to associate with the GPRS service. Enter an alphanumeric string of 1 to 63 characters.

**dscp-template downlink template_name**

Associates a DSCP template with the GPRS service.

**template_name** specifies a configured DSCP marking template to associate with this GPRS service. Enter an alphanumeric string of 1 to 64 characters.
GPRS Service Configuration Mode Commands

**egtp-service egtp_svc_name**

Associates an eGTP service with GPRS service.

*egtp_svc_name* specifies the name for a configured eGTP service to associate with this GPRS service.

Enter an alphanumeric string of 1 to 63 characters.

The eGTP service is created with the **egtp-service** command in the *Context Configuration Mode Commands* chapter. The eGTP service provides eGTP-C protocol interface support between the SGSN and EPS nodes. For more information on the eGTP service and the supported interface type(s), refer to the *eGTP Service Configuration Mode Commands* chapter.

**Important:** Only one eGTP service can be associated with a GPRS service. The eGTP service should be configured prior to issuing this command.

**gs-service gs_svc_name**

Associates a Gs service with this GPRS service.

*gs_svc_name* specifies the name for a configured Gs service to associate with the GPRS service. Enter an alphanumeric string of 1 to 63 characters.

The Gs service is created with the **gs-service** command in the *Context Configuration Mode Commands* chapter. The Gs service provides Gs interface support between the SGSN and MSC/VLR nodes. For more information on the Gs service and the supported interface type, refer to the *Gs Service Configuration Mode Commands* chapter.

**Important:** Only one Gs service can be associated with a GPRS service. The Gs service should be configured prior to issuing this command.

**hss-peer-service hss_svc_name**

Associates an HSS peer service with this GPRS service.

*hss_svc_name* specifies the name for a configured HSS peer service to associate with this GPRS service.

Enter an alphanumeric string of 1 to 63 characters.

The HSS peer service provides S6d and S13-prime interface support via the Diameter protocol between the GPRS and an HSS (S6d) or EIR (S13-prime). For more information about the HSS peer service, refer to the **hss-peer-service** command in the *Context Configuration Mode Commands* chapter and the *HSS Peer Service Configuration Mode Commands* chapter.

**Important:** Only one HSS peer service can be associated to a service in this release. The HSS peer service should be configured prior to issuing this command.

**location-service loc_svc_name**

**map-service map_svc_name**

Associates a location service with this GPRS service.

*loc_svc_name* specifies the name for a pre-configured location service to associate with the GPRS service.

Enter an alphanumeric string of 1 to 63 characters.

The location service is created with the **location-service** command in the *Context Configuration Mode Commands* chapter. For more information on the location services, refer to the *Location Services Configuration Mode* section.
**Important:** Only one MAP service can be associated with a GPRS service. The MAP service should be configured prior to issuing this command.

```
associate
```

network-global-mme-id-mgmt-db

Associates the configured global MME ID management database with the GPRS service. This enables operators to associate a single list of MME Group IDs for use in GPRS to E-UTRAN handovers on the S4-SGSN. The global MME ID management database is configured in the LTE Policy Configuration Mode using the network-global-mme-id-mgmt-db command.

This command is available only if the SGSN S4 Interface license is enabled on the SGSN.

```
associate network-global-mme-id-mgmt-db
```

sgtp-service sgtp_svc_name

Associates an SGTP service with this GPRS service. sgtp_svc_name specifies the name for a configured SGTP service to associate with the GPRS service. Enter an alphanumeric string of 1 to 63 characters.

The SGSN GPRS Tunneling Protocol (SGTP) service manages the configuration of the GTP-C and GTP-U related parameters. For more information on the SGTP service, refer to the sgtp-service command in the Context Configuration Mode Commands chapter and/or the SGTP Service Configuration Mode Commands chapter.

**Important:** Only one SGTP service can be associated with a GPRS service. The SGTP service should be configured prior to issuing this command. When co-locating an SGSN and MME, the GPRS Service cannot be associated with the same SGTP service that is used by the MME.

```
associate sgtp-service sgtp_svc_name
```

tai-mgmt-db database_name

Associates this GPRS service with a pre-configured TAI Management Database. database_name specifies the name of a pre-configured TAI Management Database to associate with the SGSN service as an alphanumeric string of 1 through 64 characters. For more information on subscriber maps, refer to the tai-mgmt-db command in the LTE Policy Configuration Mode Commands chapter and the LTE TAI Management Database Configuration Mode Commands chapter.

This command is available only if the SGSN S4 Interface license is enabled on the SGSN.

```
associate tai-mgmt-db database_name
```

**Usage**

Use this command to associate a pre-configured service and/or DSCP marking template and/or management database with this GPRS service. The command can be repeated as necessary to configure associations for all desired services/templates/databases.

**Caution:** This is a critical configuration. The GPRS service cannot be started without this configuration. Any change to this configuration would lead to restarting the GPRS service. Removing or disabling this configuration will stop the GPRS service.

**Example**

The following command associates a previously-configured eGTP service called egtp1 in the dst_ctx context to this GPRS service:

```
associate egtp-service egtp1 context dst_ctx
```
The following command disassociates a MAP service called `map1` that was previously associated with this GPRS service:

```
no associate map-service egtp1
```

The following command associates an HSS peer service called `hss1`, previously-configured in the same context as the GPRS service, to this GPRS service:

```
associate hss-peer-service hss1
```

The following command associates a previously-configured DSCP marking template called `dscp-temp1` to this GPRS service:

```
associate dscp-template downlink dscp-temp1
```
associate-dscp-template

Identifies a DSCP template to be associated with the GPRS service.

**Important:** This command is used only in Releases 12.0 and 12.2. For Release 14.0 refer to the `associate` command.

**Important:** This command can be used before the associated DSCP template instance is created and configured but care should be used to match the template names.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
associate-dscp-template downlink template_name

no associate-dscp-template downlink
```

**Usage**

Use this command to associate DSCP templates with this GPRS service. A single template can be associated with multiple GPRS services.

**Related commands:**
- The `dscp-template` command in the SGSN Global configuration mode creates / deletes an instance of a template. This command also provides access to the mode containing all the configuration commands used to define DSCP settings for the control packets for the Iu interface and the control and data packets for the Gb interface (see the *DSCP Template Configuration Mode Commands* section).
To check the list of DSCP templates configured, use the \texttt{show sgsn-mode} command documented in the \textit{Exec Mode Commands} section.

\textbf{Example}

The following command associates the template with DSCP settings for traffic going through one of the SGSNs located in Paris mobile network:

\begin{verbatim}
associate-dscp-template dscp-template-paris3
\end{verbatim}
**associate-service**

Identifies services to be associated with the GPRS Service.

**Important:** This command is used only in Releases 12.0 and 12.2. For Release 14.0 refer to the `associate` command.

**Important:** This command can be used before the associated service instance is created and configured but care should be used to match the service names.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
[ no ] associate-service { gs name | map name | sgtp name } [ context ctxt_name ]
```

- **no**
  Removes the service association definition from the configuration.

- **gs name**
  Specifies the Gs service configuration to associate with this GPRS service.
  `name` must be a string of 1 to 63 alphanumeric characters with no spaces.

- **map name**
  Specifies the MAP service configuration to associate with this GPRS service.
  `name` must be a string of 1 to 63 alphanumeric characters with no spaces.

- **sgtp name**
  Specifies the SGTP service configuration to associate with this GPRS service.
  `name` must be a string of 1 to 63 alphanumeric characters with no spaces.

- **context ctxt_name**
  Defines the context in which the service was created.
  `ctxt_name` must be a string of 1 to 63 alphanumeric characters with no spaces.
Usage

Use this command to associate other services, that have been or will be configured, to this GPRS service.

Example

The following command associates Gs service gs1 with this GPRS service.

```
associate-service gs gs1 context sgsn2
```
cc profile

Configures the charging characteristic (CC) profile index properties.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GPRS Service Configuration
configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gprs-service)#

Syntax

[ no ] cc profile index { buckets number | interval time | tariff time1 mins hours [ time2 mins hours [ time3 mins hours [ time4 mins hours ] ] ] | volume { downlink octets | uplink octets | total octets } }

default cc profile index

no

Removes the a specific charging characteristics configuration definition.

default

Resets the charging characteristics to system defaults.

index

Configures a profile index for the parameter to be specified. index can be configured to any integer value from 0 to 15.

Important: 3GPP standards suggest that profile index values of 1, 2, 4, and 8 be used for hot billing, flat rate billing, prepaid billing and normal billing, respectively. A single charging characteristics profile can contain multiple behavior settings.

buckets number

Default: 4
Specifies the number of statistics container changes due to QoS changes or tariff time that can occur before an accounting record should be closed.
number can be configured to any integer value from 1 through 4.

interval time

time is measured in seconds and can be configured to any integer value from 60 to 40,000,000.
### GPRS Service Configuration Mode Commands

#### cc profile

```plaintext
tariff time1 mins hours time2 mins hours time3 mins hours time4 mins hours
```

Specifies time-of-day time values to close the current statistics container (but not necessarily the accounting record). Six different tariff times may be specified. If less than six times are required, the same time can be specified multiple times.

**Important:** The system assumes that the billing system uses the day/date to determine if the statistics container represents an actual tariff period.

For each of the different tariff times, the following parameters must be configured:

- **mins**: The minutes of the hour, an integer value from 0 to 59.
- **hours**: The hour of the day, an integer value from 0 to 23.

```plaintext
volume { downlink vol_down_octets uplink vol_up_octets | total total_octets }
```

Specifies the downlink, uplink, and total volumes that must be met before closing a CDR.

- **vol_down_octets**: Measured in octets; can be configured to any integer value from 100,000 to 4,000,000,000.
- **vol_up_octets**: Measured in octets; can be configured to any integer value from 100,000 to 4,000,000,000.
- **total_octets**: The total traffic volume (up and downlink) measured in octets; can be configured to any integer value from 100,000 to 4,000,000,000.

**Usage**

Charging characteristics consist of a profile index and behavior settings. This command configures profile indexes for the SGSN’s charging characteristics. The SGSN supports up to 16 profile indexes. This command works in conjunction with the `cc-sgsn` command located in the APN configuration mode that dictates which CCs should be used for subscriber PDP contexts.

**Example**

The following command configures a profile index of 10 for tariff times of 7:00 AM and 7:30 PM:

```
cr profile 10 tariff time1 0 7 time2 30 19
```
check-imei

This command configures the action the SGSN will take if the route towards the EIR is down.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GPRS Service Configuration
configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gprs-service)#

Syntax

check-imei { gf-failure-action | gf-timeout-action } { continue | reject }
default check-imei { gf-failure-action | gf-timeout-action }

default
Resets the default function to reject the Attach.

gf-failure-action
Coupled with either continue or reject, this keyword instructs the SGSN to take action if a valid EIR configuration exists under the MAP service and if the EIR is temporarily unreachable due to associated DPC/SSN inaccessible/out-of-service.

gf-timeout-action
Coupled with either continue or reject, this keyword instructs the SGSN to take action if a valid EIR configuration exists under the MAP service and the route to the EIR is available, but no response is received from the EIR.

continue
Instructs the SGSN to continue the Attach process.

reject
Instructs the SGSN to reject the Attach process.

Usage

Typically, the Attach process will be continued when there is an IMEI check timeout based on the configuration under the SGSN service configuration and/or the GPRS service configuration. But this works only if the route towards the EIR is UP and the IMEI request timer expires. This command configures the SGSN to allow the Attach process to continue in the case the route towards the EIR is down, that is the DPC / SSN is out-of-service.
Example

Use the following command to reset the default and reject Attach:

```
default check-imei gf-failure-action
```
check-imei-timeout-action

This command has been deprecated.
ciphering-algorithm

This command configures the priority, ordering, for the use of the GPRS encryption ciphering algorithms.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

`configure > context context_name > gprs-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

Syntax

```
ciphering-algorithm { negotiation-failure-action { reject [ failure-code cause_code ] | use-geo0 } priority priority [ algorithm ] } 
default ciphering-algorithm priority priority
```

default

Returns the system ciphering-algorithm priority to the default of GEA0 - which means that no ciphering will be done.

```
negotiation-failure-action { reject [ failure-code cause_code ] | use-geo0 }
```

This set of keywords configure the SGSN's action if there is not a match between the MS and SGSN ciphering algorithm configurations.

*reject*: Instructs the SGSN to reject a call when the ciphering algorithms do not match.

*failure-code cause_code*: Instructs the SGSN to include a GMM cause code in the Reject message. Enter an integer from 2 to 111; default code is 14 (GPRS services not allowed in this PLMN). Refer to the GMM failure cause codes listed below (information has been taken from section 10.5.5.14 of the 3GPP TS 124.008 v7.2.0 R7):

- 2 - IMSI unknown in HLR
- 3 - Illegal MS
- 6 - Illegal ME
- 7 - GPRS services not allowed
- 8 - GPRS services and non-GPRS services not allowed
- 9 - MSID cannot be derived by the network
- 10 - Implicitly detached
- 11 - PLMN not allowed
- 12 - Location Area not allowed
- 13 - Roaming not allowed in this location area
 ciphering-algorithm

- 14 - GPRS services not allowed in this PLMN
- 15 - No Suitable Cells In Location Area
- 16 - MSC temporarily not reachable
- 17 - Network failure
- 20 - MAC failure
- 21 - Synch failure
- 22 - Congestion
- 23 - GSM authentication unacceptable
- 40 - No PDP context activated
- 48 to 63 - retry upon entry into a new cell
- 95 - Semantically incorrect message
- 96 - Invalid mandatory information
- 97 - Message type non-existent or not implemented
- 98 - Message type not compatible with state
- 99 - Information element non-existent or not implemented
- 100 - Conditional IE error
- 101 - Message not compatible with the protocol state
- 111 - Protocol error, unspecified

**use-geo0**: Instructs the SGSN to honor the Attach/RAU Request without ciphering (geo0). This is the default action for negotiation failure.

**priority priority algorithm**

Defines the priority, order of use, for the ciphering algorithm.

**priority**: Must be an integer from 1 to 4.

**algorithm**

Identifies the algorithm to be matched to the priority. Options include:
- gea0 - No ciphering
- gea1 - GPRS Encryption Algorithm - GEA1
- gea2 - GPRS Encryption Algorithm - GEA2
- gea3 - GPRS Encryption Algorithm - GEA3

**Usage**

Use this command to specify the order (priority) of usage for the GPRS encryption algorithms. All of the GPRS encapsulation algorithms use a 64-bit key derived from a common mechanism: the mobile receives a random challenge, then the SIM calculates an authentication signature and an encryption key.

Also use this command to define the action to be taken if there is not a match between the MS and the SGSN ciphering algorithm configurations.

**Example**

The following command sets no ciphering to be used after two encryption algorithms have been used:
ciphering-algorithm priority 3 gea0

The following command configures the SGSN to reject calls if the ciphering algorithm configurations don’t match:

ciphering-algorithm negotiation-failure-action reject
dns israu-mcc-mnc-encoding

Configures either decimal or hexadecimal format for the MCC and MNC values in the DNS query.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration
classify > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

dns israu-mcc-mnc-encoding { decimal | hexadecimal }

default dns israu-mcc-mnc-encoding

default
Resets the SGSN to send the MCC and MNC values in decimal format for DNS queries.

decimal
Default.
Instructs the SGSN to send the MCC and MNC in decimal format in the DNS query.

hexadecimal
Instructs the SGSN to send the MCC and MNC in hexadecimal format in the DNS query.

**Usage**

Use this command to determine the type of encoding for the MCC and MNC to be included in the DNS query. For example:
In decimal, the MNC/MCC in a DNS query would appear like:

```
rac0017.lac42e3.mnc310.mcc722.gprs
```

In hexadecimal, the MNC/MCC in a DNS query would appear like:

```
rac0017.lac42e3.mnc0136.mcc02d2.gprs
```

**Example**

Use hexadecimal values for the MCC/MNC in the DNS query.

dns israu-mcc-mnc-encoding hexadecimal
end

Exits the current configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
dend

Usage
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the previous configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the context configuration mode.
gmm

`gmm` actually provides a set of commands used to define the GPRS mobility management parameters for the SGSN service.

**Important:** The `gmm` commands can be repeated as needed to set each timer.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

`configure > context context_name > gprs-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)##
```

**Syntax**

```plaintext

   default gmm { attach ptmsi-signature-mismatch | ciph-gmm-msg-from-unknown-ms | mobile-reachable-timeout | implicit-detach-timeout secs | negotiate-t3314-timeout | purge-timeout | T3302-timeout | T3312-timeout | T3313-timeout | T3350-timeout | T3360-timeout | T3370-timeout | trau-timeout }

   no gmm  | negotiate-t3314-timeout
```

**Default**

Disables the specified function or resets the specified timer to system defaults.

**No**

Removes the specified GMM definition from the configuration.

**accept-procedure [ new-tlli | old-tlli ]**

Default: new-tlli

This keyword enables the use of either a new TLLI (temporary logical link identifier) or an old TLLI for attach-accept or RAU-accept messages sent by the SGSN to the MS during related procedures.
attach ptmsi-signature-mismatch send-reject failure-code cause_code

Default: disabled
This keyword enables the SGSN to validate the P-TMSI signature, present in the Attach Request, against the PTMSI-SIGNATURE stored at the SGSN. The SGSN then sends an Attach Reject to the MS if the PTMSI-SIGNATURE does not match.
The P-TMSI signature validation functionality only works if the feature is enabled. But even if it is enabled, the feature does not validate in the following situations:
- when the PTMSI-SIGNATURE is absent from the 2G Attach Request.
- if the first subscriber being in DETACHED state or is purged with FREEZE-PTMSI. In both the scenarios PTMSI-SIGNATURE cannot be validated.
- when the 2G subscriber(MS2) attaches with the same P-TMSI and a different P-TMSI_Signature as previously attached 2G subscriber (MS1), both the subscriber profiles are cleared from the system.
  This is relevant where the old RAI for MS-2 is the same as the current RAI for MS-1.
Optional, a GMM failure cause_code can be configured to include in the Attach Reject if one is sent.
Refer to the GMM failure cause codes listed below (information has been taken from section 10.5.5.14 of the 3GPP TS 124.008 v7.2.0 R7):
- 2 - IMSI unknown in HLR
- 3 - Illegal MS
- 6 - Illegal ME
- 7 - GPRS services not allowed
- 8 - GPRS services and non-GPRS services not allowed
- 9 - MSID cannot be derived by the network
- 10 -Implicitly detached
- 11 - PLMN not allowed
- 12 - Location Area not allowed
- 13 - Roaming not allowed in this location area
- 14 - GPRS services not allowed in this PLMN
- 15 - No Suitable Cells In Location Area
- 16 -MSC temporarily not reachable
- 17 - Network failure
- 20 - MAC failure
- 21 - Synch failure
- 22 - Congestion
- 23 - GSM authentication unacceptable
- 40 - No PDP context activated
- 48 to 63 - retry upon entry into a new cell
- 95 - Semantically incorrect message
- 96 - Invalid mandatory information
- 97 - Message type non-existent or not implemented
- 98 - Message type not compatible with state
GPRS Service Configuration Mode Commands

- 99 - Information element non-existent or not implemented
- 100 - Conditional IE error
- 101 - Message not compatible with the protocol state
- 111 - Protocol error, unspecified

ciph-gmm-msg-from-unknown-ms { detach | ignore }

Configures how the SGSN will behave when it receives a ciphered GMM message from an unknown MS.

detach - Instructs the SGSN to send a Detach message to the MS.
ignore - Instructs the SGSN to send an Ignore (drop) message to the MS.
Default: ignore

implicit-detach-timeout secs

Specifies the implicit detach timer (IDT) value for the 2G ISR implicit detach procedure on the network side (see ISR -- Idle Mode Signaling Reduction on the S4-SGSN feature chapter in the SGSN Administration Guide for additional timer usage details).
The IDT is configurable from release 15.0 onwards and it is only applicable to 2G ISR activated calls. If ISR is not activated on a 2G call then the subscriber is detached soon after expiry of the mobile reachability timer (MNR) timer.

secs must be an integer from 240 to 86400 and the default value is 3600.

mobile-reachable-timeout mins

Default: 58 minutes
Specifies the timeout value for the mobile reachability timer (MNR). This timer is used with the IDT timer described above.

mins must be an integer from 4 to 1440.

negotiate-T3314-timeout secs

Set the number of seconds for the T3314-timeout ready timer value. Value sent out from SGSN so MS can negotiate ready timer.

secs must be an integer from 0 to 11160. Default is 44 seconds.

- If the MS does not send the ready timer in the Attach/RAU request, then the SGSN sends this T3314-timeout (ready timer) value.
- If the MS sends the requested value of the ready timer in the Attach/RAU Request, and if the requested value is less than or equal to the value of the negotiate-T3314-timeout timer, then the SGSN sends Att/RAU Accept with the requested T3314 value.
- If the MS sends the requested value of the ready timer in the Attach/RAU Request, and if the requested value is greater than the value of the negotiate-T3314-timeout timer, then the SGSN sends Att/RAU Accept with the negotiate-T3314-timeout value.

**Important:** This is the only GMM timer that can be disabled by entering no at the beginning of the command

**syntax:** no gmm negotiate-t3314-timeout

By disabling negotiation of the T3314-timeout value, if the MS sends the requested value of the ready timer in the Att/RAU Request, then the SGSN sends the T3314-timeout value in the Att/RAU Accept.
**paging-failure-action downlink-data-lockout-timer**  
*seconds [ repeat number_repeats ]*

Default: 1000 seconds.
Enables and configures the downlink data lockout timer, for the SGSN services, to reduce the frequency of mobile-initiated keep alive messages.

*seconds* set the number of seconds before timer expire, range of 0 to 10000.

*repeat*  
optionally sets the number of times (1 to 10) that the timer restarts after paging failure.  
*Note:* If repeat is not configured then paging proceeds endlessly until the MR timer expires.

[ default | no ] **gmm paging-failure-action**  
disables the downlink data lockout timer.

**purge-timeout**  
*mins*

Default: 10080 minutes
The purge timer defines the MM-context lifetime, part of the MM-context procedure on the network side. The configured value sets the duration (number of minutes) the SGSN holds the detached subscriber’s MM-context profile. If the subscriber does not reattach to the SGSN during this time, then the SGSN purges this detached subscriber’s MM-context information from its database and sends a MAP purge request towards the HLR to indicate that the subscribers profile is gracefully purged from SGSN’s database.

*mins* must be an integer from 1 to 20160.

**T3302-timeout**  
*mins*

Default: 12 minutes
Defines the number of minutes for timer to send to MS.

*mins* is an integer from 1 to 186.

**T3312-timeout**  
*min*

Default: 54 minutes
Periodic RAU update timer to send to MS.

*mins* is an integer from 0 to 186.

**T3313-timeout**  
*secs*

Default: 5 seconds
Initial page timeout timer for retransmission for Paging Requests.

*secs* is an integer from 1 to 60.

**T3314-timeout**  
*secs*

Default: 44 seconds
Ready Timer for controlling Cell Update Procedure.

*secs* must be an integer from 0 to 11519.

**T3350-timeout**  
*secs*

Default: 6 seconds
Retransmission timer for Attach Accept/RAU Accept/P-TMSI Realloc Command.

*secs* must be an integer from 1 to 20.

**T3360-timeout**  
*secs*

Default: 6 seconds
Retransmission timer for Authentication Request.

*secs* must be an integer from 1 to 20.
### T3370-timeout secs

Default: 6 seconds
Retransmission timer for Identity Request.
`secs` must be an integer from 1 to 20.

### traU-timeout secs

This timer is available in releases 9.0 and higher.
Default: 30
Specifies the number of seconds the “old” 3G SGSN waits to purge the MS’s data. This timer is started by the “old” SGSN after completion of the inter-SGSN RAU.
`secs`: Must be an integer from 5 to 60.

---

**Usage**

Use this command to set GMM timers.

**Example**

Set the t3370 timer expiration for 15 seconds:

```
  gmm t3370-timeout 15
```
llc

Configures the timers that control the data flow for the logical link control (LLC) sub-layer.

**Important:** This command may be repeated as often as necessary to define the needed timers.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

`configure > context context_name > gprs-service service_name`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-gprs-service)#`

**Syntax**

```plaintext
```

```plaintext
default llc { iov-ui-in-xid-reset | n201u-max { sapi11 | sapi3 | sapi5 | sapi9 } | nu-overflow-detection | pdu-lifetime | random-value-in iov-ui | reset-vur | T200 [ sapi1 | sapi11 | sapi3 | sapi5 | sapi7 | sapi9 ] | uplink-pdu-len-validation }
```

```plaintext
no llc { iov-ui-in-xid-reset | nu-overflow-detection | random-value-in iov-ui | reset-vur | uplink-pdu-len-validation }
```

**default**

Resets the configuration parameter to the default values.

**no**

Disables a defined configuration parameter and returns to the SGSN default.

**iov-ui-in-xid-reset**

This keyword makes it possible for the operator to configure whether or not to send IOV-UI in an XID-RESET. This is useful when the MS is not setup to accept IOV-UI (for example, MS sends Attach/RAU Requests with cksn=7) and including IOV-UI in the XID-Reset would result in Attach/RAU failure.

Default: Enabled
n201u-max sapi n pkt_size

This keyword sets the maximum number of octets, per service access point identifier (SAPI), for the downlink data packets. This is the upper limit that the SGSN will negotiate with the subscriber for packets sent from the SGSN to the BSC.

sapi n: Command must identify one of the following SAPI: sapi11, sapi3, sapi5, or sapi9.

pkt_size: Must be an integer from 140 to 1520. Default size is 1520 octets.

nu-overflow-detection high-watermark high_num low-watermark low_num increment-oc

Enables/disables overflow detection for the N(u) counter and setting overflow high/low thresholds facilitates ciphering synchronization between the MS and SGSN.

high_num: Enter an integer between 1 and 511.

low_num: Enter an integer between 0 and 510.

If the expected value of nu(Vur) is greater than or equal to the configured high-watermark, and the received nu(LFN) is less than or equal to the configured low-watermark, the SGSN increments the overflow counter (VurOC).

The recommended overflow settings are as follows: llc nu-overflow-detection high-watermark 496 low-watermark 15 increment-oc While expecting a packet with 496 < nu < 511 and a packet with 0 < nu < 15 is received, overflow is detected and VurOC is incremented.

pdu-lifetime secs

Defines LLC layer PDU lifetime at the BSC.

secs must be an integer from 0 to 90.

Default: 6

random-value-in iov-ui [ negotiation-failure-action { fallback-to-default iov-ui | reject } ]

Including this keyword enables the SGSN to negotiate the sending of a random value for the IOV-UI in the XID Request sent to the MS. If this keyword is not included, then by default the SGSN sends a zero (0) as the value of the IOV-UI in the XID message.

Including default in a command with the negotiation-failure-action keyword resets the SGSN configuration so that all calls are rejected whenever the decipering fails due to failure of the XID negotiation for random IOV-UI

If the negotiation-failure-action fallback-to-default iov-ui option is included in the configuration, then the SGSN will fall back to unencrypted mode whenever the XID negotiation for random IOV-UI negotiation fails.

If the negotiation-failure-action reject option is included in the configuration to return the SGSN to the default functionality and reject all calls when random IOV-UI negotiation fails. This option is typically used only if the negotiaiton-failure-action fallback-to-default iov-ui option has previously been part of the configuration.

The reject option conditionally causes the SGSN to reject calls, for example, when XID for random IOV-UI negotiation failure occurs during intra-RAU or standalone authentication for SMS, the SGSN moves the subscriber to STANDBY and marks the XID negotiation as a failure.

OR

Despite the reject configuration, the SGSN may respond to XID negotiation failure in one of the following manners according to associated circumstances:

• Initiates XID for new random IOV-UI negotiation:

• with the MS is in STANDBY state, any uplink packet (in either ciphered or unencrypted mode, except Attach / Intra-RAU) from the MS which results in CELL-UPDATE, READY
TIMER START and RADIO STATUS READY causes an event indication to the application.

- Initiates Detach:
  - with the MS is in STANDBY state, any uplink activity causes the SGSN to initiate a new XID exchange, which if it fails or aborts due to the reception of SUSPEND, RADIO-STATUS and READY-TIMER expiry, results in the SGSN initiating Detach.
  - when PAGING is ongoing, any Page response from the MS results in the SGSN initiating Detach.
  - during OLD_SGSN ISRAU, when any uplink data comes before T3 tunnel timer expiry then the SGSN initiates Detach.

- Handles Messages:
  - Attach and intra-RAU (from both local and non-local TLLI or from both the same and different RA) will be processed in any state.

- Moves to STANDBY state:
  - MS is moved to STANDBY state if the XID exchange failed due to any of the following cases: suspend, radio status, BVC block, BVC reset, ready timer expiry, no response received for XID exchange during INTRA-RAU/Standalone Authentication for SMS.
  - XID is ongoing in READY state and if the MS moves to either 3G or to the peer-SGSN then the subscriber is moved to STANDBY state.

```
reset-vur
```
Enables/disables the mechanism to reset the Vur value maintained at LLC if the intra RAU request is received with N(U) = 0
Default: Disabled

```
T200 sapi1 time
```
Sets the retransmission timer (in seconds) for sapi1.
`time` must be an integer of 1 to 10.
Default: 5

```
T200 sapi11 time
```
Sets the retransmission timer (in seconds) for sapi11.
`time` must be an integer of 1 to 50.
Default: 40

```
T200 sapi3 time
```
Sets the retransmission timer (in seconds) for sapi3.
`time` must be an integer of 1 to 10.
Default: 5

```
T200 sapi5 time
```
Sets the retransmission timer (in seconds) for sapi5.
`time` must be an integer of 1 to 20.
Default: 10
### T200 sapi7 time

Sets the retransmission timer (in seconds) for sapi7. 

*time* must be an integer of 1 to 40. 

Default: 20

### T200 sapi9 time

Sets the retransmission timer (in seconds) for sapi9. 

*time* must be an integer of 1 to 40. 

Default: 20

### uplink-pdu-len-validation

Available in releases 8.1 and higher. 

This feature enables validation of the size of the uplink LLC packets. With validation enabled, the SGSN will drop any uplinked packets that are larger than the negotiated limit. 

If the no form of the command is used, then this feature is disabled. The SGSN will be more flexible with uplink packet sizes. So if the SGSN and MS have a mismatch and the MS sends packets that are larger than expected, then the SGSN will not drop the packets. 

Default: Enabled.

#### Usage

Use the command repeatedly to configure additional timers and features for the LLC sub-layer.

#### Example

Set the T200 retransmission timer to timeout at 12 seconds for SAPI5:

```text
llc t200 sapi5 12
```

Use the following command to instruct the SGSN to ignore the N201_U packet size limits for uplink packets from an MS:

```text
no uplink-pdu-len-validation
```
network-sharing

This command enables or disables CS-PS coordination checking for homers (UEs in their home network) or roamers (UEs from outside the home network). The command also sets the failure code that will be sent for GPRS MOCN.

**Product**
SGSN

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration
configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
network-sharing { cs-ps-coordination { failure-code <gmm-cause> | homer | roamer } |
  failure-code <gmm-cause>

no network-sharing cs-ps-coordination { homer | roamer }

default network-sharing cs-ps-coordination
```

- **no**
  Disables CS-PS coordination check for either homers or roamers.

- **default**
  Set the CS-PS coordination parameters to default values.

**failure-code <gmm-cause>**

This keyword has two optional functions:

- When used with the `cs-ps-coordination` keyword, it sets the GMM cause code that is to be included in the message when the SGSN requests the BSC to provide CS-PS coordination. Default value is 14.

- When used as an independent keyword with the `network-sharing` command, it sets the failure cause that is used by GPRS MOCN if no failure cause is available when the SGSN sends a Reject message. Default value is 7.

**<gmm-cause>** is an integer from 2-111. Valid options include:

- 2 - IMSI unknown in HLR
- 3 - Illegal MS
- 6 - Illegal ME
- 7 - GPRS services not allowed
- 8 - GPRS services and non-GPRS services not allowed
- 9 - MSID cannot be derived by the network
- 10 - Implicitly detached
- 11 - PLMN not allowed
- 12 - Location Area not allowed
- 13 - Roaming not allowed in this location area
- 14 - GPRS services not allowed in this PLMN
- 15 - No Suitable Cells In Location Area
- 16 - MSC temporarily not reachable
- 17 - Network failure
- 20 - MAC failure
- 21 - Synch failure
- 22 - Congestion
- 23 - GSM authentication unacceptable
- 40 - No PDP context activated
- 48 to 63 - retry upon entry into a new cell
- 95 - Semantically incorrect message
- 96 - Invalid mandatory information
- 97 - Message type non-existent or not implemented
- 98 - Message type not compatible with state
- 99 - Information element non-existent or not implemented
- 100 - Conditional IE error
- 101 - Message not compatible with the protocol state
- 111 - Protocol error, unspecified

**homer**

Enables checking for CS-PS coordination for UEs from inside the home network (homers) only.

**roamers**

Enables checking for CS-PS coordination for UEs from another network (roamers) only.

**Usage**

The operator can use this command to configure CS-PS coordination checking explicitly for homer or roamers subscribers and for the failure-code to be sent when the SGSN asks the BSC to perform CS-PS coordination.

**Example**

Use a command similar to the following to have the SGSN perform CS-PS coordination checking only for all UEs from outside of the home network. `network-sharing cs-ps-coordination homer`
nri

This command configures the network resource identifier (NRI) to identify a specific SGSN. The NRI information is stored in the P-TMSI. The SGSN uses a portion of this NRI to set the parameters for Gb flex (SGSN pooling) functionality.

**Product**  
SGSN

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
nri length nri_length { nri-value nri_value | null-nri-value null_nri_value non-broadcast-lac lac_id rac rac_id [ nri-value value ] }

default nri

no nri
```

**default nri**

A default configuration has been made available beginning in Release 14.0. Using this keyword now resets the nri configuration to nri length 6 and nri-value 0.

**Important:** Behavior change in Release 14.0 -- it is no longer necessary to configure NRI as default values have been enabled.

**no**

**Important:** no nri command form is deprecated in Release 14.0. To ensure backward compatibility with configuration files created with pre-Release 14.0 builds, the no nri configuration will be automatically converted to the Release 14.0 default values of nri 6 and 0.

This command removes the configured NRI value and location information in the P-TMSI that would be retrieved by this SGSN.
**length nri_length**

Specifies the number of bits to be used in the P-TMSI, bits 23 to 18 are used to define the network resource identifier (NRI). The NRI length configuration also sets the maximum size of the pool. If not configured, the NRI length will be of zero length.

**nri_length**: Must be an integer from 1 to 6 to identify the number of bits.

**null-nri-value null_nri_value**

Configures the null NRI value which must be unique across the pool areas. This keyword is used for the offloading procedure for SGSN pooling (enabled with the sgsn offloading command, see the Exec Mode chapter).

**null_nri_value** is an integer from 0 (zero) to 63 used to identify the SGSN to be used for the offloading procedure for SGSN pooling. There is no default value for this parameter.

**non-broadcast lac lac_id rac rac_id**

Defines the non-broadcast LAC/RAC to be used in combination with the null-NRI for the offloading procedure.

**lac_id** defines a location area code associated with a BSS. Must be an integer between 1 and 65535.

**rac_id** defines the remote area code to be associated with a BSS. Must be an integer between 1 and 255.

**nri-value nri_value**

Specifies the MS-assigned value of the NRI to retrieve from the P-TMSI. This value must not exceed the maximum possible value specified by the NRI length. The NRI value must be unique across the pool or across all overlapping pools.

**nri_value** must be an integer from 1 to 63 to identify a specific SGSN in a pool. Use of 0 (zero) value is not recommended.

Multiple NRI values can be identified by providing multiple nri-values separated by a blank space for example: *nri length 6 nri-value 29 43 61*

**Usage**

Use this command to add or remove the Gb flex pool configuration for this GPRS service. The command can be repeated to specify different values for any of the keyword parameters. If more than one NRI is configured, the GPRS service will round-robin between the available NRIs when new subscribers (re)connect.

Use this command to retrieve the NRI (identity of an SGSN) stored in in bits 23 to 18 of the packet-temporary mobile subscriber identity (P-TMSI). If more than one NRI value is configured, the GPRS service will round-robin between the available NRIs when new subscribers (re)connect.

**Example**

The following command specifies the the NRI length as 5 bits, identifies SGSN 23 with LAC 222 and RAC 12 for offloading procedure with NRIs 6 and 41:

```
nri length 5 null-nri-value 34 non-broadcast lac 222 rac 12 nri-value 6 41
```
paging-policy

Configures the paging parameters for the GPRS service.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
paging-policy { last-known-area { all | bsc | cell | location-area | routing-area } + | max-retransmissions retran_num }
```

```
no paging-policy last-known-area { bsc | cell | location-area | routing-area }
```

```
default paging-policy { last-known-area | max-retransmissions }
```

---

**no**
Disables the paging-policy definition for this GPRS service configuration.

---

**default**
Resets the defaults for parameters managed by this paging policy.

---

**last-known-area**
Select one or more paging areas and enter them in preferred paging order:
- **all** : Pages in the last known BSC.
- **bsc** : Pages in last known BSC.
- **cell** : Pages in last known cell.
- **location-area** : Pages in last known location area.
- **routing-area** : Pages in last known routing area.

By default, paging occurs in the following order:
cell, BSC, routing area, location area.

---

**max-retransmission retran_num**

Configures the maximum number of retries for a page request per paging area.

- **retran_num**: Enter an integer from 0 to 5.
  - **2**: default.
○ 0: disables retransmission for paging request so that the SGSN only sends a single 2G PS-paging request to the BSC with no retransmissions.

+ Keywords can be repeated or combined as needed to complete the paging policy configuration.

Usage

Use this command to configure the order of preference for retransmitting into specified paging-areas.

Example

Use the following command to instruct the SGSN to page the cell and BSC as the last-known areas:

```
paging-policy last-known-area cell bsc
```
**peer-nsei**

This command associates a peer (remote) network service entity (NSEI) for a BSS with this GPRS service.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gprs-service)#

**Syntax**

```
peer-nsei nse_id { associate dscp-template downlink template_name | lac lac_id rac rac_id | name peer_nsei_name | pooled }

no peer-nsei nse_id [ associate dscp-template downlink | lac lac_id rac rac_id | name | pooled ]
```

- **no**
  - Removes the specified configuration from this peer-nsei configuration.

### Important:
Deleting the LAC/RAC portion of the configuration will probably result in the loss of subscriber connections.

- **nse_id**
  - Defines a specific peer NSEI configuration for this GPRS service.
  - `nse_id` - enter an integer from 0 to 65535.

- **associate dscp-template downlink template_name**
  - Identifies a specific DSCP marking template to associate with the peer-NSE. The DSCP template must first be created with SGSN Global configuration mode and then defined with the commands in the DSCP Template configuration mode. The template provides a mechanism for differentiated services code point (DSCP) marking of control packets and LLC signaling messages on Gb interfaces. This DSCP marking feature enables the SGSN to perform classifying and managing of network traffic and to determine quality of service (QoS) for the interfaces to an IP network.
  - `template_name` - enter an alphanumeric string of 1 to 64 characters.

- **lac lac_id**
  - Defines a location area code associated with the NSE BSS.
  - `lac_id` must be an integer between 1 and 65535.
rac rac_id
Defines the remote area code to be associated with the NSE BSS
rac_id must be an integer between 1 and 255.

name peer_nsei_name
Enables identifying a BSC by a name which is stored in SCT.
peer_nsei_name - enter an alphanumeric string of 1 to 64 characters.

pooled
Enables pooling with non-pooled BSCs within the pool area.

Usage
Use this command repeatedly to associate one or more LAC/RAC combinations and/or pooling with this peer-GPRS service configuration. Also repeat the command as needed to create an association with a DSCP marking template, to define a name for a BSC, and to enable pooling with non-pooled BSCs.

The Network Service Entity (NSE) at the BSS and the SGSN provides the network management functionality required for the operation of the Gb interface. Each NSE is identified by means of NSE identifier (NSEI).

Example
The following command configures the NSE with identifier as 4114 having location area code 234 and routing area code as 22:

    peer-nsei 4114 lac 234 rac 22

The following command enables Gb flex (pooling) functionality for NSEI 4414 for this GPRS service:

    peer-nsei 4114 pooled
plmn

This command identifies the Public Land Mobile Network (PLMN) for the GPRS service. It also configures the common PLMN-Id and an optional list of dedicated PLMN-Ids in support of Multi-Operator Core Network (MOCN) operation.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
plmn id mcc mcc_num mnc mnc_num [ network-sharing common-plmn mcc mcc_num mnc mnc_num [ plmn-list mcc mcc_num mnc mnc_num [ mcc mcc_num mnc mnc_num ] + ] ]
```

```
no plmn id
```

**no**

Removes the PLMN information from the configuration for the current SGSN service.

```
mcc mcc_num
```

Define the mobile country code (MCC) portion of the PLMN Id.

- `mcc_num` must be a 3 digit integer from 100 to 999. MCC values of 000-099 are Reserved codes.

```
mnc mnc_num
```

Define the mobile network code (MNC) portion of the PLMN Id.

- `mnc_num` must be a 2 or 3 digit integer from 00 to 999. MNC value of 000 is reserved.

```
network-sharing common-plmn
```

Configures the common PLMN-Id broadcast by a radio network. An MS that does not support network sharing will only see this PLMN-Id. An MS that supports network sharing (MOCN) will see this PLMN-Id and the list of PLMN-Ids configured using the `plmn-id` keyword.

```
plmn-list
```

Configures a list of PLMN-Ids that an MS will see when network sharing is enabled.

```
+
```

The plus symbol indicates that indicates that more than one more than one set of the keywords, for PLMN-Id, can be entered within a single command.
Usage
Use this command to set PLMN parameters for the current SGSN service. This command also sets the common PLMN-Id and a list of PLMN-Ids employed in network sharing (MOCN) deployments. There is no limit to the number of PLMN-Ids that can be included in the list.

Example
The following command identifies the PLMN MCC as 200 and the MNC as 10:

```
plmn id mcc 200 mnc 10
```
reporting-action event-record

This command enables the SGSN to log GMM/SM events in EDR files for 2G services.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GPRS Service Configuration
configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gprs-service)#

Syntax

reporting-action event-record

[ default | no ] reporting-action event-record

default
Disables the logging function.

no
Removes the logging function from the configuration file.

Usage

This command is one of the steps needed to enable the SGSN to create a log for events such as Attach, RAU, and Activations. The log is an EDR (event data record) in CSV format. For details about how this feature works, refer to the GMM-SM Event Logging chapter in the SGSN Administration Guide.

Related Commands:
- To enable GMM/SM event logging for 2G services, the reporting-action event-record command must be configured in the SGSN service configuration.
- To enable a log to be generated in an EDR file, the edr-module active-charging-service command must be enabled in the Context configuration mode.
- To configure parameters for the logging file characteristics and for file transfer, use the commands in the EDR Module Configuration Mode.

Example

Enable GMM/SM event logging for 3G services:

reporting-action event-record
**setup-timeout**

This command configures the maximum number of seconds allowed for session setup.

**Product**  
SGSN

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
setup-timeout seconds
```

```
default setup-timeout
```

```
default
```

Returns the configuration to the default, 60 seconds.

```
seconds
```

An integer from 1 to 100000.

**Usage**

Use this command to set the time allowed for session setup.

**Example**

The following command sets the maximum session setup time to 300 seconds:

```
setup-timeout 300
```
sgsn-context-request

This command specifies whether or not the PTMSI signature check should be skipped if the PTMSI signature is not included in the SGSN context request.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```bash
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
sgsn-context-request ptmsi-signature-absence allowed

default sgsn-context-request ptmsi-signature-absence

no sgsn-context-request ptmsi-signature-absence allowed
```

- **default**
  Returns the configuration to the default action to perform the PTMSI signature check.

- **no**
  Removes this definition from the system configuration.

**Usage**

Use this command to skip the PTMSI signature check.

**Example**

The following command instructs the system to perform the PTMSI signature check.

```
default sgsn-context-request ptmsi-signature-absence
```
sgsn-number

Define the SGSN E.164 number to be used when interacting via MAP protocol for this GPRS service.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gprs-service)#

**Syntax**

```
sgsn-number sgsn_number

no sgsn-number
```

**Usage**

Use this command to identify the ISDN number for the SGSN associated with this GPRS service. The SGSN supports multiple SGSN numbers – different numbers in the 2G GPRS service configuration and the 3G SGSN service configuration. If an HLR-initiated dialog is received, the SGSN will perform a lookup based on the IMSI and find the correct SGSN number with which the MS is associated. Subsequent messaging will use this address.

**Example**

Disable the E.164 number for this GPRS service.

```
no sgsn-number
```
This command configures the session management (SM) parameters associated with this particular GPRS service context.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)\#
```

**Syntax**

```
sm { activate-max-retransmissions num_retries | deactivate-max-retransmissions num_retries | guard-timer guard_seconds | ignore-pco-decode-error | modify-max-retransmissions num_retries | partial-apn-match | requested-apn-from-first-subrec | t3385-timeout secs | t3386-timeout secs | t3395-timeout secs | t3396 min minimum max maximum cause cause_code | trim-trailing-spaces-in-apn }
```

default sm { activate-max-retransmissions | deactivate-max-retransmissions | ignore-pco-decode-error | modify-max-retransmissions | t3385-timeout | t3386-timeout | t3395-timeout | trim-trailing-spaces-in-apn }

default

Resets the SM parameters to their defaults.

---

### activate-max-retransmissions num_retries

Defines the maximum number of retries to transmit ‘activate PDP context request’.

- **num_retries**: Must be an integer from 1 to 10.
- Default: 4

### deactivate-max-retransmissions num_retries

Defines the maximum number of retries to transmit ‘deactivate PDP context request’.

- **num_retries**: Must be an integer from 1 to 10.
- Default: 4

### guard-timer guard_seconds

Sets the number of seconds before the session manager resources are cleared.

- **guard_seconds**: is an integer from 30 to 150.
- Default: 80 seconds
ignore-pco-decode-error
Enables the SGSN to ignore received decode errors that are due to incorrectly encoded PCO IE length in SM Requests.
Default: disabled

modify-max-retransmissions num_retries
Defines the maximum number of retries to transmit ‘modify PDP context request’.
num_retries: integer from 1 to 10.
Default: 4

partial-apn-match
Enables partial matching of requested APN during APN selection.
Partial APN or APN with trailing spaces may be present in an Activate Request because incorrect information was keyed in by the user. Though it is valid to reject such Activation Requests, it increases the signaling between the MS and the SGSN. This has an impact on the radio resources.

requested-apn-from-first-subrec
Enables use of a ‘requested APN’ from the first subscription record. When this feature is enabled, the PDP Activation is not rejected during APN Selection; instead, the APN from the first subscription record is used as the requested APN and the SGSN continues with the rest of the APN Selection process.
A requested APN is an optional IE in an Activate PDP Request. To get the requested PDP type, if multiple PDP subscription records exist for the subscriber, then the MS has to include the APN information to choose the PDP subscription record during APN selection. Otherwise, such activations will be rejected during APN selection (per TS 23.060 Appendix A). Though it is valid to reject such activation requests, it increases the signaling between the MS and the SGSN, which impacts the radio resources.

t3385-timeout secs
Defines the maximum amount of time for retransmission of ‘activate request’ messages.
secs: Must be an integer from 1 to 60.
Default: 8

t3386-timeout secs
Defines the maximum amount of time for retransmission of ‘modify request’ messages.
secs: Must be an integer from 1 to 60.
Default: 8 seconds.

t3395-timeout secs
Defines the maximum amount of time for retransmission of ‘deactivate request’ messages.
secs: Must be an integer from 1 to 60.
Default: 8

trim-trailing-spaces-in-apn
Enables SGSN to strip off any trailing space(s) in requested APN.
If a requested APN in an Activate PDP Context Request has any trailing spaces, then those trailing spaces will be removed and the length field will be updated.
Usage
Repeat this command with different keywords (parameters) to configure the SM (session management) as needed for this GPRS service. Keywords can be used to optimize signaling between the MS and the SGSN to reduce the impact on the radio resources.

Example
Reset the number of retransmission messages for deactivate PDP context request to 5.

```sh
sm deactivate-max-retransmissions 5
```
sndcp

Define the sub-network dependent convergence protocol (SNDCP) network packet data unit (N-PDU) reassembly timeout interval associated with this GPRS service.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GPRS Service Configuration
configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:
[context_name]host_name(config-gprs-service)#

Syntax

sndcp reassembly-timeout seconds

default sndcp reassembly-timeout

default

Resets the timer configuration to the default value of 30 seconds.

seconds

Defines the number of seconds the SGSN waits for all the SNDCP segments to arrive before dropping all the disassembled segments.
seconds: Must be an integer from 1 to 300.

Usage

Use this command to modify the SNDCP reassembly timer. This timer starts as soon as the first N-PDU segment is received (either in-order or out-of-order). If all the segments belong to the N-PDU arrive before the timer expires then the segments are reassembled. If all the segments do not arrive before the timer expires, then the stored segments are discarded.

Example

Reset the default for the timer.

default sndcp reassembly-timeout
Chapter 147
GRE Tunnel Interface Configuration Mode Commands

The Generic Routing Encapsulation (GRE) Tunnel Interface Configuration Mode is used to create and manage the GRE tunneling interfaces for addresses, address resolution options, etc.

Mode

Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > GRE Tunnel Interface Configuration

configure > context context_name > interface interface_name tunnel > tunnel-mode gre

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-if-tunnel-mode)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
destination

This command configures the destination IP address of the tunnel by specifying the destination end address. This is a mandatory configuration for a GRE tunnel interface.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > GRE Tunnel Interface Configuration

```
configure > context context_name > interface interface_name tunnel > tunnel-mode gre
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-if-tunnel-mode)#
```

Syntax

```
[ no ] destination address ip_address
```

no

Removes or disassociates the configured destination IP address from a specific GRE tunnel interface configuration.

```
address ip_address
```

Configures the IP address for the interface.

*ip_address* must be specified using the IPv4 dotted-decimal notation.

Usage

Use this command to configure the destination IP address of the tunnel by specifying the IP address of destination tunnel end for GRE tunnel interface.

**Important:** State of source address will affect the operational state of the tunnel.

Example

The following command sets the 10.2.3.4 as destination IP address of the GRE tunnel interface:

```
destination address 10.2.3.4
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
keepalive

This command configures various parameters for sending Keepalive messages to the remote end-point in GRE tunnel interface configuration. By default sending keepalives is disabled.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > GRE Tunnel Interface Configuration

```
configure > context context_name > interface interface_name tunnel > tunnel-mode gre
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-if-tunnel-mode)#
```

**Syntax**

```
keepalive [ interval time_interval num-retry retry ]
[ default | no ] keepalive
```

- **default**
  Sets the sending of Keepalives with default parameters.
  - interval: 10 seconds
  - num-retry: 3 retries

- **no**
  Disables the keepalive and turns off the sending of Keepalives messages.

- **interval time_interval**
  Default: 10
  Specifies the time interval (in seconds) between two Keepalives sent to remote ends of GRE tunnel interface configuration.
  - *time_interval* must be an integer from 5 through 3600.

- **num-retry retry**
  Default: 3
  Specifies number of retransmission of keepalives to remote node without getting any response before the remote node is marked as dead/down.
  - *retry* must be an integer between 0 through 10.

**Usage**

Use this command to configure the parameters for sending Keepalives to the remote end-point of GRE tunnel. It also configures the interval at which GRE Keepalives are sent on the interface and number of retries.
without getting a response from the remote end-point before the tunnel is shutdown. By default, Keepalives will not be sent.

Example
The following command enables the keepalive and sets the other parameters to defaults:

```
default keepalive
```
source

This command configures the source IP address of the tunnel either by specifying the IP address (host address) or by specifying another configured non-tunnel IP interface. This is a mandatory configuration for GRE tunnel interface.

<table>
<thead>
<tr>
<th>Product</th>
<th>All</th>
</tr>
</thead>
<tbody>
<tr>
<td>Privilege</td>
<td>Security Administrator, Administrator</td>
</tr>
</tbody>
</table>
| Mode          | Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration  
                configure > context context_name > interface interface_name tunnel > tunnel-mode gre |

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-if-tunnel-mode)#
```

Syntax

```
[ no ] source { address ip_address | interface interface_name }
```

- **no**
  - Removes/disassociates the configured source IP address or host interface from a specific GRE tunnel interface configuration.

- **address ip_address**
  - Configures the IP address for the interface specifying the IP address.
  - `ip_address` must be specified using IPv4 dotted-decimal notation.

- **interface interface_name**
  - Specifies the name of the preconfigured non-tunnel IP interface, whose address is used as the source address of the GRE tunnel.

Usage

Use this command to configure the source IP address of the tunnel either by specifying the IP address (host address) or by specifying another configured non-tunnel IP interface for GRE tunnel interface.

**Important:** State of source address will affect the operational state of the tunnel.

Example

The following command sets the 10.2.3.4 as source IP address of the GRE tunnel interface:

```
source address 10.2.3.4
```
tos

This command configures the parameters/action for the type of Service (ToS) parameter in the IP tunnel transport protocol header.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > GRE Tunnel Interface Configuration

configure > context context_name > interface interface_name tunnel > tunnel-mode gre

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-if-tunnel-mode)#

Syntax

tos { value [ af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | ef | lower-bits tos_value ] | copy }

default

Sets the IP TOS to lower bits value of 0.

value [ tos_value ]

Default: af11

Specifies the IP QoS DSCP per-hop behavior to be marked on the outer header of signalling packets originating from the Access Gateway. This is a standards-based feature (RFC 2597). The following forwarding types are supported:

• af11: Assured Forwarding 11 per-hop behavior
• af12: Assured Forwarding 12 per-hop behavior
• af13: Assured Forwarding 13 per-hop behavior
• af21: Assured Forwarding 21 per-hop behavior
• af22: Assured Forwarding 22 per-hop behavior
• af23: Assured Forwarding 23 per-hop behavior
• af31: Assured Forwarding 31 per-hop behavior
• af32: Assured Forwarding 32 per-hop behavior
• af33: Assured Forwarding 33 per-hop behavior
• af41: Assured Forwarding 41 per-hop behavior
• af42: Assured Forwarding 42 per-hop behavior
• af43: Assured Forwarding 43 per-hop behavior
**be**: Best Effort forwarding per-hop behavior  
**ef**: Expedited Forwarding per-hop behavior typically dedicated to low-loss, low-latency traffic.

The assured forwarding behavior groups are listed in the table below.

<table>
<thead>
<tr>
<th></th>
<th>Class 1</th>
<th>Class 2</th>
<th>Class 3</th>
<th>Class 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low Drop</td>
<td>AF11</td>
<td>AF21</td>
<td>AF31</td>
<td>AF41</td>
</tr>
<tr>
<td>Medium Drop</td>
<td>AF12</td>
<td>AF22</td>
<td>AF32</td>
<td>AF42</td>
</tr>
<tr>
<td>High Drop</td>
<td>AF13</td>
<td>AF23</td>
<td>AF33</td>
<td>AF43</td>
</tr>
</tbody>
</table>

Traffic marked with a higher class is given priority during congestion periods. If congestion occurs to traffic with the same class, the packets with the higher AF value are dropped first.

**lower-bits** **tos_value**

Default: 0

Sets the least-significant 6 bits in the ToS byte with the specified numeric value. **tos_value** must be an integer from 0 through 255.

**copy**

This keyword instructs the system to copy the ToS value from the passenger IPv4 packet or Traffic class value from the passenger IPv6 packet to the ToS value of the IPv4 tunnel transport protocol header.

**Usage**

Use this command either to set the ToS parameter in the IPv4 tunnel transport protocol header to the specified value or instructs to copy the ToS value from the passenger IPv4 packet or Traffic class value from the passenger IPv6 packet to the ToS value of the IPv4 tunnel transport protocol header. If one of the enumerated values is set, the DSCP bits which are the six most-significant bits in the ToS byte are marked. If the integer value is set, it will be written into the six least-significant bits of the ToS byte.

**Example**

The following command instructs the system to copy the ToS value from the passenger IPv4 packet or Traffic class value from the passenger IPv6 packet to the ToS value of the IPv4 tunnel transport protocol header:

```plaintext
tos copy
```
**ttl**

This command configures the Time to live (TTL) parameter to be used in the tunnel transport protocol header for the current GRE tunnel interface.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > GRE Tunnel Interface Configuration

`configure > context context_name > interface interface_name tunnel > tunnel-mode gre`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-if-tunnel-mode)#
```

**Syntax**

```
ttl ttl_value

default ttl
```

- **default**
  
  Sets the TTL value to system default value.

- **ttl_value**
  
  Default: 15
  
  Specifies the maximum time to live to be used in the tunnel transport protocol header.
  
  The time to live (TTL) is not a measure of time but the number of hops through the network.
  
  `ttl_value` must be an integer between 1 through 255.

**Usage**

Use this command to set the TTL parameter to be used in the tunnel transport protocol header for the GRE tunnel configuration.

**Example**

The following configures the TTL to a value of 10:

```
ttl 10
```
Chapter 148
Gs Service Configuration Mode Commands

The Gs Service configuration mode configures the parameters used to setup and maintain a Gs interface for a connection between the SGSN and an MSC/VLR.

**Mode**

Exec > Global Configuration > Context Configuration > Gs Service Configuration

```
configure > context context_name > gs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gs-service)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
associate-sccp-network

This command associates a previously defined Signaling Connection Control Part (SCCP) network instance with the Gs service. This association is required to access Visitor Location Register(s) (VLRs).

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Gs Service Configuration

```
configure > context context_name > gs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gs-service)#
```

**Syntax**

```
associate-sccp-network sccp_net_id

no associate-sccp-network
```

- **no**
  Removes the associated SCCP network configuration instance from this Gs service configuration.

- **sccp_net_id**
  Identifies the SCCP network configuration instance to associate with this Gs interface to enable connection with VLR(s).
  `sccp_network_num`: Must be an integer from 1 through 12.

**Usage**

Use this command to associate the SCCP network configuration instance with the Gs interface in this service.

**Important:** A single SCCP network configuration instance can not be shared with multiple Gs services.

**Important:** To enable a Gs service, the user needs to configure `ssn` with the `bssap+` command.

**Example**

Following command associates SCCP network 2 with this Gs service.

```
associate-sccp-network 2
```
bssap+

This command defines the Base Station System Application Part Plus configuration parameters for the Gs service to enable the SGSN to access a Visitor Location Register(s) (VLRs).

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Gs Service Configuration

```
configure > context context_name > gs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gs-service)#
```

**Syntax**

```
bssap+ ssn ss_num

no bssap+ ssn ss_num
```

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
<tbody>
<tr>
<td>Removes the configured BSSAP+ subsystem number from this Gs service.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ssn ss_num</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the subsystem number to configure in this Gs interface to use BSSAP+.</td>
</tr>
</tbody>
</table>

**Usage**
Use this command to configure the BSSAP+ subsystem with Gs interface in this service to communicate with VLR(s).

**Important:** A single SCCP network configuration instance can not be shared with multiple Gs services.

**Important:** To start a Gs service, the user needs to configure the `command parameter.

**Example**

Following command configures subsystem 101 with BSSAP+ in this Gs service.

```
bssap+ ssn 101
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the previous configuration mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

exit

Usage
Return to the previous configuration mode.
max-retransmission

This command configures the retransmission values for different procedure counters in Gs service as described in TS 29.018.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Gs Service Configuration
configure > context context_name > gs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gs-service)#

Syntax

max-retransmissions { n8 | n9 | n10 | n12 } retrans_num

default max-retransmissions { n8 | n9 | n10 | n12 }

no

Removes the configured Gs procedures from this Gs service.

{ n8 | n9 | n10 | n12 }

Specifies the various Gs service procedures that are available to be used to communicate with VLR(s).

- n8: Defines the maximum number of retries for explicit IMSI detach from a non-GPRS service. Default is 2.
- n9: Defines the maximum number of retries for explicit IMSI detach from a non-GPRS service. Default is 2.
- n10: Defines the maximum number of retries for implicit IMSI detach from the GPRS service. Default is 2.
- n12: Defines the maximum number of retries for BSSAP+ to send Reset Indication messages. Default is 2.

retrans_num

Default: 2

Specifies the number of re-transmission of message for specified procedures.

retrans_num: Must be an integer from 0 through 10.

Usage

Use this command to configure the retransmission values for specific procedure counters in Gs service. Counters are based on TS 29.018.

This command can be entered for each procedure counter separately.
Example

Following command configure retransmission value as 3 for counter for procedure to send BSSAP+ Reset Indication messages in this Gs service.

```
max-retransmissions n12 3
```
non-pool-area

This command creates a non-pool area for a set of subscriber location area code (LAC) values that can be used with a specific VLR for the Gs service.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Gs Service Configuration

configure > context context_name > gs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gs-service)#

Syntax

non-pool-area non_pool_name \{ use-vlr vlr_name lac lac_num \} +

no non-pool-area non_pool_name \{ lac lac_num \}

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
<tbody>
<tr>
<td>Removes the configured non-pool area from this Gs service.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>non_pool_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the name of the non-pool area to configure with this command.</td>
</tr>
<tr>
<td><strong>non_pool_name</strong> must be an alpha and/or numeric string of 1 to 63 characters.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>use-vlr vlr_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the name of the VLR to be associated with this non-pool area.</td>
</tr>
<tr>
<td><strong>vlr_name</strong> is the name of VLR and must be an alpha and/or numeric string of 1 to 63 characters.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>lac lac_num</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the subscribers’ location area code to be attached with this non-pool area and specific VLR. This LAC of subscriber is obtained from the radio area indicator (RAI).</td>
</tr>
<tr>
<td>Including this keyword with the <strong>no</strong> form of the command enables the operator to remove a specific LAC from the non-pool area configuration.</td>
</tr>
<tr>
<td><strong>lac_num</strong> is the LAC value and must be an integer value from 1 through 65535.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>+</th>
</tr>
</thead>
<tbody>
<tr>
<td>More than one <strong>lac_num</strong>, separated by a space, can be entered within a single command.</td>
</tr>
</tbody>
</table>

Usage

This command can be repeated as necessary to define a total of 32 configured LACs for the combined **non-pool-area** and **pool-area** configurations per Gs service.
Example

Following command configure a non-pool area `starpool1` to use VLR named `starvlr1` for LAC 101 in a Gs service.

```
non-pool-area starpool1 use-vlr starvlr1 lac 101
```
pool-area

This command creates a pool area configuration instance. This command also enters the Pool Area configuration mode to define the set of VLRs to use for a pool area for a set of subscriber location area code (LAC) values in the Gs service.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Gs Service Configuration
configure > context context_name > gs-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-gs-service) #
```

**Syntax**

```
pool-area pool_name [ -noconfirm ]
no pool-area non_pool_name
```

no

Removes the configured pool area from this Gs service.

---

pool_name

Specifies the name of the pool area to configure with this command for VLR pooling and association of a LAC.

pool_name: Must be an alpha and/or numeric string of 1 to 63 characters.

---

-noconfirm

Indicates that the command is to execute without any additional prompt and confirmation from the user.

---

**Usage**

Use this command to create/enter the pool area configuration mode. This mode is used configure the set of VLRs to be used for a set of subscriber LAC.

This command can be used multiple times, subject to a limit of 128 LAC values (the total number of non-pool-area and pool-area configurations) per Gs service.

---

**Example**

The following command configures a pool area named starpool in a Gs service without any confirmation prompt.

```
pool-area starpool -noconfirm
```
sgsn-number

Define the SGSN’s E164 number to associate an SGSN with this Gs Service.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Gs Service Configuration

```
configure > context context_name > gs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gs-service)#
```

**Syntax**

```
sgsn-number E.164_number
```

<table>
<thead>
<tr>
<th>E.164_number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Defines the SGSN’s ‘telephone’ number, the ISDN number for per ITU-T E.164 numbering plan. The number must be a numerical string of 1 to 15 digits.</td>
</tr>
</tbody>
</table>

**Usage**

For releases 8.1 or higher, use this command to define the SGSN’s E.164 ISDN number. This value should match the *sgsn-number* defined for SGSN Service or GPRS Service.

**Important:** Note: the Gs Service will not start unless the SGSN’s E.164 number is configured.

**Example**

```
sgsn-number 12345678901234
```
timeout

This command configures various timers defining the wait before retransmitting a specific message for Gs service procedures.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Gs Service Configuration

configure > context context_name > gs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gs-service)#

Syntax

timeout { t6-1-timer t6_1_dur | t8-timer t8_dur | t9-timer t9_dur | t10-timer t10_dur | t12-1-timer minute t12_1_dur | t12-2-timer t12_2_dur }

[ default ] timeout { t6-1-timer | t8-timer | t9-timer | t10-timer | t12-1-timer | t12-2-timer }

default

Sets the timer value to wait in seconds/minutes to default values. Default values for timers are:
- t6-1-timer: 10 seconds
- t8-timer: 4 seconds
- t9-timer: 4 seconds
- t10-timer: 4
- t12-1-timer: 54 mins (+ 8 seconds)
- t12-2-timer: 4 seconds

t6-1-timer t6_1_dur

Default: 10
Specifies the retransmission timer value to guard the location update.
t6_1_dur is the waiting duration in seconds before retransmitting the specific message and must be an integer from 10 through 90.

t8-timer t8_dur

Default: 4
Specifies the retransmission timer value to guard the explicit IMSI detach from the GPRS service procedure.
t8_dur is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 30.
**t9-timer t9_dur**

Default: 4  
Specifies the retransmission timer value to guard the explicit IMSI detach from the non-GPRS service procedure.  
*t9_dur* is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 30.

**t10-timer t10_dur**

Default: 4  
Specifies the retransmission timer value to guard the implicit IMSI detach from the GPRS service procedure.  
*t10_dur* is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 30.

**t12-1-timer minute t12_1_dur**

Default: 54 minutes (plus 8 seconds for transmission delay)  
Specifies the retransmission timer value to control the resetting of SGSN-Reset variable procedure.  
*t12_1_dur* is the waiting duration in minutes before retransmitting reset message for the SGSN Reset variable and must be an integer from 0 through 384.

**t12-2-timer t12_2_dur**

Default: 4  
Specifies the retransmission timer value to guard the SGSN reset procedure.  
*t12_2_dur* is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 120.

**Usage**

Use this command to configure the time, for different procedure timers, to wait before retransmitting a procedure message.  
This command can be repeated for each timer to configure multiple timers.

**Example**

Following command sets the timeout duration of 4 seconds for t8 timer to wait before retransmitting the procedure message to explicitly do the IMSI detach from GPRS service:

```
default timeout t8-timer
```
vlr

This command defines a VLR configuration for use with this Gs service.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Gs Service Configuration
configure > context context_name > gs-service service_name
Entering the above command sequence results in the following prompt:
[context_name]host_name(config-gs-service)#

Syntax

vlr vir_name isdn-number E164_num [ bssap+ ssn ssn ] [ point-code pt_code ]
no vlr vir_name

no
Removes the configured VLR from the Gs service.

vir_name
Specifies the name of the VLR to configure in this Gs mode with ISDN number.
vir_name must be an alpha and/or numeric string of 1 to 63 characters.

isdn-number E164_num
Specifies the VLR number to configure with this command.
E164_num: The ISDN number for the target VLR. Value must be defined according to the E.164 numbering plan and must be a numeric string of 1 to 15 digits.

bssap+ ssn ssn
Specifies the subsystem number to configure with this VLR to use BSSAP+.
ssn: Must be an integer from 1 through 255. Default value is 252.

point-code pt_code
Specifies SS7 address of VLR in point code value to this configured VLR name.
pt_code: Must be in SS7 point code dotted-decimal ###.###.### format or decimal ####### format.

Usage
Use this command to define VLR configuration instances to be associated with the Gs service.
A maximum of 32 VLRs can be configured per Gs service.

Example
Following command configures the VLR named starvlr1 with an ISDN number 12344567, a subsystem number of 252, and a point code value of 123.345.567:

```
vlr starvlr1 isdn-number 12344567 point-code 123.345.567
```
Chapter 149
GT-Format1 Configuration Mode Commands

The GT-Format1 configuration mode is a sub-mode for either the Global Title Translation Association configuration mode or the Global Title Translation Address-Map configuration mode. This sub-mode configures a set of rules used in the global title translation (GTT) process.

Mode

Exec > Global Configuration > GTT Association Configuration > GT-Format1 Configuration

configure > global title translation association instance instance_number > gt-format format_number

Entering the above command sequence results in the following prompt:

[local]host_name(config-gtt-instance-format1)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Change the mode back to the Exec mode.
exit

Exits the configuration mode and returns to the Global configuration mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
exit
```

Usage
Return to the Global configuration mode.
nature-of-address

Configures the indicator to identify the nature of the address.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > GTT Association Configuration > GT-Format1 Configuration

```
configure > global title translation association instance <instance_number> > gt-format <format_number>
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-gtt-instance-format1)#
```

**Syntax**

```
nature-of-address { international | national | subscriber }
```

- **international**
  Identifies the numbers as international.

- **national**
  Identifies the numbers as matching the national configuration.

- **subscriber**
  Identifies the numbers as subscriber numbers.

**Usage**

Configure the identify of the GT format as national.

**Example**

```
nature-of-address national
```
odd-even-indicator

Configures the bits for matching the global title translation.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > GTT Association Configuration > GT-Format1 Configuration

configure > global title translation association instance instance_number > gt-format format_number

Entering the above command sequence results in the following prompt:

[local]host_name(config-gtt-instance-format1)#

Syntax

odd-even-indicator type

type
• odd: Sets the odd bit for matching the GTT.
• even: Sets the even bit for matching the GTT.
Chapter 150
GT-Format2 Configuration Mode Commands

The GT-Format2 configuration mode is a sub-mode for either the Global Title Translation Association configuration mode or the Global Title Translation Address-Map configuration mode. This sub-mode configures a set of rules used in the global title translation (GTT) process.

Mode

Exec > Global Configuration > GTT Association Configuration > GT-Format2 Configuration

configure > global title translation association instance instance_number > gt-format format_number

Entering the above command sequence results in the following prompt:

[local]host_name(config-gtt-instance-format2)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the configuration mode and returns to the Exec mode.

**Product**
SGSN

**Privilege**

```

**Usage**
Change the mode back to the Exec mode.
**exit**

Exits the configuration mode and returns to the Global configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Return to the Global configuration mode.
translation-type

Configures the translation type to be applied during the translation process.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > GTT Association Configuration > GT-Format2 Configuration

configure > global title translation association instance instance_number > gt-format format_number

Entering the above command sequence results in the following prompt:

[l]ocal host_name(config-gtt-instance-format2)#

Syntax

translation-type number

number

Must be an integer between 0 and 255.
Default is 0

Usage
Use this command to configure the GTT translation type to be applied during global title translation process.

Example

translation-type 232
Chapter 151
GT-Format3 Configuration Mode Commands

The GT-Format3 configuration mode is a sub-mode for either the Global Title Translation Association configuration mode or the Global Title Translation Address-Map configuration mode. This sub-mode configures a set of rules used in the global title translation (GTT) process.

Mode

Exec > Global Configuration > GTT Association Configuration > GT-Format3 Configuration

configure > global title translation association instance instance_number > gt-format format_number

Entering the above command sequence results in the following prompt:

[local]host_name(config-gtt-instance-format3)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
encoding-scheme

Configures the encoding-scheme to use during global title translation (GTT).

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > GTT Association Configuration > GT-Format3 Configuration

```bash
configure > global title translation association instance instance_number > gt-format format_number
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-gtt-instance-format3)#
```

**Syntax**

```bash
encoding scheme scheme_type
```

**scheme_type**
Select one of the following encoding scheme types to determine the encoding type to be used during GTT:

- **bcd-even**: BCD even encoding scheme
- **bcd-odd**: BCD odd encoding scheme
- **nw-specific**: Network specific encoding scheme
- **unknown**: Unknown encoding scheme

**Usage**
Select BCD even encoding for GTT

**Example**

```bash
encoding scheme bcd-even
```
end

Exits the configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Change the mode back to the Exec mode.
exit

Exits the configuration mode and returns to the Global configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the Global configuration mode.
numbering-plan

Configures the GTT process to apply one of the numbering-plans during the GT translation process.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > GTT Association Configuration > GT-Format3 Configuration

```
configure > global title translation association instance instance_number > gt-format format_number
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-gtt-instance-format3)#
```

**Syntax**

```plaintext
numbering-plan plan_type
```

**plan_type**
Select one of the following numbering plans be employed during GTT:

- **data**: Data numbering plan
- **generic**: Generic number plan
- **isdn**: ISDN tel numbering plan
- **isdn-mobile**: ISDN mobile numbering plan
- **land-mobile**: Land mobile numbering plan
- **maritime-mobile**: Maritime mobile numbering plan
- **nw-specific**: Private network / network-specific numbering plan
- **telex**: Telex numbering plan
- **unknown**: Unknown numbering plan

**Usage**
Select ISN telephone number plan for GTT process.

**Example**
The following command sets the numbering plan to use during GTT processing to isdn

```plaintext
numbering-plan isdn
```
translation-type

Configures the global title translation (GTT) process to apply a specific number for translation during the GTT process.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > GTT Association Configuration > GT-Format3 Configuration

```
configure > global title translation association instance instance_number > gt-format format_number
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-gtt-instance-format3)#
```

Syntax

```
translation-type number
```

- `number`

  Must be an integer between 0 and 255. Default is 0

Usage

Use this command to define the translation-type to be used during the global title translation process.

Example

```
translation-type 233
```
Chapter 152
GT-Format4 Configuration Mode Commands

The GT-Format4 configuration mode is a sub-mode for either the Global Title Translation Association configuration mode or the Global Title Translation Address-Map configuration mode. This sub-mode configures a set of rules used in the global title translation (GTT) process.

Mode

Exec > Global Configuration > GTT Association Configuration > GT-Format4 Configuration

configure > global title translation association instance instance_number > gt-format format_number

Entering the above command sequence results in the following prompt:

[local]host_name(config-gtt-instance-format4)#

⚠️ **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
encoding-scheme

Configures the encoding-scheme to use during GTT.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > GTT Association Configuration > GT-Format4 Configuration

configure > global title translation association instance instance_number > gt-format format_number

Entering the above command sequence results in the following prompt:

[local]host_name(config-gtt-instance-format4)#

Syntax

encoding scheme scheme_type

scheme_type

Select one of the following encoding scheme types to determine the encoding type to be used during GTT:

• bcd-even: BCD even encoding scheme
• bcd-odd: BCD odd encoding scheme
• nw-specific: Network-specific encoding scheme
• unknown: Unknown encoding scheme

Usage
Select BCD even encoding for GTT

Example

encoding scheme bcd-even
end

Exits the configuration mode and returns to the Exec mode.

Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the Global configuration mode.
nature-of-address

Configures the indicator to identify the nature of the address.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > GTT Association Configuration > GT-Format4 Configuration

```bash
configure > global title translation association instance instance_number > gt-format format_number
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-gtt-instance-format4)#
```

Syntax

```
nature-of-address { international | national | subscriber }
```

---

**international**
Identifies the numbers as international.

---

**national**
Identifies the numbers as matching the national configuration.

---

**subscriber**
Identifies the numbers as subscriber numbers.

---

Usage
Configure the identify of the GT format as national.

Example

```
nature-of-address national
```
**numbering-plan**

Configures the GTT process to apply one of the numbering-plans during the GT translation process.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > GTT Association Configuration > GT-Format4 Configuration

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-gtt-instance-format4)#
```

**Syntax**

```
numbering-plan plan_type
```

*plan_type*

Select one of the following numbering plans be employed during GTT:

- **data**: Data numbering plan
- **generic**: Generic number plan
- **isdn**: ISDN tel numbering plan
- **isdn-mobile**: ISDN mobile numbering plan
- **land-mobile**: Land mobile numbering plan
- **maritime-mobile**: Maritime mobile numbering plan
- **nw-specific**: Private network/ network-specific numbering plan
- **telex**: Telex numbering plan
- **unknown**: Unknown numbering plan

**Usage**
Select ISN telephone number plan for GTT process.

**Example**

```
numbering-plan isdn
```
translation-type

Configures the GTT process to apply a specific number for translation during the GTT process.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > GTT Association Configuration > GT-Format4 Configuration
configure > global title translation association instance instance_number > gt-format format_number

Entering the above command sequence results in the following prompt:

[local]host_name(config-gtt-instance-format4)#

**Syntax**

```bash
translation-type number
```

- `number`
  - Must be an integer between 0 and 255.
  - Default is 0.

**Usage**

Use this command to configure the translation-type to be implemented during the global title translation process.

**Example**

```bash
translation-type 231
```
Chapter 153
GTTP Server Group Configuration Mode Commands

The GTTP Server Group Configuration Mode is used to create and manage the GTTP server groups within the context or system.

GTTP server group commands facilitate the setup of the hard disk for CDR storage. They also support accounting and charging functionality within a context, and configuration of a group (list) of charging gateway function (CGF) servers on a per subscriber or per GGSN/P-GW APN level.

**Mode**

Exec > Global Configuration > Context Configuration > GTTP Server Group Configuration

```
configure > context context_name > gtpp group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

exit

**Usage**
Use this command to return to the parent configuration mode.
gtpp attribute

Enables the specification of some of the optional fields in the CDRs that the GSN (GGSN or SGSN) generates and/or how the information is to be presented. Many keywords are also applicable to S-GW and P-GW CDRs.

Product
GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

default
Resets the default attribute values for this GTPP group configuration.

no
Disables the specified optional field so that the information will not be present in generated CDRs.

apn-ambr [include-for-all-bearers | include-for-default-bearer | include-for-non-gbr-bearers]
Default: Disabled
This keyword controls the inclusion of the optional field “apn-ambr” in the PGW-CDRs in the custom24 GTPP dictionary.

Important: This keyword option will be available only if a valid license is installed. For more information, contact your Cisco account representative.

The APN Aggregate Maximum Bit Rate (AMBR) is a subscription parameter stored per APN. It limits the aggregate bit rate that can be expected to be provided across all non-GBR bearers and across all PDN connections of the same APN. Each of these non-GBR bearers potentially utilize the entire APN AMBR, e.g. when the other non-GBR bearers do not carry any traffic. The APN AMBR is present as part of QoS information.

In 15.0 and later releases, this CLI command should be configured along with the following additional options to support APN-AMBR reporting in SGW-CDRs in all GTPP dictionaries.

•include-for-all-bearers: Includes the APN-AMBR information in SGW-CDRs for all bearers (GBR and NON-GBR)
•include-for-default-bearer: Includes APN-AMBR information in SGW-CDRs only for default bearer.
•include-for-non-gbr-bearers: Includes APN-AMBR information for non-gbr-bearers.

This feature is required to enable post-processing of CDRs to verify MVNO subscribers actual QoS against invoicing systems.

Important: This CLI command and the associated options are not available for products other than S-GW and P-GW. The option “non-gbr-bearers-only” is available in S-GW and P-GW but the other options are available in S-GW only.

In the P-GW implementation, if the CLI command “gtpp attribute apn-ambr” is configured, it will be treated as “gtpp attribute apn-ambr non-gbr-bearers-only”. In case of S-GW/P-GW combo if any of the options is configured, it will be considered that the attribute is available.

apn-ni
Default: Enabled
This keyword controls the inclusion of the optional field “APN” in the x-CDRs.
**apn-selection-mode**

Default: Enabled
This keyword controls the inclusion of the optional field “APN Selection Mode” in the x-CDRs.

**camel-info**

SGSN only
Enter this keyword to include CAMEL-specific fields in SGSN CDRs. Default: Disabled

**cell-plmn-id**

SGSN only
Enter this keyword to enable the system to include the Cell PLMN ID field in the M-CDR. Default: Disabled

**charging-characteristic-selection-mode**

Default: Enabled
This keyword controls the inclusion of the optional field “Charging Characteristic Selection Mode” in the x-CDRs.

**diagnostics**

Default: Disabled
Enables the system to include the Diagnostic field in the CDR that is created when PDP contexts are released. The field will include one of the following values:

- **26** - For GGSN: if the GGSN sends “delete PDP context request” for any other reason (e.g., the operator types “clear subscribers” on the GGSN). For SGSN: The SGSN includes this cause code in the S-CDR to indicate that a secondary PDP context activation request or a PDP context modification request has been rejected due to insufficient resources.

- **36** - For GGSN: this cause code is sent in the G-CDR to indicate the PDP context has been deactivated in the GGSN due to the SGSN having sent a “delete PDP context request” to the GGSN. For SGSN, this cause code is used to indicate a regular MS or network-initiated PDP context deactivation.

- **37** - when the network initiates a QoS modification, the SGSN sends in the S-CDR to indicate that the MS initiation deactivate request message has been rejected with QoS not accepted as the cause.

- **38** - if the GGSN sends “delete PDP context request” due to GTP-C/GTP-U echo timeout with SGSN. If the SGSN sends this cause code, it indicates PDP context has been deactivated due to path failure, specifically GTP-C/GTP-U echo timeout.

- **39** - SGSN only - this code indicates the network (GGSN) has requested a PDP context reactivation after a GGSN restart.

- **40** - if the GGSN sends “delete PDP context request” due to receiving a RADIUS Disconnect-Request message.

**duration-ms**

Specifies that the information contained in the mandatory Duration field be reported in milliseconds instead of seconds (as the standards require). Default: Disabled

**dynamic-flag**

Default: Enabled
This keyword controls the inclusion of the optional field “Dynamic Flag” in the x-CDRs.
**dynamic-flag-extension**

Default: Enabled
This keyword controls the inclusion of the optional field “Dynamic Address Flag Extension” in the x-CDRs. This field is seen in the CDR when the IPv4 address is dynamically assigned for a dual PDP context. This extension field is required in the 3GPP Release 10 compliant CDRs so that the Dual Stack Bearer support is available.

**furnish-charging-information**

Default: Disabled
This keyword controls the inclusion of the optional field “pSFurnishChargingInformation” in the eG-CDRs and PGW-CDRs.

**Important:** The Furnish Charging Information (FCI) feature is applicable to all GTPP dictionaries compliant to 3GPP Rel.7 and 3GPP Rel.8 except custom43 dictionary. This keyword option will be available only if a valid license is installed. For more information, contact your Cisco account representative.

PGW-CDR and eG-CDR will contain FCI only if it is enabled at command level, i.e. using the `gtpp attribute furnish-charging-information` command in GTPP Server Group Configuration mode. Whenever FCI changes, a new Free-Format-Data (FFD) value is either appended to existing FFD or overwritten on the existing FDD depending on Append-Free-Format-Data (AFFD) flag. CDR is not generated upon FCI change.

FCI is supported in main CDR as well as in LOSDV. Whenever a trigger (volume, time, RAT, etc.) happens current available FFD at command level is added to the main body of the CDR. The same FFD at command level is added to the main body of the next CDRs until it is not appended or overwritten by next Credit-Control-Answer message at command level.

In the case of custom43 dictionary, the FCI implementation will be as follows:

- Whenever FCI changes PGW-CDR will generate CDR i.e close old bucket and will have old FCI details in the generated CDR.
- Translation for the PS-Free-Format-Data in CDR will be conversion of hexadecimal values in ASCII format (for numbers 0 to 9) to decimal values as integers.
- PS-Append-Free-Format-Data always OVERWRITE.

**imei**

Default: Disabled
For SGSN: includes the IMEI value in the S-CDR.
For GGSN: includes the IMEISV value in the G-CDR.

**imsi-unauthenticated-flag**

Default: Enabled
This keyword controls the inclusion of the optional field “IMSI Unauthenticated Flag” in the x-CDRs. When the served IMSI is not authenticated, this field “IMSI Unauthenticated Flag” if configured, will be present in the P-GW CDR record for custom35 dictionary. This field is added per 3GPP TS 32.298 v10.7.

**local-record-sequence-number**

Default: Disabled
This keyword provides both the local record sequence number and the Node ID. In the x-CDRs, this field indicates the number of CDRs generated by the node and is unique within the session manager.
The Node ID field is included in the x-CDR for any of several reasons, such as when PDP contexts are released or if partial-CDR is generated based on configuration. The field will consist of a AAA Manager identifier automatically appended to the name of the SGSN or GGSN service.

The name of the SGSN or GGSN service may be truncated, because the maximum length of the Node ID field is 20 bytes. Since each AAA Manager generates CDRs independently, this allows the Local Record Sequence Number and Node ID fields to uniquely identify a CDR.

**Important:** If this keyword is enabled and the **gtpp centralized-lrsn-creation** option is enabled with the **gtpp single-source centralized-lrsn** command, then the Node ID format changes as follows: <1-byte-AAAproxy-restart-counter> <3-byte AAAproxy instance number> <node-id-suffix>. If **gtpp centralized-lrsn-creation** is not enabled, the node-id format for CDRs generated by Sessmgr is as follows: <1-byte Sessmgr restart-value> <3-byte Sessmgr instance number> <node-id-suffix>. If **gtpp centralized-lrsn-creation** is not enabled, the node-id format for CDRs generated by ACSMG is as follows: <1-byte ACSmgr restart-value> <3-byte ACSmgr instance number> <Active charging service-name>.

**losdv**
Default: Enabled
This keyword controls the inclusion of the optional field “List of Service Data” in the x-CDRs.

**ms-timezone**
Default: Enabled
This keyword controls the inclusion of the optional field “MS-Timezone” in the x-CDRs.

**msisdn**
Default: Enabled
This keyword controls the inclusion of the optional field “MSISDN” in the x-CDRs.

**node-id**
Default: Enabled
This keyword controls the inclusion of the optional field “Node ID” in the x-CDRs.

**node-id-suffix STRING**
Default: Disabled
Specifies the configured Node-ID-Suffix to use in the NodeID field of GTPP CDRs as an alphanumeric string of 1 through 16 characters. Each Session Manager task generates a unique NodeID string per GTPP context.

**Important:** The NodeID field is a printable string of the *ndddSTRING* format: *n*: The first digit is the Sessmgr restart counter having a value between 0 and 7. *dd*: The number of sessmgr instances. Uses the specified NodeID-suffix in all CDRs. The “Node-ID” field consists of sessMgr Recovery counter (1 digit) n + AAA Manager identifier (3 digits) ddd + the configured Node-Id-suffix (1 to 16 characters) STRING. If the centralized LRSN feature is enabled, the “Node-ID” field will consist of only the specified NodeID-suffix (NodeID-prefix is not included). If this option is not configured, then GTPP group name will be used instead (For default GTPP groups, context-name will be used).

**Important:** If this node-id-suffix is not configured, the GGSN uses the GTPP context name as the Node-id-suffix (truncated to 16 characters) and the SGSN uses the GTPP group named as the node-id-suffix.
pdsn-connection-id
Default: Enabled
This keyword controls the inclusion of the optional field “PDN Connection ID” in the x-CDRs.

pdp-address
Default: Enabled
This keyword controls the inclusion of the optional field “PDP Address” in the x-CDRs.

pdp-type
Default: Enabled
This keyword controls the inclusion of the optional field “PDP Type” in the x-CDRs.

pgw-plmn-id
Default: Enabled
This keyword controls the inclusion of the optional field “PGW PLMN-ID” in the x-CDRs.

plmn-id [ unknown-use ]
Default: Enabled
For SGSN, reports the SGSN PLMN Identifier value (the RAI) in the S-CDR provided if the dictionary supports it.
For GGSN, reports the SGSN PLMN Identifier value (the RAI) in the G-CDR if it was originally provided by the SGSN in the GTP create PDP context request. It is omitted if the SGSN does not supply one.
Normally when SGSN PLMN-id information is not available, the attribute sgsnPLMNIdentifier is not included in the CDR. This keyword enables the inclusion of the sgsnPLMNIdentifier with a specific value when the SGSN PLMN-id is not available.
unknown-use hex_num: is aa hexadecimal number from 0x0 through 0xFFFFFF that identifies a foreign SGSN that has not provided a PLMN-id. For GGSN only.

rat
Default: Enabled
For SGSN: includes the RAT (identifies the radio access technology type) value in the S-CDR.
For GGSN: includes the RAT (identifies the radio access technology type) value in the G-CDR.

recordextension
Default: Disabled
This keyword controls the inclusion of the optional field “RecordExtension” in the x-CDRs.

record-extensions rat
Default: Disabled
Enables network operators and/or manufacturers to add their own recommended extensions to the CDRs according to the standard record definitions from 3GPP TS 32.298 Release 7 or higher.

served-mnai
Default: Disabled
This keyword controls the inclusion of the optional field “Served MNAI” in the x-CDRs.
served-pdp-pdn-address-extension
Default: Disabled
In support of IPv4v6 dual-stack PDP address types, this keyword causes the service to include IPv4v6 address information in the CDR. The IPv4 address goes in the Served PDP PDN Address Extension field and the IPv6 address goes in the Served PDP Address or Served PDP PDN Address field.

**Important:** This attribute will not be displayed if the GTPP dictionary is set to custom34.

served-pdp-pdn-address-prefix-length
Default: Enabled
In support of IPv6 prefix delegation, this keyword causes the service to include this field “Served PDP PDN Address” in the x-CDRs.
If this field is configured, the servedPDPPDNAddress field will support reporting the IPv6 prefix length as outlined in 3GPP 32.298. The prefix length will only be reported if:
- it is configured
- it is not the default length of 64
- it is an IPv6 or IPv4v6 call

sgsn-change
Default: Enabled
This keyword is specific to SGSN and is license restricted.
This keyword controls the inclusion of the S-CDR attribute “SGSN Change” in the S-CDRs. It is enabled by default and the attribute “SGSN Change” is included in the S-CDRs by default.

sms { destination-number | recording-entity | service-centre }
This keyword is specific to the SGSN.
Entering this keyword causes the inclusion of an SMS-related field in the SMS-MO-CDR or SMS-MT-CDR.
- **destination-number:** Includes the “destinationNumber” field in the SMS-MO-CDR or SMS-MT-CDR.
- **recording-entity:** Includes the “recordingEntity” field in the SMS-MO-CDR or SMS-MT-CDR.
- **service-centre:** Includes the “serviceCentre” field in the SMS-MO-CDR or SMS-MT-CDR.

start-time
Default: Enabled
This keyword controls the inclusion of the optional field “Start-Time” in the x-CDRs.

stop-time
Default: Enabled
This keyword controls the inclusion of the optional field “Stop-Time” in the x-CDRs.

uli
Default: Enabled
This keyword controls the inclusion of the optional field “User Location Information” in the x-CDRs.

user-csg-information
Default: Disabled
This keyword controls the inclusion of the optional field “User CSG Information” in the x-CDRs.

**Important:** Currently, UCI values are only supported for SGW-CDRs. This attribute will not be displayed if the GTPP dictionary is set to custom11, custom34, or custom35.

```
+ Indicates that this command can be entered multiple times to configure multiple attributes.
```

**Usage**

This command dictates some of the optional information fields that should be reported in CDRs generated by the GGSN. In addition, it controls how the information for some of the mandatory fields are reported. Fields described as optional by the standards but not listed above will always be present in the CDRs, except for Record Extensions (which will never be present).

**Example**

The following command disables the inclusion of the field “SGSN Change” in the S-CDR:

```
no gtpp attribute sgsn-change
```

**Example**

The following command dictates that the time provided in the Duration field of the CDR is reported in milliseconds:

```
gtpp attribute duration-ms
```
gtpp charging-agent

Configures the IP address and port of the system interface within the current context used to communicate with the CGF or the GSS.

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

```
configure > context context_name > gtpp group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
gtpp charging-agent address ip_address [ port port ]
```

```
no gtpp charging-agent
```

- **no**
  Removes a previously configured charging agent address.

- **address ip_address**
  Specifies the IP address of the interface configured within the current context that is used to transmit G-CDR records to the CGF or the GSS.
  `ip_address` is expressed in IPv4 dotted-decimal notation.

- **port port**
  Specifies the Charging Agent UDP port as an integer from 1 through 65535. If the port is not defined, the default port number 49999 will be used.

**Important:** Configuring GTPP charging-agent on port 3386 may interfere with ggsn-service configured with the same ip address.
Usage

This command can be used to establish a UDP interface to connect to the GSS or this command can establish a Ga interface to connect to the CFG. These interfaces must exist in the same context in which GTPP functionality is configured (refer to the `gtpp` commands in this chapter).

This command instructs the system as to what interface to use. The IP address supplied is also the address by which the GGSN/SGSN is known to the CGF or the GSS. Therefore, the IP address used for the Ga or UDP interface could be identical to one bound to a GGSN/SGSN service (a Gn interface).

If no GGSN/SGSN services are configured in the same context as the Ga/UDP interface, the address configured by this command is used to receive unsolicited GTPP packets.

Example

The following command configures the system to use the interface with an IP address of 192.168.13.10 as the accounting interface with port 20000 to the CGF:

```bash
    gtpp charging-agent address 192.168.13.10
    gtpp charging-agent address 192.168.13.10 port 20000
```
**gtpp data-request sequence-numbers**

Configures the range of sequence numbers to be used in the GTPP data record transfer record (DRT). Use this command to set the start value for the sequence number.

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

```
configure > context context_name > gtpp group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
gtpp data-request sequence-numbers start { 0 | 1 }
```

**default gtpp data-request sequence-numbers start**

<table>
<thead>
<tr>
<th>default</th>
<th>Default is 0 (zero).</th>
</tr>
</thead>
</table>

| start { 0 | 1 } |
|----------------|
| Specifies the value of the start sequence number for the GTPP Data Record Transfer Request. Default: 0 |
| - 0: Designates the start sequence number as 0. |
| - 1: Designates the start sequence number as 1. |

**Usage**

When the GGSN/P-GW/SGSN is configured to send GTPP echo request packets, the SGSN always uses 0 as the sequence number in those packets. Re-using 0 as a sequence number in the DRT packets is allowed by the 3GPP standards; however, this CLI command ensures the possibility of inter-operating with CGFs that cannot properly handle the re-use of sequence number 0 in the echo request packets.

**Example**

The following command sets the sequence to start at 1.

```
gtpp data-request sequence-numbers start 1
```
**gtpp deadtime**

Configures the amount of time the GGSN/SGSN waits before attempting to communicate with a CGF that was previously marked as unreachable (non-responsive).

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
- `configure > context context_name > gtpp group group_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
gtpp deadtime time
```

```
default gtpp deadtime
```

**default**
- `default`
  - Resets the deadtime to the default of 120 seconds.

**time**
- `time`
  - Specifies the amount of time (in seconds) that must elapse before the system attempts to communicate with a CGF that was previously unreachable.
  - `time` is an integer from 1 to 65535. Default: 120

**Usage**

If the system is unable to communicate with a configured CGF, after a pre-configured number of failures the system marks the CGF as being down.
This command specifies the amount of time that the system waits prior to attempting to communicate with the downed CGF.
Refer to the `gtpp detect-dead-server` and `gtpp max-retries` commands for additional information on the process the system uses to mark a CGF as down.

**Example**

The following command configures the system to wait 60 seconds before attempting to re-communicate with a CGF that was marked as down:

```
gtpp deadtime 60
```
gtpp dead-server suppress-cdrs

Configures the action the GGSN or the SGSN will take on CDRs generated during a communication failure between the GGSN or the SGSN and the GTPP servers.

Product
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
- `configure > context context_name > gtpp group group_name`

Entering the above command sequence results in the following prompt:

```
/context_name/host_name(config-gtpp-group)#
```

Syntax

```
[ no | default ] gtpp dead-server suppress-cdrs
```

- **no**
  - Removes the suppression instruction from the configuration and sets the CDR suppression mode as disabled.

- **default**
  - Resets to the default mode: disable suppression of CDRs when GTPP server detected as “dead” or unreachable.

Usage

**For the GGSN/P-GW:** This command works in conjunction with the `gtpp detect-dead-server` to set an action when a communication failure is detected between the GGSN and a configured GTPP server. It disables the archiving of CDRs on the system when the GTPP server is unreachable or dead.

**For the GGSN, P-GW, and SGSN:** During a communication or server failure, the GGSN, P-GW, or SGSN typically retains the GTPP requests until the system buffer runs out of resources. This command enables suppression of the CDRs, so with this command the GGSN, P-GW, or the SGSN will start purging all CDRs associated with this GTPP group as soon as the GGSN/P-GW/SGSN detects that the GTPP server is down or that a communication failure has occurred. The CDRs generated, for the period while the server is down/unreachable, will also be purged.

Example

The following command configures the system to start purging CDRs when a communication failure with a server is detected:

```
gtpp dead-server suppress-cdrs
```
**gtpp detect-dead-server**

Configures the number of consecutive communication failures that could occur before the system marks a CGF as “dead” (unreachable).

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

```
configure > context context_name > gtpp group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
gtpp detect-dead-server consecutive-failures max_number
```

```
default gtpp detect-dead-server consecutive-failures
```

```
default
```

Resets the system to the default number of consecutive failures.

```
consecutive-failures max_number
```

Default: 5

Specifies the number of failures that could occur before marking a CGF as down as an integer from 0 through 1000. If 0 (zero) is the value entered, the system will mark the CGF as dead after a single instance of max-retries has been attempted with no success, regardless of configured deadtime.

**Usage**

This command works in conjunction with the **gtpp max-retries** parameter to set a limit to the number of communication failures that can occur with a configured CGF.

The **gtpp max-retries** parameter limits the number of attempts to communicate with a CGF. Once that limit is reached, the system treats it as a single failure. The **gtpp detect-dead-server** parameter limits the number of consecutive failures that can occur before the system marks the CGF as down and communicate with the CGF of next highest priority.

If all of the configured CGFs are down, the system ignores the detect-dead-server configuration and attempt to communicate with highest priority CGF again.

If the system receives a GTPP Node Alive Request, Echo Request, or Echo Response message from a CGF that was previously marked as down, the system immediately treats it as being active.
Refer to the `gtp max-retries` command for additional information.

**Example**

The following command configures the system to allow 8 consecutive communication failures with a CGF before it marks it as down:

```
gtp detect-dead-server consecutive-failures 8
```
**gtpp dictionary**

Designates specific dictionary used by GTPP for specific context.

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

`configure > context context_name > gtpp group group_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
gtpp dictionary { custom1 | custom10 | custom11 | custom12 | custom13 | custom14 |
custom15 | custom16 | custom17 | custom18 | custom19 | custom20 | custom21 | custom22 | custom23 | custom24 | custom25 | custom26 | custom27 | custom28 | custom29 | custom30 | custom31 | custom32 | custom33 | custom34 | custom35 | custom36 | custom37 | custom38 | custom39 | custom4 | custom40 | custom41 | custom42 | custom43 |
custom44 | custom45 | custom46 | custom47 | custom48 | custom49 | custom5 | custom50 | custom51 | custom52 | custom53 | custom54 | custom55 | custom56 | custom57 | custom58 | custom59 | custom6 | custom60 | custom7 | custom8 | custom9 | standard }
```

default gtpp dictionary

```
default
```

Configures the default dictionary.

```
custom1
```

Custom-defined dictionary. It conforms to TS 32.015 v 3.6.0 for R99. It supports the encoding of IP addresses in text format for G-CDRs.

```
custom2
```

Custom-defined dictionary.

```
custom3
```

Custom-defined dictionary. It conforms to TS 32.015 v 3.6.0 for R99 but it does support the encoding of IP addresses in binary format for CDRs.
Custom-defined dictionary. It conforms to TS 32.015 v 3.6.0 for R99 except that:
- the Data Record Format Version information element contains 0x1307 instead of 0x1308
- “QoSRequested” is not present in the LoTV containers
- “QoSnegotiated” is added only for the first container and the container after a QoS change

Custom-defined dictionaries.

Custom-defined dictionaries for GGSN only.

Custom-defined dictionary for customization of G-CDR records for GGSN only. This is compliant to 3GPP TS 32.298 (R6 v 6.5.0) for proprietary fields and encoding.

Custom-defined dictionary for customization of S-CDR records for SGSN only. This is compliant to 3GPP TS 32.298 (R6 v 6.6.0) for proprietary fields and encoding.

Custom-defined dictionaries for GGSN only.

Custom-defined dictionaries based on 3GPP 32.298 v6.4.1 for SGSN only.
- custom31: Custom-defined dictionary for S-CDR encoding. Includes a field appended for PLMN-ID.
- custom33: Custom-defined dictionary for S-CDR encoding. Includes a field appended for PLMN-ID and does not support diagnostic or SGSN-change fields.

Default: Enabled
A dictionary conforming to TS 32.215 v 4.6.0 for R4 (and also R5 - extended QoS format).

Usage

Use this command to designate specific dictionary used by GTPP for specific context.

Important: Note that the following warning message will be displayed whenever an existing GTPP dictionary is being changed or a new GTPP dictionary is configured irrespective of whether or not the calls are active on the system.
Warning: It is not recommended to change the dictionary when the system has active calls.
Are you sure? [Yes|No]: n

Important: This change will require user's input on the CLI console for GTPP dictionary configuration / change.
The following command configures the system to use custom3 dictionary to encode IP address in Binary format in G-CDRs:

```
gtpp dictionary custom3
```
gtpp duplicate-hold-time

Configures the number of minutes to hold onto CDRs that are possibly duplicates while waiting for the primary CGF to come back up.

Product
GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

gtpp duplicate-hold-time minutes minutes

default gtpp duplicate-hold-time

default

Resets the configuration to the default value of 60 minutes for the duplicate hold time.

minutes

When the primary CGF is down, the number of minutes to hold onto CDRs that may be duplicates. minutes must be an integer from 1 to 10080. Default is 60.

Usage

Use this command to configure how long to hold onto CDRs, that are possibly duplicates, while waiting for the primary CGF to come back up. If the GGSN determines that the primary CGF is down, CDRs that were sent to the primary CGF, but not acknowledged, are sent by the GGSN to the secondary CGF as “possibly duplicates”. When the primary CGF comes back up, the GGSN uses GTPP to determine whether the possibly duplicate CDRs were received by the primary CGF. Then the secondary CGF is told whether to release or cancel those CDRs. This command configures how long the system should wait for the primary CGF to come back up. As soon as the configured time expires, the secondary CGF is told to release all of the possibly duplicate CDRs.

Example

Use the following command to set the amount of time to hold onto CDRs to 2 hours (120 minutes):

    gtpp duplicate-hold-time minutes 120
gtpp echo-interval

Configures the frequency at which the system sends GTPP echo packets to configured CGFs.

Product
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
configure > context context_name > gtpp group group_name

Syntax

```
gtpp echo-interval time

default | no } gtpp echo-interval

default
Resets the configuration to the default echo-interval of 60 seconds.

no
Disables the use of the echo protocol except for the scenarios described in the Usage section for this command.

time
Specifies the number of seconds for sending GTPP echo packets as an integer from 60 to 3600. Default: 60.
```

Usage
The GTPP echo protocol is used by the system to ensure that it can communicate with configured CGFs. The system initiates this protocol for each of the following scenarios:

- Upon system boot
- Upon the configuration of a new CGF server on the system using the `gtpp server` command as described in this chapter
- Upon the execution of the `gtpp test accounting` command as described in the Exec Mode Commands chapter of this reference
Upon the execution of the `gtpp sequence-numbers private-extensions` command as described in this chapter,

The echo-interval command is used in conjunction with the `gtpp max-retries` and `gtpp timeout` commands as described in this chapter.

In addition to receiving an echo response for this echo protocol, if we receive a GTPP Node Alive Request message or a GTPP Echo Request message from a presumed dead CGF server, we will immediately assume the server is active again.

The alive/dead status of the CGFs is used by the AAA Managers to affect the sending of CDRs to the CGFs. If all CGFs are dead, the AAA Managers will still send CDRs, (refer to the `gtpp deadtime` command), albeit at a slower rate than if a CGF were alive. Also, AAA Managers independently determine if CGFs are alive/dead.

**Example**

The following command configures an echo interval of 120 seconds:

```
gtpp echo-interval 120
```
**gtpp egcdr**

Configures the eG-CDR and P-CDR (P-GW CDR) parameters and triggers.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

```
configure > context context_name > gtpp group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
gtpp egcdr { closure-reason admin-disconnect | management-intervention | normal-release } | final-record { [ include-content-ids | all | only-with-traffic ] } | closing-cause { same-in-all-partials | unique } ] | losdv-max-containers max_losdv_containers | lotdv-max-containers max_lotdv_containers | rulebase-max-length rulebase_name_max_length | service-data-flow threshold { interval interval | volume { downlink bytes | uplink bytes } | total bytes | uplink bytes | downlink bytes } | service-idle-timeout { 0 | service_idle_timeout } }
```

```
default gtpp egcdr { closure-reason admin-disconnect | final-record include-content-ids | only-with-traffic closing-cause same-in-all-partials | losdv-max-containers | lotdv-max-containers | service-idle-timeout 0 }
```

```
no gtpp egcdr { rulebase-max-length | service-data-flow threshold { interval | volume { downlink | uplink } | total | uplink | downlink } } }
```

---

**Important:** This behavioral change is limited to PGW-CDR Release 8 dictionaries only.

**closing-reason:** Configures the record closing reason for PGW-CDR.

**management-intervention:** Specifies to send Management-Intervention as causeForRecordClosing in PGW-CDRs. By default, Management-Intervention will be sent as the record closure reason for PGW-CDRs.
• **normal-release**: Specifies to send Normal Release as causeForRecordClosing in PGW-CDRs.

```plaintext
final-record [ [ include-content-ids { all | only-with-traffic } ] [ closing-cause { same-in-allpartials | unique } ] ]
```

Enables configuration of the final eG-CDR/P-CDR.

• **include-content-ids**: Controls which content-ids are being included in the final eG-CDR/P-CDR.
  - **all**: Specifies that all content-ids be included in the final eG-CDR/P-CDRs.
  - **only-with-traffic**: Specifies that only content-ids with traffic be included in the final eG-CDR/P-CDRs.

• **closing-cause**: Configures closing cause for the final eG-CDR/P-CDR.
  - **same-in-allpartials**: Specifies that the same closing cause is to be included for multiple final eG-CDR/P-CDRs.
  - **unique**: Specifies that the closing cause for final eG-CDR/P-CDRs is to be unique.

```plaintext
losdv-max-containers max_losdv_containers
```

Specifies the maximum number of List of Service Data Volume (LoSDV) containers in one eG-CDR/P-CDR.

*max_losdv_containers* must be an integer from 1 through 255.
Default: 10

```plaintext
lotdv-max-containers max_lotdv_containers
```

Specifies the maximum number of List of Traffic Data Volume (LoTDV) containers in one eG-CDR/P-CDR.

*max_lotdv_containers* must be an integer from 1 through 8.
Default: 8

```plaintext
rulebase-max-length rulebase_name_max_length
```

Specifies the maximum character length of charging rulebase name in LOSDVs of eG-CDR/P-GW-CDR.

*rulebase_name_max_length* must be an integer from 0 through 63. Zero (0) means the rulebase name is added as-is.
Default: None. That is, full (un-truncated) charging rulebase name will go in LOSDVs of eG-CDR/P-GW-CDR.

```plaintext
service-data-flow threshold { interval interval | volume { downlink bytes [ uplink bytes ] | total bytes | uplink bytes [ downlink bytes ] } }
```

Configures the thresholds for closing a service data flow container within an eG-CDR/P-CDR.

• **interval interval**: Specifies the time interval (in seconds) to close the eG-CDR/P-CDR if the minimum time duration thresholds for service data flow containers satisfied in flow-based charging. The interval is an integer from 60 through 40000000. Default: Disabled

• **volume { downlink bytes [ uplink bytes ] | total bytes | uplink bytes [ downlink bytes ] }**: Specifies the volume octet counts for the generation of the interim eG-CDR/P-CDRs to the service data flow container in FBC.
  - **downlink bytes**: Specifies the limit for the number of downlink octets after which the eG-CDR/P-CDR is closed.
  - **total bytes**: Specifies the limit for the total number of octets (uplink+downlink) after which the eG-CDR/P-CDR is closed.
  - **uplink bytes**: Specifies the limit for the number of uplink octets after which the eG-CDR/P-CDR is closed.
bytes must be an integer from 10000 through 400000000.

A service data flow container has statistics for an individual content ID. When the threshold is reached, the service data flow container is closed.

In 12.3 and earlier releases, when the CLI command `gtpp egcdr service-data-flow threshold interval` was configured to ‘n’ seconds, the difference between “timeOfFirstUsage” and “timeOfReport” of LOSDV was always ‘n’ seconds for the LOSDVs closed due to “service-data-flow” threshold. Here, changeTime of LOSDV was reported incorrectly. It was always timeOfFirstUsage + ‘n’. This does not hold true when the traffic for a particular content ID was not continuous.

In StarOS release 14.0 and later, when the command `gtpp egcdr service-data-flow threshold interval` is configured to ‘n’ seconds, the difference between “timeOfFirstUsage” and “timeOfReport” of LOSDV can be any value between 1 and ‘n’ seconds depending on the continuity of traffic. If the traffic is not continuous, the difference is less than ‘n’ seconds. And if the traffic is continuous the difference will be ‘n’ seconds. When this CLI command is configured in the GTPP Server Group Configuration mode, each LOSDV will be closed at configured regular interval after the arrival of first packet.

**service-idle-timeout { 0 | service_idle_timeout}**

 Specifies a time period during which if no data is reported for a service flow, the service container is closed and added to eG-CDR/P-CDR (as part of LOSDV container list) with service condition change as ServiceIdleOut.

0: Specifies there is no service-idle-timeout trigger.

*service_idle_timeout* is an integer from 10 through 86,400. Default: 0

**Usage**

Use this command to configure individual triggers for eG-CDR/P-CDR generation.

**Example**

Use the following command to set the maximum number of LoSDV containers to 7:

```
gtpp egcdr losdv-max-containers 7
```
**gtpp error-response**

Configures the response when the system receives an error response after transmitting a DRT (data record transfer) request.

**Product**

GGSN

P-GW

SAEGW

SGSN

S-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

```
configure > context context_name > gtpp group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
gtpp error-response { discard-cdr | retry-request }
```

**default gtpp error-response**

- **default**
  
  Resets the system’s configuration to the default value for error-response. Default is retry-request.

- **discard-cdr**
  
  Purges the request upon receipt of an error response and not to retry.

- **retry-request**
  
  Retries sending a DRT after receiving an error response. This is the default behavior.

**Usage**

This command configures the system’s response to receiving an error message after sending a DRT request.

**Example**

```
gtpp error-response discard-cdr
```
**gtpp max-cdrs**

Configures the maximum number of charging data records (CDRs) to be included in a packet.

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**

```
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
configure > context context_name > gtpp group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
gtpp max-cdrs max_cdrs [ wait-time wait_time ]
default gtpp max-cdrs
```

- **default**
  Sets the default configuration.

- **max_cdrs**
  Specifies the maximum number of CDRs to insert in a single packet as an integer from 1 through 255.
  Default: 1

- **wait-time wait_time**
  Specifies the number of seconds the GSN waits to send the packet while accumulating CDRs as defined by `max-cdrs`. If the `wait-time` interval expires before `max-cdrs` is reached, this keyword over-rides and the packet is sent. Default: Disabled
  `wait_time` is an integer from 1 through 300.

**Important:** The `wait-time` interval can only be enabled if the value for `max-cdrs` is greater than 1.

**Usage**

The system places CDRs into a packet until either `max-cdrs` is met, `wait-time` times out, or the maximum PDU size, configured by the `gtpp max-pdu-size` command, is met.

The `gtpp max-pdu-size` and the `wait-time` parameters take priority over `max-cdrs`. 
**Important:** This command’s configuration is ignored if CDRs are stored on an SMC hard disk.

**Example**

The following command configures the system to place a maximum of 10 CDRs in a single GTPP packet with a wait-time of 30 seconds:

```
gtp max-cdrs 10 wait-time 30
```
gtpp max-pdu-size

Configures the maximum payload size of a single GTPP packet that could be sent by the system.

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
- configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

- `gtpp max-pdu-size pdu_size`
- `default gtpp max-pdu-size`

**Usage**

The GTPP packet contains headers (layer 2, IP, UDP, and GTPP) followed by the CDR. Each CDR contains one or more volume containers. If a packet containing one CDR exceeds the configured maximum payload size, the system creates and send the packet containing the one CDR regardless. The larger the packet data unit (PDU) size allowed, the more volume containers that can be fit into the CDR. The system performs standard IP fragmentation for packets that exceed the system’s maximum transmission unit (MTU).

**Important:** The maximum size of an IPv4 PDU (including the IPv4 and subsequent headers) is 65,535. However, a slightly smaller limit is imposed by this command because the system’s max-pdu-size doesn't include the IPv4 and UDP headers, and because the system may need to encapsulate GTPP packets in a different/larger IP packet (for sending to a backup device).
Example

The following command configures a maximum PDU size of 2048 octets:

```
gtp max-pdu-size 2048
```
gtpp max-retries

Configures the maximum number of times the system attempts to communicate with an unresponsive CGF.

Product

SAEGW
SGSN
S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

gtpp max-retries max_attempts

default gtpp max-retries

Usage

This command works in conjunction with the gtpp detect-dead-server and gtpp timeout parameters to set a limit to the number of communication failures that can occur with a configured CGF. When the value specified by this parameter is met, a failure is logged. The gtpp detect-dead-server parameter specifies the number of consecutive failures that could occur before the server is marked as down. In addition, the gtpp timeout command controls the amount of time between re-tries. If the value for the max-retries is met, the system begins storing CDRs in Random Access Memory (RAM). The system allocates memory as a buffer, enough to store one million CDRs for a fully loaded chassis (a maximum of one outstanding CDR per PDP context). Archived CDRs are re-transmitted to the CGF until they are acknowledged or the system’s memory buffer is exceeded.

Example

The following command configures the maximum number of re-tries to be 8.
gtpp max-retries 8
gtpp mbms bucket

Configures the traffic data volume (bucket) limit of charging buckets due to QoS changes of tariff time that can occur before a G-MBMS-CDR should be closed.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

gtpp mbms buckets number
[ no ] gtpp mbms buckets

no

Disables the configured traffic data volume bucket limits trigger for G-MBMS-CDR generation for MBMS user service data.

number

Specifies the number of statistics container changes due to QoS changes or tariff time that can occur before a G-MBMS-CDR should be closed as an integer from 1 through 4. Default: 4

Usage

Use this command to configure the traffic data volume (bucket) based G-MBMS-CDR generation triggers for MBMS user data service.

Example

The following command configures the bucket-based trigger to generate G-MBMS-CDRs after changes in 2 container:

gtpp mbms buckets 2
**gtpp mbms interval**

Configures the interval duration for interval-based triggers for GTPP MBMS Charging Data Record (G-MBMS-CDR) generation.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

```
configure > context context_name > gtpp group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#!
```

**Syntax**

```
gtpp mbms interval duration_sec

no gtpp mbms interval
```

- **no**
  
  Disables the interval-based trigger for G-MBMS-CDR generation for MBMS user service data.

- **duration_sec**
  
  Specifies the normal time duration (in seconds) that must elapse before closing an accounting record provided that any or all of the following conditions occur:
  
  - Downlink traffic volume is reached within the time interval
  - Tariff time based trigger occurred within the time interval
  - Data volume (up and downlink) bucket trigger occurred within the time interval

  **duration_sec** is an integer from 60 through 40,000,000. Default: Disabled

**Usage**

Use this command to configure the G-MBMS-CDR generation triggers for MBMS user data service.

**Example**

The following command configures the interval-based trigger to generate G-MBMS-CDRs in every 60 seconds:

```
gtpp mbms interval 60
```
gtpp mbms tariff

Configures the tariff slots for tariff-based triggers for GTPP MBMS Charging Data Record (G-MBMS-CDR) generation.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:
[context_name]host_name(config-gtpp-group)#

Syntax

gtpp mbms tariff time1 mins hours [ time2 mins hours [ time3 mins hours [ time4 mins hours ] ] ]

no gtpp mbms tariff

Specifies time-of-day time values to close the current statistics container (but not necessarily the accounting record). Default: Disabled

**Important:** The system assumes that the billing system uses the day/date to determine if the statistics container represents an actual tariff period.

For each of the different tariff times, the following parameters must be configured:

- **mins:** Minute of the hour, an integer from 0 through 59.
- **hours:** Hour of the day, an integer from 0 through 23.

Usage
Use this command to configure the tariff-time-based triggers for G-MBMS-CDR generation in MBMS user data service.

Example
The following command configures the tariff-time-based trigger to generate G-MBMS-CDRs every day at 11 hours and 30 min:

gtpp mbms tariff time1 30 11
gtpp mbms volume

Configures the download traffic data volume based trigger for GTPP MBMS Charging Data Record (G-MBMS-CDR) generation.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

gtpp mbms volume download_bytes

no gtpp mbms volume

no

Disables the configured download traffic data volume based trigger for G-MBMS-CDR generation for MBMS user service data.

volume download_bytes

Specifies the threshold of downlink data volumes that (in bytes) must be met before a G-MBMS-CDR should be closed as an integer from 100000 through 400000000. Default: Disabled

Usage

Use this command to configure the traffic data volume (download) based G-MBMS-CDR generation triggers for MBMS user data service.

Example

The following command configures the traffic data volume (download) limit to trigger to generate G-MBMS-CDRs after reaching 150,000 octets:

    gtpp mbms volume download_bytes
gtpp redirection-allowed

Configures the system to allow/disallow the redirection of CDRs when the primary CGF is unavailable.

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

```
configure > context context_name > gtpp group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
[ default | no ] gtpp redirection-allowed
```

- **default**
  
  Resets the system to allow redirection of CDRs.

- **no**
  
  Removes the redirection definition from the configuration.

**Usage**

This command allows operators to better handle erratic network links, without having to remove the configuration of the backup server(s) via the **no gtpp server** command. This functionality is enabled by default.

If the **no gtpp redirection-allowed** command is executed, the system only sends CDRs to the primary CGF. If that CGF goes down, the system will buffer the CDRs in memory until the CGF comes back or until the system runs out of buffer memory. In addition, if the primary CGF announces its intent to go down (with a GTPP Redirection Request message), the system responds to that request with an error response.

**Example**

The following command configures the system to allow the redirection of CDRs when the primary CGF is unavailable:

```
default gtpp redirection-allowed
```
gtpp redirection-disallowed

This command has been obsoleted and is replaced by the gtpp redirection-allowed command.
gtpp server

Configures the charging gateway function (CGF) accounting server(s) with in GTPP server group that the system is to communicate with.

**Product**

GGSN
P-GW
SAEGW
SGSN
S-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
gtpp server ip_address [ max msgs ] [ priority priority ] [ udp-port port ] [ node-alive { enable | disable } ] [ -noconfirm ]
```

```
no gtpp server ip_address [ udp-port port ]
```

**no**

Deletes a previously configured CGF.

**ip_address**

Specifies the IP address of the CGF in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

**max msgs**

Specifies the maximum number of outstanding or unacknowledged GTPP packets (from any one AAA Manager task) allowed for this CGF before the system begins buffering the packets.

msgs can be configured to an integer from 1 to 256. Default: 256

**priority priority**

Default: 1000

Specifies the relative priority of this CGF as an integer from 1 through 1000. When multiple CGFs are configured, the priority is used to determine which CGF server to send accounting data to. When configuring two or more servers with the same priority you will be asked to confirm that you want to do this.

If you use the -noconfirm option, you are not asked for confirmation and multiple servers could be assigned the same priority.
GTPP Server Group Configuration Mode Commands

GTPP Server Group Configuration Mode Commands

udp-port <port>

Specifies the UDP port over which the GGSN communicates with the CGF, as an integer from 1 through 65535. Default: 3386

node-alive { enable | disable }

Enable or disables GGSN sending Node Alive Request to a GTPP Server (such as CGF). This configuration can be done per GTPP Server. Default: Disable.

-noconfirm

Executes this command without any additional prompt and confirmation from the user.

Usage

Use this command to configure the CGF(s) that the system sends CDR accounting data to.

Multiple CGFs can be configured using multiple instances of this command subject to the following limits:

- Up to 4 CGFs can be configured in one GTPP server group
- Total of 32 CGFs can be configured per context.

Each configured CGF can be assigned a priority. The priority is used to determine which server to use for any given subscriber based on the routing algorithm that has been implemented. A CGF with a priority of “1” has the highest priority.

Important: The configuration of multiple CGFs with the same IP address but different port numbers is not supported.

Each CGF can also be configured with the maximum allowable number of unacknowledged GTPP packets. Since multiple AAA Manager tasks could be communicating with the same CGF, the maximum is based on any one AAA Manager instance. If the maximum is reached, the system buffers the packets Random Access Memory (RAM). The system allocates memory as a buffer, enough to store one million CDRs for a fully loaded chassis (a maximum of one outstanding CDR per PDP context).

Example

The following command configures a CGF with an IP address of 192.168.2.2 and a priority of 5.

gtpp server 192.168.2.2 priority 5

The following command deletes a previously configured CGF with an IP address of 100.10.35.7:

no gtpp server 100.10.35.7
gtpp source-port-validation

Configures whether the system validates the UDP source port in received GTPP messages.

Product

  GGSN
  P-GW
  SAEGW
  SGSN
  S-GW

Privilege

  Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

[ default | no ] gtpp source-port-validation

  default
  Restores this parameter to its default setting of enabled.

  no
  Validates the IP source address but not the UDP source port.

Usage

This command configures whether the system validates the UDP source port in received GTPP messages.

Example

The following command disables UDP port validation:

  no gtpp source-port-validation
gtpp storage-server

Configures information for the GTPP back-up storage server.

Product
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

[ no ] gtpp storage-server  ip_address port port_num

no
Removes a previously configured back-up storage server.

ip_address
The IP address of the back-up storage server expressed in IPv4 dotted-decimal notation.

port port_num
Specifies the UDP port number over which the GGSN communicates with the back-up storage server. Default: 3386

Usage
This command identifies the connection to the GSS. One backup storage server can be configured per GTPP group.

Example
The following command configures a GSS with an IP address of 192.168.1.2:

    gtpp storage-server 192.168.1.2
gtpp storage-server local file

Configures the parameters for GTPP files stored locally on the GTPP storage server.

Product

SAEGW
SGSN
S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

```

default gtpp storage-server local file { compression | format | name { format | prefix } | purge-processed-files | rotation { cdr-count | time-interval | volume } start-file-seq-num }

no gtpp storage-server local file { purge-processed-files | push | rotation { cdr-count | time-interval } }
```

```
no

Removes a previously configured parameters for local storage of CDR files on HDD on SMC card.
```

```
compression { gzip | none }

Configures the type of compression to be used on the files stored locally.
gzip – Enables Gzip file compression.
none – Disables Gzip file compression -this is the default value.
```
format custom1 .. 8

Configures the file format to be used to format files to be stored locally.

**custom1** — File format custom1 - this is the default file format.

**custom2 to custom5** Customer specific CDR file formats.

**custom6** — File format custom6 with a block size of 8K for CDR files.

**custom7** — File format custom7 is a customer specific CDR file format.

**custom8** — File format custom8 is a customer specific CDR file format. It uses node-id-suffix_date_time_fixed-length-seq-num.u format for file naming where:

- **date** is date in MMDDYY (01132010) for mat
- **time** is time in HHMMSS (023508) format
- **fixed-length-seq-num** is the fixed length of the sequence number for a specific file having a 6-digit counter starting from 000001 and ending at 999999. When file sequence reaches 999999, the sequence is reset to 000001.

name format string

Allows the format of the CDR filenames to be configured independently so that the name format contains the file name with conversion specifications.

**string** — is an alphanumeric string of 1 through 127 characters. It must begin with the % (percent sign).

- **%y** = year as a decimal number without century (range 00 to 99).
- **%Y** = year as a decimal number with century.
- **%m** = month as a decimal number (range 01 to 12).
- **%d** = day of the month as a decimal number (range 01 to 31).
- **%H** = hour as a decimal number 24-hour format (range 00 to 23).
- **%h** = hour as a decimal number 12-hour format (range 01 to 12).
- **%M** = minute as a decimal number (range 00 to 59).
- **%S** = second as a decimal number (range 00 to 60). (The range is up to 60 to allow occasional leap seconds.)
- **%Q** = file sequence number. Field width may be specified between the % and the Q. If the natural size of the field is smaller than this width, then the result string is padded (on the left) to the specified width with 0s
- **%N** = No of CDRs in the file. Field width may be specified between the % and the N. If the natural size of the field is smaller than this width, then the result string is padded (on the left) to the specified width with 0s
- **%%%** = This field is used to add % to the CDR file name.

**max-file-seq-no**: This can be configured optionally. It indicates the maximum value of sequence number in file name (starts from 1). Once the configured max-file-seq-no limit is reached, the sequence number will restart from 1. If no max-file-seq-no is specified then file sequence number ranges from 1-4294967295.

By default the above keyword is not configured (default gtpp storage-server local file name format). In which case the CDR filenames are generated based on the file format as before (maintains backward compatibility).
**name prefix prefix**

Defines the prefix to be used for the file name. By default the file name prefix would be “GTPP-group-name + VPN-ID”. It is possible to have a NULL value prefix where the system would enter a default, which would be *group vpn*, *prefix* - is an alphanumeric string of 1 through 64 characters, Do not enter a value (NULL).

**purge-processed-files [ file-name-pattern file_pattern | purge-interval purge_dur ]**

Enables the GSN to periodically (every 4 minutes) delete locally processed (*.p) CDR files from the HDD on the SMC card. Default: Disabled

This keyword also deletes the processed push files (tx.*,under $CDR_PATH/TX/tk.*) a well when purging is enabled instead of "*.p:*.P".

**Important:** This option is available only when GTPP server storage mode is configured for local storage of CDRs with the *gtpp storage-server mode local* command.

Optional keyword *file-name-pattern file_pattern* provides an option for user to control the pattern of files. *file_pattern* must be mentioned in "*.p:*.P:tx.*" format in a string of size 1 through 127, which is also the default format. Wildcards * and: (synonymous to |) are allowed.

Optional keyword *purge-interval purge_dur* provides an option for user to control the purge interval duration (in minutes). *purge_dur* must be an integer from 1 through 259200. Default value 60.

**push { encrypted-url encrypted_url | url url } [ encrypted-secondary-url encrypted_url | secondary-url url ] [ via-local-context ]**

Enables push method to transfer local CDR files to remote system.

encrypted-url: Defines use of an encrypted url.

encrypted_url must be an alphanumeric string of 1 through 8192 characters in SFTP format.

url: Location where the CDR files are to be transferred.

url must be an alphanumeric string of 1 through 1024 characters in the format: scheme://user:password@host

encrypted-secondary-url: Defines use of an encrypted secondary url.

encrypted_url must be an alphanumeric string of 1 through 8192 characters in SFTP format.

secondary-url: Secondary location where the CDR files are to be transferred, in case primary is unreachable.

url must be an alphanumeric string of 1 through 1024 characters in the format: scheme://user:password@host

**Important:** When a file transfer to primary fails four times, the transfer of files will automatically be failed over to the secondary server. The transfer will switch back to the original primary after 30 minutes, or if there are four transfer failures to the secondary server.

via-local-context: Pushes the CDR files via SPIO in the local context.

Default: Pushes via the group's context.

**Important:** If the push is done through gtpp context, then the push rate is lesser compared to via local context as the HDD is attached to the local context.
rotation { cdr-count count | time-interval time [ force-rotation ] | volume size }

Specifies rotation related configuration for GTPP files stored locally.

cdr-count count: Configures the CDR count for the file rotation as an integer from 1000 through 65000. Default value 10000.

time-interval time: Configures the time interval for file rotation (in seconds) as an integer from 30 through 86400. Default: 3600 (1 hour).

force-file-rotation: Forces CDR file-rotation at a specified interval configured via the time-interval keyword, even if no CDRs were generated. By default this keyword is Disabled.

volume size: Configures the file volume (in megabytes) for file rotation as an integer from 2 through 40. This trigger can not be disabled. Default: 10

start-file-seq-num seq_num | recover-file-seq-num

Default: disabled

Enables the continuous file sequence number function. start-file-seq-num specifies the lowest number to be used as a file sequence number in the case of an aaaproxy or a chassis restart/reboot.

seq_num is an integer from 1 to 4294967295. Entering a value of 1 disables the recover file sequence number function. Entering any other number, for example 10, would instruct the system to always start from 10 as the file sequence number in the event of an aaaproxy or chassis reload.

When files are moved, the file sequence numbers are synced and stored in both RAM and the hard disk drive (HDD). recover-file-seq-num instructs the system to recover the last (largest) stored file sequence number, in the event of an aaaproxy/chassis restart/reboot, to continue file sequence numbering rather than resetting the file sequence numbering to the lowest start file sequence number.

Usage

This command configures the parameters for storage of GTPP packets as files on the local server - meaning the hard disk drive (HDD).

Example

The following command configures rotation for every 1.5 hours for locally stored files.

```
gtpp storage-server local file rotation time-interval 5400
```

Configuring file name format along with max-file-seq-no:

```
gtpp storage-server local file name format processed_2g_%Y%m%d_%5Q_%N.cdr max-file-seq-no 2345
```

Configuring file name prefix with a NULL value:

```
gtpp storage-server local file name prefix NULL
```

Configure the file name pattern and purge interval to setup file purging from the HDD:

```
gtpp storage-server local file purge-processed-files file-name-pattern *.z purge-interval 4
```
gtpp storage-server max-retries

Configures the maximum number of times the system attempts to communicate with an unresponsive GTPP back-up storage server.

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
- configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
[ default ] gtpp storage-server max-retries max_attempts
```

- **default**
  - Restores the system to the default value of 2 retry attempts.

- **max_attempts**
  - Specifies the number of times the system attempts to communicate with a GTPP back-up storage server that is not responding as an integer from 1 to 15. Default: 2

**Usage**

This command works in conjunction with the **gtpp storage-server timeout** parameters to set a limit to the number of communication failures that can occur with a configured GTPP back-up storage server. The **gtpp storage-server timeout** command controls the amount of time between retries. Refer to the description of this command for additional information.

**Example**

The following command configures the maximum number of re-tries to be 8.

```
gtpp storage-server max-retries 8
```
gtpp storage-server mode

Configures the storage mode (local, remote or streaming for CDRs) to be used. Local storage mode is available with ASR 5000 platforms only.

Product
GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

```plaintext
gtpp storage-server mode { local | remote | streaming }
default gtpp storage-server mode
```

default

Returns the GTPP group configuration to the default “remote” value for the GTPP storage server mode.

local

Specifies the use of the hard disk for storing CDRs. Default: Disabled

---

**Important:** This option is available with ASR 5000 platforms only.

remote

Specifies the use of an external server for storing CDRs. This is the default value.

---

**Important:** When the external server is down, the Session Managers will start buffering up to a maximum of 26400 CDRs or a total of 120 MB worth of CDRs, whichever limit reaches first. The maximum CDR limit specified is per the session manager. The chassis level limit varies depending on the number of session manager instances and number of active cards.
streaming

Specifies the use of HDD to store CDRs in case if CGF fails and then stream the CDRs to the CGF when CGF is up. Streaming can be done in a First-In-First-Out (FIFO) mode. Default: streaming (FIFO)

streaming: This keyword allows the operator to configure “streaming” mode of operation for GTPP group. When this keyword is supplied the CDRs will be stored in following fashion:

- When GTPP link is active with CGF, CDRs are sent to a CGF via GTPP and local hard disk is NOT used as long as every record is acknowledged in time.

- If the GTPP connection is considered to be down, all streaming CDRs will be saved temporarily on the local hard disk and once the connection is restored, unacknowledged records will be retrieved from the hard disk and sent to the CGF.

In the streaming mode, when the CGF becomes active, CDRs in HDD are streamed in a First-In-First-Out order. In this mode, newly generated CDRs are routed to CGF via HDD.

Usage

This command configures whether the CDRs should be stored on the hard disk of the SMC or remotely, on an external server.

Example

The following command configures use of a hard disk for storing CDRs.

```
gtpp storage-server mode local
```
gtpp storage-server timeout

Configures the amount of time that must pass with no response before the system re-attempts to communicate with the GTPP back-up storage server.

Product
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
  - configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

Syntax

```
[ default ] gtpp storage-server timeout duration
```

- **default**
  - Restores the timeout duration to the default of 30 seconds.

- **duration**
  - Specifies the maximum amount of time (in seconds) that the system waits for a response from the GTPP back-up storage server before assuming the packet is lost.
  - `duration` is an integer from 30 through 120. Default: 30

Usage

This command works in conjunction with the `gtpp storage-server max-retries` command to establish a limit on the number of times that communication with a GTPP back-up storage server is attempted before a failure is logged.

This parameter specifies the time between retries.

Example

The following command configures a retry timeout of 60 seconds:

```
gtpp storage-server timeout 60
```
gtpp suppress-cdrs zero-volume

Suppresses the CDRs with zero byte data count, so that the OCG node is not overloaded with a flood of CDRs. By default this mode is “disabled”.

Important: The Zero Volume CDR Suppression is a license-controlled feature. For more information, contact your Cisco account representative.

Product
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

gtpp suppress-cdrs zero-volume { final-cdr | internal-trigger-cdr | external-trigger-cdr } +

{ default | no } gtpp suppress-cdrs zero-volume

default | no
Disables the CDR suppression mode. By default this command is disabled and system will not suppress any CDR.

final-cdr
Suppresses only the Final Zero Volume CDRs i.e. the CDRs that are generated when the session ends.

internal-trigger-cdr
Supresses Zero Volume interim CDRs that are generated due to internal triggers such as volume limit, time limit, tariff change or user generated interims through the CLI commands.

external-trigger-cdr
Supresses Zero Volume interim CDRs that are generated due to external triggers such as QoS Change, RAT change and so on.
gtpp suppress-cdrs zero-volume

Usage

Use this command to suppress the CDRs (G-CDRs, eG-CDR, PGW-CDRs, SGW-CDRs, SGSN CDRs) with zero-volume session due to any reason. This feature allows the customers to suppress the CDRs with zero byte data count, so that the OCG node is not overloaded with a flood of CDRs.

The CDRs can be categorized as follows:

- **final-cdr**: These CDRs are generated when the session ends.
- **internal-trigger-cdr**: These CDRs are generated due to internal triggers such as volume limit, time limit, tariff change or user generated interims through the CLI commands.
- **external-trigger-cdr**: These CDRs are generated due to external triggers such as QoS Change, RAT change and so on. All triggers which are not considered as final-cdrs or internal-trigger-cdrs are considered as external-trigger-cdrs.

Customers can select the CDRs they want to suppress. This feature is disabled by default to ensure backward compatibility.

Example

The following command configures the system to suppress Zero Volume Final CDRs, interim CDRs due to internal and external triggers:

```
gtpp suppress-cdrs zero-volume final-cdr internal-trigger-cdr external-trigger-cdr
```
**gtpp suppress-cdrs zero-volume-and-duration**

Suppresses the CDRs created by session having zero duration and/or zero volume. By default this mode is “disabled”.

**Product**
- GGSN
- P-GW
- SAEGW
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
  ```
  configure > context context_name > gtpp group group_name
  ```

**Syntax**
- `gtpp suppress-cdrs zero-volume-and-duration { gcdrs [ egcdrs ] | egcdrs [ gcdrs ] }
- default gtpp suppress-cdrs zero-volume-and-duration

- **default**
  - Disables the CDR suppression mode.

- **gcdrs [ egcdrs ]**
  - Specifies that this command will handle G-CDRs before eG-CDR/P-CDRs.

- **egcdrs [ gcdrs ]**
  - Specifies that this command will handle eG-CDR/P-CDRs before G-CDRs.

**Usage**
Use this command to suppress the CDRs (G-CDRs and eG-CDR/P-CDRs) which were created due with zero-duration session and zero-volume session due to any reason. By default this command is disabled and system will not suppress any CDR.

**Example**
The following command configures the system to suppression the eG-CDR/P-CDRs created for a zero duration session or zero volume session:

```
gtpp suppress-cdrs zero-volume-and-duration egcdrs gcdrs
```
gtpp timeout

Configures the amount of time that must pass with no response before the system re-attempts to communicate with the CGF.

Product
GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

Syntax
[ default ] gtpp timeout time

default
Resets the systems GTPP timeout value to 20 seconds.

time
Specifies the maximum amount of time (in seconds) the system waits for a response from the CGF before assuming the packet is lost.
time is an integer from 1 through 60. Default: 20

Usage
This command works in conjunction with the gtpp max-retries command to establish a limit on the number of times that communication with a CGF is attempted before a failure is logged.
This parameter specifies the time between retries.

Example
The following command configures a retry timeout of 30 seconds:

    gtpp timeout 30
**gtpp transport-layer**

Selects the transport layer protocol for Ga interface for communication between AGW (GSNs) and GTPP servers.

**Product**

GGSN
P-GW
SAEGW
SGSN
S-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
gtpp transport-layer { tcp | udp }
```

```
default gtpp transport-layer
```

**Usage**

Use this command to select the TCP or UDP as the transport layer protocol for Ga interface communication between GTPP servers and AGWs (GSNs).

**Example**

The following command enables TCP as the transport layer protocol for the GSN’s Ga interface.

```
gtpp transport-layer tcp
```
gtpp trigger

Disables GTPP trigger conditions that cause either partial CDR record closure or opening of a new CDR record container. GTPP Triggers are specified in 3GPP TS 32.251 v6.6.0. All GTPP trigger changes take effect immediately, except *volume-limit*.

**Product**
- ECS
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
- `configure > context context_name > gtpp group group_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```

default gtpp trigger

default

Sets the specified trigger condition back to the default setting. All trigger conditions are enabled by default.

no

Disables the specified trigger condition.
GTPP Server Group Configuration Mode Commands

gtpp trigger

---

apn-ambr-change [ default-bearer-only | all-non-gbr-bearers | all-bearers ]

Default: Disabled
Enables APN AMBR trigger only for default-bearer or for all bearers for that PDN or selectively for apn-non-gbr bearers.

---

**Important:** This keyword option will be available only if a valid license is installed. For more information, contact your Cisco account representative.

The APN Aggregate Maximum Bit Rate (AMBR) is a subscription parameter stored per APN. It limits the aggregate bit rate that can be expected to be provided across all non-GBR bearers and across all PDN connections of the same APN. Each of these non-GBR bearers potentially utilize the entire APN AMBR, e.g. when the other non-GBR bearers do not carry any traffic.

In 15.0 and later releases, this CLI command should be configured along with the following additional options to enable APN-AMBR trigger for SGW-CDRs in all GTPP dictionaries.

- **default-bearer-only**: Adds container only to default bearer.
- **all-non-gbr-bearers**: Adds container to all non-gbr-bearers.
- **all-bearers**: Adds containers for all bearers.

---

**Important:** This CLI command and the associated options are not available for products other than S-GW and P-GW.

The first container of each CDR includes apn-ambr fields along with QoS. In the following containers this field is present if previous change condition is "QoS change" or "APN AMBR Change".

---

cell-update

Enables the cell update trigger for S-CDRs, if the dictionary specified in the **gtpp dictionary** configuration includes support for cell update. This trigger is available only for 2G. Currently, custom18 dictionary supports the cell update trigger.

---

dcca

This keyword enables or disables the addition of LOSDV in PGW-CDR for the following DCCA generated triggers.

- Time Threshold Reached
- Volume Threshold Reached
- Service Specific Unit Threshold Reached
- Time Exhausted
- Volume Exhausted
- Validity Timeout
- Reauthorization Request
- Continue Ongoing Session
- Retry And Terminate Ongoing Session
- Terminate Ongoing Session
GTPP Server Group Configuration Mode Commands

- Service Specific Unit Exhausted
- Envelope Closure

**direct-tunnel**
Enables the direct tunnel trigger for CDRs.

**egcdr max-losdv**
Enables the trigger for an eG-CDR/P-CDR if the List of Service Data Volume (LoSDV) containers crosses the configured limit for LOSDV containers. Default: Disabled

**ggsn-preservation-mode-change**
This keyword is for GGSN only. This trigger enables the preservation-mode-change trigger for G-CDR.

**inter-plmn-sgn-change**
This keyword is for GGSN only. Disabling this trigger ignores an Inter-PLMN SGSN change and doesn't release a G-CDR. Default: Enabled

**ms-timezone-change**
This keyword is specific to GGSN. No partial record closure for a time zone change occurs when this trigger is disabled. MS time zone change should be applicable only for 3GPP R6 based GTPP dictionaries. Default: Enabled

**plmn-id-change**
This trigger keyword is specific to the 2G SGSN and is proprietary (non-standard). Enables the PLMNID change trigger for S-CDRs if the dictionary specified in the `gtpp dictionary` configuration supports the PLMNID change. If enabled, the SGSN generates a partial S-CDR when the MS changes the PLMN while under the same SGSN (intra-system intra-SGSN PLMN-ID handover). Currently, custom18 dictionary supports this trigger. Default: Disabled

**qos-change**
Enables the QoS-change trigger for CDRs. Disabling this trigger ignores a QoS-change and does not open a new CDR for it. Default: Enabled

When QoS changes are observed, the system generates only containers. However, when the max-container condition is reached, an interim CDR is generated.

**rat-change**
Enables or disables the partial record closure for a RAT change. If disabled, no partial record closure for a RAT change occurs. RAT change should be applicable only for 3GPP R6 based GTPP dictionaries. Default: Enabled

In SGSN, RAT change trigger (2G<->3G) means inter-service handoff (SGSN service <-> GPRS service). If this trigger is enabled, after the RAT change interim CDR is generated. After this RAT change CDR, CDR thresholds such as volume/time etc. and GTPP Group are applicable from new service. If RAT change trigger is disabled, the CDR thresholds and GTPP group etc. will not change and will continue to use from old service.

After the RAT change, the System Type field in CDR changes to indicate the new system type. If this trigger is disabled, then the next CDR generated will indicate System Type, but the data count in the CDR does not
necessarily belong to the system type indicated in CDR; instead, it may belong to both 2G and 3G as CDR is not closing when handover takes place.

**Important:** The System Type field in CDR-related change is not applicable to customized CDR formats, which does not use the System Type field.

```text
generate { cdr | container }: Sets generation of CDR or just a Container on a RAT change.

cdr: Generates a CDR on a RAT-change.

container: Generates a container only on a RAT-change.
```

**routing-area-update**

Enables the routing-area-update trigger for CDRs.

**service-idle-out**

This keyword enables or disables the addition of LOSDV in PGW-CDR when a service idles out.

Note that the CDR module receives service idle out trigger from DCCA module when the quota hold timer expires, or from ACS manager when rulebase has a service idle out configuration.

```text
serving-node-change-limit [ also-intra-sgsn-multiple-address-group-change ]
```

This keyword is enabled for P-GW, S-GW, and GGSN. However, the `also-intra-sgsn-multiple-address-group-change` is enabled only for GGSN. Default: Enabled

Disabling this trigger ignores an SGSN change and does not add the SGSN IP address into the SGSN address list of the CDR. This helps to reduce the release of CDRs due to SGSN changes crossing the configured limit.

**also-intra-sgsn-multiple-address-group-change:** This keyword includes Intra-SGSN group changes as an SGSN change.

```text
sgsn-change-limit [ also-intra-sgsn-multiple-address-group-change ]
```

This keyword is obsolete and is available to maintain the backward compatibility for existing customers. The new keyword for `sgsn-change-limit` is `serving-node-change-limit`. Default: Enabled

Disabling this trigger ignores an SGSN change and does not add the SGSN IP address into the SGSN address list of the CDR. This helps to reduce the release of CDRs due to SGSN changes crossing the configured limit.

**also-intra-sgsn-multiple-address-group-change:** This keyword includes Intra-SGSN group changes as an SGSN change.

**tariff-time-change**

When this trigger is disabled, container closure does not happen for a tariff-time change. Default: Enabled

This trigger is applicable for G-MB-CDRs for MBMS session too.

**time-limit**

When this trigger is disabled, no partial record closure occurs when the configured time limit is reached. Default: Enabled

This trigger is applicable for G-MB-CDRs for MBMS session too.

**uli-change**

Enables the user location update trigger for eG-CDRs/PGW-CDRs/SGW-CDRs, if the dictionary specified in the GTPP dictionary configuration includes support for user location update trigger. Default: Enabled
volume-limit

When this trigger is disabled no partial record closure occurs when volume limit is reached. Default: Enabled

This trigger is applicable for G-MB-CDRs for MBMS session too.

Usage

Use this command to disable or enable GTTP triggers that can cause partial CDR record closure or cause a new CDR to be created.

Example

The following command disables partial record closure when a configured time limit is reached:

```
gtp trigger time-limit
```

The following command re-enables partial record closure when a configured time limit is reached:

```
no gtp trigger time-limit
```
Chapter 154
GTP-U Service Configuration Mode Commands

The GTP-U Service Configuration Mode is used to manage parameters applied to incoming GTP-U packets.

Mode

Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpu-service)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
bind

Configures the IP address to use for GTP-U data packets.

Product

ePDG
GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege

Administrator

Mode

Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpu-service)#

Syntax

[  no  ] bind { ipv4-address ipv4_address [ crypto-template crypto_template ] [ ike-bind-address { ipv4_address } ] [ ipv6-address ipv6_address ] | ipv6-address ipv6_address [ crypto-template crypto_template ] [ ike-bind-address { ipv6_address } ] [ ipv4-address ipv4_address ] }

no

removes a configured IP address from this service.

ipv4-address ipv4_address

Binds this service to the IPv4 address of a configured interface.

ipv4_address must be entered using IPv4 dotted-decimal notation.

bearer-type non-ims-media | ims-media | all

Specifies the type of bearer to be associated with the bind address. Default behavior is for that the address will be used for all bearer types.

non-ims-media Configures bind address for non-ims media only.

ims-media Configures bind address for ims-media traffic only.

all configures bind address to handle all types of bearer traffic. This is the default setting.

ipv6-address ipv6_address

Binds this service to the IPv6 address of a configured interface.

ipv6_address must be entered using IPv6 colon-separated-hexadecimal notation.
**crypto-template crypto_template**

Configures crypto template for IPSec, which enables IPSec tunneling for this GTP-U address. Must be followed by the name of an existing crypto template. 
`crypto_template` must be an alphanumeric string of 1 through 127 characters.

**ike-bind-address ip_address**

Configures an IKE bind address. Must be followed by IPv4 or IPv6 address; IP address type must be the same as the GTP-U address type.

`ipv4_address` must be entered using IPv4 dotted-decimal notation.

`ipv6_address` must be entered using IPv6 colon-separated-hexadecimal notation.

**bearer-type non-ims-media | ims-media | all**

Specifies the type of bearer to be associated with the bind address. Default behavior is for that the address will be used for all bearer types.

`non-ims-media` configures bind address for non-ims media only.

`ims-media` configures bind address for ims-media traffic only.

`all` configures bind address to handle all types of bearer traffic. This is the default setting.

**Usage**

Use this command to bind the service to an interface for sending/receiving GTP-U packets.

**Important:** A GTP-U service can support a maximum of 12 GTP-U endpoints/interfaces.

**Example**

The following command configures the IPv4 address for this GTP-U service as 10.2.3.4:

```
bind ipv4-address 10.2.3.4
```
echo-interval

Configures the rate at which GPRS Tunneling Protocol (GTP) v1-U echo packets are sent.

Product
- ePDG
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration
configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpu-service)#

Syntax

```
echo-interval seconds [ dynamic [ smooth-factor multiplier ] ]
{ default | no } echo-interval
```

- **default**
  Disables the configured echo-interval setting.

- **no**
  Removes the configured echo-interval setting.

- **seconds**
  Specifies the number of seconds between the sending of a GTP-Uv1 echo packet. `seconds` must be an integer from 60 through 3600. Default: 60

- **dynamic [ smooth-factor multiplier ]**
  Enables the dynamic echo timer for the GTP-U service.
  
  `smooth-factor multiplier`: Introduces a multiplier into the dynamic echo timer as an integer from 1 through 5. Default: 2

Usage

Use this command to configure the rate at which GTP-Uv1 echo packets are sent.

Example

```
```
The following command sets the rate between the sending of echo packets at 120 seconds:

```
echo-interval 120
```
echo-retransmission-timeout

Configures the timeout for GTP-U echo message retransmissions for this service.

Product
- ePDG
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

Privilege

Mode
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpu-service)#

Syntax

echo-retransmission-timeout seconds

default echo-retransmission-timeout

default

Returns the command to its default setting of 5.

seconds

Default: 5

Configures the echo retransmission timeout, in seconds, for the GTP-U service as an integer ranging from 1 to 20.

Usage

Use this command to configure the amount of time, in seconds, before the GTP-U service transmits another echo request message. The value set in this command is used, as is, for the default echo. If dynamic echo is enabled (echo-interval dynamic) the value set in this command serves as the dynamic minimum (if the RTT multiplied by the smooth factor is less than the value set in this command, the service uses this value).

Example

The following command sets the retransmission timeout for echo messages to 2 seconds:

echo-retransmission-timeout 2
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

exit

Usage
Use this command to return to the parent configuration mode.
extension-header

Configures the addition of an extension header in the GTP-U packet header, allowing for error indication messages.

Product
GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpu-service)#

Syntax

[ default | no ] extension-header source-udp-port

default

Returns the command to its default setting of disabled.

no

Disables the feature.

source-udp-port

Configures extension header type UDP Port support in GTP-U header for GTP-U Error Indication messages.

Usage

Use this command to configure the addition of an extension header in the GTP-U packet to allow for error indication messages

Example

The following command enables the inclusion of an extension header to allow for error indication messages:

extension-header source-udp-port
### ip qos-dscp

Configures the quality of service (QoS) differentiated service code point (DSCP) per-hop behavior (PHB) to be marked on the outer header of signalling packets originating from the LTE component.

**Product**
- ePDG
- P-GW
- SAEGW
- S-GW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

*configure > context context_name > gtpu-service service_name*

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpu-service)#
```

**Syntax**

```
ip qos-dscp { af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | cs1 | cs2 | cs3 | cs4 | cs5 | cs6 | cs7 | ef }
```

- **default**
  Sets/restores default value.

- **no**
  Disables DSCP marking.

**af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | cs1 | cs2 | cs3 | cs4 | cs5 | cs6 | cs7 | ef**

Specifies the IP QoS DSCP PHB to be marked on the outer header of signalling packets originating from the LTE component. This is a standards-based feature (RFC 2597 and RFC 2474).

Note that CS (class selector) mode options below are provided to support backward compatibility with the IP precedence field used by some network devices. CS maps one-to-one to IP precedence, where CS1 is IP precedence value 1. If a packet is received from a non-DSCP aware router that used IP precedence markings, then the DSCP router can still understand the encoding as a Class Selector code point.

The following forwarding types are supported:

- **af11**: Designates the use of Assured Forwarding 11 PHB.

  This is the default setting.

- **af12**: Designates the use of Assured Forwarding 12 PHB.

- **af13**: Designates the use of Assured Forwarding 13 PHB.
• **af21**: Designates the use of Assured Forwarding 21 PHB.
• **af22**: Designates the use of Assured Forwarding 22 PHB.
• **af23**: Designates the use of Assured Forwarding 23 PHB.
• **af31**: Designates the use of Assured Forwarding 31 PHB.
• **af32**: Designates the use of Assured Forwarding 32 PHB.
• **af33**: Designates the use of Assured Forwarding 33 PHB.
• **af41**: Designates the use of Assured Forwarding 41 PHB.
• **af42**: Designates the use of Assured Forwarding 42 PHB.
• **af43**: Designates the use of Assured Forwarding 43 PHB.
• **be**: Designates the use of Best Effort forwarding PHB.
• **cs1**: Designates the use of Class Selector code point “CS1”.
• **cs2**: Designates the use of Class Selector code point “CS2”.
• **cs3**: Designates the use of Class Selector code point “CS3”.
• **cs4**: Designates the use of Class Selector code point “CS4”.
• **cs5**: Designates the use of Class Selector code point “CS5”.
• **cs6**: Designates the use of Class Selector code point “CS6”.
• **cs7**: Designates the use of Class Selector code point “CS7”.
• **ef**: Designates the use of Expedited Forwarding PHB typically dedicated to low-loss, low-latency traffic.

The assured forwarding behavior groups are listed in the table below.

<table>
<thead>
<tr>
<th></th>
<th>Class 1</th>
<th>Class 2</th>
<th>Class 3</th>
<th>Class 4</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Low Drop</strong></td>
<td>AF11</td>
<td>AF21</td>
<td>AF31</td>
<td>AF41</td>
</tr>
<tr>
<td><strong>Medium Drop</strong></td>
<td>AF12</td>
<td>AF22</td>
<td>AF32</td>
<td>AF42</td>
</tr>
<tr>
<td><strong>High Drop</strong></td>
<td>AF13</td>
<td>AF23</td>
<td>AF33</td>
<td>AF43</td>
</tr>
</tbody>
</table>

Traffic marked with a higher class is given priority during congestion periods. If congestion occurs to traffic with the same class, the packets with the higher AF value are dropped first.

**Usage**

Use this command to implement DSCP marking only for GTP-U ECHO Request and Response messages.

**Example**

Use the following command to set the use of Best Effort forwarding PHB:

```
ip qos-dscp be
```
ipsec-allow-error-ind-in-clear

Configures whether error-indication is dropped or sent without IPSec tunnel.

Product
S-GW
SAEGW
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpu-service)#

Syntax

[ default | no ] ipsec-allow-error-ind-in-clear

- default
  Error-indication is dropped if no IPSec tunnel is present for that peer.

- no
  Disables the feature.

Usage

Use this command to determine whether error-indication is dropped or sent without an IPSec tunnel. On receiving data packets for a session that does not exist, error-indication needs to be sent back to the peer. If there is no IPSec tunnel present with that peer, error-indication may be either dropped or sent without any IPSec tunnel.

Example

The following command allows error-indication to be sent without any IPSec tunnel:

ipsec-allow-error-ind-in-clear
ipsec-tunnel-idle-timeout

Configures the IPSec tunnel idle timeout after which IPSec tunnel deletion is triggered.

**Product**
S-GW
SAEGW
SGSN

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

```
configure > context context_name > gtpu-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpu-service)#
```

**Syntax**

```
ipsec-tunnel-idle-timeout seconds

default ipsec-tunnel-idle-timeout
```

**seconds**
Default: 60
Specifies the number of seconds an IPSec tunnel is idle before tunnel deletion is triggered. **seconds** must be an integer from 10 through 600.

**default**
Returns the command to its default setting of 60.

**Usage**

When there are no bearers on a particular IPSec tunnel, GTPUMGR initiates the delete for that tunnel. This timer helps to avoid unnecessary IPSec tunnel deletions for an idle tunnel.

**Example**

The following command sets the IPsec tunnel idle timeout to 100 seconds:

```
ipsec-tunnel-idle-timeout 100
```
max-retransmissions

Configures the maximum retry limit for GTP-U echo retransmissions.

Product
- ePDG
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration
configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpu-service)#

Syntax

max-retransmissions num
no max-retransmissions

num

Default: 4
Specifies the number of GTP-U echo message retransmissions allowed before triggering a path failure error condition. num must be an integer from 0 through 15.

no

Disables the feature.

Usage

Use this command to set the maximum number of GTP-U echo message retransmissions in order to define a limit that triggers a path failure error.

Example

The following command sets the maximum GTP-U echo message retransmissions for this service to 10:

max-retransmissions 10
path-failure clear-trap

Configures a trigger for clearing the path failure trap.

**Product**
- ePDG
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

```
configure > context context_name > gtpu-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpu-service)#
```

**Syntax**

```
path-failure clear-trap gtp echo
```

[ default | no ] path-failure clear-trap

---

gtp echo

Sets the clearing trigger/trap to detect a failure upon reaching the maximum number of GTP-U echo message retransmissions.

---

default

Resets the command to its default setting of enabled.

---

no

Disables the feature.

**Usage**

Use this command to set the detection policy for path failures. By default, path failure trap is cleared on receiving first control plane message for that GTP-U peer allocation.

**Example**

The following command sets the clearing trigger to detect failures upon reaching the maximum number of GTP-U echo message retries:

```
path-failure clear-trap gtp echo
```
path-failure detection-policy

Configures a path failure detection policy on GTP-U echo messages that have been retransmitted the maximum number of retry times.

Product
- ePDG
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

Entering the above command sequence results in the following prompt:

[context_name] host_name(config-gtpu-service)#

Syntax

path-failure detection-policy gtp echo

[ default | no ] path-failure detection-policy

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>gtp echo</td>
</tr>
</tbody>
</table>
Sets the detection policy to detect a failure upon reaching the maximum number of GTP-U echo message retransmissions.

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
</tr>
</tbody>
</table>
Resets the command to its default setting of enabled.

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
</tr>
</tbody>
</table>
Disables the feature.

Usage

Use this command to set the detection policy for path failures.

Example

The following command sets the path failure detection policy to detect failures upon reaching the maximum number of GTP-U echo message retries:

path-failure detection-policy gtp echo
retransmission-timeout

Configures retransmission timeout for GTPU echo message retransmissions for this service.

**Important:** In release 14.0 and later versions, this command is replaced by the `echo-retransmission-timeout` command.

**Product**
- ePDG
- GGSN
- P-GW
- SAEGW
- S-GW

**Privilege**
Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > GTP-U Service Configuration
  - configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpu-service)#
```

**Syntax**

```
retransmission-timeout seconds
```

**default retransmission-timeout**

```
default
```

Returns the command to its default setting of 5.

```
default
```

**seconds**

```
default
```

Default: 5

Specifies the number of seconds between the re-sending of GTP-U echo messages. `seconds` must be an integer from 1 through 20.

**Usage**

Use this command to set the number of seconds between the retransmission of GTP-U echo messages.

**Example**

The following command sets the number of seconds between the sending of GTP-U echo messages to 7:

```
retransmission-timeout 7
```
sequence-number

Enables addition of the sequence number to every GTP-U packet. Default is disabled.

Product

GGSN
HSGW
P-GW
SAEGW
SGSN
S-GW

Privilege

Administrator

Mode

Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpu-service)#

Syntax

[ no ] sequence-number

no

Disables addition of the sequence number to every GTP-U packet.

Usage

Use this command to enable/disable addition of the sequence number to every GTP-U packet coming from Gi interface and going towards Gn/Gp interface. If GTP-U packets are received out of sequence, sequence numbers would allow the packets to be reordered.

Example

The following command enables addition of the sequence number to every GTP-U packet:

`sequence-number`
udp-checksum

Inserts UDP-checksum in the UDP header of GTP-U packet.

Product
GGSN
HNB-GW
P-GW
SGSN
S-GW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpu-service)#

Syntax

udp-checksum { no-optimize | optimize }
[ default | no ] udp-checksum

default
Through releases 14.0: Enables the UDP checksum, but no optimization is attempted. Releases 15.0 and later: Enables the UDP checksum, and attempts optimization of the UDP checksum in UDP header of GTPU packet using the inner payload transport checksum.

no
Outer UDP checksum is marked as 'ZERO,' effectively disabling UDP checksum. Applicable only for IPv4 data.

no-optimize
No optimization attempt over UDP checksum in UDP header of GTP-U packet.

optimize
Attempts optimization of UDP checksum in UDP header of GTP-U packet using inner payload transport checksum.

Usage
This command is used for enabling optimization of UDP checksum in UDP header of the GTP-U packet. An option to completely disable the UDP checksum of GTP-U packet is also introduced.

Example
The following command enables the optimization of UDP checksum in UDP header of the GTP-U packet:

```
udp-checksum optimize
```
Chapter 155
HA Proxy DNS Configuration Mode Commands

The HA Proxy DNS Configuration Mode is used to create rules for Home Agent (HA) proxy DNS intercept lists that redirect packets with unknown foreign DNS addresses to a home network DNS server.

**Important:** HA Proxy DNS Intercept is a license-enabled feature.

**Mode**

Exec > Global Configuration > Context Configuration > Proxy DNS Configuration

```
configure > context context_name > proxy-dns intercept-list list_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-proxy-dns-intercept-list)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
**pass-thru**

Sets IP addresses that should be allowed through the proxy DNS intercept feature.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Proxy DNS Configuration

```
configure > context context_name > proxy-dns intercept-list list_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-proxy-dns-intercept-list)#
```

**Syntax**

```
[ no ] pass-thru ip_address [ /ip_mask ]
```

- `no`
  Removes the DNS IP address from the pass-thru rule.

- `pass-thru ip_address [ /ip_mask ]`
  Specifies an DNS IP address that is allowed through the intercept feature.
  
  `ip_address[/ip_mask]`: Specifies the IP address and network mask bits. `ip_address[/ip_mask]` is specified using IPv4 dotted decimal or IPv6 colon-separated-hexadecimal notation. The mask bits are a numeric value which is the number of bits in the subnet mask (CIDR notation).

**Usage**

Use this command to identify DNS IP addresses that should be allowed through the intercept feature. For a more detailed explanation of the proxy DNS intercept feature, see the `proxy-dns intercept-list` command in the Context Configuration Mode Commands chapter. A maximum of 16 intercept rules (either `redirect` or `pass-thru`) are allowed for each intercept list.

**Important:** To allow packets through that do not match either the `pass-thru` or `redirect` rules, set a `pass-thru` rule address as: 0.0.0.0/0. If a packet does not match either the `pass-thru` or `redirect` rule, the packet is dropped.

**Example**

The following command allows a foreign network’s DNS with an IP address of 10.2.55.12 to avoid being redirected:

```
pass-thru 10.2.55.12
```
redirect

Redirects DNS IP addresses from foreign networks matching an IP address in this command to a home network DNS.

Product:
HA

Privilege:
Security Administrator, Administrator

Mode:
Exec > Global Configuration > Context Configuration > Proxy DNS Configuration

configure > context context_name > proxy-dns intercept-list list_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-proxy-dns-intercept-list)#

Syntax:

[ no ] redirect any [ primary-dns ip_address [ secondary-dns ip_address ] ]

no

Removes the DNS IP address from the redirect rule.

primary-dns ip_address

Specifies the IP address of the primary home network DNS.

ip_address is specified using IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

secondary-dns ip_address

Specifies the IP address of the secondary home network DNS.

ip_address is specified using IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

Usage:

Use this command to identify DNS IP addresses from foreign networks that are to be redirected to the home DNS. For a more detailed explanation of the Proxy DNS feature, see the proxy-dns intercept-list command in the Context Configuration Mode Commands chapter. A maximum of 16 intercept rules (either redirect or pass-thru) are allow for each intercept list.

Since this command is configured in the source context, the destination context containing the path to the home network DNS is identified using the Context Configuration Mode command ip dns-proxy source-address.

Important: If a packet does not match the pass-thru or redirect rule, the packet is dropped. If primary-dns or secondary-dns is not configured, DNS messages are redirected to the primary-dns-server (or the secondary-dns-server) configured for the subscriber OR inside the context.

Example:

The following command identifies a foreign network DNS with an IP address of 10.2.55.12 and redirects it to a primary home network DNS with an IP address of 10.3.4.5:
predirect 10.2.55.12 primary-dns 10.3.4.5
Chapter 156
HA Service Configuration Mode Commands

The HA Service Configuration Mode is used to create and manage the Home Agent (HA) services within the current context.

**Mode**

Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
a11-signalling-packets

Applies Differentiated Services Code Point (DSCP) marking for IP headers carrying outgoing signalling packets.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

`configure > context context_name > ha-service service_name`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-ha-service)#`

**Syntax**

```
all-signalling-packets ip-header-dscp ip-header-dscp{ default | no } all-signalling-packets ip-header-dscp
```

**no**

Disables DSCP marking for IP header encapsulation for the HA service.

**default**

Configures DSCP marking for IP header encapsulation for a specific HA service.

**ip-header-dscp**

Is a hexadecimal number between 0x0 and 0x3F.

**Usage**

The following command is used to apply DSCP marking for IP header carrying outgoing signalling packets.

**Example**

The following command applies DSCP marking for IP header carrying outgoing signalling packets.

```
all-signalling-packets ip-header-dscp 0x2f
```
aaa

Configures the sending of subscriber session AAA accounting by the HA service.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

aaa { accounting [ roaming ] | group string }

no aaa { accounting | group }

default aaa accounting

  no
  Enables AAA accounting for the HA service.

  default
  Configures AAA parameters for specific HA service

  accounting
  accounting Enables the sending of AAA accounting information for subscriber sessions by the Home Agent (HA), by default is enabled.
  roaming Enables the sending of AAA accounting information for subscriber sessions by the Home Agent (HA) only for roaming subscribers.

  group
  group configures aaa group for ha-service, group has lower priority than subscriber/apn config.
  string: size ranges between 1 and 63.

Usage

Enabling the HA service will send all accounting data (start, stop, and interim) to the configured AAA servers.

The chassis is shipped from the factory with the AAA accounting enabled.
Important: In order for this command to function properly, AAA accounting must be enabled for the context in which the HA service is configured using the aaa accounting subscriber radius command.

Example

The following command disables aaa accounting for the HA service:

```
no aaa accounting
```
access-network

Configures a specific access network configuration.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
access-network accounting identifier access_network_accounting_identifier
no access-network accounting identifier
```

**no**
Disables a specific access network configuration.

**accounting**
Specifies an access network configuration for accounting

**identifier**
Specifies an access network accounting identifier

**access_network_accounting_identifier**
This is an alphanumeric string of 1 through 128 characters.

**Usage**
This command is used to configure an access network for accounting.

**Example**
The following command configures an access network for accounting with the identifier *idnt*:

```
access-network accounting identifier idnt
```
associate

Associates an HA-service with a QoS policy.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

associate qci-qos-mapping string

no associate qci-qos-mapping

no

Disables the association of an HA-service with a QoS policy.

qci-qos-mapping string

Maps a QoS Class Identifier (QCI) for this HA service.

string is an alphanumeric string of 1 through 63 characters.

Usage

This command associates an HA-service with a QoS policy.

Example

The following command associates an HA-service with a QCI map01:

associate qci-qos-mapping map01
authentication

Configures authentication parameters for a specific HA service within a context.

Product
HA
ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name] host_name(config-ha-service)#

Syntax

authentication { aaa-distributed-mip-keys [ disabled | optional | required ] | dmu
refresh-key | imsi-auth] mn-aaa { allow-noauth | always| dereg-noauth | noauth | renew
reg-noauth | renew-and-dereg-noauth } | mn-ha { allow-noauth | always } | pmip-auth | stale-key-disconnect }

no authentication { imsi-auth | pmip-auth }

default authentication { aaa-distributed-mip-keys | dmu-refresh-key | imsi-auth | mn-aaa | mn-ha | pmip-auth | stale-key-disconnect }

no
Disables the parameter.

default
Resets the specified option to its default setting.

aaa-distributed-mip-keys [ disabled | optional | required ]
Configures use of AAA distributed MIP keys for authenticating RRQ for WiMAX HA calls.
Default is disabled.

disabled: Disables using AAA distributed WiMAX Mobile IP (MIP) keys for authenticating MIP RRQ.
optional: Uses AAA distributed WiMAX MIP keys for authenticating RRQ with fallback option to use static/3GPP2 based MIP keys.
required: AAA distributed WiMAX MIP keys for authenticating MIP RRQ are mandatory

dmu-refresh-key
Typically, when a Dynamic Mobile IP Update (DMU) resets, the next MIP re-registration causes MN-HA authorization failure and the HA rejects the MIP RRQ. This parameter enables the HA to retrieve the MN-HA key again from the AAA during the call and to use the freshly retrieved key value to recheck authentication. Default is disabled.
**imsi-auth**

Enable uses the International Subscriber Mobile identity (IMSI) to determine if MN-AAA or MN-FAC extensions are not present in the RRQ.
Default is disabled.

```
imsi-auth
```

**mn-aaa { allow-noauth | always | dereg-noauth | noauth | renew-reg-noauth | renew-and-dereg-noauth }**

Specifies how mobile node-to-AAA authentication extension in registration requests from the mobile node should be handled by the HA service.
Default is always.

- **allow-noauth**: Specifies that the HA service does not require authentication for every mobile node registration request. However, if the mn-aaa extension is received, the HA service will authenticate it.
- **always**: Specifies that the HA service will perform authentication each time a mobile node registers.
- **dereg-noauth**: Disables authentication request upon de-registration.
- **noauth**: Specifies that the HA service will not look for mn-aaa extension and will not authenticate it.
- **renew-reg-noauth**: Specifies that the HA service will not perform authentication for mobile node re-registrations. Initial registration and de-registration will be handled normally.
- **renew-and-dereg-noauth**: Disables authentication request upon re-registration and de-registration.

```
mn-aaa { allow-noauth | always | dereg-noauth | noauth | renew-reg-noauth | renew-and-dereg-noauth }
```

**mn-ha { allow-noauth | always }**

Specifies whether the HA service looks for an MN-HA authentication extension in the RRQ.
Default is always.

- **allow-noauth**: Allows a request that does not contain the auth extension.
- **always**: A request should always contain the auth extension to be accepted.

```
mn-ha { allow-noauth | always }
```

**pmip-auth**

Specifies whether the HA service looks for an MN-HA authentication extension in the RRQ.
Default is always.

- **allow-noauth**: Allows a request that does not contain the auth extension.
- **always**: A request should always contain the auth extension to be accepted.

```
pmip-auth
```

**stale-key-disconnect**

If MN-HA auth fails for MIP renew and dereg, disconnects the call immediately.
Disabled by default.

```
stale-key-disconnect
```

**Usage**

The **authentication** command, combined with a keyword, can be used to specify how the system will perform authentication of registration request messages.

**Example**

The following command configures the HA service to always perform mobile node authentication for every registration request.
```
authentication mn-aaa always
```

The following command configures the HA service to always look for an MN-HA authentication extension in the RRQ.
```
authentication mn-ha always
```
bind

Binds the HA service to a logical IP interface serving as the Pi interface and specifies the maximum number of subscribers that can access this service over the interface.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration
```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:
```
[context_name]host_name(config-ha-service)#
```

**Syntax**
```
bind address address|range_address ip_mask | range_address/bitmask [ max-subscribers count ]
```
```
no bind address
```

**address**
Specifies the IP address (address) of the interface configured as the Pi interface. *address* is specified in IPv4 dotted-decimal notation.

**range_address ip_mask | range_address/bitmask**
Specifies the pool of IP addresses (IPv4) of the interface configured as the Pi interface with an enterprise HA (EHA). *ip_mask* and *bit_mask* specify the number of subnet bits, representing the subnet mask in CIDR notation and must be a value between 1 to 32. *range_address* is a preconfigured range of IPv4 addresses in Loopback Interface Configuration Mode to enable the Enterprise HA support with enhanced capacity and configured

**max-subscribers count**
Default: 2500000
Specifies the maximum number of subscribers that can access this service on this interface. *count* can be configured to an integer from 0 through 4000000.

**Important:** The maximum number of subscribers supported is dependant on the license key installed and the number of active packet processing cards installed in the system.
Usage

Associate the HA service to a specific logical IP address. The logical IP address or interface takes on the characteristics of a Pi interface. Only one interface can be bound to a service. The interface should be configured prior to issuing this command. This command also sets a limit as to the number of simultaneous subscribers sessions that can be facilitated by the service/interface at any given time.

When configuring the `max-subscribers` option, be sure to consider the following:

- The total number of interfaces that you will configuring for use as Pi interfaces
- The maximum number of subscriber sessions that all of these interfaces may handle during peak busy hours
- The average bandwidth for each of the sessions
- The type of physical port to which these interfaces will be bound

Taking these factors into account and distributing your subscriber session across all available interfaces will allow you to configure your interfaces to optimally handle sessions without degraded performance.

IP range support is provided through `ranged_address` value. This value enables the pool of IPv4 addresses to support Enterprise HA on HA service to connect enhanced number of enterprise nodes. Refer HA Administration Guide for more information.

Use the `no bind address` command to delete a previously configured binding.

Example

The following command would bind the logical IP interface with the address of 192.168.3.1 to the HA service and specifies that a maximum of 600 simultaneous subscriber sessions can be facilitated by the interface/service at any given time.

```
bind address 192.168.3.1 max-subscribers 600
```

The following command disables a binding that was previously configured:

```
no bind address
```

The following command binds the range of IP addresses with HA service to be used with Enterprise HA support:

```
bind address 10.2.3.0/24
```
encapsulation

Configures Mobile IP (MIP) encapsulation types supported for a specific HA service.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
[ no ] encapsulation allow { gre | keyless-gre }
```

**no**
Disables MIP encapsulation types supported for specific HA service

**allow**
Allows encapsulation type for MIP data.

```
**gre**
Default: Enabled.
Specifies the use of Generic Routing Encapsulation (GRE) for MIP data.
```

```
**keyless-gre**
Default: Disabled.
Specifies the use of GRE without exchanging keys for MIP data.
```

**Usage**
Use to disable or re-enable the use of GRE encapsulation or Key-less encapsulation for MIP sessions.
In case of chassis HA operating with other vendor equipment, which does not support the 3GPP2 to exchange key, this command with **keyless-gre** keyword will make the chassis HA to accept MIP data with legacy GRE.

**Example**
To disable GRE for MIP sessions, enter the following command:

```
no encapsulation allow gre
```

To re-enable GRE for MIP sessions, enter the following command:

```
encapsulation allow gre
```

To enable key-less GRE for MIP sessions, enter the following command:
encapsulation allow keyless-gre
end

Exits the current configuration mode and returns to the Exec mode.

end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

`exit`

**Usage**

Use this command to return to the parent configuration mode.
fa-ha-spi

Configures the security parameter index (SPI) for specific HA service parameters.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
fa-ha-spi remote-address { fa_ip_address | fa_ip_address_mask } spi-number number {
encrypted secret enc_secret | secret secret } [ allow-fa-ha-auth-extension ] [ description string ] [ disallow-fa-ha-auth-extension ] [ hash-algorithm { hmac-md5 | md5 | rfc2002-md5 } ] [ replay-protection { nonce | timestamp [ timestamp-tolerance tolerance ] } ] [ timestamp-tolerance tolerance ]
```

```
no fa-ha-spi remote-address { fa_ip_address | fa_ip_address_mask } spi-number number
```

```
no
```

Disables the security parameter index (SPI) for specific HA service parameters.

```
remote-address { fa_ip_address | fa_ip_address_mask }
```

Specifies the IP address of the FA. `fa_ip_address` is entered using IPv4 dotted-decimal notation with CIDR for the subnet mask.

**Important:** The system supports unlimited peer FA addresses per HA but only maintains statistics for a maximum of 8,192 peer FAs. If more than 8,192 FAs are attached, older statistics are overwritten.

```
spi-number number
```

Specifies the SPI (number) which indicates a security context between the FA and the HA in accordance with RFC 2002.

`number` is an integer value from 256 through 4294967295.

```
encrypted secret enc_secret | secret secret
```

Configures the shared-secret between the HA service and the FA. The secret can be either encrypted or non-encrypted.

`encrypted secret enc_secret`: Specifies the encrypted shared key between the HA service and the FA. `enc_secret` must be an alphanumeric string of 1 through 236 characters that is case sensitive.
secret secret: Specifies the shared key between the HA service and the FA. secret must be an alphanumeric string of 1 through 236 characters that is case sensitive.

allow-fa-ha-auth-extension
Allows validation of FA HA Authentication extension.

description string
This is a description for the SPI. string must be an alphanumeric string of 0 through 31 characters.

hash-algorithm { hmac-md5 | md5 | rfc2002-md5 }
Default: hmac-md5
Specifies the hash-algorithm used between the HA service and the FA.
  hmac-md5: Configures the hash-algorithm to implement HMAC-MD5 per RFC 2002bis.
  md5: Configures the hash-algorithm to implement MD5 per RFC 1321.
  rfc2002-md5: Configures the hash-algorithm to implement keyed-MD5 per RFC 2002.

replay-protection { timestamp [ timestamp-tolerance tolerance ] | nonce }
Specifies the replay-protection scheme that should be implemented by the FA service for this SPI.
  nonce: Configures replay protection to be implemented using NONCE per RFC 2002.
  timestamp: Configures replay protection to be implemented using timestamps per RFC 2002.
  timestamp-tolerance: Specifies the allowable difference (tolerance) in timestamps that is acceptable. If the difference is exceeded, then the session will be rejected. tolerance is measured in seconds and can be configured to an integer from 1 and 65535. The default is 60.

Usage
An SPI is a security mechanism configured and shared by the HA service and the FA. Please refer to RFC 2002 for additional information.
Though it is possible for FAs and HAs to communicate without SPIs being configured, the use of them is recommended for security purposes. It is also recommended that a “default” SPI with a remote address of 0.0.0.0/0 be configured on both the HA and FA to prevent hackers from spoofing addresses.

Important: The SPI configuration on the HA must match the SPI configuration for the FA service on the system in order for the two devices to communicate properly.

A maximum of 2,048 SPIs can be configured per HA service.
Use the no version of this command to delete a previously configured SPI.

Example
The following command configures the FA service to use an SPI of 512 when communicating with an HA with the IP address 192.168.0.2. The key that would be shared between the HA and the FA service is q397F65. When communicating with this HA, the FA service will also be configured to use the rfc2002-md5 hash-algorithm.

    fa-ha-spi remote-address 192.168.0.2 spi-number 512 secret q397F65 hash-algorithm rfc2002-md5

The following command deletes the configured SPI of 400 for an HA with an IP address of 172.100.3.200:

    no fa-ha-spi remote-address 172.100.3.200 spi-number 400
**gre**

Configures Generic Routing Encapsulation (GRE) parameters.

**Product**

HA

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
gre { checksum | checksum-verify | reorder-timeout timeout | sequence-mode { none | reorder } | sequence-numbers }
```

```default gre { checksum | checksum-verify | reorder-timeout | sequence-mode | sequence-numbers }
```

**no**

Disables the specified functionality.

**default**

Sets or restores default value assigned for specified parameter.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>checksum</strong></td>
<td>disabled</td>
<td>Enables the introduction of the checksum field in outgoing GRE packets.</td>
</tr>
<tr>
<td><strong>checksum-verify</strong></td>
<td>disabled</td>
<td>Enables verification of the GRE checksum (if present) in incoming GRE packets.</td>
</tr>
<tr>
<td><strong>reorder-timeout timeout</strong></td>
<td>100</td>
<td>Configures the maximum number of milliseconds to wait before processing reordered out-of-sequence GRE packets. timeout must be an integer from 0 through 5000.</td>
</tr>
<tr>
<td>**sequence-mode { none</td>
<td>reorder }**</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>none</strong>: Disables reordering of incoming out-of-sequence GRE packets.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>reorder</strong>: Enables reordering of incoming out-of-sequence GRE packets.</td>
</tr>
</tbody>
</table>
sequence-numbers

Default: Disabled
Enables the insertion of sequence numbers into the GRE packets.

Usage
Use this command to configure how the HA service handles GRE packets.

Example
To set the maximum number of milliseconds to wait before processing reordered out-of-sequence GRE packets to 500 milliseconds, enter the following command:

```
gre reorder-timeout 500
```

To enable the reordering of incoming out of sequence GRE packets, enter the following command:

```
gre sequence-mode reorder
```

To enable the insertion or removal of GRE sequence numbers in GRE packets, enter the following command:

```
gre sequence-numbers
```
idle-timeout-mode

Configures the sessions idle-timer reset behavior.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
idle-timeout-mode { aggressive | handoff | normal } [ upstream-only ]
```

**default idle-timeout-mode**

```
default
Resets the idle timeout mode to the default settings.
```

```
aggressive
Resets the session idle timer only when MIP user data is detected. This is the default behavior.
```

```
handoff
Resets the session idle timer when MIP user data is detected and an inter-Access Gateway/FA handoff occurs.
```

```
normal
Resets the session idle timer when MIP user data is detected and any MIP control signaling occurs.
```

```
upstream-only
Only upstream user data (data from the mobile node) resets the idle timer for the session. This is disabled by default.
```

**Usage**

Use this command to set how the current HA service resets the idle timer for a session.

**Example**

To reset the idle timer whenever user data is detected or whenever an inter-Access Gateway/FA occurs, use the following command:

```
idle-timeout-mode handoff
```
ikev1

Configures IPSec Internet Key Exchange (IKE) parameters.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

`configure > context context_name > ha-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
ikev1 { aaa-context aaa_context_string | peer-fa IPAddress crypto-map crypto_map_string [ encrypted ] [ secret secret_string ] | skew-lifetime seconds }no ikev1 { aaa-context | peer-fa IPAddress | skew-lifetime }
```

no

Disables IPSec IKE parameters.

**aaa-context aaa_context_string**
Configures AAA context from which to retrieve IKE keys. Must be followed by the context name.

`aaa_context_string` is an alphanumeric string of 1 through 63 characters.

**peer-fa IPAddress**
Sets the IKE crypto-map for a peer Foreign Agent (FA).

`IPAddress` is IP address entered using IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

**crypto-map crypto_map_string**
Configures IKE crypto-map. Must be followed by the crypto-map name.

`crypto_map_string` is an alphanumeric string of 1 through 63 characters.

**encrypted** designates use of encryption

**secret secret_string** uses a secret that is shared between FA and HA. `secret_string` is an alphanumeric string of 1 through 256 characters.

**skew-lifetime seconds**
Configures the “S” lifetime Skew (in seconds). `seconds` is an integer from 1 through 65534. Default is 10.

**Usage**
Use this command to configure IPSec IKE parameters.

**Example**

```
ikev1 peer-fa 11.22.33.44 crypto-map er encrypted secret ert
**ip context-name**

Specifies name of the destination context to be applied to the subscribers.

This configuration overrides the local subscriber configuration as well as the return attributes sent by RADIUS. All calls coming to this HA service are assigned this destination context; the IP address is allocated from the specified IP pool or group that is configured in the context specified in the service.

**Product**

HA

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HA Service Configuration

```
classify > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
ip context-name name

{ default | no } ip context-name

name

Specifies the name of the context to assign the subscriber to once authenticated. *name* must be an alphanumeric string from 1 through 79 characters.

no

Usage**

Removes the current assigned context from the subscriber’s data. Set the name of the destination context to be applied to the subscribers.

**Example**

```
ip context-name sampleName
no ip context-name
```
ip local-port

Configures the local User Datagram Protocol (UDP) port for the Pi interface’s IP socket on which to listen for Mobile IP Registration messages.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

Syntax

ip local-port number

default ip local-port

default

Sets or restores the default value assigned for the IP local port.

number

Specifies the UDP port number.

number is an integer from 1 through 65535. Default is 434.

Usage

Specify the UDP port that should be used for communications between the FA service and the HA.

Example

The following command specifies a UDP port of 3950 for the HA service to use to communicate with the HA on the Pi interface:

    ip local-port 3950
ip pool

Specifies name of the IP address pool or group to use for subscriber IP address allocation. This configuration overrides the local subscriber configuration, as well as the return attributes sent by RADIUS. All calls coming to this HA service are assigned this destination context and an IP address is allocated from the specified IP pool or group that is configured in the context specified in the service.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

Syntax

```
ip pool name
{ default | no } ip pool

name
Specifies the logical name of the IP address pool. name must be an alphanumeric string of 1 through 31 characters.

no
Removes the specified IP address pool specified from the current context or disables the option for an IP pool.

default
Clears the IP address pool or group setting.
```

Usage
Define a pool of IP addresses for the context to use in assigning IPs for this service.

Example
The specifies name of the IP address pool or group to use for subscriber IP address allocation:

```
   ip pool pool1
```

The following command removes the specified IP address pool:

```
   no ip pool pool1
```
min-reg-lifetime

Configures Mobile IP session minimum registration lifetime, in seconds.

**Product**

HA

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
[ no | default ] min-reg-lifetime min_reg_lifetime_seconds
```

**no**

Disables the min registered lifetime.

**default**

Configures Mobile IP session minimum registration lifetime to default which is 0.

```
default
```

**min-reg-lifetime**

Configures Mobile IP session minimum registration lifetime.

```
min_reg_lifetime_seconds
```

Variable in the range between 1 and 65534.

**Usage**

Use this command to configure Mobile IP session minimum registration lifetime, in seconds, between 1 and 65534. Default is 0 seconds.

**Example**

Use the following command to configure mobile IP session to minimum registered life time to 100 seconds:

```
min-reg-lifetime 100
```
**mn-ha-spi**

Configures the security parameter index (SPI) between the HA service and the mobile node (MN).

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```bash
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
mn-ha-spi spi-number number [ description string ] [ encrypted secret enc_secret ] [ hash-algorithm { hmac-md5 | md5 | rfc2002-md5 } ] [ permit-any-hash-algorithm ] [ replay-protection { nonce | timestamp } ] [ secret secret ] [ timestamp-tolerance tolerance ]
```

```bash
no mn-ha-spi spi-number number
```

**spi-number number**

Specifies the SPI (number) which indicates a security context between the mobile node and the HA service in accordance with RFC 2002. `number` can be configured to an integer from 256 through 4294967295.

**description string**

This is a description for the SPI. `string` is an alphanumeric string of 1 through 31 characters.

**encrypted secret enc_secret | secret secret**

Configures the shared-secret between the HA service and the mobile node. The secret can be either encrypted or non-encrypted.

- **encrypted secret `enc_secret`**: Specifies the encrypted shared key between the HA service and the mobile node. `enc_secret` must be an alphanumeric string of 1 through 254 characters that is case sensitive.
- **secret `secret`**: Specifies the shared key between the HA service and the mobile node. `secret` must be an alphanumeric string of 1 through 127 characters that is case sensitive.

The `encrypted` keyword is intended only for use by the chassis while saving configuration scripts. The system displays the `encrypted` keyword in the configuration file as a flag that the variable following the `secret` keyword is the encrypted version of the plain text secret key. Only the encrypted secret key is saved as part of the configuration file.

**hash-algorithm { hmac-md5 | md5 | rfc2002-md5 }**

Default: hmac-md5

Specifies the hash-algorithm used between the HA service and the mobile node.

- **hmac-md5**: Configures the hash-algorithm to implement HMAC-MD5 per RFC 2002bis.
- **md5**: Configures the hash-algorithm to implement MD5 per RFC 1321.
- **rfc2002-md5**: Configures the hash-algorithm to implement keyed-MD5 per RFC 2002.
permit-any-hash-algorithm
Default: disabled
Allows verification of the MN-HA authenticator using all other hash-algorithms after failure with configured hash-algorithm. The successful algorithm is logged to aid in troubleshooting and used to create the MN-HA authenticator in the Registration Reply message.

replay-protection { nonce | timestamp }
Default: timestamp
Specifies the replay-protection scheme that should be implemented by the HA service for this SPI.
nonce: configures replay protection to be implemented using NONCE per RFC 2002.
timestamp: configures replay protection to be implemented using timestamps per RFC 2002.

timestamp-tolerance tolerance
Default: 60
Specifies the allowable difference (tolerance) in timestamps that is acceptable. If the difference is exceeded, then the session will be rejected. If this is set to 0, timestamp tolerance checking is disabled at the receiving end.
Tolerance is measured in seconds and can be configured to an integer from 0 through 65535.

Usage
An SPI is a security mechanism configured and shared by the HA service and the mobile node. Please refer to RFC 2002 for additional information.
Use the no version of this command to delete a previously configured SPI.

Example
The following command configures the HA service to use an SPI of 640 when communicating with a mobile node. The key that would be shared between the mobile node and the HA service is q397F65.

    mn-ha-spi spi-number 640 secret q397F65

The following command deletes the configured SPI of 400:

    no mn-ha-spi spi-number 400
nat-traversal

This command enables NAT traversal and also configures the forcing of UDP tunnels for NAT traversal.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

[ default | no ] nat-traversal [ force-accept ]

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
</table>
| Disables NAT traversal or disables forcing the acceptance of UDP tunnels for NAT traversal.

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
</table>
| Reset the defaults for this command.
Default: NAT traversal disabled, force-accept disabled.

<table>
<thead>
<tr>
<th>force-accept</th>
</tr>
</thead>
</table>
| This keyword configures the HA to accept requests when NAT is not detected but the Force (F) bit is set in the RRQ with the UDP Tunnel Request. By default this type of request is rejected if NAT is not detected.

Usage
Use this command to enable NAT traversal and enable the forcing of UDP tunnels for NAT traversal.

Example
The following command enables NAT traversal for the current HA service and forces the HA to accept UDP tunnels for NAT traversal:

```
nat-traversal force-accept
```
**optimize tunnel-reassembly**

Designates that tunnel reassembly optimization will be used for fragmented large packets passed between HA and FA. Default is disabled.

**Product**

HA

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HA Service Configuration

```bash
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
[ default | no ] optimize tunnel-reassembly
```

**Usage**

Enabling this functionality fragments large packets prior to encapsulation for easier processing.

Tunnel reassembly optimization is disabled by default.

**Important:** You should not use this command without first consulting Cisco Systems Technical Support. This command applies to very specific scenarios where packet reassembly is not supported at the far end of the tunnel. There are cases where the destination network may either discard the data, or be unable to reassemble the packets.

**Important:** This functionality works best when the HA service is communicating with an FA service running in a system. However, an HA service running in the system communicating with an FA from a different manufacturer will operate correctly even if this parameter is enabled.

**Example**

Use the `no` version of this command to disable tunnel optimization if enabled.

The following command enables tunnel reassembly optimization:

```
optimize tunnel-reassembly
```
per-domain statistics-collection

Enables per-domain statistics collection.

**Product**  
HA

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > Global Configuration > Context Configuration > HA Service Configuration  
```
configure > context context_name > ha-service service_name
```
Entering the above command sequence results in the following prompt:
```
[context_name]host_name(config-ha-service)#
```

**Syntax**
```
[ no ] per-domain statistics-collection
```

**Usage**

Use this command to enable per-domain statistics collection.

**Example**

The following command enables per-domain statistics collection.
```
per-domain statistics-collection
```
**policy bc-query-result**

Configure the binding cache (BC) query Response Result code.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
policy bc-query-result network-failure code
```

**default policy bc-query-result network-failure**

```
    network-failure code
```

**Usage**

Use this command to specify the type of response code to send in a P-MIP BC query result.

**Example**

The following command sets the P-MIP BC query result response code to 0xFFFE:

```
policy bc-query-result network-failure 0xFFFE
```
policy nw-reaching-fail

Specifies the action to take upon detection of an up-stream network-reachability failure.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

policy nw-reaching-fail { redirect ip_addr1 [ weight value ] [ ip_addr2 [ weight value ] ... ip_addr16 [ weight value ] ] reject [ use-reject-code { admin-prohibited | insufficient-resources } ] }

no policy nw-reaching-fail { redirect ip_addr1 ... ip_addr16 }

no

Deletes the network reachability policy completely or deletes the specified redirect addresses from the policy.

reject [ use-reject-code { admin-prohibited | insufficient-resources } ]

Upon network reachability failure reject all new calls for this context.

text-reject-code { admin-prohibited | insufficient-resources }: When rejecting calls send the specified reject code. If this keyword is not specified the admin-prohibited reject code is sent by default.

reject [ use-reject-code { admin-prohibited | insufficient-resources } ]

Upon network reachability failure reject all new calls for this context. If no reject code is specified, the HA sends a registration reply code of 81H (admin-prohibited).

text-reject-code { admin-prohibited | insufficient-resources }: Use the specified reject code when rejecting traffic.

admin-prohibited: When this keyword is specified and traffic is rejected, the error code 81H (admin-prohibited) is returned.

insufficient-resources: When this keyword is specified and traffic is rejected, the error code 82H (insufficient resources) is returned.

redirect ip_addr1 [ weight value ] [ ip_addr2 [ weight value ] ... ip_addr16 [ weight value ] ]

Upon network reachability failure redirect all calls to the specified IP address.

ip_addr1: This must entered using IPv4 dotted-decimal notation. Up to 16 IP addresses and optional weight values can be entered on one command line.
**weight value:** When multiple addresses are specified, they are selected in a weighted round-robin scheme. If a weight is not specified the entry is automatically assigned a weight of 1. `value` must be an integer from 1 through 10.

**Usage**

Use this command to set the action for the HA service to take upon a network reachability failure.

**Important:** Refer to the Context Configuration mode command `nw-reachability server` to configure network reachability servers.

**Important:** Refer to the Subscriber Configuration mode command `nw-reachability-server` to bind the network reachability to a specific subscriber.

**Important:** Refer to the `nw-reachability server server_name` keyword of the Context Configuration mode `ip pool` command to bind the network reachability server to an IP pool.

**Example**

To set the HA service to reject all new calls on a network reachability failure, enter the following command:

```
policy nw-reachability-fail reject
```

Use the following command to set the HA service to redirect all calls to the HA at IP address `192.168.100.10` and `192.168.200.10` on a network reachability failure:

```
policy nw-reachability-fail redirect 192.168.100.10 192.168.200.10
```
policy overload

Configures the overload policy within the HA service.

**Product**

HA

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
policyoverload { redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ] | reject[ use-reject-code { admin-prohibited | insufficient-resources } ] }

no policyoverload [ redirect address [ address2...address16 ] ]
```

Deletes a previously set policy or removes a redirect IP address.

- **overload**: Without any options deletes the complete overload policy from the PDSN service.
- **overload redirect address [address2 ... address16]**: deletes up to 16 IP addresses from the overload redirect policy. The IP addresses must be expressed in IP v4 dotted-decimal notation.

```
redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ]
```

This option enables a redirect policy for overloading conditions. When a redirect policy is invoked, the HA service rejects new sessions with a Registration Reply Code of 136H (unknown home agent address) and provides the IP address of an alternate HA. This command can be issued multiple times.

- **address**: The IP address of an alternate HA expressed in IP v4 dotted-decimal notation. Up to 16 IP addresses can be specified either in one command or by issuing the redirect command multiple times. If you try to add more than 16 IP addresses to the redirect policy, the CLI issues an error message. If you specify an IP address and weight that already exists in the redirect policy the new values override the existing values.

- **weight weight_num**: When multiple addresses are specified, they are selected in a weighted round-robin scheme. Entries with higher weights are more likely to be chosen. If a weight is not specified the entry is automatically assigned a weight of 1. weight_num must be an integer from 1 through 10.

```
reject [ use-reject-code { admin-prohibited | insufficient-resources } ]
```

This option causes any overload traffic to be rejected. If no reject code is specified, the HA sends a registration reply code of 81H (admin-prohibited).

- **use-reject-code { admin-prohibited | insufficient-resources }**: Use the specified reject code when rejecting traffic.
admin-prohibited: When this keyword is specified and traffic is rejected, the error code 81H (admin-prohibited) is returned.

insufficient-resources: When this keyword is specified and traffic is rejected, the error code 82H (insufficient resources) is returned.

Usage
The system invokes the overload policy if the number of calls currently being processed exceeds the licensed limit for the maximum number of sessions supported by the system.
The system automatically invokes the overload policy when an on-line software upgrade is started.
Use the no version of this command to restore the default policy.
The setting for overload policy is reject.

Example
The following command enables an overload redirect policy for the HA service that will send overload calls to either of two destinations with weights of 1 and 10 respectively:

```
policy overload redirect 192.168.100.10 weight 1 192.168.100.20 weight 10
```
reg-lifetime

Configures Mobile IP session registration lifetime.

Product

HA

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > HA Service Configuration configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

reg-lifetime time

{ default | no } reg-lifetime

no

Sets the registration lifetime to infinite.

default

Sets the registration lifetime to default value, 600.

time

Specifies the registration lifetime in seconds. 
time is an integer from 1 through 65534.

Usage

Use this command o limit a mobile node’s lifetime. If the mobile node requests a shorter lifetime than what is specified, it is granted. However, Per RFC 2002, should a mobile node request a lifetime that is longer than the maximum allowed by this parameter, the HA service will respond with the value configured by this command as part of the Registration Reply. The default is 600 seconds.

Example

The following command configures the registration lifetime for the HA service to be 2400 seconds:

reg-lifetime 2400

The following command configures an infinite registration lifetime for MIP calls:

no reg-lifetime
reverse-tunnel

Enables use of reverse tunneling for Mobile IP session. Use no reverse-tunnel command to disable. If disabled, mobile node (MN) packets are not tunneled to the HA in the reverse direction.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax
reverse-tunnel

{ default | no } reverse-tunnel

---

no

Indicates the reverse tunnel option is to be disabled. When omitted, the reverse tunnel option is enabled.

---

default

Indicates the reverse tunnel option is to be set to the default. When omitted, the reverse tunnel option is enabled.

Usage
Reverse tunneling involves tunneling datagrams originated by the mobile node to the HA service via the FA. When an MN arrives at a foreign network, it listens for agent advertisements and selects an FA that supports reverse tunnels. The MN requests this service when it registers through the selected FA. At this time, the MN may also specify a delivery technique such as Direct or the Encapsulating Delivery Style.

Among the advantages of using reverse-tunneling are that:
- All datagrams from the mobile node seem to originate from its home network
- The FA can keep track of the HA to which the mobile node is registered and tunnel all datagrams from the mobile node to its HA

Use the no version of this command to disable reverse tunneling. If reverse tunneling is disabled, and the mobile node does not request it, triangular routing will be performed.
Routing will be used.
The default setting is reverse tunnel enabled.

**Important:** If reverse tunneling is disabled on the system and a mobile node requests it, the call will be rejected with a reply code of 74H (reverse-tunneling unavailable).
Example

The following command disables reverse-tunneling support for the HA service:

```
no reverse-tunnel
```
**revocation**

Configures the Registration Revocation feature for a specific HA service.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```bash
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
revocation { enable | max-retransmission number | negotiate-i-bit | retransmission-timeout secs | send-nai-ext | trigger { handoff | idle-timeout } }
no revocation { enable | negotiate-i-bit | send-nai-ext | trigger { handoff | idle-timeout } }
```

```
default revocation [ enable ] [ max-retransmission ] [ negotiate-i-bit ] [ retransmission-timeout ] [ send-nai-ext ] [ trigger { handoff | idle-timeout } ]
default
```

```
no
```

Completely disables registration revocation on the HA, disables trigger handoff, or disables revocation on idle timer expiration.

```
default
```

Sets or restores the default value assigned for specified parameter.

```
enable
```

Enables the MIP registration revocation feature on the HA. When enabled, if revocation is negotiated with an FA and a MIP binding is terminated, the HA can send a Revocation message to the FA. This feature is disabled by default.

```
max-retransmission number
```

Default: 3
The maximum number of retransmissions of a Revocation message before the revocation fails. `number` must be an integer from 0 through 10.

```
negotiate-i-bit
```

Default: disabled
Enables the HA to negotiate the i-bit via PRQ/RRP messages and processes the i-bit revocation messages.
**retransmission-timeout secs**
Default: 3
The number of seconds to wait for a Revocation Acknowledgement from the FA before retransmitting the Revocation message. *secs* must be an integer from 1 through 10.

**send-nai-ext**
Default: off
Enables sending the NAI extension in the revocation message.

**trigger { handoff | idle-timeout }**

**handoff**: Default: Enabled
Triggers the HA to send a Revocation message to the FA when an inter-Access Gateway/FA handoff of the MIP session occurs. If this is disabled, the HA is never triggered to send a Revocation message.

**idle-timeout**: Default: Enabled
Triggers the HA to send a Revocation message to the FA when a session idle timer expires.

---

**Usage**

Use this command to enable or disable the MIP revocation feature on the HA or to change settings for this feature. Both the HA and the FA must have Registration Revocation enabled and FA/HA authorization must be in use for Registration Revocation to be negotiated successfully.

**Example**

The following command enables Registration Revocation on the HA:

```
revocation enable
```

The following command sets the maximum number of retries for a Revocation message to 10:

```
revocation max-retransmission 10
```

The following command sets the timeout between retransmissions to 3:

```
revocation retransmission-timeout 3
```

The behavior of send MIP revocation to FA is as follows:

- 1st retry: Retransmit in 3 seconds after previous MIP revocation send.
- 2nd retry: Retransmit in 6 seconds after previous MIP revocation send (9 seconds after sending initial MIP revocation).
- 3rd retry: Retransmit in 12 seconds after previous MIP revocation send (21 seconds after sending initial MIP revocation).
- 4th retry: Retransmit in 24 seconds after previous MIP revocation send (45 seconds after sending initial MIP revocation).
- 5th retry: Retransmit in 48 seconds after previous MIP revocation send (93 seconds after sending initial MIP revocation).

---

**Important**: The value of retransmission-timeout doubles. HA disconnects the session forcibly in 120 seconds after sending initial MIP revocation.
**setup-timeout**

The maximum time allowed for session setup in seconds. Default is 60 seconds.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

`configure > context context_name > ha-service service_name`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-ha-service)#`

**Syntax**

```
setup-timeout seconds

default setup-timeout

default

Sets or restores the default value.

seconds

Default: 60 seconds
The maximum amount of time (in seconds) to allow for setup of a session. `seconds` must be an integer from 1 through 1000000
```

**Usage**

Use this command to set the maximum amount of time allowed for setting up a session.

**Example**

To set the maximum time allowed for setting up a session to 5 minutes (300 seconds), enter the following command:

```
setup-timeout 300
```
**simul-bindings**

Specifies the maximum number of “care-of” addresses that can simultaneously be bound for the same user as identified by NAI and Home address.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
simul-bindings number
```

**default simul-bindings**

```
default

Sets or restores the default value.
```

```
number

Configures the maximum number of simultaneous “care-of” bindings that the HA service will maintain for any given subscriber.

is an integer from 1 through 3.
```

**Usage**

Per RFC 2002, the HA service creates a mobile binding record (MBR) for each subscriber session it is facilitating. Each MBR is associated with a care-of address. As the mobile node roams, it is possible that the session will be associated with a new care of address.

Typically, the HA service will delete an old binding and create a new one when the information in the Registration Request changes. However, the mobile could request that the HA maintain previously stored MBRs. This command allows you to configure the maximum number of MBRs that can be stored per subscriber if the requested. The default value is 3.

**Example**

The following command configures the HA service to support up to 4 MBRs per subscriber:

```
simul-bindings 4
```
### threshold dereg-reply-error

Sets an alarm or alert based on the number of de-registration reply errors per HA service.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```sh
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:
```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```sh
threshold dereg-reply-error high_thresh [ clear low_thresh ]
```

```sh
no threshold dereg-reply-error
```

- **no**
  - Deletes the alert or alarm.

- **high_thresh**
  - Default: 0
  - Specifies the high threshold number of de-registration reply errors that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to an integer from 0 through 100000.

- **clear low_thresh**
  - Default: 0
  - The low threshold number of de-registration reply errors that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to an integer from 0 through 100000.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to set an alert or an alarm when the number of de-registration reply errors is equal to or greater than a specified number of calls per second. Alerts or alarms are triggered for the number of de-registration reply errors on the following rules:

- **Enter condition:** Actual number of de-registration reply errors > High Threshold
- **Clear condition:** Actual number of de-registration reply errors < Low Threshold

**Example**

```sh
threshold dereg-reply-error 50
clear low_thresh
```
The following command configures a de-registration reply error threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```
threshold reg-reply-error 1000 clear 500
```
threshold init-rrq-rcvd-rate

Sets an alarm or alert based on the average number of calls setup per second for the context.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
threshold init-rrq-rcvd-rate high_thresh [ clear low_thresh ]
```

```
no threshold init-rrq-rcvd-rate
```

```
no
```

Deletes the alert or alarm.

```
high_thresh
```

Default: 0

Specifies the high threshold average number of calls setup per second that must be met or exceeded within the polling interval to generate an alert or alarm. `high_thresh` is an integer from 0 through 100000.

```
clear low_thresh
```

Default: 0

The low threshold average number of calls setup per second that must be met or exceeded within the polling interval to clear an alert or alarm. `low_thresh` is an integer from 0 through 100000.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to set an alert or an alarm when the average number of calls setup per second is equal to or greater than a specified number of calls per second.

Alerts or alarms are triggered for the number of calls setup per second based on the following rules:

- **Enter condition:** Actual number of calls setup per second is greater than the high threshold.
- **Clear condition:** Actual number of calls setup per second is less that the low threshold.

**Example**
The following command configures a number of calls setup per second threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```plaintext
threshold init-rrq-rcvd-rate 1000 clear 500
```
threshold ipsec-call-req-rej

Configures a threshold for the total IPSec calls request rejected.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
threshold ipsec-call-req-rej high_thresh [ clear low_thresh ]

no threshold ipsec-call-req-rej
```

**no**

Deletes the alert or alarm.

```
high_thresh
Default: 0
Specifies the high threshold number of IPSec call requests rejected per second that must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 1000000.
```

```
clear low_thresh
Default: 0
Specifies the low threshold number of IPSec call requests rejected per second that must be met or exceeded within the polling interval to clear an alert or alarm.
low_thresh is an integer from 0 through 1000000.
```

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to set an alert or an alarm when the number of IPSec call requests rejected is equal to or greater than a specified number per second. Alerts or alarms are triggered for the number of IPSec IKE requests on the following rules:

- **Enter condition:** Actual number of IPSec IKE requests is greater than the high threshold.
- **Clear condition:** Actual number of IPSec IKE requests is less than the low threshold.
Example

The following command configures a number of IPSec call requests rejected threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-call-req-rej 1000 clear 800
```
threshold ipsec-ike-failrate

Configures a threshold for the percentage of IPSec IKE failures.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

threshold ipsec-ike-failrate high_thresh [ clear low_thresh ]

no threshold ipsec-ike-failrate

---

no

Deletes the alert or alarm.

---

high_thresh

Default: 0

Specifies the high threshold percentage of IPSec IKE failures per second that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh is an integer from 0 through 100.

---

clear low_thresh

Default: 0

Specifies the low threshold percentage of IPSec IKE failures per second that must be met or exceeded within the polling interval to clear an alert or alarm.

low_thresh is an integer from 0 through 100.

---

**Important**: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

---

Usage

Use this command to set an alert or an alarm when the percentage of IPSec IKE failures is equal to or greater than a specified number per second.

Alerts or alarms are triggered for the percentage of IPSec IKE failures on the following rules:

- **Enter condition**: Percentage of IPSec IKE failures is greater than the high threshold.
- **Clear condition**: Percentage of IPSec IKE failures is less than the low threshold.
Example

The following command configures a percentage of IPSec IKE failures threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-ike-failrate 90 clear 80
```
threshold ipsec-ike-failures

Configures a threshold for the total IPSec IKE failures.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
threshold ipsec-ike-failures high_thresh [ clear low_thresh ]
```

```
no threshold ipsec-ike-failures
```

- **no**
  Deletes the alert or alarm.

- **high_thresh**
  Default: 0
  Specifies the high threshold number of IPSec IKE failures per second that must be met or exceeded within the polling interval to generate an alert or alarm.
  `high_thresh` is an integer from 0 through 1000000.

- **clear low_thresh**
  Default: 0
  Specifies the low threshold number of call IPSec IKE failures per second that must be met or exceeded within the polling interval to clear an alert or alarm.
  `low_thresh` is an integer from 0 through 1000000.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to set an alert or an alarm when the number of IPSec IKE failures is equal to or greater than a specified number per second.

Alerts or alarms are triggered for the number of IPSec IKE failures on the following rules:

- **Enter condition:** Actual number of IPSec IKE failures is greater than the high threshold.
- **Clear condition:** Actual number of IPSec IKE failures is less than the low threshold.
Example

The following command configures a number of IPSec IKE failures threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-ike-failures 1000 clear 800
```
**threshold ipsec-ike-requests**

Configures a threshold for the total IPSec IKE requests.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config- ha-service)#
```

**Syntax**

```
threshold ipsec-ike-requests high_thresh [ clear low_thresh ]
```

```
no threshold ipsec-ike-requests
```

- **no**
  Deletes the alert or alarm.

- **high_thresh**
  Default: 0
  Specifies the high threshold number of IPSec IKE requests per second that must be met or exceeded within the polling interval to generate an alert or alarm.
  *high_thresh* is an integer from 0 through 1000000.

- **clear low_thresh**
  Default: 0
  Specifies the low threshold number of call IPSec IKE requests per second that must be met or exceeded within the polling interval to clear an alert or alarm.
  *low_thresh* is an integer from 0 through 1000000.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to set an alert or an alarm when the number of IPSec IKE requests is equal to or greater than a specified number per second.

Alerts or alarms are triggered for the number of IPSec IKE requests on the following rules:

- **Enter condition:** Actual number of IPSec IKE failures is greater than the high threshold.
- **Clear condition:** Actual number of IPSec IKE failures is less than the low threshold.
Example

The following command configures a number of IPSec IKE requests threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```bash
threshold ipsec-ike-requests 1000 clear 800
```
threshold ipsec-tunnels-established

Configures a threshold for the total IPSec tunnels established.

Product

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

threshold ipsec-tunnels-established high_thresh [ clear low_thresh ]

no threshold ipsec-tunnels-established

no

Deletes the alert or alarm.

high_thresh

Default: 0

Specifies the high threshold number of IPSec tunnels established per second that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh is an integer from 0 through 1000000.

clear low_thresh

Default: 0

Specifies the low threshold number of call IPSec tunnels established per second that must be met or exceeded within the polling interval to clear an alert or alarm.

low_thresh is an integer from 0 through 1000000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of IPSec tunnels established is equal to or greater than a specified number per second.

Alerts or alarms are triggered for the number of IPSec tunnels established on the following rules:

• Enter condition: Actual number of IPSec tunnels established is greater than the high threshold.
• Clear condition: Actual number of IPSec tunnels established is less than the low threshold.
Example

The following command configures a number of IPSec tunnels established threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-tunnels-established 1000 clear 800
```
threshold ipsec-tunnels-setup

Configures a threshold for the total IPSec tunnels setup.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration
configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

```plaintext
[context_name]host_name(config-ha-service)#
```

**Syntax**

```plaintext
threshold ipsec-tunnels-setup high_thresh [ clear low_thresh ]

no threshold ipsec-tunnels-setup
```

**no**

Deletes the alert or alarm.

**high_thresh**

Default: 0
Specifies the high threshold number of IPSec tunnels setup per second that must be met or exceeded within the polling interval to generate an alert or alarm.

`high_thresh` is an integer from 0 through 1000000.

**clear low_thresh**

Default: 0
Specifies the low threshold number of call IPSec tunnels setup per second that must be met or exceeded within the polling interval to clear an alert or alarm.

`low_thresh` is an integer from 0 through 1000000.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to set an alert or an alarm when the number of IPSec tunnels setup is equal to or greater than a specified number per second.

Alerts or alarms are triggered for the number of IPSec tunnels setup on the following rules:

- **Enter condition:** Actual number of IPSec tunnels setup is greater than the high threshold.
- **Clear condition:** Actual number of IPSec tunnels setup is less than the low threshold.
Example

The following command configures a number of IPSec tunnels setup threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-tunnels-setup 1000 clear 800
```
threshold reg-reply-error

Set an alarm or alert based on the number of registration reply errors per HA service.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

threshold reg-reply-error high_thresh [ clear low_thresh ]

no threshold reg-reply-error

---

no

Deletes the alert or alarm.

---

high_thresh

Default: 0
Specifies the high threshold number of registration reply errors that must be met or exceeded within the polling interval to generate an alert or alarm. high_thresh is an integer from 0 through 100000.

---

clear low_thresh

Default: 0
Specifies the low threshold number of registration reply errors that must be met or exceeded within the polling interval to clear an alert or alarm. low_thresh is an integer from 0 through 100000.

---

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

---

Usage

Use this command to set an alert or an alarm when the number of registration reply errors is equal to or greater than a specified number of calls per second.

Alerts or alarms are triggered for the number of registration reply errors on the following rules:

- **Enter condition:** Actual number of registration reply errors is greater than the high threshold.
- **Clear condition:** Actual number of registration reply errors is less than the low threshold.

---

Example
The following command configures a registration reply error threshold of \(1000\) and a low threshold of \(500\) for a system using the Alarm thresholding model:

```bash
threshold reg-reply-error 1000 clear 500
```
threshold rereg-reply-error

Set an alarm or alert based on the number of re-registration reply errors per HA service.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
threshold rereg-reply-error high_thresh [ clear low_thresh ]
```

```
no threshold rereg-reply-error
```

- **no**
  Deletes the alert or alarm.

- **high_thresh**
  Default: 0
  Specifies the high threshold number of re-registration reply errors that must be met or exceeded within the polling interval to generate an alert or alarm. `high_thresh` is an integer from 0 through 100000.

- **clear low_thresh**
  Default: 0
  Specifies the low threshold number of re-registration reply errors that must be met or exceeded within the polling interval to clear an alert or alarm. `low_thresh` is an integer from 0 through 100000.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to set an alert or an alarm when the number of re-registration reply errors is equal to or greater than a specified number of calls per second.

Alerts or alarms are triggered for the number of re-registration reply errors on the following rules:

- **Enter condition:** Actual number of re-registration reply errors is greater than the high threshold.

- **Clear condition:** Actual number of re-registration reply errors is less than the low threshold.

**Example**
The following command configures a reregistration reply error threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```bash
threshold dereg-reply-error 1000 clear 500
```
wimax-3gpp2 interworking

Configures the interworking between WiMAX and 3GPP2 network at HA. This support provides handoff capabilities from 4G to 3G (PDSN) network access and vice-versa.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[(context_name)host_name(config-ha-service)]#

**Syntax**

```
[ no | default ] wimax-3gpp2 interworking
```

- **no**
  Disables the pre-configured interworking between WiMAX and 3GPP2 networks at HA level.

- **default**
  Configures the **WiMAX-3GPP2 interworking** to default setting: disabled.

**Usage**

Use this command to enable/disable the interworking between WiMAX and 3GPP2 network for seamless session continuity.

This functionality provides HA support for both 4G and 3G technology HA (WiMAX HA and PDSN/HA) for handoff from 4G and 3G network access (ASN GW/FA and PDSN/FA) and vice-versa.

**Important:** Use this command in conjunction with the `authentication aaa-distributed-mip-keys required` command.

**Example**

The following command enables the interworking for a subscriber between WiMAX and 3GPP2 network.

```
wimax-3gpp2 interworking
```
Chapter 157
HD Storage Policy Configuration Mode Commands

The HD Storage Policy Configuration Mode is used to configure directory name and file parameters for Diameter record files being stored on the HD storage device.

Mode

Exec > Global Configuration > HD Storage Policy Configuration

configure > hd storage-policy policy_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hd-storage-policy)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
directory

Configures the name of the directory on the HD storage drive where Diameter records are stored.

**Product**
- HSGW
- P-GW
- SAEGW
- S-GW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > HD Storage Policy Configuration

```
configure > hd storage-policy policy_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hd-storage-policy)#
```

**Syntax**

```
directory name dir_name

default directory name
```

- **default**
  Returns the command to its default setting of using the policy name as the directory name.

- **name dir_name**
  Specifies the name to be applied to the directory. *dir_name* must be an alphanumeric string of 1 through 63 characters.
  When configured, the actual directory path is:

  `/hd-raid/records/<record-type>/<dir_name>/`

  So if the directory name variable is entered as “sgwpgw”, the path is:

  `/hd-raid/records/acr/sgwpgw`

**Usage**

Use this command to name a directory on the HD storage drive where Diameter records are to be stored.

**Example**

The following command configures a directory named *cdr1*:

```
directory name cdr1
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
file

Configures file parameters for Diameter records being stored on the HD storage device.

Product
HSGW
P-GW
SAEGW
S-GW

Privilege
Administrator

Mode
Exec > Global Configuration > HD Storage Policy Configuration
configure > hd storage-policy policy_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hd-storage-policy)#

Syntax

file { format acr { custom1...custom10 } | name { extension string | prefix string } | rotation { record-count num | time-interval sec | volume mb mbytes } }

default file { format acr | name prefix | rotation { record-count | time-interval | volume } }

no file { extension | rotation { record-count | time-interval } }

---

default

Returns the command to the default settings for the specified keywords.

---

no

Removes the configuration for the specified parameters.

---

format acr { custom1...custom10 }

Default: custom1
Specifies the file format used when storing records on the HD storage device. custom1 is a vendor-specific file format.

---

name { extension string | prefix string }

Specifies a string to be pre-pended or appended to the filenames. By default, the policy name is used for the prefix.

extension string: Specifies a file extension to append to the filename. string must be an alphanumeric string of 1 through 10 characters.

prefix string: Specifies a file prefix to append to the filename. string must be an alphanumeric string of 1 through 63 characters. This parameter replaces the policy name used by default.
rotation { record-count num | time-interval sec | volume mb mbytes }

Specifies the triggers that prompt file rotation on the HD storage drive. All options can be configured and upon reaching any of the thresholds, file rotation is initiated.

- **record-count num**: File rotation occurs when the number of records reaches the number configured in this keyword. *num* must be an integer from 1000 through 65000. Default = 10000
- **time-interval sec**: File rotation occurs at time intervals (in seconds) configured by this keyword. *sec* must be an integer from 30 through 86400. Default = 3600 (1 hour)
- **volume mb mbytes**: File rotation occurs when the record volume exceeds the value (in megabytes) configured by this keyword. *mbytes* must be an integer from 2 through 40. Default = 4

### Usage

Use this command to configure file parameters for Diameter records being stored on the HD storage device.

### Example

The following command sets the file rotation thresholds for files being stored on the HD storage device:

```plaintext
file rotation volume mb 4
file rotation record-count 15000
file rotation time-interval 7200
```

The following command replaces the policy name as the prefix of all files being stored through this policy with the prefix *sgw*:

```plaintext
file name prefix sgw
```
A new service “henbgw-access-service” is defined under Context Configuration Mode to initialize HeNB-GW functionality. This service configuration controls the S1-MME interface for communication between HeNB-GW to HeNB(s). HeNBs connect to the S1-MME bind address configured in this service.

**Mode**

Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

```bash
configure > context context_name > henbgw-access-service service_name
```

Entering the above command sequence results in the following prompt:

```bash
[context_name]host_name(config-henbgw-access-service)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
associate henbgw-network-service

Associates a previously configured HeNB-GW Network service to the this HeNB-GW Access service. An HeNB-GW Network service must be configured in Context Configuration mode before using this configuration.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

configure > context context_name > henbgw-access-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-access-service)#

Syntax

associate henbgw-network-service svc_name [ context context_name ]

no associate henbgw-network-service

no

Removes the associated HeNB-GW Network service from this HeNB-GW Access service configuration.

svc_name

Identifies the name of the pre-configured HeNB-GW Network service to associate with this HeNB-GW Access service.

svc_name is an alphanumeric string of 1 through 63 characters.

context context_name

Identifies the name of the context to which the HeNBGW service belongs.

context_name is an alphanumeric string of 1 through 79 characters.

Usage

Use this command to bind/associate a pre-configured HeNB-GW Network service to the this HeNB-GW Access service. The HeNB-GW Network service can be configured in Context configuration mode. The associate configuration is used to establish associations with other helper services in general.

Example

Following command associates an HeNB-GW Network service named henb-network with specific HeNB-GW Access service.

associate henbgw-network-service henb-network
associate sctp-param-template

Associates a previously configured SCTP Parameter Template to the this HeNB-GW Access service. A SCTP Parameter Template must be configured globally before using this configuration.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Syntax

associate sctp-param-template template_name

no associate sctp-param-template

no

Removes the associated SCTP Parameter Template from this HeNB-GW Access service configuration.

template_name

Identifies the name of the pre-configured SCTP Parameter Template to associate with this HeNB-GW Access service.

模板_name is an alphanumeric string of 1 through 63 characters.

Usage

Use this command to bind/associate a pre-configured SCTP Parameter Template to the this HeNB-GW Access service. The SCTP Parameter Template can be configured global mode. The associate configuration is used to establish associations with other helper services in general.

Example

Following command associates an SCTP Parameter Template named sctp_tmpl with specific HeNB-GW Access service.

associate sctp-param-template sctp_tmpl
associate x2gw-service

This command Configures x2gw-service for this HENBGW ACCESS service.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

configure > context context_name > hembgw-access-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hembgw-access-service)#

Syntax

associate x2gw-service associate_x2gw-service_name context context_name

no associate x2gw-service

no
Removes the association of x2gw-service interface from this HeNB-GW Access service configuration.

associate_x2gw-service_name
Name of the service that will be used by this HENBGW ACCESS service to associate with. Name of the string is an alphanumeric, 1 through 63 characters.

context_name
Name of the context that will be used by this HENBGW ACCESS service to associate with. Name of the string is an alphanumeric, 1 through 79 characters.

Usage
Use this command to associate x2gw-service with HENBGW Access service.

Example

Following command associates an x2gw-service with specific HeNB-GW Access service with name gate123:

associate x2gw-service gate123
bind s1-mme

Binds the pre configured HeNB-GW Access Service to the IP address of the S1-MME interface.

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

```text
configure > context context_name > henbgw-access-service service_name
```

Entering the above command sequence results in the following prompt:

```text
[context_name]host_name(config-henbgw-access-service)#
```

**Syntax**

```text
bind s1-mme { ipv4-address | ipv6-address } ip_addr max-subscribers max_sub
no bind s1-mme
```

- **no**
  Removes the binding of S1-MME interface from this HeNB-GW Access service configuration.

- **ip_addr**
  Identifies the IP address of the S1-MME interface to associate with this HeNB-GW Access service. `addr_val` must be entered in the IPv4 (dotted decimal notation) or IPv6 (: / :: notation).

- **max-subscribers max_sub**
  Configures the maximum number of subscribers HENBGW ACCESS service can support. `max_sub` is an integer ranging from 0 through 4000000.

**Usage**

Use this command to bind the pre configured IPv4 address of the S1-MME interface to the HeNB-GW Access Service.

**Example**

Following command binds the S1-MME interface having 192.68.111.61 IP address with specific HeNB-GW Access service.

```text
bind s1-mme ipv4-address 192.68.111.61
```
csg-optimized-paging

Configures the support for Paging Optimization Function on this HeNB-GW Access service based on the CSG-ID in the Paging message.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

cfg-configure > context context_name > hnbgw-access-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hnbgw-access-service)#

Syntax

[ no ] csg-optimized-paging

no

Removes the paging optimization function from this HeNB-GW Access service configuration.

Usage

Use this command to enable the CSG-ID based paging optimization function to the HeNB-GW Access Service.

Example

Following command enables the CSG-ID based paging optimization on a specific HeNB-GW Access service.

csg-optimized-paging
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
exit

**Usage**
Use this command to return to the parent configuration mode.
**mme-id**

Configures the MME ID for this HeNB-GW Access service. For this configuration, MME Group ID and MME Code has to be configured.

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

configure > context context_name > henbgw-access-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-access-service)#

**Syntax**

```
mme-id group-id mme_group_id mme-code mme_code

no mme-id
```

**no**
Removes the configured MME ID from this HeNB-GW Access service configuration.

```
mme_group_id
```

Identifies the MME Group ID which must be entered as an integer between 32768 and 65535.

```
mme_code
```

Identifies the MME code which is again an integer value between 0 and 255.

**Usage**

Use this command to configure the MME Identifier which includes the MME Group ID and MME Code for this HeNB-GW Access service. MME ID configuration is required, because it is the same ID which HeNB-GW sends in response messages to HeNBs.

⚠️ **Caution:** Changing the MME ID is a disruptive operation. HeNB-GW service is restarted on any change.

**Example**

Following command configures 32770 as the MME Group ID and 105 as MME code on a specific HeNB-GW Access service.

```
mme-id group-id 32770 mme-code 105
```
**plmn**

Configures the PLMN identifier for this HeNB-GW Access service. Other identifiers that are configured along with the PLMN include the MCC and MNC values too.

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

`configure > context context_name > hembgw-access-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hembgw-access-service)#
```

**Syntax**

```
[ no ]plmn id mcc mcc_val mnc mnc_val
```

- **no**
  Removes the existing PLMN configuration from this HeNB-GW Access service configuration.

- **mcc_val**
  Identifies the mobile country code for the IMSI which must be entered between 100 and 999 as a string of size 3.

- **mnc_val**
  Identifies the Mobile Network Code which is a value between 00 and 999, as a string of size 2 to 3.

**Usage**

Use this command to configure the PLMN related configuration for this HeNB-GW Access service.

**Example**

Following command configures 123 as the MCC value and 456 as the MNC value as part of the PLMN configuration for this HeNB-GW Access service.

```
plmn id mcc 123 mnc 456
```
s1-mme ip qos-dscp

This command configures the quality of service (QoS) differentiated service code point (DSCP) marking for IP packets sent out on the S1-MME interface, from the HeNB-GW to the HeNB(s).

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

configure > context context_name > henbgw-access-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-access-service)#

Syntax

```plaintext
s1-mme ip qos-dscp { af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | cs0 | cs1 | cs2 | cs3 | cs4 | cs5 | cs6 | cs7 | ef }

default s1-mme ip qos-dscp
```

```plaintext
qos-dscp { af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | cs0 | cs1 | cs2 | cs3 | cs4 | cs5 | cs6 | cs7 | ef }

Default: af11

Specifies the DSCP for the specified QoS traffic pattern. qos-dscp can be configured to any one of the following:

af11: Assured Forwarding 11 per-hop-behavior (PHB)
af12: Assured Forwarding 12 PHB
af13: Assured Forwarding 13 PHB
af21: Assured Forwarding 21 PHB
af22: Assured Forwarding 22 PHB
af23: Assured Forwarding 23 PHB
af31: Assured Forwarding 31 PHB
af32: Assured Forwarding 32 PHB
af33: Assured Forwarding 33 PHB
af41: Assured Forwarding 41 PHB
af42: Assured Forwarding 42 PHB
af43: Assured Forwarding 43 PHB
be: Best effort forwarding PHB
```

```plaintext
cs0: Designates use of Class Selector 0 PHB. This is same as DSCP Value BE
cs1: Designates use of Class Selector 1 PHB
cs2: Designates use of Class Selector 2 PHB
cs3: Designates use of Class Selector 3 PHB
cs4: Designates use of Class Selector 4 PHB
cs5: Designates use of Class Selector 5 PHB
cs6: Designates use of Class Selector 6 PHB
cs7: Designates use of Class Selector 7 PHB
```
**Usage**

DSCP levels can be assigned to specific traffic patterns to ensure that data packets are delivered according to the precedence with which they are tagged. The diffserv markings are applied to the IP header of every subscriber data packet transmitted over the S1-MME interface(s).

**Example**

The following command sets the DSCP-level for data traffic sent over the S1-MME interface to `af12`:

```
s1-mme ip qos-dscp af12
```

**ef:** Expedited forwarding PHB
s1-mme sctp port

This command configures the local Stream Control Transmission Protocol (SCTP) port used for binding the SCTP socket to communicate with the HeNBs over S1-MME interface.

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

configure > context context_name > hembgw-access-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hembgw-access-service)#

**Syntax**

```
s1-mme sctp port port_num

default s1-mme sctp port
```

**default**
Sets the SCTP port to the default value of 36412 to communicate with the HeNBs using S1-MME interface.

**port_num**
Specifies the SCTP port number to communicate with the HeNBs using S1-MME interface as an integer from 1 through 65535. Default: 36412

**Usage**

Use this command to assign the SCTP port with SCTP socket to communicate with the HeNB using S1AP. Only one SCTP port can be associated with one MME service.

**Example**

The following command sets the default SCTP port number 699 for to interact with Home eNodeB using S1AP on S1-MME interface:

```
default s1-mme sctp port
```
s1u-relay

This command configures the S1-U Relay service for the HeNB-GW Access service. The user enters in the S1-U Relay configuration mode using this command.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration
configure > context context_name > henbgw-access-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-access-service)#

Syntax
[no] s1u-relay

no

Removes the S1-U Relay service function from this HeNB-GW Access service configuration.

Usage
Use this command to enable the S1-U Relay service function to the HeNB-GW Access Service. S1-U relay service is disabled by default.

Example
Following command enables the S-U Relay service on a specific HeNB-GW Access service.

s1u-relay
security-gateway

This command configuration defines the IPv4 address to be used as the connection point for establishing IKEv2 sessions and specify the crypto template to use for the security gateway (SeGW) for the HeNB-GW Access service.

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

```
configure > context context_name > hengw-access-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hengw-access-service)#
```

**Syntax**

```
security gateway bind ipv4-address ip_addr crypto-template template_name [ context ctxt_name ]
```

```
no security gateway bind
```

<table>
<thead>
<tr>
<th><strong>no</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Removes the security gateway related configuration associated with this HeNB-GW Access service configuration.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>ip_addr</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Identifies the security gateway address used for this HeNB-GW Access service. It must be entered in dotted decimal notation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>template_name</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Identifies the crypto template name for security gateway for this HeNB-GW Access service. It must be entered a string of size 0 to 127.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>ctxt_name</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Identifies the context name where crypto template is defined for this HeNB-GW Access service. It must be entered a string of size 1 to 79.</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to configure the security gateway (SeGW) related configuration for this HeNB-GW Access service. SeGW configuration includes crypto template configuration as part of IPSec settings, therefore if the crypto-template is defined in a different context than the current HeNB-GW Access service, the context name has to be specified.

**Example**
Following command configures 192.68.111.15 as the SeGW address and crypto-temp as the crypto template name on a specific HeNB-GW Access service.

```
security gateway bind ipv4-address 192.68.111.15 crypto-template crypto-temp
```
timeout

Configures the the maximum duration of the session for this HeNB-GW Access service, in seconds, before system automatically reports/terminates the session.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

command > context context_name> henbgw-access-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-access-service)#

Syntax

timeout long-duration dur action { detection | disconnect }

no timeout long-duration

no

Removes the currently setup maximum duration of session.

dur

Specifies the number of seconds for the session’s timeout duration, before system automatically terminates the session or a defined action is to be taken.

dur is an integer from 1 through 2147483647. Default: 0

Usage

Use this command to configure the maximum duration of the session, in seconds, before system automatically reports/terminates the session of this HeNB-GW Access service.

Example

The following command sets the timeout duration of 60 seconds for a particular HeNB-GW Access service and disconnect the session:

    timeout long-duration 60 action disconnect
Chapter 159
HeNB-GW Network Service Configuration Mode Commands

A new service "henbgw-network-service" is defined under the Context configuration mode in order to support HeNB-GW functionality. This service configuration controls the S1-MME interface functionality between HeNB-GW and MME node.

Mode

Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

configure > context context_name > henbgw-network-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-network-service)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**anr-info-retrieval**

This command enables the HeNB-GW to intercept and respond to the Automatic Neighbor Relation (ANR) related SON messages with the requested information.

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

```
configure > context context_name > henbgw-network-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-henbgw-network-service)#
```

**Syntax**

```
[ no | default ] anr-info-retrieval
```

- **no**
  Removes the ANR information retrieval related function from this HeNB-GW Network service configuration.

- **default**
  Sets/Restores the default value assigned for the ANR information retrieval related function from the configured HeNB-GW Network service.

**Usage**

Use this command to enable the ANR information retrieval function to the HeNB-GW Network Service.

**Example**

Following command enables the ANR information retrieval function on a specific HeNB-GW Network service.

```
anr-info-retrieval
```
associate sctp-param-template

Associates a previously configured SCTP Parameter Template to the this HeNB-GW Network service. A SCTP Parameter Template must be configured globally before using this configuration.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Syntax

associate sctp-param-template template_name

no associate sctp-param-template

template_name

Identifies the name of the pre-configured SCTP Parameter Template to associate with this HeNB-GW Network service.

Usage
Use this command to bind/associate a pre-configured SCTP Parameter Template to the this HeNB-GW Network service. The SCTP Parameter Template can be configured global mode. The associate configuration is used to establish associations with other helper services in general.

Example
Following command associates an SCTP Parameter Template named sctp_tmpl with specific HeNB-GW Network service.

associate sctp-param-template sctp_tmpl
default-paging-drx

This command is used to configure the Default paging DRX value that is sent to the MME(s) in the S1 SETUP request message.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

configure > context context_name > hengbw-network-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-network-service) #

Syntax

default-paging-drx { v128 | v256 | v32 | v64 }

default default-paging-drx

default

Sets/Restores the default value assigned for Default-Paging-DRX for the configured HeNB-GW Network service.

Any one of the following DRX values can be configured:

- v128: Designates use of Paging DRX v128.
- v256: Designates use of Paging DRX v256.
- v32: Designates use of Paging DRX v32.
- v64: Designates use of Paging DRX v64.

Usage

Use this command to configure the Default Paging DRX value for this HeNB-GW Network service.

Example

Following command configures v256 as the Default Paging DRX value on a specific HeNB-GW Network service.

default-paging-drx v256
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

configure > context context_name > henbgw-network-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-network-service)#

Syntax

dend

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

configure > context context_name > hnbgw-network-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-network-service)#

Syntax

exit

Usage

Use this command to return to the parent configuration mode.
**logical-enb**

This command enables the configuration of one or more logical eNodeBs within the HeNB-GW.

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

```bash
configure > context context_name > henbgw-network-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-henbgw-network-service)#
```

**Syntax**

```bash
logical-enb global-enb-id plmn id mcc mcc_val mnc mnc_val { home-enb-id henb_id | macro-enb-id menb_id [ -noconfirm ] }

[ no ] logical-enb global-enb-id plmn id mcc mcc_val mnc mnc_val { home-enb-id henb_id | macro-enb-id menb_id }
```

---

**no**
Removes the configured logical eNodeB from this HeNB-GW Network service configuration.

**mcc mcc_val**
Identifies the mobile country code for the IMSI which must be entered between 100 and 999, as a string of size 3.

**mnc mnc_val**
Identifies the Mobile Network Code which is a value between 00 and 999, as a string of size 2 to 3.

**home-enb-id henb_id**
Identifies the Home eNodeB ID which is an integer from 1 to 268435455.

**macro-enb-id menb_id**
Identifies the Macro eNodeB ID which is again an integer value between 1 and 1048575.

**-noconfirm**
Creates a new HeNB-GW network service without prompting for confirmation.
Usage

Use this command for the configuration of one or more logical eNodeBs within the HeNB-GW. The Logical eNodeB configuration can be used to support load balancing within a pool of TAIs (i.e. Multiple logical eNodeBs can service calls connecting from a specific set of TAIs). It can also be used to create and support disjoint serving areas, that is each logical eNodeB will serve a different set of TAIs.

At least one logical eNodeB configuration is required to START an HeNB-GW Network service.

⚠️ Caution: Deleting or modifying any of the parameters for a fully configured logical eNodeB is a disruptive operation. It will result in the termination of SCTP connections to MMEs from that logical eNodeb.

Example

Following command configures a logical eNodeB having Home eNodeB ID as 1000 on a specific HeNB-GW Network service.

```bash
logical-enb global-enb-id plmn id mcc 123 mnc 456 home-enb-id 1000
```
paging-rate-control

This command is used to configure the Paging-Rate-Control which determines the maximum number of paging messages per second which an HeNB-GW can handle received from the MME(s).

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

configure > context context_name > henbgw-network-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-network-service)#

Syntax

paging-rate-control number_of_msg

no paging-rate-control

no

Removes the configured rate of paging messages from this HeNB-GW Network service configuration.

number_of_msg

Identifies the number of paging messages to be handled by the HeNBGW service per second. This number must be entered as an integer between 1 and 65535 (min 1 and max 65535).

Usage

Use this command to configure the number of paging messages per second to be handled by this HeNB-GW Network service. MME ID configuration is required, because it is the same ID which HeNB-GW sends in response messages to HeNBs.

This parameter is not part of logical-enb configuration and therefore it would include paging messages received from all the MMEs to which this HeNB-GW is connected on the network side.

Important: Paging messages exceeding the configured rate are dropped. Total Paging and Dropped Statistics is updated in the logs.

Example

Following command configures 32770 as the number of paging messages per second to be handled on a specific HeNB-GW Network service.

    paging-rate-control 32770
**pws**

This command sets values for parameters related to public warning system feature.

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

```
configure > context context_name > henbgw-network-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-henbgw-network-service)#
```

**Syntax**

```
pws { kill-request-timeout kill_req_timeout_seconds | restart-indication-timeout restart_ind_timeout_seconds | warning-request-timeout warn_req_timeout_seconds }

default pws { kill-request-timeout | restart-indication-timeout | warning-request-timeout }
```

**Usage**

Use this command to set the values for parameters related to public warning system feature for this HeNB-GW Network service.

**Example**

Following command configures the Warning request timeout value to 100 seconds.

```
pws warning-request-timeout 100
```
s1ap-max-retransmissions

This command configures the number of times node level S1AP message is retransmitted towards MME.

**Product**

HeNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

```plaintext
configure > context context_name > henbgw-network-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-henbgw-network-service)#
```

**Syntax**

```plaintext
s1ap-max-retransmissions number_of_retries

default s1ap-max-retransmissions
```

**default**

Configures the default number of S1AP retransmissions for this HeNB-GW Network service configuration. Default number of retransmissions is 4.

**number_of_retries**

Identifies the number of S1AP retransmissions to be configured. This number must be entered as an integer between 1 and 5.

**Usage**

Use this command to configure the maximum number of Node level S1AP retransmissions for this HeNB-GW Network service.

⚠️ **Caution:** Configuring s1ap-max-retransmissions to 0 will disable the S1AP retransmission support.

**Example**

Following command configures default (which is also 4) S1AP retransmission on a specific HeNB-GW Network service.

```plaintext
default s1ap-max-retransmissions
```
s1ap-retransmission-timeout

This command configures the timeout interval to support Node Level S1AP retransmissions if there is no response received from the peer (MME).

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

configure > context context_name > hbgw-network-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hbgw-network-service)#

Syntax

s1ap-retransmission-timeout number_of_secs

default s1ap-retransmission-timeout

default

Configures the default S1AP retransmission timeout for this HeNB-GW Network service configuration.
Default retransmission timeout is 60 seconds.

number_of_secs

Identifies the number seconds as the S1AP retransmission timeout to be configured. This number must be entered as an integer between 1 and 600.

Usage
Use this command to configure the timeout interval to support Node Level S1AP retransmissions for this HeNB-GW Network service.

Example
Following command configures 100 as the S1AP retransmission timeout on a specific HeNB-GW Network service.

s1ap-retransmission-timeout 100
Chapter 160
HSGW Service Configuration Mode Commands

The HSGW Service Configuration Mode is used to create and manage a configuration allowing the HRPD Serving Gateway (HSGW) to communicate, send and receive call data, and session flows to/from a evolved Access Network/evolved Packet Control Function (eAN/ePCF) in an eHRPD network.

**Mode**

Exec > Global Configuration > Context Configuration > HSGW Service Configuration

`configure > context context_name > hsgw-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
a11-signalling-packets

Enables the DSCP marking feature for IP headers carrying outgoing A11-signalling A11 packets (such as RRP, RU, SU).

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
a11-signalling-packets ip-header-dscp value

[ default | no ] all-signalling-packets ip-header-dscp
```

**Usage**

Use this command to enable or disable the DSCP marking feature for IP headers carrying outgoing A11-signalling A11 packets. DSCP marking is disabled by default.

**Example**

The following command configures the HSGW service to support DSCP marking for IP headers on A11 packets in outgoing A11-signalling traffic:

```
a11-signalling-packets ip-header-dscp 0x21
```
associate

Associates accounting policies and QCI-QoS mapping parameters with this HSGW service.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

associate { accounting-policy name | qci-qos-mapping name }

no associate { accounting-policy [ name ] | qci-qos-mapping }

no

Removes the specified associated policy or mapping from the service.

accounting-policy name

Specifies an existing accounting policy to associate with the HSGW service as an alphanumeric string of 1 through 63 characters.

qci-qos-mapping name

Specifies an existing QCI-QoS mapping configuration as an alphanumeric string of 1 through 63 characters. QCI-QoS mapping is configured through the qci-qos-mapping command in the Global Configuration Mode.

Usage

Use this command to associate an accounting policy with the HSGW service.

Example

The following command associates an accounting policy named acct2 to the HSGW service:

associate accounting-policy acct2
bind address

Binds the service to a logical IP interface serving as the A10 interface and specifies the maximum number of subscribers that can access this service over the configured interface.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

bind address ip_address [ max-subscribers num ]

no bind address

no

Removes the interface binding from this service.

address ip_address

Specifies the IP address of the A10/A11 interface in IPv4 dotted-decimal notation.

max-subscribers num

Specifies the maximum number of subscribers that can access this service on this interface as an integer from 0 through 2500000. Default: 2500000

Important: The maximum number of subscribers supported is dependant on the license key installed and the number of active PSCs in the system. A fully loaded system with 13 active PSCs can support 3,000,000 total subscribers. Refer to the license key command and the Usage section (below) for additional information.

Usage

Associate the HSGW service to a specific logical IP address. The logical IP address or interface takes on the characteristics of an A10/A11 interface that provides the session connectivity to/from an eAN/PCF. Only one interface can be bound to a service. The interface should be configured prior to issuing this command.

This command also sets a limit as to the number of simultaneous subscribers sessions that can be facilitated by the service/interface at any given time.

When configuring the max-subscribers option, be sure to consider the following:

- The total number of A10/A11 interfaces you will configure
- The total number of subscriber sessions that all of the configured interfaces may handle during peak busy hours
• An average bandwidth per session multiplied by the total number of sessions
• The type of physical port (10/100Base-T or 1000Base-Tx) that these interfaces will be bound to

Taking these factors into account and distributing your subscriber session across all available interfaces will allow you to configure your interfaces to optimally handle sessions without degraded performance.

**Example**

The following command would bind the logical IP interface with the address of 112.334.556.778 to the HSGW service and specifies that a maximum of 200,000 simultaneous subscriber sessions can be facilitated by the interface/service at any given time:

```
bind address 112.334.556.778 max-subscribers 200000
```
**context-retention-timer**

Configures the maximum number of consecutive seconds that a UE session context (which includes the LCP, authentication and A10 session context for a given UE) is maintained by the HSGW before it is torn down.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

`configure > context context_name > hsgw-service service_name`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-hsgw-service)#`

**Syntax**

```
context-retention-timer timeout [ sec ]
[ default | no ] context-retention-timer timeout
```

- **default**
  Disables the timer.

- **no**
  Disables the timer.

- **timeout [ sec ]**
  Specifies the amount of time (in seconds) that the session context is maintained before it is disassembled as an integer from 1 through 3600. Default: 60.
  In Release 15.0 and later, the maximum value has been increased to 86400 seconds (24 hours).

**Usage**
Use this command to configure a timer to retain session contexts for a specified amount of time before disassembling it.

**Example**
The following command allows the HSGW to maintain session contexts for 120 seconds before tearing them down:

```
context-retention-timer timeout 120
```
data-available-indicator

Enables sending the Data Available Indicator extension in A10/A11 Registration Reply messages.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

`configure > context context_name > hsgw-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
data-available-indicator
```

**Usage**

Use this command to enable the sending of the Data Available Indicator extension in A10/A11 Registration Reply messages.
data-over-signaling

Enables the data-over-signaling marking feature for A10 packets.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
[ default | no ] data-over-signaling
```

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Enables the data-over signaling feature for A10 packets.</td>
</tr>
<tr>
<td>no</td>
<td>Disables the data-over signaling feature for A10 packets.</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to enable or disable the data-over signaling feature for A10 packets.
**dns-pgw**

Identifies the location of the DNS client to the HSGW service and enables/disables P-GW load balancing using DNS SRV lookup.

**Product**

HSGW

**Privilege**

Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HSGW Service Configuration

`configure > context context_name > hsgw-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
| dns-pgw { context name | selection { topology [ weight ] | weight } } |
|----------------------|---------------------------------------------|
| [ default | no ] dns-pgw { context | selection { topology [ weight ] | weight } } |
```

---

**default**

Returns the command to its default setting of the current context.

By default, topology will be enabled and weight will be disabled.

---

**no**

Removes the configured DNS client context name or P-GW DNS selection criteria from this service.

---

**context name**

Specifies an existing context in which the DNS client is configured as an alphanumeric string of 1 through 79 characters.

---

**selection { topology [ weight ] | weight }**

Specifies P-GW DNS selection criteria.

**topology**: Enables topology selection, which selects a P-GW topologically closer to the HSGW.

**topology weight**: Enables topology selection with weight.

**weight**: Enables selection with weight only when both preference values are the same; disables topology selection.

---

**Usage**

Use this command to identify to the HSGW service the context where the DNS client is configured. The DNS client is used to identify an FQDN for the peer P-GW. This command defaults to the same context as the HSGW service.

In addition, this command enables and disables P-GW load balancing using DNS SRV lookup by defining P-GW DNS selection criteria.
Example

The following command identifies the context where the DNS client is configured as `isp3`:

```
dns-pgw context isp3
```

The following command enables P-GW DNS topology selection with weight:

```
dns-pgw selection topology weight
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
**fqdn**

Configures the Fully Qualified Domain Name (FQDN) for this HSGW service.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
fqdn  domain_name
```

- **default**
  
  Returns the command to the default setting of “null”.

- **no**
  
  Removes the configured FQDN name from this service.

- **domain_name**
  
  Specifies an FQDN for the HSGW service as an alphanumeric string of 1 through 256 characters.

⚠️ **Important:** In order to properly interact with other nodes in the network, the FQDN should be 96 alpha and/or numeric characters or less.

**Usage**

Use this command to configure an FQDN for this HSGW service. The FQDN is used when matching a P-GW with an HSGW.

**Topology Matching**

You may specify which P-GW you wish an HSGW interface to connect with by enabling topology matching within the FQDNs for both the HSGW service and P-GW service. Topology matching selects geographically closer nodes and reduces backhaul traffic for a specified interface.

The following optional keywords enable or disable topology matching when added to the beginning of an FQDN:

- `topon.<interface_name>`.
Beginning an FQDN with `topon` initiates topology matching with available P-GWs in the network. Once this feature is enabled, the rest of the FQDN is processed from right to left until a matching regional designator is found on a corresponding P-GW FQDN.

*topoff.<interface_name>.*

By default, topology matching is disabled. If you enable topology matching for any interfaces within a node, however, all interfaces not using this feature should be designated with `topoff`.

**Example**

The following command configures this HSGW service with an FQDN of `abc123.com`:

```
fqdn abc123.com
```

The following command configures this HSGW service with an FQDN that enables topology matching:

```
fqdn topon.<interface_name>.hsgw01.bos.ma.node.epc.mnc<value>.
mcc<value>.3gppnetwork.org
```

**Important:** The associated P-GW service must have a corresponding FQDN similar to the following:

```
topon.<interface_name>.pgw01.bos.ma.node.epc.mnc<value>.mcc<value>.3gppnetwork.org
```
fragment

Enables or disables Point-to-Point Protocol (PPP) payload fragmentation.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```bash
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
[ default | no ] fragment ppp-data
```

---

**default**

Returns the command to its default setting of enabled.

---

**no**

Disables PPP payload fragmentation.

**Usage**

Use this command to enable or disable PPP payload fragmentation.
**gre**

Configures Generic Routing Encapsulation (GRE) parameters for the A10 protocol within the HSGW service.

**Product**

HSGW

**Privilege**

Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
gre { checksum | checksum-verify | flow control [ action { disconnect-session | resume-session } ] [ timeout msecs ] + | ip-header-dscp value { all-control-packets | setup-packets-only } | reorder-timeout msecs | segmentation | sequence-mode { none | reorder } | sequence-numbers | threegpp2-ext-headers qos-marking }

default gre { checksum | checksum-verify | flow-control | ip-header-dscp | reorder-timeout | sequence-mode | sequence-numbers | threegpp2-ext-headers qos-marking }

no gre { checksum | checksum-verify | flow-control | ip-header-dscp | segmentation | sequence-numbers | threegpp2-ext-headers qos-marking }
```

**default**

Restores the specified parameter to its default setting.

**no**

Disables the specified functionality.

**checksum**

Enables the introduction of the checksum field in outgoing GRE packets. Default: disabled

**checksum-verify**

Enables verification of the GRE checksum (if present) in incoming GRE packets. Default: disabled

**flow-control [ action { disconnect-session | resume-session } ] [ timeout msecs ] +**

Default: no GRE flow-control

Enables 3GPP2 GRE flow control which causes the HSGW to send flow control enabled Normal Vendor Specific Extensions (NVSE) in A11 RRPs.

```
action { disconnect-session | resume-session }
```

Default: disconnect-session
Specifies the action to be taken when timeout is reached:

- **disconnect-session**: Ends the session and releases the call.
- **resume-session**: Switches flow control to XON and resumes delivery of packets to the RAN.

### `timeout msecs`

Specifies the amount of time (in milliseconds) to wait for an XON indicator from the RAN (after receiving an XOFF). Also sets the action to be taken if the timeout limit is reached.

- **msecs**: an integer from 1 through 1000000. Default: 1000

### `ip-header-dscp value { all-control-packets | setup-packets-only }`

Default: Disabled

Configures QoS Differentiated Services Code Point (DSCP) marking for GRE packets.

- **value**: Represents the DSCP setting as the first six most-significant bits of the ToS field. It can be configured to any hexadecimal value from 0x0 through 0x3F.

- **all-control-packets**: Dictates that the DSCP marking is to be provided in all GRE control packets.
- **setup-packets-only**: Dictates that the DSCP marking is to be provided only in GRE setup packets.

### `reorder-timeout msecs`

Configures the maximum number of milliseconds to wait before processing reordered out-of-sequence GRE packets as an integer from 0 through 5000. Default: 100

### `segmentation`

Enables GRE Segmentation for the HSGW service. Default: disabled

### `sequence-mode { none | reorder }

Default: none

Configures handling of incoming out-of-sequence GRE packets.

- **none**: Specifies that sequence numbers in packets are ignored and all arriving packets are processed in the order they arrive.
- **reorder**: Specifies that out of sequence packets are stored in a sequencing queue until one of the conditions is met:
  
  - The reorder timeout occurs: All queued packets are sent for processing and the accepted sequence number is updated to the highest number in the queue.
  - The queue is full (five packets): All packets in the queue are sent for processing, the reorder timer is stopped and the accepted sequence number is updated to the highest number in the queue.
  - An arriving packet has a sequence number such that the difference between this and the packet at the head of the queue is greater than five. All the packets in the queue are sent for processing, the reorder timer is stopped and the accepted sequence number is updated to the highest number that arrived.
  - A packet arrives that fills a gap in the sequenced numbers stored in the queue and creates a subset of packets whose sequence numbers are continuous with the current accepted sequence number. This subset of packets in the queue is sent for processing. The reorder timer continues to run and the accepted sequence number is updated to the highest number in the subset delivered.

### `sequence-numbers`

Enables insertion of GRE sequence numbers in data that is about to be transmitted over the A10 interface. Data coming into the system containing sequence numbers but that is out of sequence is not re-sequenced.
threegpp2-ext-headers qos-marking

When threegpp2-ext-headers qos-marking is enabled and the PCF negotiates capability in the A11 RRQ, the HSGW will include the QoS optional data attribute in the GRE 3gpp2 extension header.

The no keyword, enables qos-marking in the GRE header based on the tos value in the header.

Usage

Use this command to set GRE parameters for the A10 protocol within the HSGW service.

Example

The following command configures the HSGW service to support the inclusion of GRE sequence numbers in outgoing traffic:

```
   gre sequence-numbers
```
Enables the use of Robust Header Compression (RoHC) and enters the HSGW Service ROHC Configuration Mode where RoHC parameters are configured for the service.

Configures the local User Datagram Protocol (UDP) port for the A10/A11 interface IP socket.

Sets the parameters for IP source validation. Source validation is useful if packet spoofing is suspected or for verifying packet routing and labeling within the network. Source validation requires the source address of received packets to match the IP address assigned to the subscriber (either statically or dynamically) during the session.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration
configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

```
ip { header-compression rohc | local-port number | source-violation { clear-on-valid-packet | drop-limit num | period secs | reneg-limit num } }
default ip { header-compression rohc | local-port | source-violation { drop-limit | period | reneg-limit } }
no ip { header-compression rohc | source-violation clear-on-valid-packet }
```

**default**

Resets the keyword to its default value.

**no**

**header-compression rohc**: Removes the RoHC configuration from this service.

**ip source-violation clear-on-valid-packet**: Disables the ability of the service to reset the reneg-limit and drop-limit counters after receipt of a properly addressed packet.

**header-compression rohc**

Specifies that Robust Header Compression will be applied to sessions using this service and enters the HSGW Service RoHC Configuration Mode where RoHC parameters are configured.

**local-port number**

Specifies the UDP port number as an integer from 1 through 65535. Default: 699
source-violation { clear-on-valid-packet | drop-limit num | period secs | reneg-limit num }

clear-on-valid-packet
Configures the service to reset the reneg-limit and drop-limit counters after receipt of a properly addressed packet. Default: disabled
drop-limit num
Specifies the number of allowed source violations within a detection period before forcing a call disconnect as an integer from 1 through 1000000. If num is not specified, the value is set to the default. Default: 10
period secs
Specifies the length of time (in seconds) for a source violation detection period to last; drop-limit and reneg-limit counters are decremented each time this value is reached.
The counters are decremented in this manner: reneg-limit counter is reduced by one (1) each time the period value is reached until the counter is zero (0); drop-limit counter is halved each time the period value is reached until the counter is zero (0). If secs is not specified, the value is set to the default.
secs is an integer from 1 through 1000000. Default: 120
reneg-limit num
Sets the number of allowed source violations within a detection period before forcing a PPP renegotiation. If num is not specified, the value is set to the default.
num is an integer from 1 through 1000000. Default: 5

Usage

Header Compression RoHC: Use this command to specify that sessions using this service will have Robust Header Compression applied and configure parameters supporting RoHC.
Entering this command results in the following prompt:

    [context_name]hostname(config-ip-header-compression-rohc)#

HSGW Service RoHC Configuration Mode commands are defined in the HSGW Service RoHC Configuration Mode Commands chapter.
Local Port: Specify the UDP port that should be used for communications between the Packet Control Function (PCF) and the HSGW.

Important: The UDP port setting on the PCF must match the local-port setting for the HSGW service on the system in order for the two devices to communicate.

Source Violation: This function is intended to allow the operator to configure a network to prevent problems such as when a user gets handed back and forth between two HSGWs a number of times during a handoff scenario.
This function operates in the following manner:
When a subscriber packet is received with a source address violation, the system increments both the IP source-violation reneg-limit and drop-limit counters and starts the timer for the IP-source violation period.
Every subsequent packet received with a bad source address during the IP-source violation period causes the reneg-limit and drop-limit counters to increment.
For example, if reneg-limit is set to 5, then the system allows 5 packets with a bad source address (source violations), but on the 5th packet, it re-negotiates PPP.
If the drop-limit is set to 10, the above process of receiving 5 source violations and renegotiating PPP occurs only once. After the second 5 source violations, the call is dropped. The period timer continues to count throughout this process.
If the configured source-violation period is exceeded at any time before the call is dropped, the reneg-limit counter is checked. If the reneg-limit counter is greater than zero (0), the reneg-limit is decremented by 1. If the reneg-limit counter equals zero, the drop-limit is decremented by half.

**Example**

The following command specifies a UDP port of 3950 for the HSGW service to use to communicate with the PCF on the A10/A11 interface:

```
ip local-port 3950
```

The following command sets the drop limit to 15 and leaves the other values at their defaults:

```
ip source-violation drop-limit 15
```
**lifetime**

Specifies how long an A10 connection can exist before its registration is considered expired.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

    configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

    [context_name]host_name(config-hsgw-service)#

**Syntax**

    lifetime time

    [ default | no ] lifetime

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Resets the lifetime value to the default setting of 1800 seconds.</td>
</tr>
<tr>
<td>no</td>
<td>Specifies that an A10 connection can exist for an infinite amount of time.</td>
</tr>
<tr>
<td>time</td>
<td>Specifies the time (in seconds) that an A10 connection can exist before its registration is considered expired as an integer from 1 through 65534. Default: 1800</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to set a limit to the amount of time that a subscriber session can remain up whether or not the session is active or dormant. If the lifetime timer expires before the subscriber terminates the session, the connection is terminated automatically.

**Example**

The following command specifies a time of **3600** seconds (1 hour) for subscriber sessions on this HSGW service:

    lifetime 3600
max-retransmissions

Configures the maximum number of times the HSGW service will attempt to communicate with an eAN/PCF before it marks it as unreachable.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

max-retransmissions count

default max-retransmissions

---

default

Resets the maximum number of allowed retransmissions to the default value of 5.

---

count

Specifies the maximum number of times the HSGW service will attempt to communicate with an eAN/PCF before it marks it as unreachable.

count is an integer from 1 through 1000000. Default: 5

---

Usage

Use this command to limit the number of retransmissions to an eAN/PCF before marking it as unreachable. If the value configured is reached, the call is dropped.

Example

The following command configures the maximum number of retransmissions for the HSGW service to 3:

max-retransmissions 3
**mobile-access-gateway**

Identifies the mobile access gateway (MAG) context through which MIPv6 calls are to be routed.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```bash
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
mobile-access-gateway context context_name [ mag-service service_name ]
```

```
no mobile-access-gateway context
```

- **no**
  - Removes the configured MAG context route from this service.

```
context context_name [ mag-service service_name ]
```

- **context**
  - Specifies the name of the context and, optionally, the service through which MIPv6 sessions are to be routed.
  - `context_name` is an existing context expressed as an alphanumeric string of 1 through 79 characters.
  - `service_name` is an existing MAG service expressed as an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to specify where MIPv6 sessions are routed through this service.

**Example**

The following command identifies the MAG context `MAG1` as the context through which MIPv6 sessions are to be routed and further narrows the route by specifying the service name (`mag_serv3`):

```
mobile-access-gateway context MAG1 mag-service mag_serv3
```
network-initiated-qos

Enables the use of network initiated QoS functionality.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

[ default | no ] network-initiated-qos

default

Returns the command to its default setting of enabled.

no

Disables the ability to use network initiated QoS functionality.

Usage

Use this command to enable or disable support for network initiated QoS functionality. Network initiated QoS is enabled by default.

When network initiated QoS functionality is enabled, if the vendor specific network control protocol (VSNCP) protocol configuration options (PCO) arrive from the UE with the BCM set, the HSGW CCR-I includes the Network-Request-Support AVP. If the PCRF behavior returns a BCM of MS+NW when this AVP is received, then flows originating from the network (RSVP Resv) would be triggered upon a PCC-Rule install.
plmn id

Configures Public Land Mobile Network identifiers used to determine if a mobile station is visiting, roaming or belongs to this network.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

plmn id mcc number mnc number

mcc number mnc number

mcc number: Specifies the mobile country code (MCC) portion of the PLMN identifier as an integer from 100 through 999.

mnc number: Specifies the mobile network code (MNC) portion of the PLMN identifier as a 2- or 3-digit integer from 00 through 999.

Usage
The PLMN identifier is used to aid the HSGW service in the determination of whether or not a mobile station is visiting, roaming, or home. Multiple P-GW services can be configured with the same PLMN identifier. Up to five PLMN IDs can be configured for each P-GW Service. The configured IDs are used in Diameter-EAP-Request messages (as a Visited-Network-Identifier AVP).

Example
The following command configures the PLMN identifier with an MCC of 462 and MNC of 2:

plmn id mcc 462 mnc 02
policy overload

Specifies how an HSGW service should handle overload conditions.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration
configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:
[context_name]host_name(config-hsgw-service)#

Syntax

policy overload { redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ] | reject [ use reject-code { admin-prohibite | insufficient-resources } ] } } 

default policy overload

no policy overload [ redirect address [ address2 ] ... [ address16 ] ]

default
Returns the command to its default setting of “reject” with the “admin-prohibited” code.

no
Removes a specified “redirect address” from this service.

redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ]

This option enables a redirect policy for overloaded conditions. When a redirect policy is invoked, the HSGW service rejects new sessions with an A11 Registration Reply Code of 88H (unknown HSGW address) and provides the IP address of an alternate HSGW. This command can be issued multiple times.

address: The IP address of an alternate HSGW expressed in IPv4 dotted decimal notation. Up to 16 IP addresses can be specified either in one command or by issuing the redirect command multiple times. If you try to add more than 16 IP addresses to the redirect policy the CLI issues an error message. If you specify an IP address and weight that already exists in the redirect policy the new values override the existing values.

weight weight_num: When multiple addresses are specified, they are selected in a weighted round-robin scheme. Entries with higher weights are more likely to be chosen. If a weight is not specified, the entry is automatically assigned a weight of 1 (default). weight_num must be an integer value from 1 through 10.

reject [ use reject-code { admin-prohibite | insufficient-resources } ]

This option will cause any overload traffic to be rejected. The HSGW sends an A11 Registration Reply Code of 82H (insufficient resources).
use-reject-code admin-prohibited: When this keyword is specified and traffic is rejected, the error code admin prohibited is returned instead of the error code “insufficient resources”. This is the default behavior.

use-reject-code insufficient-resources: When this keyword is specified and traffic is rejected, the error code “insufficient resources” is returned instead of the error code admin prohibited.

Usage

Policies can be implemented to dictate HSGW service behavior for overload conditions. The system invokes the overload policy if the number of calls currently being processed exceeds the licensed limit for the maximum number of sessions supported by the system. The system automatically invokes the overload policy when an on-line software upgrade is started. Use the no policy overload command to delete a previously configured policy. If after deleting the policy setting you desire to return the policy parameter to its default setting, use the default policy command.

The chassis is shipped from the factory with the policy options overload disabled.

Example

The following command configures the HSGW service to redirect overload traffic to two IPv4 addresses, one priority weighted 1 and the other priority weighted 5:

```
policy overload redirect 10.2.3.4 weight 1 10.2.3.5 weight 5
```
profile-id-qci-mapping

Associates a configured mapping table for RP QoS Profile ID to LTE QoS Class Index (QCI) mapping with this service.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```text
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service) #
```

**Syntax**

```
profile-id-qci-mapping name

no profile-id-qci-mapping [ name ]
```

- **no**
  Removes all profile maps or a specific profile map from this service.

- **name**
  Specifies the name of an existing Profile ID - QCI Mapping table to be associated with this service as an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to associate the HSGW service with a configured Profile ID - QCI Mapping table. The table is configured in the Global Configuration Mode using the `profile-id-qci-mapping-table` command.

**Example**

The following command associates a Profile ID - QCI Mapping table named `table3` with this service:

```
profile-id-qci-mapping table3
```
registration-deny

Configures parameters related to registration rejection.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

registration-deny { handoff connection-setup-record-absent | newcall connection-setup-record-absent } [ use-deny-code { poorly-formed-request | reason-unspecified } ]

[ default | no ] registration-deny { handoff connection-setup-record-absent | newcall connection-setup-record-absent }

default | no
Returns the command to its default settings.

handoff connection-setup-record-absent
When enabled, the HSGW denies or discards handoff R-P sessions that do not have an Airlink Connection Setup record in the A11 Registration Request. Default is disabled. Default HSGW behavior is to accept such requests.

newcall connection-setup-record-absent
When enabled, the HSGW denies or discards new R-P sessions that do not have the Airlink Connection Setup record in the A11 Registration Request. Default is disabled. Default HSGW behavior is to accept such requests.

use-deny-code { poorly-formed-request | reason-unspecified }
Sets the specified Registration Deny Code when denying a new call or handoff because of a missing connection setup record.

Usage
Use this command to configure parameters relating to the rejection of registration requests.

Example

The following command denies registration for registration requests missing the connection setup record and replies with a use deny code of “poorly formed request”: 
registration-deny handoff connection-setup-record-absent use-deny-code poorly-formed-request
retransmission-timeout

Configures the maximum allowable time for the HSGW service to wait for a response from the eAN/PCF before it attempts to communicate with the eAN/PCF again (if the system is configured to retry the PCF), or marks the eAN/PCF as unreachable.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

retransmission-timeout time

[ default | no ] retransmission-timeout

default
Resets the timeout setting to the default value of 3.

no
Deletes a previously configured timeout value.

time
Specifies the maximum allowable time (in seconds) for the HSGW service to wait for a response from the eAN/PCF before it: a) attempts to communicate with the eAN/PCF again (if the system is configured to retry the PCF), or b) marks the eAN/PCF as unreachable.

time is an integer from 1 through 1000000. Default: 3

Usage
Use the retransmission timeout command in conjunction with the max-retransmissions command in order to configure the HSGW service’s behavior when it does not receive a response from a particular PCF.

Example
The following command configures a retransmission timeout value of 5 seconds:

retransmission-timeout 5
rsvp

Configures resource reservation protocol (RSVP) parameters for this HSGW service in support of the network initiated QoS feature.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration
configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

rsvp { max-retransmissions count | retransmission-timeout seconds }

[ default | no ] rsvp { max-retransmissions | retransmission-timeout }

---

default
Reset the maximum number of allowed retransmissions to the default value of 5 or the timeout setting to the default value of 3.

no
Disables the feature.

max-retransmissions count
Specifies the maximum retransmission count of RP control packets as an integer from 1 through 1000000. Default: 5

retransmission-timeout seconds
Specifies the maximum amount of time (in seconds) to allow for retransmission of RP control packets as an integer from 1 through 1000000. Default: 3

Usage
Use this command to set RSVP parameters for this HSGW service in support of the network initiated QoS feature.

Example
The following command configures the maximum number of retransmissions to 3:

```
rsvp max-retransmissions 3
```
setup-timeout

Specifies the maximum amount of time allowed for session setup.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration
configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

setup-timeout seconds

[ default| no ] setup-timeout

default
 Resets the command to the default value of enabled with a timeout of 60 seconds.

no
 Disables the feature.

seconds
 Specifies the maximum amount of time (in seconds) to allow for setup of a session in this service as an integer from 1 though 1000000. Default: 60

Usage
Use this command to set the maximum amount of time allowed for setting up a session.

Example
The following command sets the maximum time allowed for setting up a session to 5 minutes (300 seconds):

setup-timeout 300
spi remote-address

Configures the security parameter index (SPI) between the HSGW service and the evolved Access Network/evolved Packet Control Function (eAN/ePCF). This command also configures the redirection of calls based on the PCF zone.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration
configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
spi remote-address { pcf_ip_address | ip_addr_mask_combo } spi-number number { encrypted secret enc_secret | secret secret } [ description string ] [ hash-algorithm { md5 | rfc2002-md5 } ] [ replay-protection { nonce | timestamp } ] [ timestamp-tolerance tolerance ] [ zone zone_id ]

no spi remote-address pcf_ip_address spi-number number
```

- **pcf_ip_address** | **ip_addr_mask_combo**
  - **pcf_ip_address**: Specifies the IP address of the ePCF. **pcf_ip_address** is an IP address expressed in IPv4 dotted decimal notation or IPv6 colon separated notation.
  - **ip_addr_mask_combo**: Specifies the IP address and mask bits of the PCF. **ip_addr_mask_combo** must be specified using the form “IP Address/Mask Bits” where the IP address must in IPv4 dotted-decimal or IPv6 colon-separated notation, and the mask bits are a numeric value corresponding to the number of bits in the subnet mask.

- **spi-number number**
  - Specifies the SPI which indicates a security context between the PCF and the HSGW as an integer from 256 through 4294967295.

- **encrypted secret** | **secret**
  - **encrypted secret** **enc_secret**: Specifies the encrypted shared key (**enc_secret**) between the PCF and the HSGW service. **enc_secret** must be between 1 and 236 alpha and/or numeric characters and is case sensitive.
  - **secret** **secret**: Specifies the shared key (**secret**) between the PCF and the HSGW service. **secret** must be between 1 and 127 alpha and/or numeric characters and is case sensitive.

The **encrypted** keyword is intended only for use by the chassis while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the
**secret** keyword is the encrypted version of the plain text secret key. Only the encrypted secret key is saved as part of the configuration file.

```plaintext
description string
This is a description for the SPI expressed as an alphanumeric string of 1 through 31 characters.
```

```plaintext
hash-algorithm { md5 | rfc2002-md5 }
Specifies the hash-algorithm used between the HSGW service and the PCF. Default: md5
md5: Configures the hash-algorithm to implement MD5.
rfc2002-md5: Configures the hash-algorithm to implement keyed-MD5.
```

```plaintext
replay-protection { nonce | timestamp }
Specifies the replay-protection scheme that should be implemented by the HSGW service. Default: timestamp
nonce: Configures replay protection to be implemented using NONCE (Number ONCE).
timestamp: Configures replay protection to be implemented using timestamps.
```

```plaintext
timestamp-tolerance tolerance
Specifies the allowable difference (in seconds) between timestamps as an integer from 0 through 65535. If the difference is exceeded, the session will be rejected. If set to 0, timestamp tolerance checking is disabled at the receiving end. Default: 60
```

```plaintext
zone zone_id
Specifies the different PCF zones to configure in HSGW service. Mapping of a zone-number to a set of HSGWs can be done per HSGW service basis.
zone_id is an integer value from 1 through 32. A maximum of 32 PCF zones can be configured for a HSGW service.
```

**Usage**

An SPI is a security mechanism configured and shared by the PCF and the HSGW service. Please refer to IETF RFC 2002: IP Mobility Support for additional information.

Multiple SPIs can be configured if the HSGW service is communicating with multiple eAN/ePCFs.

**Important:** The SPI configuration on the PCF must match the SPI configuration for the HSGW service on the system in order for the two devices to communicate properly.

**Example**

This command used with the `zone` keyword redirects all calls on the basis of PCF zone to the specific HSGW on the basis of parameters configured using the `policy pcf-zone-match` command.

The following command configures the HSGW service to use an SPI of 256 when communicating with a PCF with the IP address 192.168.0.2. The key that would be shared between the PCF and the HSGW service is q397F65.

```
spi remote-address 192.168.0.2 spi-number 256 secret q397F65
```

The following command creates the configured SPI of 400 for an PCF with an IP address of 172.100.3.200 and zone id as 11:

```
spi remote-address 172.100.3.200 spi-number 400 zone 11
```
ue-initiated-qos

Configures the HSGW behavior for UE initiated QoS requests.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration
configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

[ default | no ] ue-initiated-qos

----------

default

Returns the HSGW to the default behavior, where UE initiated QoS requests are accepted and forwarded to the PCRF via Gxa interface.

----------

no

Enables rejection of UE initiated QoS request for dedicated bearer in HSGW service. HSGW does not forward the request to the PCRF over Gxa and instead rejects the UE initiated QoS immediately.

Usage

Use this command to enable or disable support for UE initiated QoS functionality.
By default, UE initiated QoS requests are accepted and forwarded to the PCRF via Gxa interface. If PCRF rejects the UE initiated QoS, UE request is rejected.
This command allows rejection of UE initiated QoS request for dedicated bearer in HSGW service. HSGW does not forward the request to the PCRF over Gxa and instead rejects the UE initiated QoS immediately.

Example

The following command rejects UE-initiated QoS request for dedicated bearer in HSGW service:

no ue-initiated-qos
**unauthorized-flows**

Configures the service to wait a specified number of seconds before triggering a QoS update to downgrade an unauthorized flow.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
unauthorized-flows qos-update wait-timeout seconds
```

```
[ default | no ] unauthorized-flows qos-update wait-timeout
```

- **default**
  Returns the command to its default setting.

- **no**
  Removes the configure wait-timeout setting for this service.

```
qos-update wait-timeout seconds
```

Specifies the number of seconds to wait before triggering the QoS update to downgrade the unauthorized flow as an integer from 1 through 65534.

**Usage**

Use this command to specific a wait timeout trigger for flows that are unauthorized by policy rules received via the Gxa interface from the PCRF. When the wit timer expires, the HSGW triggers a QoS update to downgrade the unauthorized flow.

**Example**

The following command configures the HSGW service to apply the wait time of 30 seconds after receiving an flow unauthorized by the PCRF:

```
unauthorized-flow qos-update wait-timeout 30
```
Chapter 161
HSGW Service RoHC Configuration Mode Commands

The HSGW Service RoHC Configuration Mode is used to configure Robust Header Compression (RoHC) parameters for the service.

Mode

Exec > Global Configuration > Context Configuration > HSGW Service Configuration > HSGW Service RoHC Configuration

`configure > context context_name > hsgw-service service_name > ip header-compression rohc`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ip-header-compression-rohc)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
cid-mode

This mode allows you to configure options that apply during RoHC compression for the service.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration > HSGW Service RoHC Configuration

```
configure > context context_name > hsgw-service service_name > ip header-compression rohc
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ip-header-compression-rohc)#
```

Syntax

```
cid-mode { large | small } max-cid integer
default cid-mode
```

**default cid-mode**

- **default**
  
  Reset all options in the RoHC Profile Compression Configuration mode to their default values.

- **large**
  
  Use large packets with optional information for RoHC

- **small**
  
  This is the default packet size.
  Use small RoHC packets.

- **max-cid integer**
  
  Specifies the highest context ID number to be used by the compressor as an integer from 0 through 15 when small packet size is selected, and 0 through 31 when large packet size is selected. Default: 15

Usage

Use this command to set the RoHC packet size and define the maximum

Example

The following command sets large RoHC packet size and sets the maximum CID to 100:

```
cid-mode large max-cid 100
```

The following command sets the cid-mode to the default settings of small packets and max-cid 0:

```
default cid-mode
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
end

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
exit

**Usage**
Use this command to return to the parent configuration mode.
**mrru**

Specifies the size of the largest reconstructed reception unit that the decompressor is expected to reassemble from segments. The size includes the CRC. If maximum received reconstructed unit (MRRU) is negotiated to be 0, no segment headers are allowed on the channel.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration > HSGW Service RoHC Configuration

configure > context context_name > hsgw-service service_name > ip header-compression rohc

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ip-header-compression-rohc)#
```

**Syntax**

```
mrru num_octets

default mrru
```

**default mrru**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>mrru num_octets</th>
<th>default mrru</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>default</strong></td>
<td>Resets the value of this command to its default setting of 0.</td>
<td></td>
</tr>
<tr>
<td><strong>num_octets</strong></td>
<td>Specifies the number of allowed octets for the MRRU as an integer from 0 through 65535. Default: 0</td>
<td></td>
</tr>
</tbody>
</table>

**Usage**

Use this command to set the size, in octets, of the largest reconstructed reception unit that the decompressor is expected to reassemble from segments.

**Example**

The following command sets the largest reconstructed reception unit to 1024 octets:

```
mrru 1024
```

The following command resets the MRRU size to its default of 0 octets:

```
default mrru
```
profile

Specifies the header compression profiles to use. A header compression profile is a specification of how to compress the headers of a specific kind of packet stream over a specific kind of link. At least one profile must be specified.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration > HSGW Service RoHC Configuration

configure > context context_name > hsgw-service service_name > ip header-compression rohc

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ip-header-compression-rohc)#

Syntax

profile { [ esp-ip ] [ rtp-udp ] [ udp-ip ] [ uncompressed-ip ] }

default profile

default
Default: esp-ip rtp-udp udp-ip uncompressed-ip
Returns the RoHC profile configuration to its default setting.

esp-ip
Enables RoHC Profile 0x0003 which is for ESP/IP compression, compression of the header chain up to and including the first ESP header, but not subsequent subheaders.

rtp-udp
Enables RoHC Profile 0x0001 which is for RTP/UDP/IP compression

udp-ip
Enables RoHC Profile 0x0002 which is for UDP/IP compression; compression of the first 12 octets of the UDP payload is not attempted.

uncompressed-ip
Enables RoHC Profile 0x0000 which is for sending uncompressed IP packets.

Usage

Use this command to specify the RoHC header compression profiles.

Example

The following command sets the profiles to use as esp-ip and rtp-udp:
profile esp-ip rtp-udp
Chapter 162
HLR Configuration Mode Commands

The HLR Configuration Mode provides the commands and parameters to configure the home location register (HLR) node that is the database containing the subscriber profile and connection information for a specific GPRS/UMTS core network.

The HLR Configuration Mode is a sub-mode derived from the MAP Configuration Mode which controls the MAP service configuration. It is the MAP service that provides the application-layer protocol support used to connect the HLR to other nodes in the network such as the SGSN.

Exec > Global Configuration > Context Configuration > MAP Service Configuration > HLR Configuration
configure > context context_name > map-service service_name > hlr

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-map-service-service_name-hlr)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
The `acn-version-retention` command configures the ACN version retention method.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > MAP Service Configuration > HLR Configuration
configure > context context_name > map-service service_name > hlr

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-map-service-service_name-hlr)#
```

**Syntax**

```
acn-version-retention { per-imsi-prefix | per-subscriber }

default acn-version-retention
```

---

**default**

Returns the configuration to the default value: retains the version information per IMSI prefix.

---

**per-imsi-prefix**

Retain ACN version information, for communication with the HLR, on a per IMSI prefix basis.

---

**per-subscriber**

Retain ACN version information, for communication with the HLR, on a per subscriber basis.

---

**Usage**

By default, the SGSN sends ACN version 3 SAI (service area identity) to the HLR. If the SGSN receives an error message indicating that the HLR does not support that version, then the SGSN tries again with an ACN version 2 SAI. Next time the SGSN communicates with that HLR, it retains that version information and version persists based on the IMSI prefix.

Use this command to enable the SGSN to retain version according to subscriber.

---

**Example**

Configure the SGSN to retain version information according to the IMSI prefix:

```
default acn-version-retention
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the MAP Service configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
exit

**Usage**
Return to the MAP Service configuration mode.
imsi

This command sets up IMSI (International Mobile Subscriber Identity) based configuration. The IMSI prefix includes the mobile country code (MCC) and the mobile network code (MNC).

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > MAP Service Configuration > HLR Configuration

configure > context context_name > map-service service_name > hlr

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-map-service-service_name-hlr)#
```

**Syntax**

```
[ no ] imsi { any | starts-with prefix_number } { imsi [ sgsn-source-address-format point-code-ssn [ source-ssn ssn ] | isdn isdn_number | mobile-global-title mgt_number [ max-gt-address-len max_gt_address ] | point-code pt-code ] }
```

- **no**
  Removes the imsi-prefix definition from the configuration.

- **any**
  Configures acceptance of any IMSI prefix.

- **starts-with prefix_number**
  Selects IMSI prefix-based routing.
  prefix_number is a string of up to 15 integers.

- **imsi**
  Enables configurable default behavior for routing.
  Entering imsi with the any keyword preserves the default behavior and the E.212 address is used as a destination address and the MAP request will be sent towards the HLR.
  If this keyword is not used with the any keyword, then the MAP request will be rejected.

- **isdn isdn_number**
  Defines the E.164 number of the HLR.
  isdn_number is a string of integers, up to 15.

- **mobile-global-title mgt_number [ max-gt-address-len max_gt_address_length ]**
  Defines the mobile global title address that the MCC/MNC portion of the IMSI will be converted to. If the maximum GT address length is specified (optional) and if the length of the MGT string is greater than defined, then the least significant digits will be omitted.
**Usage**

Routing will be done according to IMSI parameters configured with this command or according to the mobile global title address (replacing the MCC/MNC portion of the IMSI) is so specified.

**Example**

```plaintext
imsi starts-with 3 isdn 123456789 sgsn-source-address-format at point-code-ssn
```
policy routing

This command configures the policy for the routing of MAP messages. If this command is not configured or disabled (with the default keyword), then routing is done according to the configuration of the IMSI parameters.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > MAP Service Configuration > HLR Configuration
configure > context context_name > map-service service_name > hlr

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-map-service-service_name-hlr)#

Syntax

policy routing { hlr-isdn | ms-isdn }

default policy routing

no policy routing

---

default

Resets the policy routing to the system default, disabled.

---

no

Removes the policy routing configuration from the system.

---

hlr-isdn

Selects HLR-ISDN based routing.

---

ms-isdn

Selects mobile station (MS)-ISDN based routing.

---

Usage

Use this command to set the policy for routing MAP messages.

Example

policy routing hlr-isdn
release-compliance

Enables/disables the sending of EPS information in the Update GPRS Location Request message to the HLR.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > MAP Service Configuration > HLR Configuration

```
configure > context context_name > map-service service_name > hlr
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-map-service-service_name-hlr)#
```

**Syntax**

```
release-compliance release-8

no release-compliance
```

---

**release-compliance release-8**

Enables the sending of EPS information in the UGL Request message to the HLR. This setting sets the 3GPP release compliance to *Release 8 and above*.

**no release-compliance**

Disables the sending of EPS information in the UGL Request message to the HLR. This command sets the 3GPP release compliance setting to *Pre-release 8*. This is the default setting.

---

**Usage**

Use this command to enable or disable the sending of EPS information in the UGL Request message to the HLR.

Operators can use the `show map-service all` command to view the current 3GPP release compliance setting.

**Example**

This command enables the sending of EPS information in the UGL Request message to the HLR.

```
release-compliance release-8
```
Chapter 163
HNB-CS Network Configuration Mode Commands

The HNB-CS Network configuration mode provides the commands to create, provide, and manage the circuit switched (CS) network instance allowing the Home Evolved NodeB Gateway (HNB-GW) access with the CS core network in a 3G UMTS network.

**Mode**

Exec > Global Configuration > HNB-CS Network Configuration

`configure > cs-network cs_instance`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-cs-network-instance_id)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
associate alcap-service

Associates a previously defined Access Link Control Application Part (ALCAP) service with the CS network instance for multiplexing of different users onto one AAL2 transmission path using channel IDs (CIDs). This configuration is provided to support IuCS-over-ATM functionality.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-CS Network Configuration
configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

Syntax

associate alcap-service svc_name context ctx_name

no associate alcap-service

Syntax

no

Removes the associated ALCAP service from this HNB-CS network instance configuration.

svc_name

Identifies the name of the ALCAP service preconfigured in Context configuration mode to associate with an HNB-CS network instance for multiplexing of different users onto one AAL2 transmission path using channel IDs (CIDs).

svc_name must be a preconfigured ALCAP service.

Only one instance of this command can be configured.

⚠️ Caution: If this CLI is not configured any RAB-ASST-REQ requesting AAL2 connection setup shall be rejected with an appropriate cause.

context ctx_name

Specifies the name of the context in which ALCAP service is configured.

cxt_name must be an existing context name in which this ALCAP service is configured.

Usage

Use this command to configure IuCS-over-ATM support. This association of ALCAP protocol service configuration in HNB-CS network instance provides multiplexing of different users onto one AAL2 transmission path using channel IDs (CIDs).
**Caution:** If this CLI is not configured any RAB-ASST-REQ message requesting AAL2 connection setup shall be rejected with an appropriate cause.

**Important:** This command must not be used more than once to configure Iu-CS-over-ATM support.

**Example**

Following command associates ALCAP service `alcap_svc1` configured in context named `Ctx_alcap1` with specific HNB-CS network instance:

```
associate alcap-service alcap_svc1context ctx_alcap1
```
associate rtp pool

Associates a previously defined RTP pool (IP pool) with the CS network instance to be used for assignment of IP address/port as RTP streams end point address over IuCS interface. This configuration support is provided for RTP stream management feature in an HNB-GW service.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-CS Network Configuration

*configure > cs-network cs_instance*

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

Syntax

associate rtp pool pool_name context ctx_name

no associate rtp pool

no

Removes the associated RTP pool (IP pool) from this HNB-CS network instance configuration.

*pool_name*

Identifies the name of the RTP IP pool preconfigured in Context configuration mode to associate with an HNB-CS network instance to be used for assignment of IP address/port over the IuCS interface RTP streams. *pool_name* must be an existing IP pool name configured in Context configuration mode.

**Important:** For IP pool (RTP pool) configuration, refer *Context Configuration Commands Mode* chapter.

*context ctx_name*

Specifies the name of the context in which RTP pool (IP pool) is configured. *ctx_name* must be an existing context name in which this IP pool is configured.

Usage

Use this command to associate RTP pool (IP Pool) with an HNB-CS network instance for allotment of IP address/port over IuCS interface for RTP streams across all sessions. A fixed range of RTP ports from 5000 through 65000 shall be used to allocate to RTP stream.

**Important:** This command must be used to provide IP address/port for RTP streams end point address over IuCS interface.
**Important:** This configuration support is provided for RTP stream management feature on an HNB-GW service.

Example

Following command associates RTP pool named `rtp_1` with specific HNB-CS network instance:

```
associate rtp pool rtp_1
```
associate sccp-network

Associates a predefined Signaling Connection Control Part (SCCP) network ID with the CS network instance in order to route the messages towards MSC/VLR over IuCS interface.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-CS Network Configuration

```
configure > cs-network cs_instance
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-cs-network-instance_id)#
```

**Syntax**

```
associate-sccp-network sccp_net_id

no associate-sccp-network
```

**no**
Removes the associated SCCP network ID from this HNB-CS network instance configuration.

```
sccp_network_id
```

Identifies the predefined SCCP network ID to associate with an HNB-CS network instance over IuCS/IuFlex interface to enable connection with MSC/VLR(s).

*sccp_network_id* must be a predefined SCCP network ID in Global configuration mode.

**Usage**

Use this command to associate a preconfigured SCCP network ID over IuCS interface in HNB-GW service to connect with CS network elements; i.e. MSC.

**Important:** The SCCP network ID must be defined in Global Configuration mode before using it with this command.

**Important:** A single SCCP network configuration instance can not be shared with multiple HNB-CS network instances.

**Example**

Following command associates SCCP network 2 with specific HNB-CS network instance:

```
associate-sccp-network 2
```
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
global-rnc-id

Configures the Radio Network Concentrator (RNC) identifier in a Radio Network PLMN associated with HNB-CS network configuration instance. The RNC identifier is provided to the HNB during HNB-REGISTRATION.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-CS Network Configuration

configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

Syntax

[ no ] global-rnc-id mcc mcc_num mnc mnc_num id id rnc_id

no

Deletes the RNC, MMC, and MNC information from the HNB-CS Network configuration instance.

mcc mcc_num

Specifies the mobile country code (MCC) part of radio network PLMN identifier as an integer value from 100 through 999.

mnc mnc_num

Specifies the mobile network code (MNC) part of radio network PLMN identifier as a 2- or 3-digit integer from 00 through 999.

Usage

Use this command to configure RNC id to associate Radio Network PLMN which will be sent to HNBs from HNB-GW during HNB-REGISTRATION procedure. Depending upon the requirement the RNC Identifier can be provided at the desired granularity.

Example

The following command configures the HNB-GW service to return an RNC identifier as 102 when an HNB-REGISTRATION request is received with LAC 1, and RAC 2:

   global rnc-id mcc 102 mnc 02 id 2
map core-network-id

Maps/associates the CS core network id to a default Mobile Switching Center (MSC) in network using MSC point code in HNB-CS network to allow HNBs to access UMTS network.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-CS Network Configuration

configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

Syntax

map core-network-id cn_id point-code msc_point_code

no map core-network-id cn_id

no

Removes the mapping of a CS core network id with particular MSC point code.

cn_id

Specifies the core network identifier configured to represent a UMTS CS core network as an integer from 0 through 4095.

Multiple instance of this command can be mapped with different MSC point code.

point-code msc_point_code

Specifies the SS7 address of the default MSC in the CS network in point code value to a configured HNB-CS network instance.

point_code is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ############ format.

Only one instance of this MSC point code can be mapped with one CS core network id.

Usage

Use this command to map a UMTS CS core network identifier with a particular MSC point code.

This command can be entered multiple times with same MSC point code to map with one or more CS core network Id, but a particular core network identifier can be mapped to one MSC only.

This command is instrumental in Iu-Flex functionality, whenever HNB-GW receives RESET/RESET-RES messages from MSC with Global CN-ID information element, the response from HNB-GW is sent to the node configured for that particular Global CN-ID.

If the RESET/RESET-RES messages do not have Global CN-ID IE, then the response of those messages is directed to the default MSC which is configured using msc point-code command in this mode.

Example

The following command configures the CS core network identifier 101 with an MSC point code 1.2.3:
map core-network-id 101 point-code 1.2.3

The following command configures the CS core network identifier 102 with the same MSC point code 1.2.3:

map core-network-id 102 point-code 1.2.3
map idnns

Configures the mapping of Intra-Domain NAS Node Selector (IDNNS) IE received from UE in RUA connect message towards HNB-GW to MSC point code. This is an important configuration for CS network resource sharing over Iu-Flex interface.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-CS Network Configuration
configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

Syntax

map idnns range idnns_start to idnns_end point-code msc_point_code [ backup point-code bkup_msc_point_code ]

no map idnns range idnns_start to idnns_end

no

Removes the entries of mapping of range of IDNNS received from UE with particular MSC point code.

range idnns_start to idnns_end

Specifies the range of IDNNS received from the UE to map with a particular MSC point code during initial CS core network node selection.

idnns_start is an integer from 0 through 1023 that should be less than idnns_end.
idnns_end must be an integer from 0 through 1023 that should be more than idnns_start.
The command can be entered more than once to map multiple IDNNS ranges to the same MSC, but overlapping and mapping of the same range to different MSC point codes is not allowed.

point-code msc_point_code

Specifies the SS7 address of the MSC in the CS network to map with a range of IDNNS values.

msc_point_code is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ####### format.

backup point-code bkup_msc_point_code

Specifies the SS7 address of the MSC to be used as a backup in the CS network to map with a range of IDNNS values.
bkup_msc_point_code is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ####### format.
Usage

Use this command to map a NRI received from UE during initial CS network node selection to MSC point code through NRI range mapping over Iu-Flex interface.

The IDNNS refers to the information element in RUA connect message from UE towards RAN (HNB-GW). In IDNNS IE, if the choice of routing mentioned is other than local P-TMSI, then the value it provides is used against this configuration to map the MSC point code.

If backup MSC point-code is specified, then specified MSC works as backup for the IDNS range configured. This Backup MSC is selected if the mapped MSC for a given IDNNS range is going for offloading using `offload-msc point-code` command.

The command can be entered more than once to map multiple IDNNS ranges to same MSC point code, but overlapping and mapping of same range to different MSC point code is not allowed.

Example

The following command maps the IDNNS range from 101 to 201 with MSC point code 1.2.3 and point code 7.8.9 as backup MSC point code:

```
map nri range 101 to 201 point-code 1.2.3 backup point-code 7.8.9
```

The following command removes all IDNNS range matching entries between 301 to 399 from the configuration:

```
no map idnns range 301 to 399
```
map lac

Configures the mapping of the Location Area Code (LAC) received from UE to an MSC point code. This is an important configuration for CS network resource sharing without Iu-Flex interface configuration.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-CS Network Configuration
configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

Syntax

map lac range lac_start to lac_end point-code msc_point_code

no map lac range lac_start to lac_end

no

Removes the entries of mapping of range of LACs received from UE with particular MSC point code.

range lac_start to lac_end

Specifies the range of LACs received from UE to map with particular MSC point code during initial CS core network node selection.

lac_start is an integer from 0 through 65535 that should be less than lac_end.
lac_end is an integer from 0 through 65535 that should be more than lac_start.
The command can be entered more than once to map multiple LAC ranges to same MSC, but overlapping is not allowed.

point-code msc_point_code

Specifies the SS7 address of the MSC in the CS network to map with a range of LAC values.
point_code is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ####### format.

Usage

Use this command to map a LAC, received from UE during HNB registration, for MSC selection over IuCS interface through LAC range mapping with MSC point code.
This configuration is used during initial CS core network node selection when the LAC from the UE is available. This configuration is used when the core network is not using Iu-Flex interface for MSC selection.
The command can be entered more than once to map multiple LAC ranges to same MSC point code.
**Important:** This command can be used together with Iu-Flex configuration, but MSC selection based on LAC takes place only if Iu-Flex is not configured. If both Iu-Flex and LAC are configured then selection of MSC is based on Iu-Flex configuration only.

**Example**

The following command maps the LAC range from 20 to 50 with MSC point code 1.2.3:

```
map lac range 20 to 50 point-code 1.2.3
```

The following command removes all LAC range matching entries between 20 to 50 from the configuration:

```
no map lac range 20 to 50
```
map nri

Configures the mapping of Network Resource Identifier (NRI) sent from UE to the MSC point code. This is an important configuration for CS network resource sharing over Iu-Flex interface.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > HNB-CS Network Configuration

configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

Syntax

map nri range nri_start to nri_end point-code msc_point_code

no map nri range nri_start to nri_end

<table>
<thead>
<tr>
<th>range nri_start to nri_end</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the range of NRIs received from UE to map with particular MSC point code during initial CS core network node selection.</td>
</tr>
<tr>
<td><em>nri_start</em> is an integer from 0 through 1023 that should be less than <em>nri_end</em>.</td>
</tr>
<tr>
<td><em>nri_end</em> is an integer from 0 through 1023 that should be more than <em>nri_start</em>.</td>
</tr>
<tr>
<td>The command can be entered more than once to map multiple NRI ranges to same MSC, but overlapping is not allowed.</td>

</tr>
<tr>
<td><em>point_code</em> is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ####### format.</td>
</tr>
</tbody>
</table>

Usage

Use this command to map a NRI received from UE during initial CS network node selection to MSC point code through NRI range mapping over Iu-Flex interface.

This configuration is used during initial CS core network node selection when the network resource identifier (NRI) from the UE is available. The NRI range is mapped to MSC point code. This configuration is used when the core network uses Iu-Flex interface.

The command can be entered more than once to map multiple NRI ranges to same MSC point code. It is possible to configure multiple ranges to more than one MSC however this configuration is required only when the CS core network is configured as Multi-Operator Core Network (MOCN).
When the CS core network is not MOCN and one range is mapped to more than one MSC then MSC is selected randomly in a non-predictable manner.

**Example**

The following command maps the NRI range from 101 to 201 with MSC point code 1.2.3:

```
map nri range 101 to 201 point-code 1.2.3
```

The following command maps the NRI range from 301 to 399 with MSC point code 1.2.3:

```
map nri range 301 to 399 point-code 1.2.3
```

The following command removes all NRI range matching entries between 301 to 399 from the configuration:

```
no map nri range 301 to 399
```
**msc deadtime**

Configures a timer on the HNB-GW to manage MSC availability in a CS core network on receiving of a PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from an SCCP instance.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-CS Network Configuration

`configure > cs-network cs_instance`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-cs-network-instance_id)#
```

**Syntax**

```
msc deadtime { immediate | dur } [ no | default ] msc deadtime
```

- **no**
  Marks the peer node (MSC) as always available; it can never be marked down for a specific HNB-CS network instance.

- **default**
  Sets the default action for HNB-GW and provisions it as such that the peer node (MSC) is marked down as soon as HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP in a specific HNB-CS network instance. Default: Enabled

- **immediate**
  Sets the HNB-GW to mark the peer node (MSC) down immediately and clears all Iu-CS connections towards the MSC. Default: Disabled

- **dur**
  Sets the duration (in seconds) for a timer that starts when the HNB-GW receives a PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer MSC. On expiry of this timer the peer MSC is marked as dead and all Iu-CS connections towards that MSC are released.
  
  *dur* is an integer from 1 through 30.
  Only one instance of this command can be configured.

**Usage**

This command is used to configure a timer on HNB-GW to manage MSC availability in a CS core network on receiving of PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP. This configuration plays important role during RANAP reset procedure as well.
Timer value sets the duration in seconds for a timer which started once HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer MSC. On expiry of this timer the peer MSC is marked as dead and all Iu-CS connections towards that MSC shall be released.

**Important:** This command can be entered only once. Reentering this command overwrites the previous parameters.

**Example**

The following command configures the deadtime timer value for 10 seconds on HNB-GW. Once HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer MSC the HNB-GW waits for configured period and on expiry of timer it marks the specific MSC as dead:

```
msc deadtime 10
```
**msc point-code**

Configures the default MSC point-code within an HNB-CS network instance. This command is used when HNB-GW is to be connected to only one MSC with in a CS network or as default MSC for all HNBs connected through specific HNB-CS network instance.

**Product**

HNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > HNB-CS Network Configuration  
`configure > cs-network cs_instance`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-cs-network-instance_id)#
```

**Syntax**

```
[ no ] msc point-code point_code
```

- **no**
  
  Removes the configured default MSC point code from a specific HNB-CS network instance.

**Caution:** Removing the MSC point code is a disruptive operation and affects all HNB sessions which are connected to particular MSC through an HNB-CS network instance.

**msc point-code**

Specifies the SS7 address of the default MSC in the CS network to this configured HNB-CS network instance.

*point_code* is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ############ format. Only one instance of this command can be configured.

**Usage**

Use this command to configure a default MSC to which HNB connects for CS network access through HNB-GW service.

Point-code is an SS7 address for an element in the SS7 network. Point-codes must be defined in dotted-decimal format in a string of 1 to 11 digits. Format options include:

- 0.0.1 to 7.255.7 for point-code in the ITU range.
- 0.0.1 to 255.255.255 for point-code in the ANSI range.
- 0.0.1 to 15.31.255 for point-code in the TTC Range.
- a string of 1 to 11 digits in dotted-decimal to represent a point-code in a different range.
**Important:** This command can be entered only once. If entered again the previous value shall be overwritten.

**Example**

The following command configures a default MSC with point code 101.201.101 for HNBs to access CS network through HNB-GW service in this HNB-CS network instance:

```
msc point-code 101.201.101
```
**nri length**

Configures the network resource identifier (NRI) length in bits to identify a specific MSC serving in a pooled area. At least one NRI value has to be assigned to an MSC serving in a pool. The NRI is coded inside the temporary mobile subscriber identity (TMSI), located within bits 14 to 23 with a variable length between 0 and 10 bits. Operator needs to set this NRI length to indicate the number of bits that shall be used for the NRI field to set the parameters for Iu-Flex (MSC pooling) functionality.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-CS Network Configuration
configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local] host_name(config-cs-network-instance_id)#

**Syntax**

```
nri length nri_value

default nri length
```

**default**

Sets the NRI length to the default value of 0 and disables the Iu-Flex (MSC pooling) functionality.

```
nri length nri_value
```

Default: 0

Specifies the number of bits to be used in the P-TMSI (bits 23 to 18) to define the network resource identifier (NRI). The NRI length configuration also sets the maximum size of the pool. If not configured, the NRI length is of zero length. 

`length` is an integer from 1 to 10 that identifies the number of bits. When a non-zero value is configured the CS network is considered to be a pool.

**Usage**

Use this command to enable the Iu-Flex functionality on HNB-GW. This command identifies a unique MSC serving a pooled area for Iu-Flex functionality and at least one NRI value has to be assigned to an MSC serving in a pool. It performs MSC pooling/offloading scenario over Iu-Flex interface. The NRI is stored in the bits 14 to 23 of TMSI. The HNB-GW uses a portion of this NRI to set the parameters for Iu-Flex (MSC pooling) functionality.

If more than one NRI is configured, the HNB-GW service does round-robin between the available NRIs when new subscriber(s) (re)connect.

This command must be used in conjunction with `null nri` command to configure MSC pooling/offloading over Iu-Flex interface.

**Example**
The following command sets the HNB-GW to a bit length of 6 to derive the values from the NRI field (stored in bits 14 to 23 of TMSI) to set the parameters for Iu-Flex (MSC pooling) functionality:

```plaintext
nri length 6
```
null-nri

Configures the null NRI for load redistribution in support of Iu-Flex functionality. The NRI value defined with this command must be unique across the pool areas. This null-NRI is used by HNB-GW for load redistribution during MSC offloading.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-CS Network Configuration

configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

Syntax

null-nri null_nri_value

no null-nri null_nri_value

no

Disables/removes the configured null-NRI value used for MSC offloading procedure.

null_nri_value

Specifies the null-NRI value to be used by HNB-GW for load redistribution during MSC offloading as an integer from 0 through 1023.
Without MOCN configuration this value can be entered only once.
For MOCN a unique null-NRI must be assigned to each MOCN operator identified by its PLMN-ID (MCC+MNC).
A 0 (zero) value configured as a null-NRI indicates the keyword is not to be used. There is no default value for this parameter.

Usage

Use this command to identify the MSC to be used by HNB-GW for load redistribution during MSC offloading over an Iu-Flex interface.
There is one unique null-NRI in a PLMN supporting pool functionality.
Without MOCN configuration this command can be entered only once. For MOCN a unique null-NRI must be assigned to each MOCN operator identified by its PLMN-ID (MCC+MNC).

Example

The following command sets the null-NRI as 1001 to be used by HNB-GW for load redistribution during MSC offloading:

null-nri 1001
offload-msc

Provisions the HNB-GW to enable or disable the exclusion of a particular primary MSC node during an NAS Node Selection Function (NNSF) procedure when it needs to be offloaded while using Iu-Flex functionality on the HNB-GW.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-CS Network Configuration

configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config cs-network-instance_id)#

**Syntax**

```
[ no ] offload-msc point-code msc_point_code
```

- **no**
  Removes the specified primary MSC point code from the exclusion list for NNSF function on HNB-GW and re-enables the inclusion of the primary MSC to be considered by HNB-GW.

- **point-code msc_point_code**
  Specifies the SS7 address of the primary MSC in the CS network to be excluded for NNSF function on HNB-GW when it needs to be offloaded via Iu-Flex functionality.

  *point_code* is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ############ format.

  Only one instance of this primary MSC point code can be mapped with one CS core network id.

**Usage**

Use this command to provision the HNB-GW to enable or disable the exclusion of the primary MSC node when it needs to be offloaded.

When this command is enabled for exclusion of primary MSC node during NNSF function in HNB-GW, the HNB-GW excludes the particular node from being considered.

User can re-enable the inclusion of the primary MSC node to be considered for NNSF functionality by **no offload-msc point-code** command.

**Important:** Offload check is only for the primary point code and NOT for the backup point code.

**Example**

This command can be used for planned maintenance as well.

The following command configures the HNB-GW to exclude the primary MSC point code 1.2.3 from being considered in NSSF function for Iu-Flex support:

```
offload-msc point-code 1.2.3
```
The following command re-enables the inclusion of MSC point code 1.2.3 from being considered in NSSF function for Iu-Flex support:

```plaintext
no offload-msc point-code 1.2.3
```
ranap reset

Configures various Radio Access Network (RAN) Application Part reset procedure parameters for CS network association in an HNB access network.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-CS Network Configuration

configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

**Syntax**

```
ranap reset { ack-timeout timer_value | guard-timeout g_timer | hnbgw-initiated | max-retransmissions retries }
```

```
default ranap reset { ack-timeout | guard-timeout | hnbgw-initiated | max-retransmissions }
```

```
no ranap { hnbgw-initiated }
```

---

**default**
Resets the RANAP RESET parameters in HNB-CS Network configuration instance.

---

**no**
Disables the RANAP RESET procedure related parameters in an HNB-CS Network configuration instance.

---

**ack-timeout timer_value**
Sets the timer value (in seconds) to wait for Reset Acknowledge from MSC. This is used during HNB-GW initiated RANAP RESET procedure in HNB-CS Network configuration instance.

*timer_value* is an integer value from 5 through 10. Default: 10

---

**guard-timeout g_timer_value**
Sets the timer value (in seconds) to send Reset Acknowledge to MSC. After this duration the HNB-GW sends RESET-ACK to MSC. This is used during MSC initiated RANAP RESET procedure in HNB-CS Network configuration instance.

*g_timer_value* is an integer value from 5 through 10. Default: 10

---

**hnbgw-initiated**
Enables the HNB-GW Initiated RANAP RESET procedures. Default: Disabled
max-retransmission retries

Sets the maximum number of retries allowed for transmission of RESET-ACK message to MSC. This is used during RANAP RESET procedure in HNB-CS Network configuration instance.

retries is an integer value from 0 through 2. When 0 is used retransmission is disabled. Default: 1

use-actual-plmn

Actual PLMN will be sent in RANAP Reset/Reset Resource. By default, Common PLMN will be sent.

Usage

Use this command to configure the RANAP RESET procedure related parameters in HNB-CS Network configuration for multiple HNB-GW service support.

Example

The following command configures the HNB-GW initiated RANAP RESET Procedure for an HNB-CS Network configuration instance:

```
ranap reset hnbgw-initiated
```
The 3G UMTS Home-NodeB Gateway Global Configuration Mode provides the global configurations for multiple HNB-GW services on a chassis to manage the access to the UMTS core network in a 3G UMTS network through a Femto node. This configuration mode is supported from StarOS 14.0 onward.

Mode

Exec > Global Configuration > HNB-GW Global Configuration

configure > hnbgw-global

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnggw-global)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
access-control-db

Configures the access control database parameters in HNB-GW Global configuration mode to control HNB and UE access to the HNB-GW node.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > HNB-GW Global Configuration

configure > hnbgw-global

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnggw-global)#

Syntax

access-control-db imsi-purge-timeout { immediate | dur }

default access-control-db imsi-purge-timeout

default

Sets the default value to HNB-UE access control database on a chassis for HNB-GW Global configuration instance.

The default timeout duration for purging of the IMSI White List from the HNB-GW Access Control database is 24 hours. The HNB-GW service waits for 24 hours after all referenced HNBs have de-registered before purging the records.

immediate

Sets the HNB-GW Global configuration instance to purge the HNB-UE access control database immediately after all referenced HNBs have de-registered.

imsi-purge-timeout dur

Sets the timeout duration (in minutes) for the access control database to wait before purging the IMSI values received as a White List from HMS/BAC.

After all HNBs have de-registered, the Access Control database on HNB-GW maintains the IMSI White List received from HMS/BAC during HNB registration procedure for the configured durations before purging the list.

dur is an integer from 1 through 1440.

Usage

Use this command to configure the HNB-UE access control database parameters on a chassis for HNB-GW Global configuration instance.

This command sets the timeout duration to maintain the IMSI White List received from HMS/BAC during HNB registration procedure in HNB-GW Global configuration instance for the configured dur in minutes after de-registration of all referenced HNBs from HNB-GW node and then purge the database.
Example

Following command sets the HNB-GW Global configuration instance to purge all IMSI records from HNB-UE access control database immediately after all referenced HNBs de-registered from HNB-GW service instance.

```
access-control-db imsi-purge-timeout immediate
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
end

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

exit

Usage
Use this command to return to the parent configuration mode.
paging hybrid-hnb

Configures paging optimization parameters for hybrid HNBs connected through Hybrid Access mode in the HNB-GW Global parameter.

Product
HNB-GW
Privilege
Security Administrator, Administrator
Mode
Exec > Global Configuration > HNB-GW Global Configuration
configure > hnbgw-global
Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-global)#

Syntax

paging hybrid-hnb always

paging hybrid-hnb hnb-where-ue-registered [hnbs-having-imsi-in-whitelist] fallback {always | never |only-if-with-paging-area}

paging hybrid-hnb hnbs-having-imsi-in-whitelist fallback {always | never |only-if-with-paging-area}

paging hybrid-hnb never

paging hybrid-hnb only-if-with-paging-area

default paging hybrid-hnb

default
Sets the default behavior of paging optimization configuration for a hybrid HNB while using Hybrid Access mode support.
By default the HNB-GW pages hybrid HNBs only if paging-area IE is received in the paging message.

{always | never | only-if-with-paging-area}
Sets the HNB-GW Global parameter to page hybrid HNB for a paging message.
always: Sets the system to ALWAYS page the hybrid HNBs irrespective of paging-area IE is received in paging messages.
never: Sets the system to NEVER page any hybrid HNB.
only-if-with-paging-area: Sets the system to page the hybrid HNBs only when paging-area IE is received in paging messages.

hnb-where-ue-registered fallback {always | never | only-if-with-paging-area}
Sets the HNB-GW Global parameter to page hybrid HNB from where the UE is registered.
always: Sets the system to ALWAYS page the hybrid HNBs from where the UE is registered. If the UE is not registered then it pages the hybrid HNBs irrespective of paging-area IE is received in paging messages.
never: Sets the system to page the hybrid HNBs from where the UE is registered. If the UE is not registered then it NEVER pages any hybrid HNB.
only-if-with.paging-area: Sets the system to ALWAYS page the hybrid HNBs from where the UE is registered. If the UE is not registered then it pages the hybrid HNBs only when paging-area IE is received in paging messages.

hnbs-having-imsi-in-whitelist fallback {always | never | only-if-with-paging-area}

Sets the HNB-GW Global parameter to page hybrid HNB where HNB have IMSI in white-list.
always: Sets the system to ALWAYS page Hybrid HNB which have requested IMSI in whitelist. If no such Hybrid HNB is found, then system will page Hybrid HNBs irrespective of presence or absence of paging-area IE in paging messages.
ever: Sets the system to ALWAYS page Hybrid HNB which have requested IMSI in whitelist. If no such Hybrid HNB is found, then system will NEVER page Hybrid HNBs irrespective of presence or absence of paging-area IE in paging messages.
only-if-with-paging-area: Sets the system to ALWAYS page Hybrid HNB which have requested IMSI in whitelist. If no such Hybrid HNB is found, then system will page hybrid HNB only when paging-area IE is found in paging messages.

Usage
Use this command to configure the paging optimization parameters for hybrid HNBs connected through Hybrid Access mode in HNB-GW Global parameter.

Example
The following command configures the HNB-GW Global parameter to page an hybrid HNB from where the UE is registered and paging-area IE is received in paging message:

```bash
ing hybrdid-hnb hnb-where-ue-registered fallback only-if-with-paging-area
```
paging open-hnb

Configures paging optimization parameters for open HNBs connected through Hybrid Access mode in the HNB-GW Global parameter.

⚠️ Important: This command is deprecated from release 16.0.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-GW Global Configuration
configure > hnbgw-global
Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnggw-global)#
```

**Syntax**

```
paging open-hnb [hnb-where-ue-registered fallback] {always | never | only-if-with-paging-area}
default paging open-hnb
```

**default**
Sets the default behavior of paging optimization configuration for an open HNB while using Open Access mode support.
By default the HNB-GW pages open HNBs only if paging-area IE is received in the paging message.

```
default {always | never | only-if-with-paging-area}
```

Sets the HNB-GW Global configuration instance to page open HNB for a paging message.

- **always**: Sets the system to ALWAYS page the open HNBs irrespective of paging-area IE is received in paging messages.
- **never**: Sets the system to NEVER page any open HNB.
- **only-if-with-paging-area**: Sets the system to page the open HNBs only when paging-area IE is received in paging messages.

```
hnb-where-ue-registered fallback {always | never | only-if-with-paging-area}
```

Sets the HNB-GW Global configuration instance to page open HNB from where the UE is registered.

- **always**: Sets the system to ALWAYS page the open HNBs from where the UE is registered. If the UE is not registered then it pages the open HNBs irrespective of paging-area IE is received in paging messages.
- **never**: Sets the system to page the open HNBs from where the UE is registered. If the UE is not registered then it NEVER pages any open HNB.
- **only-if-with-paging-area**: Sets the system to ALWAYS page the open HNBs from where the UE is registered. If the UE is not registered then it pages the open HNBs only when paging-area IE is received in paging messages.
Usage

Use this command to configure the paging optimization parameters for open HNBs connected through Open Access mode in HNB-GW Global configuration instance.

Example

The following command configures the HNB-GW Global configuration instance to page an open HNB from where the UE is registered and `paging-area` IE is received in paging message:

```plaintext
paging open-hnb hnb-where-ue-registered fallback only-if-with-paging-area
```
sctp

Configures the SCTP-related parameters like timeout duration for various timers and cookie life over an IuH interface on a chassis for HNB-GW Global configuration instance.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-GW Global Configuration
configure > hnbgw-global

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-global)#

Syntax

sctp { alpha-rto alpha_rto_dur | beta-rto beta_rto_dur | max-in-strms in_strms | max-out-strms out_strms | max-retx { assoc | init | path } max_retry }

default sctp { alpha-rto | beta-rto | max-in-strms | max-out-strms | max-retx { assoc | init | path } }

default
Restores the SCTP parameters to default value in HNB-GW Global configuration instance. Default values for all parameters are as follows:

• alpha-rto: 5 seconds
• beta-rto: 10 seconds
• max-in-strms: 4
• max-out-strms: 4
• max-retx assoc: 10 retries
• max-retx init: 5 retries
• max-retx path: 5 retries

alpha-rto alpha_rto_dur
Sets the alpha retransmission timeout duration (in seconds) for SCTP association between HNB and HNB-GW as an integer from 0 through 65535. A “zero” value disables the timer in this configuration. Default: 5

beta-rto beta_rto_dur
Sets the beta retransmission timeout duration (in seconds) for SCTP association between HNB and HNB-GW an integer from 0 through 65535. A “zero” value disables the timer in this configuration. Default: 10
max-retx { assoc | init | path } max_retry

Sets the maximum number of retries allowed in SCTP states for SCTP association between HNB and HNB-GW.

**assoc**: Sets the maximum number of consecutive retransmissions to its peer is allowed. If the value of this counter exceeds the limit configured with this keyword the HNB-GW considers the peer HNB unreachable and stop transmitting any more data to it. The SCTP association is automatically closed when the peer endpoint becomes unreachable. Default number of attempts max_retry for this state is 10.

**init**: Sets the maximum attempts allowed after T1-init timer expires. If the T1-init timer expires then the HNB-GW retransmits INIT chunk and re-start the T1-init timer without changing state. This is repeated up to the configured times with this configuration. After that, the HNB-GW aborts the initialization process. Default number of attempts max_retry for this state is 5.

**path**: Sets the maximum attempts allowed after T3-rtx timer expires. Each time the T3-rtx timer expires on any address, or when a HEARTBEAT sent to an idle address is not acknowledged within a RTO, the error counter of that destination address incremented. When the value in the error counter exceeds this protocol parameter of that HNB address, the HNB-GW marks the destination transport address as inactive. Default number of attempts max_retry for this state is 5.

**max_retry** is an integer from 0 through 255.

max-in-strms in_strms

Sets the maximum number of inward SCTP streams allowed on HNB-GW for an associated HNB in an SCTP association as an integer from 1 through 16. Default: 4

max-out-strms out_strms

Sets the maximum number of outgoing SCTP streams allowed from HNB-GW for an associated HNB in an SCTP association as an integer from 1 through 16. Default: 4

**Usage**

Use this command to configure the SCTP protocol messaging and session management parameters in SCTP association between HNB and HNB-GW.

**Example**

The following command sets the maximum number of inward SCTP streams allowed to 4 on HNB-GW for the SCTP association:

```
default max-in-strms
```
tnnsf-timer

Configures the NAS Node Selection Function (NNSF) timer (T-NNSF) which is used by the HNB-GW to store the IMSI and the relevant Global-CN-ID in the short term after Paging. This timer is used for Iu-Flex feature support.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-GW Global Configuration

configure > hnbgw-global

Entering the above command sequence results in the following prompt:

[local] host_name(config-hnggw-global)#

Syntax

```
        tnnsf-timer dur

[ no | default ] tnnsf-timer
```

no
Disables/removes the configured timer value of NNSF timer (T-NNSF) for HNB-GW Global configuration instance.

default
Sets the timer value of NNSF timer (T-NNSF) for HNB-GW Global configuration instance to default value of 30 seconds.

```
        tnnsf-timer dur
```

Configures the NNSF timer (in seconds) which is used by the HNB-GW to store the IMSI and the relevant Global-CN-ID as an integer from 10 through 60. Default: 30

Usage

Use this command to configure the NNSF timer value in seconds for Iu-Flex support. Whenever the MSC sends the paging request with IMSI, the HNB-GW stores the Global_CN_ID of the node which issued the paging request message for the given IMSI and HNB-GW starts the tnnsf-timer. HNBGW stores the mapping of IMSI to Global_CN_ID until the tnnsf-timer expires

Example

The following command sets the NNSF timer value to 30 seconds on a chassis for HNB-GW Global configuration instance:

```
default tnnsf-timer
```
Chapter 165  
HNB-GW Service Configuration Mode Commands

The 3G UMTS Home-NodeB Gateway Service Configuration Mode manages access to the UMTS core network in a 3G UMTS network through a Femto node.

**Mode**

Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

`configure > context context_name > hnbgw-service service_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbgw-service)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
access-control-db

Configures the access control database parameters in an HNB-GW service instance to control HNB and UE access to the HNB-GW node.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnb-gw-service service_name

Entering the above command sequence results in the following prompt:

[local] host_name(config-hnb-gw-service) #

Syntax

access-control-db imsi-purge-timeout {immediate | dur }

default access-control-db imsi-purge-timeout

default

Sets the default value to HNB-UE access control database on HNB-GW service instance.
The default timeout duration for purging of the IMSI White List from the HNB-GW Access Control database is 24 hours. The HNB-GW service waits for 24 hours after all referenced HNBs have de-registered before purging the records.

immediate

Sets the HNB-GW service to purge the HNB-UE access control database immediately after all referenced HNBs have de-registered.

imsi-purge-timeout dur

Sets the timeout duration (in minutes) for the access control database to wait before purging the IMSI values received as a White List from HMS/BAC.
After all HNBs have de-registered, the Access Control database on HNB-GW maintains the IMSI White List received from HMS/BAC during HNB registration procedure for the configured durations before purging the list.
dur is an integer from 1 through 1440.

Usage

Use this command to configure the HNB-UE access control database parameters on HNB-GW service.
This command sets the timeout duration to maintain the IMSI White List received from HMS/BAC during HNB registration procedure in HNB-GW service for the configured dur in minutes after de-registration of all referenced HNBs from HNB-GW node and then purge the database.

Example
Following command sets the HNB-GW service instance to purge all IMSI records from HNB-UE access control database immediately after all referenced HNBs de-registered from HNB-GW service instance.

```
access-control-db imsi-purge-timeout immediate
```
**associate cbs-service**

Configures CBS service for this HNBGW service.

**Product**

HNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

```
configure > context context_name > hnbgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-hnbgw-service)#
```

**Syntax**

```
associate cbs-service svc_name

no associate cbs-service
```

**no**

Removes the configured CBS service from this HNB-GW service configuration.

**svc_name**

Identifies the name of the pre-configured CBS service to associate with an HNB-GW service. **svc_name** is an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to configure CBS service for HNB-GW service.

**Example**

Following command configures CBS service named *cbs-hnb1* with specific HNB-GW service.

```
associate cbs-service cbs-hnb1
```
associate gtpu-service

Associates a previously configured GTP-U service to bind the HNB-GW service with an HNB towards the HNB side. A GTP-U service must be configured in Context Configuration mode before using this configuration.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

```
configure > context context_name > hnbgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbgw-service)#
```

**Syntax**

```
associate gtpu-service svc_name

no associate gtpu-service
```

no

Removes the associated GTP-U service from this HNB-GW service configuration.

```
svc_name
```

Identifies the name of the pre-configured GTP-U service to associate with an HNB-GW service towards the Home-NodeB side.

svc_name is an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to configure GTP-U data plan between HNB-GW service and Home-NodeB. The service defined for GTP-U can be configured in Context configuration mode.

**Important:** Another GTP-U service can be used to bind the HNB-GW service towards the Core Network and can be configured in HNB-PS Configuration mode. For more information on GTP-U service configuration, refer *GTP-U Service Configuration Mode Commands*.

**Example**

Following command associates GTP-U service named *gtpu-hnbl* with specific HNB-GW service towards Home-NodeB side.

```
associate gtpu-service gtpu-hnbl
```
associate rtp pool

Associates a previously defined RTP pool (IP pool) with the HNB-GW service. This pool is used by HNB-GW to send an IP address to HNB where HNB uses it to map the RTP streams over Iuh interface. This command is used for RTP stream management on HNB-GW.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnb-gw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnb-gw-service)#

Syntax

associate rtp pool pool_name

no associate rtp pool

no

Removes the associated RTP pool (IP pool) from this HNB-GW service configuration.

pool_name

Specifies the name of the pre-configured RTP IP pool that the HNB-GW uses to assign IP addresses when mapping RTP streams over the Iuh interface.

pool_name is an alphanumeric string of 1 through 31 characters.

Important: For IP pool (RTP pool) configuration, refer ip pool command in Context Configuration Mode Commands chapter.

Usage

Use this command to associate an RTP pool (IP Pool) with an HNB-GW service for allotment of RTP IP address to HNB-GW node and send the same to HNB for RTP stream management support. The HNB maps the RTP streams with received IP address(es) while communicating with HNB-GW over Iuh interface where HNB-GW communicates with MSC/VLR through IuCS-over-IP tunnel.

This command is used for RTP stream management on HNB-GW.

Important: This command must be used to provide IP address for mapping of RTP streams on Iuh interface between HNB and HNB-GW.

Example
Following command associates RTP pool named `rtp_1` with HNB-GW service for RTP stream end point from Home-NodeB:

```
associate rtp pool rtp_1
```
**authorised-macro-lai macro-info-ie-absent-action**

This command configures the Action if Macro Coverage information IE is absent in HNB Location Information. The HNB will be accepted for Action Accept and rejected for Action Reject.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

```
configure > context context_name > hnbgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbgw-service)#
```

**Syntax**

```
authorised-macro-lai macro-info-ie-absent-action { accept | reject }
```

**Example**

The following command accepts HNB even if Macro Coverage information IE is absent in HNB Location Information:

```
authorised-macro-lai macro-info-ie-absent-action accept
```
**authorised-macro-lai mcc**

This command configures MCC of Pre-Configured macro lai range for HNB Authorisation.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

`configure > context context_name > hnbgw-service service_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbgw-service)#
```

**Syntax**

```
[ no ]authorised-macro-lai mcc mcc mnc mnc lac range min to max
```

- `no`
  Removes the MCC of Pre-Configured macro lai range for HNB Authorisation.

- `mcc mcc`
  MCC of Pre-Configured macro lai range for HNB Authorisation.
  `mcc` is a number ranging from 100 through 999.

- `mnc mnc`
  MNC of Pre-Configured macro lai range for HNB Authorisation.
  `mnc` is a number ranging from 00 through 999.

- `lac range min to max`
  LAC of Pre-Configured macro lai range for HNB Authorisation.
  LAC is configured as range, if single lac make min is equal to max.
  Macro LAC from `min` to `max` integer values between 0 through 65535.

**Usage**

Use this command to configure the MCC of Pre-Configured macro lai range for HNB Authorisation.

**Example**

The following command configures the MCC of Pre-Configured macro lai range for HNB Authorisation with `mcc 888`, `mnc 44` and `lac range from 10 to 1000`:

```
authorised-macro-lai mcc 678 mnc 788 lac range 10 to 1000
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
handin

Allows or disallows the incoming hand-over of an MS in HNB-GW via the Serving Radio Network Subsystem (SRNS) Relocation procedure for the specified packet switched/circuit switched (PS/CS) core network (CN) domain.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

`configure > context context_name > hnbgw-service service_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbgw-service)#
```

**Syntax**

```
[ no | default ] handin cn-domain [ cs | ps ]
```

---

**no**

Disallows the incoming MS hand-over for the particular CN domain via SRNS Relocation procedure in an HNB-GW service instance.

If hand-over is restricted the relocation request will be rejected with rejection cause “Relocation Not Supported In Target RNC Or Target System”.

---

**default**

Sets the HNB-GW service instance to allow the incoming MS hand-over for the particular CN domain via SRNS Relocation procedure in an HNB-GW service instance.

---

**cs**

Sets the HNB-GW service instance to allow the incoming MS hand-over for the CS core network domain via SRNS Relocation procedure in an HNB-GW service instance.

---

**ps**

Sets the HNB-GW service instance to allow the incoming MS hand-over for the PS core network domain via SRNS Relocation procedure in an HNB-GW service instance.

---

**Usage**

Use this command to set HNB-GW service instance for allowing/disallowing incoming hand-over of an MS in HNB-GW via SRNS Relocation procedure for PS or CS core network domain.

If hand-over is restricted the Relocation Request message will be rejected with rejection cause “Relocation Not Supported In Target RNC Or Target System”.

---

**Example**

The following command configures the HNB-GW service instance to allow hand-over of an MS in HNB-W via SRNS Relocation procedure for PS core network domain:
handin ps
**hnb override-vsa location-based-service**

This command enables / disables overriding of a particular vendor specific attribute of configured location based HNB Service.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

```configure > context context_name > hnbgw-service service_name```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-hnbgw-service)#
```

**Syntax**

```hnb override-vsa location-based-service```

```no hnb override-vsa location-based-service```

```default hnb override-vsa location-based-service```

**no**

Disables the overriding of vendor specific attribute for location based service.

**default**

When set to default, overriding of vendor specific attribute will be disabled.

**Usage**

Use this command to enable / disable overriding of a particular vendor specific attribute of configured location based HNB Service.

**Example**

The following command enables overriding of a particular vendor specific attribute of configured location based HNB Service :

```hnb override-vsa location-based-service```
**hnb-access-mode hybrid**

This command configures the Hybrid HNB access mode in HNB-GW service instance and related parameters.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

`configure > context context_name > hnbgw-service service_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbgw-service)##
```

**Syntax**

```
hnb-access-mode hybrid [ max-non-access-controlled-ue num ]
```

- `no hnb-access-mode hybrid`
- `default hnb-access-mode hybrid`

**no**
Disables the Hybrid Access Mode of HNB service.

**default**
Sets the default configuration of Hybrid Access Mode support. The default value of Maximum Non-Access-Controlled UEs per Hybrid HNB is 64.

By default, HNB-GW allows registration of Non-Access-Controlled UEs per Hybrid HNB and a maximum of 16 UEs can register from a hybrid HNB in an HNB-GW service instance.

**max-non-access-controlled-ue num**
Maximum Non-Access-Controlled UEs per Hybrid HNB.

- `num` is an integer from 0 through 64.

**Usage**

Use this command to configure the Hybrid HNB access mode in HNB-GW service instance and related parameters.

**Example**

The following command configures the Hybrid HNB access mode in HNB-GW service instance and related parameters.:

```
hnb-access-mode hybrid
```
**hnb-access-mode mismatch-action**

This command configures the mismatch action of HNB access mode in HNB-GW service instance and related parameters.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

`configure > context context_name > hnbgw-service service_name`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-hnbgw-service) #
```

**Syntax**

```
hnb-access-mode mismatch-action { accept-aaa-value | hnb-reg-rej }

default hnb-access-mode mismatch-action
```

**default**
Sets the default Hybrid Access Mode of HNB service. The default value of Maximum Non-Access-Controlled UEs per Hybrid HNB is 64.

**accept-aaa-value**
Supports the Accept AAA value.

**hnb-reg-rej**
Supports the HNB Registration Reject.

**Usage**
Use this command to configure the mismatch action of HNB access mode in HNB-GW service instance and related parameters.

**Example**
The following command configures the mismatch action of HNB access mode in HNB Service to Accept AAA value:

```
hnb-access-mode mismatch-action accept-aaa-value
```
hnb-access-mode open

Configures the Open HNB access mode in HNB-GW service instance and related parameters.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration
configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-service)#

Syntax

hnb-access-mode open [ max-registered-ue reg_ue_open]

no hnb-access-mode open

default hnb-access-mode open

no

Disables Open Access mode support.
If disabled and an Open HNB tries to register, the HNB-GW sends HNB-Registration-Reject message with “OAM Intervention” cause.

Important: UE-Reg/CS-Call/PS-Call requests (both existing and future) is allowed from already registered Open HNBs even after operator has disabled the Open Access support. No new Open HNB registration is allowed once operator disables the Open Access support.

default

Sets the default configuration of Open Access mode support.
By default, HNB-GW allows registration of Open HNBs and a maximum of 64 UEs can register from an open HNB in an HNB-GW service instance.

max-registered-ue reg_ue_open

Sets the HNB-GW service instance to allow the maximum number of UEs through an open HNB under Open Access mode support.

reg_ue_open defines the maximum number of UEs that can register from an Open HNB as an integer from 1 through 64.
If a UE tries to register from an Open HNB which has already reached to the configured limit configured, the HNB-GW sends HNB-Registration-Reject message with “ue not allowed in this hnb” cause in an HNB-GW service instance.
**Usage**

Use this command to configure the HNB-GW service instance for Open Access Mode support and related parameters.

This command enables Open Access mode support to allow the UEs that can register from an Open HNB. If a UE tries to register from an Open HNB with an HNB-GW service instance, which is already reached to the limit configured through `max-registered-ue reg_ue_open` the HNB-GW sends HNB-Registration-Reject message with "ue not allowed in this hnb" cause.

**Important:** If Operator has reduced the maximum number of UEs allowed per Open HNB during the session, this will not have any effect on already registered UEs/CS-Calls/PS-Calls even if previously configured `reg_ue_open` is beyond the newly configured `reg_ue_open` value. Limits are respected while handling new requests.

**Example**

The following command configures the HNB-GW service instance to allow 16 UEs to register through an open HNB:

```
  hnb-access-mode open max-registered-ue 16
```
hnb-identity

Configures and also allows modification to the HNB ID before it is sent to the AAA server for authentication in HNB-GW service instance.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnbw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbw-service)#

Syntax

[ default | no ] hnb-identity oui discard-leading-char

no
Disables discarding of leading character of HNB-id if it contains Organizationally Unique Identifier

default
Enables the default behavior of discarding of leading character of HNB-id if it contains Organizationally Unique Identifier. By default this feature is deactivated.

oui discard-leading-char

This CLI allows to modify the HNB ID before it is sent to the AAA server for authentication. By using this CLI, first character of the HNB-id can be removed if the HNB-id follows the format: ‘1<OUI>-<SerialNumber>@<realm>’.

Example

The following command configures the discarding of leading character of HNB-id if it contains Organizationally Unique Identifier:

hnb-identity oui discard-leading-char
ip iu-qos-dscp

Enables or disables the DSCP marking parameter for data packets carried over an IuCS/IuPS interface towards MSC/SGSN. By default this command is **Disabled**.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-service)#

**Syntax**

```
ip iu-qos-dscp protocol udp payload { gtpu | rtcp | rtp } dscp_code
[ default | no ] ip iu-qos-dscp protocol udp payload { gtpu | rtcp | rtp } dscp_code
```

- **no**
  
  Use this keyword to place the configuration in **pass-through** mode (no marking of DSCP). Use of this keyword is allowed even when there is no previous DSCP parameter set.

  **Important:** In this configuration the **no** keyword does not disable or remove a previous configuration.

- **default**
  
  Enables the DSCP marking on HNB-GW and set/restores the QoS parameters to their default setting.

  ```
  udp payload { gtpu | rtcp | rtp } dscp_code
  ```

  Specifies the QoS traffic pattern towards MSC/SGSN in SCTP protocol association over IuCS/IuPS interface. By this keyword the Traffic classes specified by a user based on UDP protocol and GTPU, RTCP, and RTP type of payload identified based on the transport level port numbers.

  Default DSCP code in UDP traffic are:

  - **GTP-U**: cs1
  - **RTCP**: ef
  - **RTP**: af41

  ```
  dscp_code
  ```

  Specifies the QoS DSCP codes supported for SCTP and UDP traffic and its payloads towards MSC/SGSN over IuCS/IuPS interface.

  **following type of DSCP codes** **dscp_code** **are supported over IuH interface:**
• af11: Marks traffic as Assured Forwarding 11 PHB (high throughput data)
• af12: Marks traffic as Assured Forwarding 12 PHB (high throughput data)
• af13: Marks traffic as Assured Forwarding 13 PHB (high throughput data)
• af21: Marks traffic as Assured Forwarding 21 PHB (low latency data)
• af22: Marks traffic as Assured Forwarding 22 PHB (low latency data)
• af23: Marks traffic as Assured Forwarding 23 PHB (low latency data)
• af31: Marks traffic as Assured Forwarding 31 PHB (multimedia streaming)
• af32: Marks traffic as Assured Forwarding 32 PHB (multimedia streaming)
• af33: Marks traffic as Assured Forwarding 33 PHB (multimedia streaming)
• af41: Marks traffic as Assured Forwarding 41 PHB (multimedia conferencing). This is the default DSCP code for RTP payloads in UDP protocol.
• af42: Marks traffic as Assured Forwarding 42 PHB (multimedia conferencing)
• af43: Marks traffic as Assured Forwarding 43 PHB (multimedia conferencing)
• cs1: Marks traffic with Class Selector 1 (low priority data). This is the default DSCP code for GTP-U payloads in UDP protocol.
• cs2: Marks traffic with Class Selector 2 (OAM)
• cs3: Marks traffic with Class Selector 3 (broadcast video)
• cs4: Marks traffic with Class Selector 4 (real-time interactive)
• cs5: Marks traffic with Class Selector 5 (signaling). This is the default DSCP code for all SCTP payloads.
• cs6: Marks traffic with Class Selector 6 (network control)
• df: Marks traffic as Default Forwarding (best effort: DSCP = 0)
• ef: Marks traffic as Expedited Forwarding PHB (telephony). This is the default DSCP code for RTCP payloads in UDP protocol.

Usage
Use this command to enable/disable the DSCP marking for data packets over IuCS/PS interface. This command assigns the DSCP levels to specific traffic patterns in order to ensure that the packets are delivered according to the precedence with which they are tagged. The Diffserv markings are applied to the IP header of every subscriber data packet transmitted over IuCS/IuPs interface(s) towards MSC/SGSN.

This command adds DSCP marking on egress traffic going towards CN (CS/PS). To make the configuration pass-through mode or not marking DSCP at all in the packets, no variant of command is used. Use of no is allowed even when there is no previous DSCP configuration done.

Important: By default this command is Disabled.

Important: When DSCP configuration is not specified, the system works in pass-through mode and DSCP values in the ingress (from CN) and egress (to HNB) data packets remain unchanged. Multiple traffic classes can share the same code point value.
Following type shown in following tables respectively:

Table 31. Supported DSCP Codes and Service Class

Example

The DSCP level can be configured for multiple traffic patterns within a single instance of this command.

The following command configures the DSCP code for the SCTP IuCS/IuPS streaming traffic pattern for all payloads to be ef:

\[ \text{ip iu-qos-dscp protocol sctp payload all ef} \]
### ip iuh-qos-dscp

Enables or disables the DSCP marking parameter for control and data packets transmitted over an IuH interface towards HNB. By default this command is **Disabled**.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

```
configure > context context_name > hnbw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbw-service)#
```

**Syntax**

```
ip iuh-qos-dscp protocol { sctp payload all | udp payload { gtpu | rtcp | rtp } } dscp_code
```

Use this keyword to set the configuration in **pass-through** mode. Use of this keyword is allowed even when there is no previous DSCP parameter set.

**Important:** In this configuration the `no` keyword does not disable/remove a previous configuration.

```
[ default | no ] ip iuh-qos-dscp protocol { sctp payload all | udp payload { gtpu | rtcp | rtp } } dscp_code
```

**default**

Enables the DSCP marking on HNB-GW and set/restores the QoS parameters to its default setting.

```
sctp payload all dscp_code
```

Specifies the QoS traffic pattern towards HNB in SCTP protocol association over IuH interface. By this keyword the Traffic classes specified by a user based on SCTP protocol and all type of payload identified based on the transport level port numbers. By default DSCP codes **cs5** is supported for all payloads in SCTP protocol.

```
udp payload { gtpu | rtcp | rtp } dscp_code
```

Specifies the QoS traffic pattern towards HNB in SCTP protocol association over IuH interface. By this keyword the Traffic classes specified by a user based on UDP protocol and GTPU, RTCP, and RTP type of payload identified based on the transport level port numbers. Default DSCP code in UDP traffic are:

- **GTP-U:** `cs1`
**rtcp**: ef
**rtp**: af41

dscp_code

Specifies the QoS DSCP codes supported for SCTP and UDP traffic and its payloads towards HNB over IuH interface. The following type of DSCP codes dscp_code are supported over IuH interface:

- **af11**: Marks traffic as Assured Forwarding 11 PHB (high throughput data)
- **af12**: Marks traffic as Assured Forwarding 12 PHB (high throughput data)
- **af13**: Marks traffic as Assured Forwarding 13 PHB (high throughput data)
- **af21**: Marks traffic as Assured Forwarding 21 PHB (low latency data)
- **af22**: Marks traffic as Assured Forwarding 22 PHB (low latency data)
- **af23**: Marks traffic as Assured Forwarding 23 PHB (low latency data)
- **af31**: Marks traffic as Assured Forwarding 31 PHB (multimedia streaming)
- **af32**: Marks traffic as Assured Forwarding 32 PHB (multimedia streaming)
- **af33**: Marks traffic as Assured Forwarding 33 PHB (multimedia streaming)
- **af41**: Marks traffic as Assured Forwarding 41 PHB (multimedia conferencing). This is the default DSCP code for RTP payloads in UDP protocol.
- **af42**: Marks traffic as Assured Forwarding 42 PHB (multimedia conferencing)
- **af43**: Marks traffic as Assured Forwarding 43 PHB (multimedia conferencing)
- **cs1**: Marks traffic with Class Selector 1 (low priority data). This is the default DSCP code for GTP-U payloads in UDP protocol.
- **cs2**: Marks traffic with Class Selector 2 (OAM)
- **cs3**: Marks traffic with Class Selector 3 (broadcast video)
- **cs4**: Marks traffic with Class Selector 4 (real-time interactive)
- **cs5**: Marks traffic with Class Selector 5 (signaling). This is the default DSCP code for all SCTP payloads.
- **cs6**: Marks traffic with Class Selector 6 (network control)
- **df**: Marks traffic as Default Forwarding (best effort: DSCP = 0)
- **ef**: Marks traffic as Expedited Forwarding PHB (telephony). This is the default DSCP code for RTCP payloads in UDP protocol.

**Usage**

Use this command to enable/disable the DSCP marking for control and data packets carried by the IP protocols and their payloads on IuH. This command assigns the DSCP levels to specific traffic patterns in order to ensure that the packets are delivered according to the precedence with which they are tagged. The DiffServ markings are applied to the IP header of every subscriber data packet transmitted over IuH interface(s) towards HNB.
This command adds DSCP marking on egress traffic going towards HNB. To make the configuration pass-through mode or not marking DSCP at all in the packets, no variant of command is used. Use of no is allowed even when there is no previous DSCP configuration done.

**Important:** By default this command is Disabled.

**Important:** When DSCP configuration is not specified, system works in pass-through mode and DSCP value in the ingress (from CN) and egress (to HNB) control and data packets remain unchanged. Multiple traffic classes can share the same code point value.

The DSCP level can be configured for multiple traffic patterns within a single instance of this command.

**Example**

The following command configures the DSCP code for the SCTP IuH streaming traffic pattern for all payloads to be ef:

```
ip iuh-qos-dscp protocol sctp payload all ef
```
paging cs-domain

Configures paging optimization parameters for CS domain in the HNB-GW service instance.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnb-gw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnb-gw-service)#

Syntax

paging cs-domain { handle-unknown-imsi { use-cn.paging-area | use-whitelist } | phase1
page-last-known-hnb timeout timeout_val1 | phase2 paging-grid-fan-out timeout
timeout_val2 | phase3 paging-area-fan-out timeout timeout_val3 }

no paging cs-domain { handle-unknown-imsi { use-cn.paging-area | use-whitelist } | phase1
page-last-known-hnb | phase2 paging-grid-fan-out | phase3 paging-area-fan-out }

default paging cs-domain { handle-unknown-imsi { use-cn.paging-area | use-whitelist } | phase1
page-last-known-hnb timeout | phase2 paging-grid-fan-out timeout | phase3 paging-
area-fan-out timeout }

default
Sets the default behavior of paging optimization configuration for the a specific HNB-GW service.

no
Removes paging optimization configuration for an appended option in a specific HNB-GW service.

handle-unknown-imsi
Handles Unknown IMSIs Options.

use-cn.paging-area
Uses paging area provided by Core Network for forwarding the Page Req to all open/hybrid HNBs.

use-whitelist
Uses whitelist of HNBs for forwarding the Page req to all closed/hybrid HNBs.

phase1
Paging Phase1 Configuration - Forwards Page Req to last-known-hnb.
**page-last-known-hnb**
Page the last known HNB for the call.

**timeout timeout_val1**
Sets the timeout value in seconds for the last-known-hnb paging configuration. It is an integer value ranging from 1 to 30.

**phase2**
Paging Phase2 Configuration - Forwards Page Req to all HNBs in the Grid of last-known-hnb.

**paging-grid-fan-out**
Pages the last known paging grid.

**timeout_val2**
Sets the timeout value in seconds for the grid fan-out paging configuration. It is an integer value ranging from 1 to 30.

**phase3**
Paging Phase3 Configuration - Forwards Page Req to all HNBs in the LAI of last-known-hnb.

**paging-area-fan-out**
Pages the last known paging area.

**timeout_val3**
Sets the timeout value in seconds for the area fan-out paging configuration. It is an integer value ranging from 1 to 30.

**Usage**
Use this command to configure the CS domain paging optimization parameters for a specific HNB-GW service instance.

**Example**
The following command configures the CS domain paging optimization for grid fan-out timeout as 15 seconds for a specific HNB-GW service:

```
    paging cs-domain phase2 paging-grid-fan-out timeout 15
```
paging imsi-purge-timer

Configures paging optimization based on the timer for purging the unregistered IMSIs in the HNB-GW service instance.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

```bash
configure > context context_name > hnbgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbgw-service)#
```

**Syntax**

```bash
 paging imsi-purge-timer timeout timeout_val1
```

```bash
 default paging imsi-purge-timer timeout
```

**Usage**
Sets the default value for the IMSI purge timer as 3 hours.

```bash
 default
```

Sets the timeout value for the IMSI purge timer in hours. It is an integer ranging 1 to 12.

```bash
 timeout_val1
```

**Example**
Use this command to configure the timer value for purging the unknown IMSIs for paging optimization configuration in a specific HNB-GW service instance.

The following command configures the IMSI purge timer as 4 hours for a specific HNB-GW service instance:

```bash
 paging imsi-purge-timer timeout 4
```
paging ps-domain

Configures paging optimization parameters for PS domain in the HNB-GW service instance.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration
configure > context context_name > hnb-gw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnb-gw-service)#

**Syntax**

```
paging ps-domain { handle-unknown-imsi { use-cn-paging-area | use-whitelist } } | phase1 page-last-known-hnb timeout timeout_val1 | phase2 paging-grid-fan-out timeout timeout_val2 | phase3 paging-area-fan-out timeout timeout_val3 }

no paging ps-domain { handle-unknown-imsi [ use-cn-paging-area | use-whitelist ] } | phase1 page-last-known-hnb | phase2 paging-grid-fan-out | phase3 paging-area-fan-out }

default paging ps-domain { handle-unknown-imsi [ use-cn-paging-area | use-whitelist ] } | phase1 page-last-known-hnb timeout | phase2 paging-grid-fan-out timeout | phase3 paging-area-fan-out timeout }
```

**default**
Sets the default behavior of paging optimization configuration for the a specific HNB-GW service.

**no**
Removes paging optimization configuration for an appended option in a specific HNB-GW service.

**handle-unknown-imsi**
Handles Unknown IMSIs Options.

**use-cn-paging-area**
Uses paging area provided by Core Network for forwarding the Page Req to all open/hybrid HNBs.

**use-whitelist**
Uses whitelist of HNBs for forwarding the Page req to all closed/hybrid HNBs.

**phase1**
Paging Phase1 Configuration - Forwards Page Req to last-known-hnb.
**page-last-known-hnb**

Page the last known HNB for the call.

**timeout timeout_val1**

Sets the timeout value in seconds for the last-known-hnb paging configuration. It is an integer value ranging from 1 to 30.

**phase2**

Paging Phase2 Configuration - Forwards Page Req to all HNBs in the Grid of last-known-hnb.

**paging-grid-fan-out**

Pages the last known paging grid.

**timeout_val2**

Sets the timeout value in seconds for the grid fan-out paging configuration. It is an integer value ranging from 1 to 30.

**phase3**

Paging Phase3 Configuration - Forwards Page Req to all HNBs in the LAI of last-known-hnb.

**paging-area-fan-out**

Pages the last known paging area.

**timeout_val3**

Sets the timeout value in seconds for the area fan-out paging configuration. It is an integer value ranging from 1 to 30.

**Usage**

Use this command to configure the PS domain paging optimization parameters for a specific HNB-GW service instance.

**Example**

The following commandconfigures the PS domain paging optimization grid fan-out timeout as 20 seconds for a specific HNB-GW service:

```
paging ps-domain phase2 paging-grid-fan-out timeout 15
```
**paging open-hnb**

Configures paging optimization parameters for open HNBs connected through Open Access mode in the HNB-GW service instance. In this release it is used to configure paging optimization for Open Access mode support only. This command is deprecated release 15.0 onwards. Paging optimization can be configured using other `paging` commands available in this chapter.

**Important:** From Release 14.0 and onward this command is part of HNB-Global Configuration Mode.

**Important:** From Release 16 and later, this command has been deprecated.

**Product**

HNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

`configure > context context_name > hnbgw-service service_name`

Entering the above command sequence results in the following prompt:

`[local]host_name(config-hnbgw-service)#`

**Syntax**

```
paging open-hnb [hnb-where-ue-registered fallback ] {always | never | only-if-with-paging-area}

default paging open-hnb
```

**default**

Sets the default behavior of paging optimization configuration for an open HNB while using Open Access mode support. By default the HNB-GW pages open HNBs only if paging-area IE is received in the paging message.

```
{always | never | only-if-with-paging-area}
```

Sets the HNB-GW service instance to page open HNB for a paging message.

**always:** Sets the system to ALWAYS page the open HNBs irrespective of paging-area IE is received in paging messages.

**never:** Sets the system to NEVER page any open HNB.

**only-if-with-paging-area:** Sets the system to page the open HNBs only when paging-area IE is received in paging messages.

```
hnb-where-ue-registered fallback {always | never | only-if-with-paging-area}
```

Sets the HNB-GW service instance to page open HNB from where the UE is registered.

**always:** Sets the system to ALWAYS page the open HNBs from where the UE is registered. If the UE is not registered then it pages the open HNBs irrespective of paging-area IE is received in paging messages.
HNB-GW Service Configuration Mode Commands

```
never: Sets the system to page the open HNBs from where the UE is registered. If the UE is not registered then it NEVER pages any open HNB.
only-if-with-paging-area: Sets the system to ALWAYS page the open HNBs from where the UE is registered. If the UE is not registered then it pages the open HNBs only when paging-area IE is received in paging messages.
```

Usage

Use this command to configure the paging optimization parameters for open HNBs connected through Open Access mode in HNB-GW service instance.

Example

The following command configures the HNB-GW service instance to page an open HNB from where the UE is connected and paging-area IE is received in paging message:

```
paging open-hnb hnb-where-ue-registered fallback only-if-with-paging-area
```
radio-network-plmn

Creates, remove and enters the HNB-RN-PLMN Configuration mode. In this mode you can configure various parameters for radio network public mobile land networks (PLMNs). A maximum of 16 radio PLMN-IDs can be configured in an HNB-GW service.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-service)#

Syntax

radio-network-plmn mcc mcc_num mnc mnc_num [ -noconfirm ]

no radio-network-plmn mcc mcc_num mnc mnc_num

Removes the configured radio network PLMN identifier for an HNB-GW service.

⚠️ Caution: Removing the PLMN-ID is a disruptive operation; the HNB-GW service will be re-started.

mcc mcc_num
Specifies the mobile country code (MCC) part of radio network PLMN identifier as an integer value from 101 through 998.

mnc mnc_num
Specifies the mobile network code (MNC) part of radio network PLMN identifier as a 2- or 3-digit integer from 01 through 998.

-noconfirm
Executes the command without any additional prompt and confirmation from the user.

Usage
Use this command to configure the radio network PLMN identifier for an HNB-GW service. This command also creates a configuration mode to configure various parameters for defined radio network PLMN identifier in HNB-GW service.
Caution: Changing or removing the PLMN-ID is a disruptive operation; the HNB-GW service will be re-started.

Entering this command results in the following prompt:

```
[context_name] hostname(config-radio-network-plmn) #
```

A maximum of 16 radio network PLMN identifiers are supported for an HNB-GW service.

Example

The following command configures the radio network PLMN identifier with MCC value as 102 and MNC value as 20 for an HNB-GW service:

```
radio-network-plmn mmc 102 mnc 20
```
ranap reset

Configures various Radio Access Network (RAN) Application Part reset procedure parameters in an HNB access network.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration
configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-service)#

Syntax

ranap reset {ack-timeout timer_value | guard-timeout g_timer | hnbgw-initiated | max-retransmissions retries}

default ranap reset {ack-timeout | guard-timeout | hnbgw-initiated | max-retransmissions }

no ranap hnbgw-initiated

default
Resets the RANAP RESET parameters on HNB-GW service instance.

no
Disables the RANAP RESET procedure related parameters in an HNB-GW service instance.

ack-timeout timer_value
Sets the timer value (in seconds) to wait for Reset Acknowledge from SGSN/MSC. This is used during HNB-GW initiated RANAP RESET procedure in HNB-GW service instance.
timer_value is an integer value from 5 through 10. Default: 10

guard-timeout g_timer_value
Sets the timer value (in seconds) to send Reset Acknowledge to SGSN/MSC. After this duration the HNB-GW sends RESET-ACK to SGSN/MSC. This is used during SGSN/MSC initiated RANAP RESET procedure in HNB-GW service instance.
g_timer_value is an integer value from 5 through 10. Default: 10

hnbgw-initiated
Enables the HNB-GW Initiated RANAP RESET procedures. Default: Disabled
max-retransmission retries

Sets the maximum number of retries allowed for transmission of RESET-ACK message to SGSN/MSC. This is used during RANAP RESET procedure in HNB-GW service instance.

retries is an integer value from 0 through 2. When 0 is used retransmission is disabled. Default: 1

Usage

Use this command to configure the RANAP RESET procedure related parameters in HNB-GW service.

Example

The following command configures the HNB-GW initiated RANAP RESET Procedure for an HNB-GW service:

```bash
ranap reset hnbgw-initiated
```
**rtcp report**

Enables or disables the generation of RTP Control Protocol (RTCP) packet/report types on a per HNB-GW service instance basis. It also sets the time interval in seconds between two consecutive RTCP reports.

**Product**

HNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnbw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbw-service)#

**Syntax**

rtcp report interval *dur*

[ no | default ] rtcp report interval

---

**no**

Disables the RTCP report generation on HNB-GW service. When RTP configuration is not explicitly mentioned, this is the default behavior.

**default**

Restores the report interval value to its default value of 5 seconds.

**interval *dur***

Sets the time interval (in seconds) between two consecutive RTCP reports as an integer from 5 through 30. Default: 5

**Usage**

Use this command to configure the enabling or disabling of the generation of RTCP packet/report types on a per HNB-GW service instance basis and sets the specified time interval in seconds between two consecutive RTCP reports.

RTCP enables the receiver to detect if there is any packet loss and needs to compensate for any delay jitter. RTP and RTCP protocols work independently of the underlying Transport layer and Network layer protocols. Whenever this command is disabled, RTCP report generation stops from the next expiry of the previously configured interval and after enabling, reports are generated only for the calls that established as new calls in the future. For existing calls reports generated as per configuration in place.

RTCP reports are generated for each RAB for RTP received from and sent to IuH interface.

**Important:** The same interval is applicable for all kinds of RTCP packets/reports across all sessions on an HNB-GW service.
Example

The following command configures the RTCP report generation interval to 15 seconds on an HNB-GW service for RTP stream:

```bash
rtcp report interval 15
```
**rtp mux**

Configures the HNB-GW service to allow an Home-NodeB to multiplex multiple RTP streams in one IP packet. This support is provided for RTP stream management feature on HNB-GW.

**Product**

HNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

```conf
configure > context context_name > hnbgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbgw-service)#
```

**Syntax**

```
[ no | default ] rtp mux
```

- **default**
  
  Sets the multiplexing option to default state of “disabled”.

- **no**
  
  Removes the configured option to multiplex multiple RTP stream in one packet by Home-NodeB in HNB-GW configuration.

**Usage**

Use this command to allow an Home-NodeB to multiplex multiple RTP streams in one IP packet. This configuration support is provided for RTP stream management feature on HNB-GW and it is disabled by default.

**Example**

The following command sets the HNB-GW to allow HNB to multiplex multiple RTP stream in one packet:

```
rtp mux
```
sctp bind

Configures the SCTP IP address and port that is used for binding the SCTP socket to communicate with the Home-NodeB over an Iuh interface within an HNB-GW service.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

```
configure > context context_name > hnbgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbgw-service)#
```

**Syntax**

```
sctp bind { address address | port port_num }

[ no ] sctp bind { address | port }
```

- **no**
  Removes the SCTP binding.

- **address address**
  Specifies the IP address of the HNB-GW Iuh interface in IPv4 dotted-decimal.

- **port port_num**
  Specifies the SCTP port number to communicate with the Home-NodeBs using Iuh interface as an integer form 1 through 65535.

**Usage**

Use this command to assign the SCTP IP address and port with SCTP socket on HNB-GW to communicate with the Home-NodeB using Iuh interface. This SCTP configuration provides the IP-address and listen port where HNB-GW service shall bind to listen for incoming SCTP associations from HNB.

**Example**

The following command sets the SCTP port number 999 on HNB-GW to listen from Home-NodeB over Iuh interface:

```
sctp bind port 999
```

The following command sets the SCTP address 10.2.3.4 of HNB-GW to use with Home-NodeB over Iuh interface:

```
sctp bind address 10.2.3.4
```
sctp checksum-type

Configures SCTP checksum-type.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Syntax

sctp checksum-type { adler32 | crc32 }

default sctp checksum-type

Usage
Use this command to configure SCTP checksum-type.

Example

The following command sets the SCTP checksum-type to adler32 on HNB-GW:

    sctp checksum-type adler32
sctp connection-timeout

Configures the SCTP connection timeout duration to explicitly remove the SCTP association with a non-responsive HNB in an HNB-GW service.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration
`configure > context context_name > hnbgw-service service_name`

Entering the above command sequence results in the following prompt:

`[local]host_name(config-hnbgw-service)#`

**Syntax**

```
sctp connection-timeout dur
[ default | no ] sctp connection-timeout
```

- **no**
  Disables the connection time out configuration on HNB-GW service.

- **default**
  Restores the connection timeout duration value to its default value of 10 seconds.

- **dur**
  Sets the connection timeout duration (in seconds) after which the association is explicitly removed. In case of an HNB de-registration scenario, the HNB-GW waits for configured amount time before initiating the procedure to clear the SCTP association.
  `dur` is an integer from 5 through 30. Default: 10

**Usage**

Use this command to configure the minimum duration value before removing the SCTP association between a non-responding HNB and HNB-GW. If HNB registration not happened within the configured period after the SCTP association is established then the SCTP association is explicitly removed. In a scenario where an HNB de-registered due to any reason, the HNB-GW waits for the configured amount of time before initiating the procedure to clear the SCTP association.

**Example**

The following command sets the SCTP connection timeout duration to 15 seconds on HNB-GW after expiry of which the SCTP association is removed:

```
sctp connection-timeout 15
```
sctp cookie-life

Configures the SCTP valid cookie-life, Min 5000ms and Max 120000ms with granularity of 100ms.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

```
configure > context context_name > hnbgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbgw-service)#
```

Syntax

```
sctp cookie-life dur
```

```
default sctp cookie-life
```

```
default
```

Restores the SCTP cookie-life value.

```
dur
```

Sets the SCTP cookie-life (in seconds).

```
dur is an integer from 50 through 1200.
```

Usage

Use this command to configure the SCTP valid cookie-life.

Example

The following command sets the SCTP cookie-life value to 55 on HNB-GW:

```
sctp cookie-life 55
```
**sctp heart-beat-timeout**

Configures the SCTP heartbeat timer parameters for SCTP connection over an IuH interface in an HNB-GW service instance.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

`configure > context context_name > hnbgw-service service_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbgw-service)#
```

**Syntax**

```
sctp heart-beat-timeout dur

[ default | no ] sctp heart-beat-timeout
```

- **no**
  Disables the heartbeat timer configuration for SCTP over IuH in HNB-GW service instance.

- **default**
  Restores the default time out value for heartbeat timer to 30 seconds.

- **dur**
  Sets the heartbeat timer timeout duration (in seconds) after which the next heartbeat command is sent to HNB from HNB-GW in SCTP over an IuH interface. In an HNB de-registration scenario, the HNB-GW waits for configured amount time before initiating the procedure to clear the SCTP association. `dur` is an integer from 1 through 300. Default: 30

**Usage**

Use this command to configure the minimum duration value before retransmitting the HEARTBEAT chunk to HNB from HNB-GW in SCTP transmission. By default HNB-GW monitors the reachability of the idle HNBs by sending a HEARTBEAT chunk periodically to the HNB address. Each time the HEARTBEAT timer expires on any address, or when a HEARTBEAT sent to an idle address is not acknowledged within a Retransmission Timeout duration, the error counter of that HNB incremented. When the value in the error counter exceeds the protocol parameter for maximum retransmission for that destination address, the HNB-GW mark the destination HNB as inactive and a notification is sent to the upper layer.

**Example**

The following command sets the SCTP HEARTBEAT timeout duration to 15 seconds on HNB-GW after expiry of which the HNB-GW retransmits the HEARTBAT chunk to HNB over SCTP association:
sctp heart-beat-timeout 15
sctp mtu-size

This command configures SCTP mtu-size, Min 508 bytes and Max is 65535 bytes with granularity of 1 byte.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-service)#

Syntax

sctp mtu-size { max | min | start } size

default sctp mtu-size { max | min | start }

default

Sets the SCTP mtu-size to its default value.

size

size is an integer from 508 through 65535.

Usage

Use this command to configure the SCTP mtu-size.

Example

The following command configures the SCTP mtu-size max value to 555 on HNB-GW:

sctp mtu-size max 555
sctp rto

This command sets the SCTP Retransmission Timeout value.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration
configure > context context_name > hnbw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbw-service)#

Syntax

sctp rto { initial initial_value | max max_value | min min_value }

default sctp rto { initial | max | min }

default
Sets the SCTP Retransmission Timeout value to default.

initial_value
initial_value is SCTP Retransmission Timeout initial value, which is an integer from 1 through 1200.

max_value
max_value is SCTP Retransmission Timeout max value (Min 500 ms and max 120000 ms with granularity of 100 ms), which is an integer from 5 through 1200.

min_value
min_value is SCTP Retransmission Timeout max value (Min 100 ms and max 5000 ms with granularity of 100 ms), which is an integer from 1 through 50.

Usage
Use this command to set the SCTP Retransmission Timeout value.

Example
The following command sets the SCTP max Retransmission Timeout value to 555 on HNB-GW:

sctp rto max 555
sctp sack-frequency

This command configures the SCTP Selective Ack Frequency.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration
configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-service)#

Syntax

sctp sack-frequency value

default sctp sack-frequency

- default
  Sets the SCTP sack-frequency value to default.

- value
  Min value is 1 and Max value is 5.
  value is an integer from 1 through 5.

Usage
Use this command to configure the SCTP Selective Ack Frequency.

Example
The following command configure the SCTP Selective Ack Frequency to 5 on HNB-GW:

```
sctp sack-frequency 55
```
sctp sack-period

This command is used to configure SCTP Selective Ack Period in Seconds.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-service)#

Syntax

**sctp sack-period** value

default sctp sack-period

default

Sets the SCTP sack-period value to default.

value

Min 0 ms and Max is 500ms with granularity of 100ms.

Value is an integer from 0 through 5.

Usage

Use this command to configure the SCTP Selective Ack Period in Seconds.

Example

The following command configures the SCTP Selective Ack Period in Seconds to 5 on HNB-GW:

```
sctp sack-period 55
```
security-gateway bind

Binds the SeGW in an HNB-GW service to a logical IP interface serving as an Iuh interface and associates an IPsec IKEv2 crypto-map template.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-service)#

Syntax

security-gateway bind address address crypto-template cryp_name [ context ctx_name]

no security-gateway bind

no

Removes a previously configured IPsec IP address use for binding the IKEv2 IPSec tunnel (local bind address) to communicate with the Home-NodeBs using Iuh interface.

bind address address

Specifies the IP address for the Iuh interface for the IPSec tunnel. This is the IP address where the HNB-GW service is bound and that is provided to the Home-NodeB during HNB-GW discovery. The IP address is expressed in IPv4 dotted-decimal.

crypto-template cryp_name

Specifies the Crypto-map template to be used for IPsec IKEv2 tunneling for the interface configured as an Iuh.

cryp_name specifies the name of the pre-configured Crypto-map template which is configured in Crypto-Map Template Configuration mode and associated with the HNB-GW service to create an IPSec tunnel with a Home-NodeB during HNB-GW discovery procedure over an Iuh interface.

context ctx_name

Specifies the name of the pre-configured context in which the Security Gateway service is configured. By default this command uses the HNB-GW service context for the security Gateway configuration.

Usage

Use this command to associate or tie the HNB-GW service to a specific logical IP address that is used for binding the Iuh socket to communicate with the Home-NodeB using IPSec tunnel. A maximum of one IP address can be configured with this command for one HNB-GW service.
The HNB-GW passes the IP address during setting up the HNB-GW discovery procedure with the Home-NodeB.

⚠️ **Caution:** This is a critical configuration. The HNB-GW service cannot be started without this configuration. Any change to this configuration would lead to restarting the HNB-GW service and removing or disabling this configuration stops the HNB-GW service.

**Example**

The following command binds the logical IP interface with the address of 10.2.3.4 to the HNB-GW service using existing IPsec Crypto-Map template `crypto1` to establish IPSec tunnel with Home-NodeB:

```
security-gateway bind address 10.2.3.4 crypto-template crypto1
```

The following command disables a binding that was previously configured:

```
security-gateway bind address
```
**sessmgr-to-cbsmgr-pacing-timer**

This command configures pacing timer value for SABP messages being sent from Sessmgr to CBSmgr. Default value is 100ms.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

`configure > context context_name > hnbgw-service service_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbgw-service)#
```

**Syntax**

```
(sessmgr-to-cbsmgr-pacing-timer miliseconds)
```

**Usage**
Pacing timer value in miliseconds which is an integer from 10 through 500.

**Example**

Use this command to configure pacing timer value for SABP messages being sent from Sessmgr to CBSmgr.

The following command sets pacing timer value for SABP messages being sent from Sessmgr to CBSmgr to 50:

```
(sessmgr-to-cbsmgr-pacing-timer 50)
```
tnnsf-timer

Configures the NAS Node Selection Function (NNSF) timer (T-NNSF) which is used by the HNB-GW to store the IMSI and the relevant Global-CN-ID in the short term after Paging. This timer is used for Iu-Flex feature support.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

```bash
configure > context context_name > hnbw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbw-service)#
```

**Syntax**

```
tnnsf-timer dur
[no | default] tnnsf-timer
```

- **no**
  Disables/removes the configured timer value of NNSF timer (T-NNSF) from HNB-GW service instance.

- **default**
  Sets the timer value of NNSF timer (T-NNSF) for HNB-GW service instance to default value of 30 seconds.

```
 tnnsf-timer dur
```

Configures the NNSF timer (in seconds) which is used by the HNB-GW to store the IMSI and the relevant Global-CN-ID as an integer from 10 through 60. Default: 30

**Usage**

Use this command to configure the NNSF timer value in seconds for Iu-Flex support. Whenever the MSC sends the paging request with IMSI, the HNB-GW stores the Global_CN_ID of the node which issued the paging request message for the given IMSI and HNB-GW starts the tnnsf-timer. HNBGW stores the mapping of IMSI to Global_CN_ID until the tnnsf-timer expires

**Example**

The following command sets the NNSF timer value to 30 seconds in an HNB-GW service instance:

```
default tnnsf-timer
```
ue registration-timeout

Configures the UE registration timeout duration to de-register the connected UE from an HNB-GW service.

Product
- HNB-GW

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration
- configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-service)#

Syntax

```
ue registration-timeout dur
[ default | no ] ue registration-timeout
```

- **no**
  Disables the UE registration timeout duration and explicitly de-registers UE from the HNB-GW service.

- **default**
  Restores the UE registration timeout duration value to its default value of 120 seconds.

- **dur**
  Sets the UE registration timeout duration (in seconds) after which the UE is de-registered from HNB-GW. In a scenario when all Iu connections are released for a subscriber, the HNB-GW service de-registers the UE after the configured duration only.
  
  `dur` is an integer from 60 through 300. Default: 120

Usage

Use this command to configure the minimum duration value before de-registering the UE when subscriber fails to establish the Iu connection. If subscriber’s Iu session does not established before configured period then UE is de-registered. Also in a scenario where all Iu connections are released for a subscriber, the HNB-GW service waits for configured period before starting UE deregistration procedure.

Example

The following command sets the UE registration timeout duration to 150 second on HNB-GW after expiry of which the UE is de-registered:

```
ue registration-timeout 150
```
Chapter 166
HNB-PS Network Configuration Mode Commands

The HNB-PS Network Configuration Mode is used to manage the packet switched (PS) network instance on HNB-GW service to provide HNB access with the PS core network in a 3G UMTS network.

Mode

Exec > Global Configuration > HNB-PS Network Configuration

configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-ps-network-instance_id)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**associate gtpu-service**

Associates a previously configured GTP-U service to provide a GTP-U tunnel with an SGSN towards the core network side. A GTP-U service must be configured in Context Configuration mode before using this configuration.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-PS Network Configuration

configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

[local] host_name(config-ps-network-instance_id) #

**Syntax**

```
associate gtpu-service svc_name context ctx_name
```

```
no associate gtpu-service
```

**Usage**

Use this command to configure GTP-U data plan tunnel between HNB-GW service and GSNs in core network. The service defined for GTP-U tunnel must be configured in Context configuration mode.

**Important:** Another GTP-U service can be used to bind the HNB-GW service to GTP-U tunnel with HNB in HNB access network and can be configured in HNB-GW Service Configuration mode. For more information on GTP-U service configuration, refer to *GTP-U Service Configuration Mode Commands* chapter.

**Example**

The following command associates GTP-U service *gtpu_svc1* configured in context named *Ctx_gtpu1* with specific HNB-PS network instance for GTP-U tunnel towards GSN in core network:

```
associate gtpu-service gtpu_svc1 context Ctx_gtpu1
```
**associate-sccp-network**

Associates a previously defined Signaling Connection Control Part (SCCP) network identifier with the PS network instance in order to route the messages towards the SGSN via the IuPS interface.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-PS Network Configuration
configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ps-network-instance_id)#
```

**Syntax**

```
associate-sccp-network sccp_net_id

no associate-sccp-network
```

**no**
Removes the associated SCCP network configuration instance from this HNB-PS network instance configuration.

```
sccp_net_id
```
Specifies a predefined SCCP network identifier.

**Usage**

Use this command to associate a predefined SCCP network ID with the IuPS interface in HNB-GW service to connect with PS network elements; i.e. SGSN.

**Important:** The SCCP network ID must be defined in Global Configuration mode before using it with this command.

**Important:** A single SCCP network ID can not be shared with multiple HNB-PS network instances.

**Example**

The following command associates SCCP network ID 2 with specific HNB-PS network instance:

```
associate-sccp-network 2
```
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
ALL

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
global-rnc-id

Configures the Radio Network Concentrator (RNC) identifier in a Radio Network PLMN associated with HNB-PS network configuration instance. The RNC identifier is provided to the HNB during HNB-REGISTRATION.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-PS Network Configuration
c
configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-ps-network-instance_id)#

**Syntax**

```
[ no ] global-rnc-id  mcc  mcc_num  mnc  mnc_num  id  rnc_id  [ common-plmn  mcc  mcc_num  mnc  mnc_num ]
```

- **no**
  Deletes the RNC, MMC, and MNC information from the HNB-PS Network configuration instance.

- **mcc  mcc_num**
  Specifies the mobile country code (MCC) part of radio network PLMN identifier as an integer value from 100 through 999.

- **mnc  mnc_num**
  Specifies the mobile network code (MNC) part of radio network PLMN identifier as a 2- or 3-digit integer from 00 through 999.

- **id  rnc_id**
  Specifies the RNC identifier as an integer from 0 through 4095.

- **common-plmn  mcc  mcc_num  mnc  mnc_num**
  Configures the Common PLMN for this PS Network.
  **mcc  mcc_num** configures the MCC of Common PLMN for this PS Network as an integer value from 100 through 999.
  **mnc  mnc_num** configures the MNC of Common PLMN for this PS Network as a 2- or 3-digit integer from 00 through 999.
Usage

Use this command to configure RNC id to associate Radio Network PLMN which will be sent to HNBs from HNB-GW during HNB-REGISTRATION procedure. Depending upon the requirement the RNC Identifier can be provided at the desired granularity.

Example

The following command configures the HNB-GW service to return an RNC identifier as 102 when an HNB-REGISTRATION request is received with LAC 1, and RAC 2:

```
global rnc-id mcc 102 mnc 02 id 2
```
map core-network-id

Maps/associates the PS core network identifier to a default SGSN in the network using an SGSN point code to allow HNBs to access the UMTS network.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-PS Network Configuration
configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

[local] host_name(config-ps-network-instance_id)#

**Syntax**

map core-network-id cn_id point-code sgsn_point_code

no map core-network-id cn_id

no
Removes the mapping of a PS core network id with particular SGSN point code.

**cn_id**
Specifies the core network identifier configured to represent a UMTS PS core network as an integer from 0 through 4095.
Multiple instance of this command can be mapped with different SGSN point codes.

**point-code sgsn_point_code**
Specifies the SS7 address of the default SGSN in the PS network.
point_code is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ####### format.
Only one instance of this SGSN point code can be mapped with one PS core network identifier.

**Usage**
Use this command to map a UMTS PS core network identifier with a particular SGSN point code.
This command can be entered multiple times with same SGSN point code to map with one or more PS core network Id, but a particular core network identifier can be mapped to one SGSN only.
This command is instrumental in Iu-Flex functionality, whenever HNB-GW receives RESET/RESET-RES messages from SGSN with Global CN-ID information element, the response from HNB-GW is sent to the node configured for that particular Global CN-ID.
If the RESET/RESET-RES messages do not have Global CN-ID IE, then the response of those messages is directed to the default SGSN which is configured using sgsn point-code command in this mode.

**Example**
The following command configures the PS core network identifier 101 with an SGSN point code 1.2.3:
map core-network-id 101 point-code 1.2.3

The following command configures the PS core network identifier 102 with the same SGSN point code 1.2.3:

map core-network-id 102 point-code 1.2.3
map idnns range

Configures the mapping of an Intra-Domain NAS Node Selector (IDNNS) IE received from UE in an RUA connect message towards HNB-GW. This is an important configuration for PS network resource sharing over an Iu-Flex interface.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-PS Network Configuration

configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

[local] host_name(config-ps-network-instance_id) #

Syntax

map idnns range idnns_start to idnns_end point-code sgsn_point_code [backup point-code bkup_sgsn_point_code]

no map idnns range idnns_start to idnns_end

no

Removes the entries of mapping of range of IDNNS received from UE with particular SGSN point code.

range idnns_start to idnns_end

Specifies the range of IDNNSs received from UE to map with particular SGSN point codes during the initial PS core network node selection.

idnns_start is an integer from 0 through 1023 that should be less than idnns_end.

idnns_end is an integer from 0 through 1023 that should be more than idnns_start.

The command can be entered more than once to map multiple IDNNS ranges to the same SGSN. However, overlapping and mapping of the same range to different SGSN point codes is not allowed.

point-code sgsn_point_code

Specifies the SS7 address of the SGSN in the PS network.

sgsn_point_code is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ######## format.

backup point-code bkup_sgsn_point_code

Specifies the SS7 address of the SGSN to be used as the backup in the PS network.

bkup_sgsn_point_code is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ######## format.
Usage

Use this command to map a NRI received from UE during initial PS network node selection to SGSN point code through NRI range mapping over Iu-Flex interface.

The IDNNS refers to the information element in RUA connect message from UE towards RAN (HNB-GW). In IDNNS IE, if the choice of routing mentioned is other than local P-TMSI, then the value it provides is used against this configuration to map the SGSN point code.

If backup SGSN point-code is specified, then specified SGSN works as backup for the IDNS range configured. This Backup SGSN is selected if the mapped SGSN for a given IDNNS range is going for offloading using `offload-sgsn point-code` command.

The command can be entered more than once to map multiple IDNNS ranges to same SGSN point code, but overlapping and mapping of same range to different SGSN point code is not allowed.

Example

The following command maps the IDNNS range from 101 to 201 with SGSN point code 1.2.3 and point code 7.8.9 as backup SGSN point code:

```
map nri range 101 to 201 point-code 1.2.3 backup point-code 7.8.9
```

The following command removes all IDNNS range matching entries between 301 to 399 from the configuration:

```
no map idnns range 301 to 399
```
map nri range

Configures the mapping of the Network Resource Identifier (NRI) received from UE to an SGSN point code. This is an important configuration for PS network resource sharing over Iu-Flex interface.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-PS Network Configuration
   configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-ps-network-instance_id)#

Syntax

map nri range nri_start to nri_end point-code sgsn_point_code

no map nri range nri_start to nri_end

no
Removes the entries of mapping of range of NRIs received from UE with a particular SGSN point code.

range nri_start to nri_end

Specifies the range of NRIs received from UE to map with a particular SGSN point code during initial PS core network node selection.

nri_start is an integer from 0 through 1023 that should be less than nri_end.
nri_end is an integer from 0 through 1023 that should be more than nri_start.
The command can be entered more than once to map multiple NRI ranges to the same SGSN, but overlapping is not allowed.

point-code sgsn_point_code

Specifies the SS7 address of the SGSN in the PS network to map with range of NRI values.
point_code is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ####### format.

Usage

Use this command to map a NRI received from UE during initial PS network node selection to SGSN point code through NRI range mapping over Iu-Flex interface.
This configuration is used during initial PS core network node selection when the network resource identifier (NRI) from the UE is available. The NRI range is mapped to SGSN point code. This configuration is used when the core network uses Iu-Flex interface.
The command can be entered more than once to map multiple NRI ranges to same SGSN point code.
It is possible to configure multiple ranges to more than one SGSN however this configuration is required only when the PS core network is configured as Multi-Operator Core Network (MOCN).
When the PS core network is not MOCN and one range is mapped to more than one SGSN then SGSN is selected randomly in a non-predictable manner.

### Example

The following command maps the NRI range from 101 to 201 with SGSN point code 1.2.3:

```plaintext
map nri range 101 to 201 point-code 1.2.3
```

The following command maps the NRI range from 301 to 399 with SGSN point code 1.2.3:

```plaintext
map nri range 301 to 399 point-code 1.2.3
```

The following command removes all NRI range matching entries between 301 to 399 from the configuration:

```plaintext
no map nri range 301 to 399
```
nri length

Configures the network resource identifier (NRI) length in bits to identify a specific SGSN serving in a pooled area. At least one NRI value must be assigned to an SGSN serving in a pool. The NRI is coded inside of the temporary mobile subscriber identity (TMSI), located within bits 14 to 23 with a variable length between 0 and 10 bits. The operator must set this NRI length to indicate the number of bits that shall be used for the NRI field to set the parameters for Iu-Flex (SGSN pooling) functionality.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-PS Network Configuration
  configure > ps-network ps_instance
Entering the above command sequence results in the following prompt:

[local]host_name(config-ps-network-instance_id)#

Syntax

nri length nri_value

default nri length

    default
    Sets the NRI length to default value of 0 and disables the Iu-Flex (SGSN pooling) functionality.

    nri length nri_length

    Default: 0
    Specifies the number of bits to be used in the P-TMS (bits 23 to 18) to define the network resource identifier (NRI). The NRI length configuration also sets the maximum size of the pool. If not configured, the NRI length is set to zero length.
    length is an integer from 1 to 10. When a non-zero value is configured the PS network is considered to be a pool. Default: 0

Usage

Use this command to enable the Iu-Flex functionality on HNB-GW. This command identifies a unique SGSN serving a pooled area for Iu-Flex functionality and at least one NRI value has to assigned to an SGSN serving in a pool. It performs SGSN pooling/offloading scenario over Iu-Flex interface. The NRI is stored in the bits 14 to 23 of TMSI. The HNB-GW uses a portion of this NRI to set the parameters for Iu-Flex (SGSN pooling) functionality.

If more than one NRI is configured, the HNB-GW service does round-robin between the available NRIs when new subscriber(s) (re)connect.

This command must be used in conjunction with null nri command to configured SGSN pooling/offloading over Iu-Flex interface.

Example
The following command sets the HNB-GW to use bit length as 6 to derive the values from the NRI field (stored in the bits 14 to 23 of TMSI) to set the parameters for Iu-Flex (SGSN pooling) functionality:

```
nri length 6
```
null-nri

Configures the null network resource identifier (NRI) for load redistribution in support of Iu-Flex functionality. The NRI value defined with this command must be unique across the pool areas. This null-NRI is used by HNB-GW for load redistribution during SGSN offloading.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-PS Network Configuration

configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-ps-network-instance_id)#

Syntax

null-nri null_nri_value

no null-nri null_nri_value

Usage

Use this command to identify the SGSN by HNB-GW to be used for load redistribution during SGSN offloading over Iu-Flex interface.

Without MOCN configuration this command can be entered only once. In case of MOCN a unique null-NRI must be assigned to each MOCN operator identify by its PLMN-id (MCC+MNC).

Example

The following command sets the null-NRI as 1001 to be used by HNB-GW for load redistribution during SGSN offloading:

null-nri 1001
offload-sgsn

Enables or disables the exclusion of a specified primary SGSN node during the NAS Node Selection Function (NNSF) procedure when it needs to be offloaded using Iu-Flex functionality.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-PS Network Configuration
configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-ps-network-instance_id)#

Syntax

[ no ] offload-sgsn point-code sgsn_point_code

no

Removes the specified primary SGSN point code from the exclusion list for NNSF function on HNB-GW and re-enables the inclusion of the primary SGSN node to be considered by HNB-GW.

point-code sgsn_point_code

Specifies SS7 address of primary SGSN in PS network having specific point code value to be excluded for NNSF function on HNB-GW when it needs to be offloaded in Iu-Flex functionality.

point_code is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ###### format. Only one instance of this primary SGSN point code can be mapped with one PS core network id.

Usage

Use this command to provision the HNB-GW to enable or disable the exclusion of the SGSN node when it needs to be offloaded.

When this command is enabled for exclusion of SGSN node during NNSF function in HNB-GW, the HNB-GW excludes the particular node from being considered.

User can re-enable the inclusion of the SGSN node to be considered for NNSF functionality by no

offload-sgsn point-code command.

Important: The offload check is only for the primary point code and NOT for the backup point code.

Example

This command can be used for planned maintenance as well.

The following command configures the HNB-GW to exclude the primary SGSN point code 1.2.3 from being considered in NSSF function for Iu-Flex support:

offload-sgsn point-code 1.2.3
The following command re-enables the inclusion of SGSN point code 1.2.3 from being considered in NSSF function for Iu-Flex support:

```
no offload-sgsn point-code 1.2.3
```
**ranap reset**

Configures various Radio Access Network (RAN) Application Part reset procedure parameters for PS network association in an HNB access network.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-PS Network Configuration
configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ps-network-instance_id)#
```

**Syntax**

```
ranap reset { ack-timeout timer_value | guard-timeout g_timer | hnbwg-initiated | max-retransmissions retries }

default ranap reset { ack-timeout | guard-timeout | hnbwg-initiated | max-retransmissions }

no ranap { hnbwg-initiated }
```

---

**default**

Resets the RANAP RESET parameters in HNB-PS Network configuration instance.

**no**

Disables the RANAP RESET procedure related parameters in an HNB-PS Network configuration instance.

**ack-timeout timer_value**

Sets the timer value (in seconds) to wait for Reset Acknowledge from SGSN. This is used during HNB-GW initiated RANAP RESET procedure in HNB-PS Network configuration instance.

*timer_value* is an integer value from 5 through 10. Default: 10

**guard-timeout g_timer_value**

Sets the timer value (in seconds) to send Reset Acknowledge to SGSN. After this duration the HNB-GW sends RESET-ACK to SGSN. This is used during SGSN initiated RANAP RESET procedure in HNB-PS Network configuration instance.

*g_timer_value* is an integer value from 5 through 10. Default: 10

**hnbgw-initiated**

Enables the HNB-GW Initiated RANAP RESET procedures. Default: Disabled
max-retransmission retries

Sets the maximum number of retries allowed for transmission of RESET-ACK message to SGSN. This is used during RANAP RESET procedure in HNB-PS Network configuration instance.

retries is an integer value from 0 through 2. When 0 is used retransmission is disabled. Default: 1

Usage

Use this command to configure the RANAP RESET procedure related parameters in HNB-PS Network configuration for multiple HNB-GW service support.

Example

The following command configures the HNB-GW initiated RANAP RESET Procedure for an HNB-PS Network configuration instance:

    ranap reset hnbgw-initiated
sgsn deadtime

Configures a timer on HNB-GW to manage SGSN availability in a PS core network on receiving of a PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-PS Network Configuration

configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-ps-network-instance_id)#

Syntax

sgsn deadtime { immediate | dur }

[ no | default ] sgsn deadtime

---

no

Makes the peer node (SGSN) always available for all HNB-PS network instances.

---

default

Sets the default action for HNB-GW such that the peer node (SGSN) is marked down as soon as HNB-GW receives a PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP in a specific HNB-PS network instance. Default: Enabled

---

immediate

Sets the HNB-GW to mark the peer node (SGSN) down immediately and clears all Iu-PS connections towards the SGSN. Default: Disabled

---

dur

Sets the duration (in seconds) for a timer which starts once HNB-GW receives a PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer SGSN. On expiry of this timer the peer SGSN is marked as dead and all Iu-PS connections towards that SGSN are released.

dur is an integer from 1 through 30.

Only one instance of this command can be configured.

Usage

This command is used to configure a timer on HNB-GW to manage SGSN availability in a PS core network on receiving of PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP.
Timer value sets the duration in seconds for a timer which started once HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer SGSN. On expiry of this timer the peer SGSN is marked as dead and all Iu-PS connections towards that SGSN shall be released.

**Important:** This command can be entered only once. Reentering this command overwrites the previous parameters.

**Example**

The following command configures the deadtime timer value for 10 seconds on HNB-GW. Once HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer SGSN the HNB-GW waits for configured period and on expiry of timer it marks the specific SGSN as dead:

```
sgsn deadtime 10
```
sgsn point-code

Configures the default SGSN point-code with the HNB-PS network instance. This command is used when HNB-GW is to be connected to only one SGSN with in a PS network or as the default SGSN for all HNBs connected through specific HNB-PS network instance.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-PS Network Configuration

configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-ps-network-instance_id)#

Syntax

[ no ] sgsn point-code point_code

- **no**
  - Removes the configured default SGSN point code from specific HNB-PS network instance.

⚠️ **Caution:** Removing the SGSN point code is a disruptive operation and affects all HNB sessions which are connected to particular SGSN through an HNB-PS network instance.

- **point_code**
  - Specifies the SS7 address of the default SGSN in a PS network.
  - *point_code* is an SS7 point code in dotted-decimal ###.###.## or 8-digit decimal ####### format.
  - Only one instance of this command can be configured.

Usage

Use this command to configure a default SGSN to which HNB connects for PS network access through the HNB-GW service.

Point-code is an SS7 address for an element in the SS7 network. Point-codes must be defined in dotted-decimal format in a string of 1 to 11 digits. Format options include:

- 0.0.1 to 7.255.7 for point-code in the ITU range.
- 0.0.1 to 255.255.255 for point-code in the ANSI range.
- 0.0.1 to 15.31.255 for point-code in the TTC Range.
- A string of 1 to 11 digits in dotted-decimal to represent a point-code in a different range.

⚠️ **Important:** This command can be entered only once. If entered again the previous value shall be overwritten.

Example
The following command configures a default SGSN with point code 101.201.101 for HNBs to access PS network through HNB-GW service in this HNB-PS network instance:

```
sgsn point-code 101.201.101
```
Chapter 167
HNB-RN PLMN Configuration Mode Commands

This HNB Radio Network PLMN configuration mode defines the radio network PLMN parameters related to the HNB-GW connection with a UMTS Femto radio network.

Mode

Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration > HNB-RN PLMN Configuration

configure > context context_name > hnbgw-service service_name > radio-network-plmn mcc mcc_number mnc mnc_number

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hnbgw-radio-plmn)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
associate cs-network

From StarOS Release 14.0 onward this command is deprecated.
associate ps-network

From StarOS Release 14.0 onward this command is deprecated.
**authorised-macro-lai**

Configures the macro LAI based authorization parameters for this HNB-GW service.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration > HNB-RN PLMN Configuration

```bash
configure > context context_name > hnbw-service service_name > radio-network-plmn mcc mcc_number mnc mnc_number
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hnbw-radio-plmn)#
```

**Syntax**

```bash
authorised-macro-lai { macro-info-ie-absent-action { accept | reject } | mcc mcc_id mnc mnc_id lac range range_from to range_to }

default authorised-macro-lai macro-info-ie-absent-action

no authorised-macro-lai mcc mcc_id mnc mnc_id lac range range_from to range_to
```

**default**
Configures the default parameters for macro LAI based authorization for the system configuration. Default action is to reject HNB if IE is absent.

**no**
Deletes the macro LAI based authorization parameters from the system configuration.

**mcc-id**
Specifies the MCC of pre-configured macro lai range for HNB authorization as a number, ranging from 100..999

**mnc-id**
Specifies the MNC of pre-configured macro lai range for HNB authorization, ranging from 00..999

**lac range**
Specifies the LAC of pre-configured macro LAI range for HNB authorization.

**range_from**
Specifies the LAC range minimum value, which is an integer from 0..65535.
**range_to**

Specifies the LAC range maximum value, which is also an integer from 0..65535.

---

**Usage**

Use this command to configure the macro LAI based authorization parameters for an existing HNB-GW service.

**Example**

The following command configures the default action for macro LAI based authorization for an existing HNB-GW service.

```plaintext
default authorised-macro-lai macro-info-ie-absent-action
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

exit

**Usage**

Use this command to return to the parent configuration mode.
rnc-id

Configures the Radio Network Concentrator (RNC) identifier in a Radio Network PLMN associated with HNB-GW service. The RNC identifier is provided to the HNB during HNB-REGISTRATION.

**Product**

HNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration > HNB-RN PLMN Configuration

```plaintext
configure > context context_name > hnb-gw-service service_name > radio-network-plmn mcc mcc_number mnc mnc_number
```

Entering the above command sequence results in the following prompt:

```plaintext
[context_name]host_name(config-hnb-gw-radio-plmn)#
```

**Syntax**

```
[ no ] rnc-id rnc_id
```

- **no**
  
  Deletes the RNC id from the system configuration.

- **rnc-id**
  
  Specifies the RNC identifier as an integer from 0 through 4095.

**Usage**

Use this command to configure RNC id for Radio Network PLMN which will be sent to HNBs from HNB-GW during HNB-REGISTRATION procedure. Depending upon the requirement the RNC Identifier can be provided at the desired granularity.

**Example**

The following command configures the HNB-GW service to return an RNC identifier as 102 when an HNB-REGISTRATION request is received:

```
global rnc-id 102
```
Chapter 168
HSS Peer Service Configuration Mode Commands

The HSS Peer Service Configuration Mode is used to create and manage the Home Subscriber Server (HSS) Peer Service.

Mode

Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration

configure > context context_name > hss-peer-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hss-peer-service)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**auth-request**

Configures the number of authentication vectors the MME/SGSN requests in an Authentication-Information-Request (AIR) message to the HSS for each UE requiring authentication.

**Product**
- MME
- SGSN

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration

```plaintext
configure > context context_name > hss-peer-service service_name
```

Entering the above command sequence results in the following prompt:

```plaintext
[context_name]host_name(config-hss-peer-service)#
```

**Syntax**

```plaintext
auth-request num-auth-vectors num

default auth-request num-auth-vectors

num-auth-vectors num
```

Specifies the number of vectors the MME/SGSN is requesting from the HSS as an integer.

*`num`* the valid range is 1 through 3. Default = 1.

**Usage**

Use this command to configure the number of authentication vectors the MME/SGSN requests in an Authentication-Information-Request (AIR) message to the HSS for each UE requiring authentication. Receiving multiple vectors from the HSS for a given UE helps reduce the number of messages across the diameter connection plus provides the MME/SGSN with additional vectors for the UE in the event that the connection or the HSS id disabled.

**Related Commands:**

- To view the current number of requested vectors, execute the `show hss-peer-service service name <name>` command in the Exec mode.

- To set the minimum number (low watermark) of vectors to be maintained at all times, execute `min-unused-auth-vector min_num` command from the call control profile configuration mode. (SGSN only)

- For troubleshooting, check the number of free, used, or in-use vectors displayed in the output of the `show subscribers [ gprs-only | sgsn-only ] full` command. (SGSN only).

**Example**

The following command sets the number of requested vectors to 2:

```plaintext
auth-request num-auth-vectors 2
```
diameter hss-dictionary

Specifies the Diameter Credit Control dictionary for the HSS peer service.

Product
MME
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration
configure > context context_name > hss-peer-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hss-peer-service)#!

Syntax

diameter hss-dictionary { custom1 | standard | standard-r9 } [ eir-dictionary { custom1 | standard | standard-r9 } ]

default diameter hss-dictionary

default
Sets the dictionary to default standard-r9 for HSS service.

custom1
Sets the Diameter dictionary to a customer-specific HSS Diameter dictionary. Default: Disabled

standard
Sets the Diameter dictionary to the standard (3GPP release 8) HSS peer dictionary. Default: Disabled

standard-r9
Sets the Diameter dictionary to the standard HSS peer dictionary for 3GPP release 9. Default: Enabled

eir-dictionary { custom1 | standard | standard-r9}
Specifies that an Equipment Identity Register (EIR) dictionary is to be used in conjunction with the HSS Diameter dictionary.
custom1: Sets the EIR Diameter dictionary to a customer-specific EIR Diameter dictionary.
standard: Sets the EIR Diameter dictionary to the standard HSS peer dictionary.
standard-r9: Sets the EIR Diameter dictionary to the standard HSS peer dictionary for release 9.

Usage
Use this command to select the Diameter dictionary for the HSS peer service.

Example
The following command sets the Diameter dictionary to IETF RFC 4006 specific:
diameter hss-dictionary standard
**diameter hss-endpoint**

 Associates a preconfigured Diameter origin endpoint with this HSS peer service.

**Product**
MME
SGSN

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration

**Syntax**
```
diameter hss-endpoint endpoint_name [ eir-endpoint eir_endpoint_name ] [ auc-endpoint auc_endpoint_name ]
```

**Usage**
Use this command to associated a Diameter origin endpoint to create a Diameter-based S6a or S6d (SGSN) interface association in this HSS peer service to provide AAA functionality to the EPS bearer context. Optionally, use this command to associate a Diameter origin endpoint to create a Diameter-based S13 or S13’ (SGSN) interface association in this HSS peer service to provide IMEI query capability between the MME and an EIR.
Important: The configuration of all endpoints is only valid when all necessary endpoint configuration has been completed. All endpoint listed above must also be defined as valid endpoints using the commands in the Diameter Endpoint configuration mode (refer to the Diameter Endpoint Configuration Mode Commands chapter in the Command Line Interface Reference manual) for more information on Diameter endpoint configuration parameters.

Example

The following command associates the preconfigured Diameter endpoint `hss_1` with this HSS peer service for HSS interface support.

```
diameter hss-endpoint hss_1
```
**diameter suppress**

Configures the MME to restrict the sending of the Notify-Request-Message to the HSS. By default, the Notify-Request-Message is sent to the HSS.

**Product**

MME

**Privilege**

Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration

```
command > context context_name > hss-peer-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hss-peer-service)#
```

**Syntax**

```
[ no ] diameter suppress notify-request
```

no

Sets the command to the default value where the Notify-Request-Message is sent to the HSS.

**Usage**

Use this command to restrict the MME from sending the Notify-Request-Message to the HSS. This can be used to control whether handover to non-3GPP access can occur.
**diameter update-dictionary-avps**

Specifies which release of 3GPP TS 29.272 is to be used for the HSS peer service.

**Product**

MME  
SGSN

**Privilege**

Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration  
**configure** > context context_name > hss-peer-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hss-peer-service)#
```

**Syntax**

```
diameter update-dictionary-avps { 3gpp-r10 | 3gpp-r9 }
no diameter update-dictionary-avps
```

**Syntax**

**Usage**

Use this command to configure the 3GPP release that should be supported for this HSS peer service. This command is only applicable for the ‘standard’ diameter dictionary as defined in the **diameter hss-dictionary** command.
dynamic-destination-realm

Enables the MME to construct the destination realm using the MCC and MNC of foreign subscribers.

Product
MME

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration

configure > context context_name > hss-peer-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hss-peer-service)#

Syntax

[ default | no ] dynamic-destination-realm

default

Returns the configuration to the default setting, where the MME uses the configured peer realm as the destination realm.

no

Disables the dynamic destination realm configuration. This provides the same behavior as the default keyword.

Usage

This command configures the MME to derive the EPC Home Network Realm/Domain based on the user's IMSI (MNC and MCC values) and use it as the Destination Realm in all diameter messages.

For a foreign subscriber, the MME does not know the HSS nodes in all the foreign PLMNs. In this case the MME routes S6a/S6d requests directed to foreign PLMNs via a Diameter Routing Agent (DRA) using only the destination realm. The DRA in turn routes the request to the correct HSS based on the destination realm. In order to accomplish this, the MME needs to dynamically construct requests to the DRA/HSS with a Destination Realm representing the foreign PLMN of the UE.

Refer to Configuring Dynamic Destination Realm Construction for Foreign Subscribers in Chapter 2 of the MME Administration Guide for more information about configuring this feature.

Example

The following command configures the MME to derive the destination realm for foreign subscribers based on the user’s IMSI (MNC/MCC).

dynamic-destination-realm
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```text
exit
```

**Usage**
Use this command to return to the parent configuration mode.
failure-handling

Configures failure handling behavior in the event of a failure with the HSS peer service. It also defines the action on various error codes on the Diameter interface during authentication or session activities.

**Product**
- MME
- SGSN

**Privilege**
- Security Administrator
- Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration
- ```configure > context context_name > hss-peer-service service_name```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hss-peer-service)#
```

**Syntax**

```
failure-handling { authentication-information-request | check-identity-request | notify-request | purge-ue-request | update-location-request } { diameter-result-code start_error_code [ to end_error_code ] | request-timeout } action { continue | retry-and-terminate | terminate }

no failure-handling { authentication-information-request | check-identity-request | notify-request | purge-ue-request | update-location-request } diameter-result-code start_error_code [ to end_error_code ]

default failure-handling { authentication-information-request | check-identity-request | notify-request | purge-ue-request | update-location-request } request-timeout

no
```

Removes the preconfigured failure handling procedures for calls in an HSS peer service.

```
default
```

Sets the default action for failure handling procedure for calls in an HSS peer service.

For default actions on Diameter result/error codes see the *Usage* section below.

**authentication-information-request**

Configures the MME-HSS service to handle the failures in an Auth-Information-Request message.
Configures the SGSN-HSS service to handle the failures in an Auth-Information-Request message.

**check-identity-request**

Configures the MME-HSS service to handle the failures in a Check-Identity-Information-Request message.
Configures the SGSN-HSS service to handle the failures in a Check-Identity-Information-Request message.
notify-request

Configures the MME-HSS service to handle the failures in a Notify-Request message.
This option is not supported on SGSN.

purge-ue-request

Configures the MME-HSS service to handle the failures in a Purge-UE-Request message.
Configures the SGSN-HSS service to handle the failures in a Purge-UE-Request message.

update-location-request

Configures the HSS peer service to handle the failures in an Update-Location-Request message.

diameter-result-code start_error_code [to end_error_code]

Configures the HSS peer service to handle the failures for various request messages having specific single or range of Diameter result codes in a request message.

*start_error_code* specifies an individual error code for Diameter protocol as an integer from 3000 through 5999. This will be the starting of code if a range of error codes is specified with the optional keyword *to end_error_code*.

to *end_error_code* is used to specify a range of error codes to handle by this command.

*end_error_code* specifies the end error code for Diameter protocol as an integer from 3000 through 5999.

request-timeout

Configures the HSS peer service to handle the failures for various request messages if response to that message is not received before timeout duration exhausted.

action { continue | retry-and-terminate | terminate }

Specifies the action to be taken on failure of any message as a policy for failure handling.

• **continue**: This option works differently for each system.

  For the SGSN: On receipt of any error for MICR session request, the SGSN allows the HSS peer service to continue with the session procedure without any interruption. For all other request/message types, the SGSN behaves as it would if configured for the **retry-and-terminate** option.

  For the MME: The MME does not support this option and if **continue** is included in the command, the MME behaves as it would if configured for the **retry-and-terminate** option.

  For 12.0 and earlier releases the **continue** option in failure handling on SGSN for IMEI procedures has the same behavior as that of the **retry-and-terminate** option.

  **Important**: For releases after 14.0, the **continue** option for IMEI procedure on SGSN can be configured in case of timeout and error responses requests from HSS so that the requests will be re-trying on a second peer (if configured) and the call is continued. The configuration of **continue** option for IMEI procedure is as follows:

  ```
  configure
  
  context <name>
  
  hss-peer-service <name>
  ```
HSS Peer Service Configuration Mode Commands

**failure-handling**

```
failure-handling check-identity-request request-timeout
action continue

failure-handling check-identity-request diameter-result-code
<range1> to <range2> action continue

failure-handling check-identity-request diameter-result-code
<range1> action continue

exit

exit

exit
```

- **retry-and-terminate**: On receipt of any error, once the configured condition (either the request timeout or receipt of the specified result code) occurs, the system retries sending the request (AIR/ULR/NOR/PUR/MICR) to another peer that is configured in the same endpoint. If no response is received for AIR or ULR from the second peer, then the system allows the HSS peer service to terminate the session.

- **terminate**: On receipt of any error, once the configured condition (either the request timeout or receipt of the specified result code) is met, the system allows the HSS peer service to immediately terminate the session (AIR/ULR/MICR) without any further action.

---

**Usage**

Use this command to configure the failure handling behavior in the event of a communication failure with the HSS peer service.

The following are the default actions for Diameter result codes:

- For all protocol error codes 3000 to 3999, the default action is terminate. For all transient error codes 4000, 4001, 4004 to 4180, and 4182 to 4999, the default action is continue.
- For transient error codes 4002, 4003, and 4181, the default action is retry.
- For error code 4001, the default action is terminate.
- For permanent error codes 5000 to 5999, the default action is terminate.

---

**Example**

The following command will allow HSS peer service to continue if any failure in Auth-Information-Request message occurred with Diameter error code 3050:

```
failure-handling authentication-information-request diameter-result-code
3050 action continue
```
request timeout

Configures the application request timeout between the HSS peer service and HSS node. The MME/SGSN waits for this duration before retransmitting the request to corresponding HSS node.

**Product**
MME
SGSN

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration

```
configure > context context_name > hss-peer-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hss-peer-service)#
```

**Syntax**

```
request timeout dur
[ no | default ] request timeout
```

- **no**
  Disables the configured application request timeout value.

- **default**
  Sets the application request time out duration to default value of 300 seconds.

- **dur**
  Specifies the application request timeout duration (in seconds) as an integer from 1 through 300. The MME/SGSN will wait for this duration before retrying the request with corresponding HSS. Default: 20

**Usage**
Use this command to set the waiting period for HSS peer service in seconds after which the request is deemed to have failed or system will resend the request.

**Example**

The following example configures the application request timeout duration to 20 seconds:

```
default request timeout
```
zone-code-format

Configures how the MME must interpret the received zone-code values from the HSS.

Product
MME

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration

```
configure > context context_name > hss-peer-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hss-peer-service)#
```

Syntax

```
zone-code-format { ascii-string }
```

[ default ] zone-code-format

----------

`default`

Returns the command to the default setting, where the MME interprets the zone-code as an octet string.

----------

`ascii-string`

Configures the MME to interpret the zone-code as an ascii string. This option is provided to maintain backward compatibility.

When configured as ascii-string, the MME interprets the received zone-code as an ASCII string (coded in hexadecimal representation) and converts it byte by byte to an integer value. For example, if the HSS sends the zone-code value as 3032, the MME converts this to 02 (ASCII value of 0 in Hex is 0x30, ASCII value of 2 in Hex is 0x32). With this configuration, the MME accepted zone-codes only within the range of 0 to 99.

----------

Usage

This new command specifies the format of the zone-code value received from HSS to MME. The MME uses this configuration to interpret and convert the received zone-code value to an integer value and validate it against the list of allowed zone-code configured for the zone-code restriction feature.

By default, the MME interprets the received zone-code value from HSS as a octet-string (2 bytes) which is coded in full hexadecimal representation. The MME converts the entire 2 byte octet string coded in hexadecimal to integer value and it uses the same for validation for zone-code restriction feature. For example, if the HSS sends the zone-code value as 3032, MME converts this to 12338 (which is the equivalent of 0x3032).

Example

The following command configures the HSS Peer Service to interpret the zone-code received from the HSS as an ASCII string.

```
zone-code-format ascii-string
```
Chapter 169
IGMP Profile Configuration Mode Commands

The Internet Group Management Protocol (IGMP) Profile Configuration Mode is used to create and manage the IGMP parameters for an Ethernet interface.

Mode

Exec > Global Configuration > Context Configuration > IGMP Profile Configuration

```bash
configure > context context_name > ip igmp profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-igmp-profile-<profile_name>)#
```

**Important:** Available commands or keywords/variables vary based on platform type, product version, and installed license(s).
default ip igmp

Configures default IGMP parameters.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IGMP Profile Configuration

```bash
configure > context context_name > ip igmp profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-igmp-profile-<profile_name>)#
```

**Syntax**

```
default ip igmp { query | require | robustness | unsolicited-report-interval | version }
```

**Usage**
Specify the IGMP parameters for the default profile. Refer to the remaining command description in this chapter for additional information.

**Example**
To apply enable echo mode on this interface, use the following command:

```
bfd echo
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
ip igmp query

Configures the maximum response time for IGMP queries.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IGMP Profile Configuration
configure > context context_name > ip igmp profile profile_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-igmp-profile-<profile_name>)#

Syntax

ip igmp query max-response-time seconds

**max-response-time seconds**

Specify the maximum number of seconds that the system will wait for an IGMP response as an integer from 1 through 25.

Usage

Specify the maximum response time for IGMP queries.

Example

    ip igmp query max-response-time 10
ip igmp require router-alert

Sets the router alert flag to ON in IP IGMP packets.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IGMP Profile Configuration

configure > context context_name > ip igmp profile profile_name

Entering the above command sequence results in the following prompt:

/context_name host_name(config-igmp-profile-<profile_name>)#

Syntax

[ no ] ip igmp require router-alert

no

Sets the router alert flag to OFF in IP IGMP packets.

Usage
Sets the router alert flag to ON in IP IGMP packets.

Example

ip igmp require router-alert
ip igmp robustness

Sets the Robustness value in IP IGMP packets. The Robustness variable allows tuning for the expected packet loss on a subnet. If a subnet is expected to be lossy, the Robustness variable may be increased. IGMP is robust to packet losses. The Robustness variable should not be set to 1 (one).

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IGMP Profile Configuration

configure > context context_name > ip igmp profile profile_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-igmp-profile-<profile_name>)#

Syntax

ip igmp robustness value

value

Sets the robustness value as an integer from 1 through 10. Default: 2

Usage

Sets the robustness value in IP IGMP packets.

Example

ip igmp robustness 7
**ip igmp unsolicited-report-interval**

Sets the Unsolicited Report Interval which is the time between repetitions of a host's initial report of membership in a group.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IGMP Profile Configuration

```
configure > context context_name > ip igmp profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-igmp-profile-<profile_name>)#
```

**Syntax**

```
ip igmp unsolicited-report-interval seconds
```

**seconds**
Specifies the number of seconds between repetitions of a host's initial report of membership in a group as an integer from 1 through 25. Default: 10

**Usage**
Set the Unsolicited Report Interval which is the time between repetitions of a host's initial report of membership in a group.

**Example**

```
ip igmp unsolicited-report-interval 15
```
ip igmp version

Sets the IGMP version to be supported by this interface.

**Product**
All

**Privilege**

<tr>
<td>•v2: Version 2, RFC 2236</td>
<td></td>
<td></td>
</tr>
<tr>
<td>•v3: Version 3, RFC 4604</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Usage**
Set the IGMP version to be supported by this interface.

**Example**

```
ip igmp version v2
```
Chapter 170
IKEv2 Security Association Configuration Mode
Commands

The IKEv2 Security Association Configuration Mode is used to configure a Security Association (SA) at the outset of an IPSec session. A security association is the collection of algorithms and parameters (such as keys) that is being used to encrypt and authenticate a particular flow in one direction. In normal bi-directional traffic, the flows are secured by a pair of security associations.

Mode

Exec > Global Configuration > Context Configuration > IKEv2 Security Association Configuration

configure > context context_name > ikev2-ikesa transform-set set_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(cfg-ctx-ikev2ikesa-tran-set)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**default**

Sets the default properties for the selected parameter.

**Product**

ePDG
PDIF

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IKEv2 Security Association Configuration

configure > context context_name > ikev2-ikesa transform-set set_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(cfg-ctx-ikev2ikesa-tran-set)#
```

**Syntax**

```
default { encryption | group | hmac | lifetime | prf }
```

Set the defaults for the following parameters:

- **encryption**: Default algorithm for the IKEv2 IKE SA is AES-CBC-128.
- **group**: Default Diffie-Hellman group is Group 2.
- **hmac**: Default IKEv2 IKE SA hashing algorithm is SHA1-96.
- **lifetime**: Default lifetime for SAs derived from this transform-set is 86400 seconds.
- **prf**: Default PRF for the IKEv2 IKE SA is SHA1.

**Usage**

Configure default parameters for the IKEv2 IKE SA transform-set.

**Example**

Use the following configuration to set the default encryption algorithm:

```
default encryption
```
encryption

Configures the appropriate encryption algorithm and encryption key length for the IKEv2 IKE security association. AES-CBC-128 is the default.

Product
ePDG
PDIF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IKEv2 Security Association Configuration

configure > context context_name > ikev2-ikesa transform-set set_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(cfg-ctx-ikev2ikesa-tran-set)#

Syntax

encryption { 3des-cbc | aes-cbc-128 | aes-cbc-256 | des-cbc | null }

default encryption

3des-cbc
Data Encryption Standard Cipher Block Chaining encryption applied to the message three times using three different cipher keys (triple DES).

aes-cbc-128
Advanced Encryption Standard Cipher Block Chaining with a key length of 128 bits.

aes-cbc-256
Advanced Encryption Standard Cipher Block Chaining with a key length of 256 bits.

des-cbc

null
Configures no IKEv2 IKE Security Association Encryption Algorithm. All IKEv2 IPsec Child Security Association protected traffic will be sent in the clear.

Usage

IKEv2 requires a confidentiality algorithm to be applied in order to work. In cipher block cryptography, the plaintext is broken into blocks usually of 64 or 128 bits in length. In cipher block chaining (CBC) each encrypted block is chained into the next block of plaintext to be encrypted. A randomly-generated vector is applied to the first block of plaintext in lieu of an encrypted block. CBC provides confidentiality, but not message integrity.
Because RFC 4307 calls for interoperability between IPSec and IKEv2, the IKEv2 confidentiality algorithms must be the same as those configured for IPSec in order for there to be an acceptable match during the IKE message exchange. Because of RFC4307, in IKEv2, there is no viable NULL option, it is available for testing only.

**Example**

The following command configures the encryption to be aes-cbc-128:

```
encryption aes-cbc-128
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
**group**

Configures the appropriate key exchange cryptographic strength by applying a Diffie-Hellman group. Default is Group 2.

**Product**

ePDG

PDIF

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IKEv2 Security Association Configuration

```
configure > context context_name > ikev2-ikesa transform-set set_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(cfg-ctx-ikev2ikesa-tran-set)#
```

**Syntax**

```
group { 1 | 2 | 5 | 14 }
default group
```

**1**

Configures crypto strength at the Group 1 level. Lowest security.

**2**

Configures crypto strength at the Group 2 (default) level. Medium security. This is the default setting for this command.

**5**

Configures crypto strength at the Group 5 level. Higher security.

**14**

Configures crypto strength at the Group 14 level. Highest security

**Usage**

Diffie-Hellman groups are used to determine the length of the base prime numbers used during the key exchange process in IKEv2. The cryptographic strength of any key derived depends, in part, on the strength of the Diffie-Hellman group upon which the prime numbers are based.

Group 1 provides 768 bits of keying strength, Group 2 provides 1024 bits, Group 5 provides 1536 bits and Group 14 provides 2048 bits of encryption strength.

Configuring a DH group also enables Perfect Forward Secrecy, which is disabled by default.

**Example**

This command configures crypto strength at the Group 14 level. Highest security group 14:
default group
**hmac**

Configures the IKEv2 IKE SA integrity algorithm. Default is SHA1-96.

**Product**
ePDG
PDIF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IKEv2 Security Association Configuration

```plaintext
configure > context context_name > ikev2-ikesa transform-set set_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(cfg-ctx-ikev2ikesa-tran-set)##
```

**Syntax**

```
hmac { aes-xcbc-96 | md5-96 | sha1-96 | sha2-256-128 | sha2-384-192 | sha2-512-256 }
```

**default hmac**

<table>
<thead>
<tr>
<th>hmac</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aes-xcbc-96</td>
<td>HMAC-AES-XCBC uses a 128-bit secret key and produces a 128-bit authenticator value.</td>
</tr>
<tr>
<td>md5-96</td>
<td>HMAC-MD5 uses a 128-bit secret key and produces a 128-bit authenticator value.</td>
</tr>
<tr>
<td>sha1-96</td>
<td>HMAC-SHA-1 uses a 160-bit secret key and produces a 160-bit authenticator value. This is the default setting for this command.</td>
</tr>
<tr>
<td>sha2-256-128</td>
<td>HMAC-SHA-256 uses a 256-bit secret key and produces a 128-bit authenticator value.</td>
</tr>
<tr>
<td>sha2-384-192</td>
<td>HMAC-SHA-384 uses a 384-bit secret key and produces a 192-bit authenticator value.</td>
</tr>
<tr>
<td>sha2-512-256</td>
<td>HMAC-SHA-512 uses a 512-bit secret key and produces a 256-bit authenticator value.</td>
</tr>
</tbody>
</table>

**Usage**

IKEv2 requires an integrity algorithm be configured in order to work. A keyed-Hash Message Authentication Code, or HMAC, is a type of message authentication code (MAC) calculated using a cryptographic hash function in combination with a secret key to verify both data integrity.
and message authenticity. A hash takes a message of any size and transforms it into a message of a fixed size: the authenticator value. This is truncated and transmitted. The authenticator value is reconstituted by the receiver and the first truncated bits are compared for a 100 percent match.

**Example**

This command configures HMAC value md5-96:

```
hmac md5-96
```
**lifetime**

Configures the lifetime of a security association (SA) in seconds.

**Product**
- ePDG
- PDIF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IKEv2 Security Association Configuration

```
configure > context context_name > ikev2-ikesa transform-set set_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(cfg-ctx-ikev2ikesa-tran-set)#
```

**Syntax**

```
lifetime sec
```

**default lifetime**

```
lifetime sec
```

Sets the value of the timeout parameter in seconds as an integer from 60 through 86400. Default: 86400

**Usage**
The secret keys that are used for various aspects of a configuration should only be used for a limited amount of time before timing out. This exposes a limited amount of data to the possibility of hacking. If the SA expires, the options are then to either close the SA and open a new one, or renew the existing SA.

**Example**
The following command sets the lifetime timeout to 120 seconds:

```
lifetime 120
```
**prf**

Selects one of the HMAC integrity algorithms to act as the IKE Pseudo-Random Function. A PRF produces a string of bits that an attacker cannot distinguish from random bit string without knowledge of the secret key. The default is SHA1.

**Product**
ePDG
PDIF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IKEv2 Security Association Configuration

```
configure > context context_name > ikev2-ikesa transform-set set_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(cfg-ctx-ikev2ikesa-tran-set)#
```

**Syntax**

```
prf { aes-xcbc-128 | md5 | sha1 | sha2-256 | sha2-384 | sha2-512 }
```

**default prf**

---

**aes-xcbc-128**

Configure IKEv2 IKE Security Association Pseudo Algorithm to be AES-XCBC-128.

**md5**

MD5 uses a 128-bit secret key and produces a 128-bit authenticator value.

**sha1**

SHA-1 uses a 160-bit secret key and produces a 160-bit authenticator value. SHA-1 is considered cryptographically stronger than MD5, but it takes more CPU cycles to compute. This is the default setting for this command.

**sha2-256**

PRF-HMAC-SHA-256 uses a 256-bit secret key.

**sha2-384**

PRF-HMAC-SHA-384 uses a 384-bit secret key.

**sha2-512**

PRF-HMAC-SHA-512 uses a 512-bit secret key.
Usage
This command generates keying material for all the cryptographic algorithms used in both the IKE_SA and the CHILD_SAs.

Example
This configuration sets the PRF to be value sha2-256:

```
prf sha2-256
```
Chapter 171
IMEI Profile Configuration Mode

The IMEI profile configuration mode defines a set of parameters controlling the SGSN behavior when a Request is received from a device in the specified IMEI (International Mobile Equipment Identity) range. An IMEI profile is a key element in the Operator Policy feature and an IMEI profile is not used or valid unless it is associated with an IMEI range and this association is specified in an operator policy (see the Operator Policy Configuration Mode Commands chapter elsewhere in the Command Line Interface Reference).

Essentially, an IMEI profile is a template which groups a set of device-specific commands that may be applicable to one or more IMEIs. The same IMEI profile can be associated with multiple IMEI ranges and multiple operator policies.

An SGSN supports a total of 1000 IMEI profile configurations.

Mode

Exec > Global Configuration > IMEI Profile Configuration

configure > imei-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-imei-profile-profile_name)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
associate

Associate an APN remap table with this IMEI profile.

Note that an APN remap table can be associated with an IMEI profile before the table has actually been created/configured.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > IMEI Profile Configuration

configure > imei-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-imei-profile-profile_name)#

Syntax

associate apn-remap-table table_name

no associate apn-remap-table

no

Disables the configured remap table association.

table_name

Define the name of an APN remap table that is to be associated with this IMEI profile for call routing based in IMEI.

Usage

Use this command to associate an APN remap table with this IMEI profile. With such an association, it is possible to override an APN call-routing based on an IMEI.

For example, with the APN exceptions defined in an APN remap table (refer to the APN Remap Table Configuration Mode chapter), a blank APN or an incorrect APN could be overridden. So during PDP Activation for in incoming call, the call could be rerouted based on an IMEI in the range defined for the IMEI profile.

Example

Associate the APN remap table ‘remapHO’ (remaps all calls with blank APNS to the head-office) to this IMEI profile:

associate apn-remap-table remapHO
blacklist

Blacklist all mobile devices that fit the IMEI definitions associated with this IMEI profile.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > IMEI Profile Configuration
configure > imei-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-imei-profile-profile_name)#

Syntax

blacklist

remove blacklist

remove

Including this keyword with the command, removes the blacklist command from the IMEI profile configuration.

Usage
Blacklists subscribers whose devices bear IMEI that match the defined IMEI range for this profile.

Example
Use this command to blacklist all subscribers with IMEI that fall within the range set for this IMEI profile:

blacklist
description

Define a descriptive string relevant to the specific APN profile.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > IMEI Profile Configuration

configure > imei-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-imei-profile-profile_name)#

Syntax

description description

remove description

remove

Removes the configured description from this APN profile.

description

Enter an alphanumeric string of 1 to 100 alphanumeric characters. The string may include spaces, punctuation, and case-sensitive letters if the string is enclosed in double quotes (" ").

Usage

Define information that identifies this particularly APN profile.

Example

Indicate that this IMEI profile IMEIprof1 is to be used for customers in the United Kingdom and that the profile:

description "IMEIprof1 defines routing actions based on IMEI for customers in the UK."
**direct-tunnel**

Instruct the SGSN to enable/disable a direct tunnel between the RNC and the GGSN based on the IuPS service configuration.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > IMEI Profile Configuration

```configure > imei-profile profile_name```

**Syntax**

```direct-tunnel check-iups-service```

```
no direct-tunnel
```

```
no direct-tunnel
```

This command instructs the SGSN to disable the direct tunnel function between the GGSN and the RNC.

**Usage**

Direct tunnel is enabled by default on the GGSN and often on the RNC. This leaves it to the SGSN’s configuration to actually enable or disable a direct tunnel. With the SGSN, the options for configuring a direct tunnel are complex -- enable/disable on the basis of APNs, or RNCs, or GGSNs, or on the basis of the IMEI range. Refer to the SGSN Administration Guide for configuration details.

**Example**

Assuming the IuPS service configuration has enabled DT for associated RNCs, then use this command to enable DT from the RNC to the GGSN associated with this IMEI profile:

```direct tunnel check-iups-service```
end

Exits the current configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

end

Usage
Return to the Exec mode.
**exit**

Exits the current configuration mode and returns to the context configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**
Move to the previous configuration mode.
ggsn-address

Identify the target GGSN for traffic being managed by this IMEI profile.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > IMEI Profile Configuration

configure > imei-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-imei-profile-profile_name)#

Syntax

```
ggsn-address IPv4/IPv6_address
```

Enter the IP address of the target GGSN. Enter the address in either standard IPv4 dotted decimal format or in standard IPv6 colon notation format.

Usage

Use this command to define the IP address of the target GGSN to be associated with this IMEI profile.

Example

The following command identifies the address of the GGSN associated with this IMEI profile as 123.123.11.1

```
ggsn-address 123.123.11.1
```
pdp-activate

This command enables the operator to configure the SGSN to reject Secondary PDP Activation Requests from the UE based on IMEI range.

Product
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration > IMEI Profile Configuration
configure > imei-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-imei-profile-profile_name)#

Syntax

[ remove ] pdp-activate { drop | restrict } secondary-activation access-type { gprs | umts }

<table>
<thead>
<tr>
<th>remove</th>
</tr>
</thead>
<tbody>
<tr>
<td>Removes the configured value and returns the pdp-activate configuration to the default ‘not configured’ state.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>drop</th>
</tr>
</thead>
<tbody>
<tr>
<td>This keyword causes the GSN to ignore the Request.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>restrict</th>
</tr>
</thead>
<tbody>
<tr>
<td>This keyword instructs the SGSN to reject Secondary PDP Activation Requests.</td>
</tr>
</tbody>
</table>

| access-type { gprs | umts } |
|-----------------------------|
| This keyword instructs the SGSN to ignore or reject Secondary PDP Activation Requests on the basis of the UE’s access network type: |

  * **gprs** : from a 2G network.
  * **umts** : from a 3G network.

Usage

The SGSN administrator can use this command to configure the IMEI profile in the operator policy to either ignore or reject Secondary PDP Activation Requests from UEs based on an IMEI range and UE access-type. Restricting secondary PDP activation based on the IMEI (in the IMEI profile) takes precedence over secondary PDP activation that might be configured in the call control profile.

Example

Enable rejection of Secondary PDP Activation Requests for 2G callers:

    pdp-activate restrict secondary-activation access-type gprs
Chapter 172
IMS Authorization Service Configuration Mode Commands

The IMS Authorization Service Configuration Mode enables to configure IP Multimedia Subsystem (IMS) authorization services to manage policy control functions and Gx interface support.

Mode

Exec > Global Configuration > Context Configuration > IMS Authorization Service Configuration

configure > context context_name > ims-auth-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-imsa-service)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
p-cscf discovery

This command defines the method of Proxy-Call Session Control Function (P-CSCF) discovery to be used.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IMS Authorization Service Configuration

configure > context context_name > ims-auth-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-imsa-service)#

Syntax

p-cscf discovery { table { 1 | 2 } [ algorithm { ip-address-modulus | msisdn-modulus | round-robin } ] | diameter-configured }

[ default | no ] p-cscf discovery

default
Sets the P-CSCF discovery to default parameter.

no
Removes/deletes configured parameters for P-CSCF discovery.

table { 1 | 2 }
Specifies that which P-CSCF table is to be used to obtain the primary and secondary P-CSCF addresses. Total 2 tables can be configured for P-CSCF discovery.

algorithm { ip-address-modulus | msisdn-modulus | round-robin }
Specifies the algorithm to select the row from the P-CSCF table to be used for P-CSCF discovery.

  • ip-address-modulus: This algorithm divides the IP address, in binary, of the subscriber by the number of rows in the table, and the remainder is used as an index into the specified table to select the row.

  • msisdn-modulus: This algorithm divides the MSISDN value, in binary without the leading “+”, of the subscriber by the number of rows in the table, and the remainder is used as an index in the specific table to select the row.

  • round-robin: This algorithm rotates all rows in the active table for selection of the row in round-robin way. If no algorithm is specified this is the default behavior.

Default: round-robin
diameter-configured

This option enables the table number and algorithm specified by the `diameter host-select table` configuration in Policy Control Configuration mode.

Usage

Use this command to configure the table and row selection methods to select IP address/host address for P-CSCF discovery.

Example

The following command specifies table 1 with `round-robin` algorithm to select the rows with IP address for P-CSCF discovery.

```
p-cscf discovery table 1 algorithm round-robin
```
**p-cscf table**

This command adds/appends rows with primary and/or secondary IPv4/IPv6 addresses to a P-CSCF discovery table with precedence for P-CSCF discovery.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IMS Authorization Service Configuration

```
configure > context context_name > ims-auth-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-imsa-service)#
```

**Syntax**

In releases prior to 18:

```
p-cscf table { 1 | 2 } row-precedence precedence_value { address ipv4_address | ipv6-address ipv6_address } [ secondary { address ipv4_address | ipv6-address ipv6_address } ] [ weight value ]
```

```
no p-cscf table { 1 | 2 } row-precedence precedence_value
```

In 18 and later releases:

```
p-cscf table { 1 | 2 } row-precedence precedence_value { ipv4-address ipv4_address [ ipv6-address ipv6_address ] | ipv6-address ipv6_address [ ipv4-address ipv4_address ] } [ secondary { ipv4-address ipv4_address [ ipv6-address ipv6_address ] | ipv6-address ipv6_address [ ipv4-address ipv4_address ] } [ weight value ]
```

```
no p-cscf table { 1 | 2 } row-precedence precedence_value
```

**no**
Removes/deletes configured row with precedence in specified table for P-CSCF discovery address.

```
{ 1 | 2 }
```

Specifies which P-CSCF table is to be used to add/append the primary and secondary P-CSCF addresses. Two tables can be configured for P-CSCF discovery address.

**row-precedence precedence_value**

This keyword adds/appends the row with the specified row-precedence to the P-CSCF address table. In 8.1 and later releases, `precedence_value` must be an integer from 1 through 128, and a maximum of 128 rows can be added to a table. In release 8.0, `precedence_value` must be an integer from 1 through 100, and a maximum of 16 rows can be added to a table.
secondary
Specifies the secondary IPv4/IPv6 address to be entered in P-CSCF table rows.

address ip_address
Specifies the primary and/or secondary IPv4 address for P-CSCF discovery table. This keyword, if used with secondary keyword, specifies the secondary IPv4 address.
ip_address must be entered in IPv4 dotted-decimal notation.

ipv6-address ipv6_address
Specifies the primary and/or secondary IPv6 address for P-CSCF discovery table. This keyword, if used with secondary keyword, specifies the secondary IPv6 address.
ipv6_address must be entered in IPv6 colon-separated-hexadecimal notation.

weight value
This keyword designates weight to a row-precedence relative to other row-precedences configured under this table, Default value is 1. value must be an integer from 1 through 10.
Within the IMS Authorization configuration, the P-CSCF address is selected based on round robin fashion. This feature allows the customer to perform P-CSCF selection based on weight factor. With this CLI option, the user can configure and add weight (in the scale of 1 to 10) to each row, and the rows are selected based on weighted round-robin. That is, the row with higher weight parameter is selected more number of times than the row with less number of weights.

Usage
Use this command to add rows with primary and/or secondary IP addresses for P-CSCF discovery. The row is added with the specified row-precedence.
The operator can add/remove rows to the table that is not currently selected by the diameter host-select table command in Policy Control Configuration Mode.

Example
The following command adds a row in table 2 with primary IP address 10.2.3.4, secondary IP address as 50.6.7.8, and row-precedence value as 20 for P-CSCF discovery.

```
p-cscf table 2 row-precedence 20 address 10.2.3.4 secondary 50.6.7.8
```
policy-control

This command enters the Policy Control Configuration mode for Diameter Policy Control Application (DPCA) to configure Diameter authorization and policy control parameter for IMS authorization.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IMS Authorization Service Configuration

```
configure > context context_name > ims-auth-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-imsa-service)#
```

**Syntax**

```
[ no ] policy-control
```

- **no**
  Disables the pre-configured policy control parameters for IMS authorization in this IMS authorization service.

**Usage**

Use this command to enter the Policy Control Configuration Mode to configure the policy control parameters for Diameter authorization and charging policy in IMS Authorization Service. Entering this command results in the following prompt:

```
[context_name]host_name(config-imsa-dpca)#
```

Policy Control configuration commands are described in the *Policy Control Configuration Mode Commands* chapter.
qos-update-timeout

This command is obsolete in release 11.0 and later releases. This command sets the Quality of Service update timeout for a subscriber in IMS authorization service.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IMS Authorization Service Configuration

configure > context context_name > ims-auth-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-imsa-service)#

Syntax

qos-update-timeout timeout_duration

no qos-update-timeout

no

Disables the pre-configured QoS update timeout parameter in this IMS authorization service.

timeout_duration

Specifies the duration of timeout in seconds as an integer from 0 through 3600.
Default: 60

Usage

Use this command to set the maximum time to wait for a subscriber to initiate the update QoS procedure in IMS authorization service.

Example

The following command sets the QoS update timeout to 90 seconds.

qos-update-timeout 90
signaling-flag

This command specifies whether a request for a PDP context dedicated to signaling (for IMS sessions) should be granted or denied.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IMS Authorization Service Configuration

```
configure > context context_name > ims-auth-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-imsa-service)#
```

**Syntax**

```
signaling-flag { deny | permit }
```

**default signaling-flag**

```
default
```

Sets the signaling flag to default mode of deny.

```
deny
```

Denies the request for a signaling PDP context for IMS session and keeps signaling co-existed with other traffic on PDP contexts. Default: Enabled

```
permit
```

Permits the request for a signaling PDP context for IMS session and a separate signaling context activated. Default: Disabled

**Usage**

Use this command to allow or deny the activation of a dedicated PDP context for signaling. The user equipment (UE) may indicate that the PDP context should be dedicated for IP multimedia (IM) signaling by setting the IP Multimedia Core Network (IM-CN) signaling flag in the Protocol Configuration Options (PCO).

The **deny** option causes the system to inform the UE that the PDP context will not be dedicated for IM signaling and signaling will co-exist with other traffic on PDP context.

The **permit** option is used to activate the signaling context for signal traffic and the other traffic uses other PDP context for traffic with the following destinations:

- Towards the DHCP and DNS servers for the IMS domain
- Towards the P-CSCF(s)

The UE is not trusted to follow these restrictions, and the system monitors and restricts the traffic from the dedicated PDP context. The **signaling-flow class-map** command is used to configure the restrictions.
Example

The following command denies the request for a signaling PDP context for IMS session.

```
default signaling-flag
```
**signaling-flow**

This command specifies the packet filters and policy servers for bandwidth control and signaling context enforcement that define the traffic that is allowed through the dedicated signaling context.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IMS Authorization Service Configuration

`configure > context context_name > ims-auth-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-imsa-service)#
```

**Syntax**

```
signaling-flow permit server-address ipv4/ipv6_address [ server-port { port_num | range start_port to end_port } ] [ description STRING ]
```

```
no signaling-flow permit server-address ipv4/ipv6_address [ server-port { port_num | range start_port to end_port } ]
```

**no**

Disables the signaling flow option configured with this command.

**server-address ipv4/ipv6_address**

The server address refers to the destination IP address in uplink packets, and the source IP address in downlink packets.

`ipv4/ipv6_address` is an IP address in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation and can be used with a subnet mask.

A maximum of 16 signaling server addresses can be configured per IMS Authorization service.

**server-port { port_num | range start_port to end_port }**

Specifies the TCP/UDP port number(s) of the server to be used for communication.

`port_num` must be an integer from 1 through 65535.

`range start_port to end_port` provides the option to configure the range of ports on server for communication.

`start_port` must be an integer from 1 through 65535 but lesser than `end_port`, and `end_port` must be an integer from 1 through 65535 but greater than `start_port`.

**description STRING**

Specifies the customized description for configured signaling server as an alphanumeric string of 1 through 63 characters.
Usage
Traffic that matches any instance of the signaling-flow command will be forwarded via the signaling PDP context. In addition, the policy server gives policy gates to use for the signaling PDP context.

Example
The following command sets the packet filter server address to 10.2.3.4 with port number 1234 for packet filtering.

```
    signaling-flow server-address 10.2.3.4 server-port 1234
```
traffic-policy

This command specifies the action on packets which do not match any policy gates in the general purpose PDP context.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IMS Authorization Service Configuration

```bash
configure > context context_name > ims-auth-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-imsa-service)#
```

**Syntax**

```bash
traffic-policy general-pdp-context no-matching-gates direction { downlink | uplink } { forward | discard }
```

```bash
default traffic-policy general-pdp-context no-matching-gates direction { downlink | uplink }
```

**default**
Sets the default traffic policy for packets without any policy gate match in general purpose PDP context. By default packets which do not have any matching policy gate are forwarded.

**no-matching gates**
Applies traffic policy for packets which do not match any policy gate.

**direction { downlink | uplink }**
Specifies the direction of traffic to apply this traffic policy in general PDP context.

downlink: Specifies the traffic from system to MN. Default is set to forward.
uplink: Specifies the traffic from MN to system. Default is set to forward.

**forward**
Forwards the packets which do not match any policy gates. Default: Enabled

**discard**
Discards the packets which do not match any policy gates. Default: Disabled

**Usage**

This command provides configuration on traffic policy applied on packets which are not matching any policy gate in general PDP context. Packets can either be forwarded or discarded on the basis of operator’s configuration.

This command needs to be configured once for downlink and once for uplink separately.
Example

The following command discards uplink packets which do not match any policy gate in general purpose PDP context.

```
traffic-policy general-pdp-context no-matching-gates direction uplink discard
```
Chapter 173
IMS Sh Service Configuration Mode Commands

The IMS Sh Interface Configuration Mode is used to configure various Diameter parameters in order for:
PDIF to communicate with the HSS server. HSS server is used for MAC address validation in the IKEv2 exchanges to set up SAs and for storing part of the user profile. SCM to communicate with the HSS server. HSS server is used for retrieval and update of call feature parameters and call restriction data.

Mode

Exec > Global Configuration > Context Configuration > IMS Sh Interface Configuration
configure > context context_name > ims-sh-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ims-sh-service)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
diameter

This command configures Diameter parameters.

Product
PDIF
SCM

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > IMS Sh Interface Configuration
configure > context context_name > ims-sh-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ims-sh-service)#

Syntax

diameter { dictionary { custom1 | standard | endpoint string } }
default diameter { dictionary | endpoint }
no diameter endpoint

no
Removes previously configured endpoint.

default
Configures parameters to the default value.

dictionary
Specifies the dictionary to use.
  •custom1: A custom dictionary
  •standard: The standard dictionary

Important: SCM uses only the standard dictionary.

depoint string
Selects an endpoint to use in the configuration.
string must be the endpoint name, and must be an alpha and/or numeric string of 1 through 63 characters in length.

Usage
The Diameter endpoint contains information on the peer names and IP addresses and port, and the local IP address to use for Diameter.
You can have more than one Diameter endpoint configured on the chassis and the ims-sh-service needs to know which Diameter endpoint to use. This command is to select the appropriate Diameter endpoint, even if only one has been configured.

**Example**

The following example selects a diameter endpoint `diam1`:

```
diameter endpoint diam1
```
end

Exits the current mode and returns to the Exec Mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to change to the Exec Mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
exit
```

**Usage**
Use this command to return to the parent configuration mode.
failure-handling

This command configures the action to take in the event of an HSS server request failure.

Product
- PDIF
- SCM

Privilege
- Administrator

Mode
- Exec > Global Configuration > Context Configuration > IMS Sh Interface Configuration
- configure > context context_name > ims-sh-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ims-sh-service)#

Syntax

[ default ] failure-handling { profile-update-request | user-data-request } { { diameter-result-code result_code [ to result_code ] } | timeout } action { continue | retry-and-terminate | terminate } }

- default
  Resets configuration for the specified keyword to the default setting.

- profile-update-request
  Configures failure-handling as a result of a profile update request error.

- user-data-request
  Configures failure-handling as a result of a user data request.

- diameter-result-code result_code [ to result_code ]
  The Result-Code data field contains a space representing errors. Diameter provides the following classes of errors, all identified by the thousands digit in the decimal notation:
  - 3xxx (Protocol Errors)
  - 4xxx (Transient Failures)
  - 5xxx (Permanent Failure)
  result_code specifies either a result code value (diameter-result-code 3001) or a range of result code values (diameter-result-code 3000 to 9999) to which the failure-handling applies.

- action
  Configures the action to take depending on the diameter-result-code:
  - Continue the session
  - Retry and then terminate
- Terminate the session

**request-timeout action**

Configures the action to take as a result of a request timeout error:

- Continue the session
- Retry and then terminate
- Terminate the session

**Usage**

Configures all failure-handling parameters.

**Example**

The following command configures profile-update-request failure-handling using a result-code configuration with the terminate session option:

```bash
failure-handling profile-update-request diameter-result-code 3005 to 3600 action terminate
```
# request

Configures application request timeout.

## Product

- PDIF
- SCM

## Privilege

Administrator

## Mode

Exec > Global Configuration > Context Configuration > IMS Sh Interface Configuration

```
configure > context context_name > ims-sh-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ims-sh-service)#
```

## Syntax

```
request timeout secs

[ no | default ] request timeout
```

- **no**
  
  Disables a configured timeout request.

- **default**
  
  Default: 300 seconds
  
  Resets configuration to the default setting.

```
request timeout secs
```

Configures the request timeout in seconds.

- `secs` must be an integer from 1 through 300.

## Usage

Specifies the session request timeout period in seconds after which the request is deemed to have failed.

## Example

The following example configures the default timeout request of 300 seconds:

```
default request timeout
```
Chapter 174
IP VRF Context Configuration Mode Commands

The IP VRF Context Configuration Mode is used to create and manage the Virtual Routing and Forwarding (VRF) context instance for BGP/MPLS VPN, GRE, IPSec tunneling or service interfaces for virtual routing, addresses, address resolution options, etc.

Mode

Exec > Global Configuration > Context Configuration > IP VRF Context Configuration

configure > context context_name > ip vrf vrf_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-context-vrf)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
associate l2-mapping-table

Associates a global QoS-to-Level 2 mapping table with this VRF.

**Product**
ePDG
HSGW
P-GW
SAEGW
S-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IP VRF Context Configuration

`configure > context context_name > ip vrf vrf_name`

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-context-vrf)
```

**Syntax**

```
associate l2-mapping-table { name table_name | system-default }

no associate l2-mapping-table
```

**Usage**

Use this command to associates a global QoS-to-Level 2 mapping table with this VRF. Internal-QoS will be mapped to an actual L2 value (either or both of 802.1p/MPLS) using a per-VRF based table.

**Important:** If an l2-mapping-table association is made at both the VRF and VPN level, the VRF level takes precedence.
The mapping table is configured via the Global Configuration mode `qos l2-mapping-table` command.

The following command associates this VRF with Qos-to-L2 mapping table `vrf10`.

```
associate l2-mapping-table name vrf10
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

`exit`

**Usage**

Use this command to return to the parent configuration mode.
**ip guarantee**

Enables and disables local switching of framed route packets.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Administrator

**Mode**
- Exec > Global Configuration > Context Configuration
- `configure > context context_name`

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-ctx)#
```

**Syntax**

```
[no] ip guarantee framed-route local-switching
```

- **no**
  
  Disables local switching of framed route packets.

- **framed-route local-switching**
  
  Enables local switching of framed route packets. By default, this functionality is disabled.

**Usage**

Use this command to enable and disable local switching of framed route packets. This functionality will be applicable only when there are some NEMO/framed route sessions in a context.

**Example**

The following command enables local switching of framed route packets:

```
ip guarantee framed-route local-switching
```
ip maximum-routes

This command configures the maximum number of routes in an IP VRF routing table configured in this context.

**Important:** This command should only be used for framed or NEMO (Network Mobility) routes of the VRF.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IP VRF Context Configuration

```configure > context context_name > ip vrf vrf_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-context-vrf)#
```

**Syntax**

```
ip maximum-routes max_routes

no ip maximum-routes
```

- **no**
  Disables the configured maximum routes in specific IP VRF context.

- **max_routes**
  Sets the maximum number of routes in a specific IP VRF context.

  *`max_routes` must be an integer from 1 through 32768 or 65536 (release 17.0+).*

**Usage**

Use this command to configure the maximum number of routes in a particular VRF routing table. When the number of routes in the VRF is more than the maximum limit configured, a critical log is generated indicating that the number of routes is over the limit. Once the number of routes in the VRF goes under the limit, a clear log is generated.

The maximum routes configured using this command will be sent to the threshold configuration logic for appropriate action. For more information on threshold configuration, refer to descriptions of the `threshold route-service bgp-routes` and `threshold poll route-service interval` commands in the `Global Configuration Mode Commands` chapter.

**Example**

The following command sets 1000 routes as a maximum limit for specific VRF context:

```
    ip maximum-routes 1000
```
**mpls map-dscp-to-exp**

This command maps the final differentiated services code point (DSCP) bit value in the IP packet header to the final Experimental (EXP) bit value in the MPLS header for incoming traffic.

---

**Important**: This command has been deprecated beginning with Release 15.0.

**Product**

GGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IP VRF Context Configuration

```text
configure > context context_name > ip vrf vrf_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-context-vrf)#
```

**Syntax**

```text
[ no ] mpls map-dscp-to-exp dscp dscp_bit_value exp exp_bit_value
```

- **no**
  
  Disables the configured DSCP bit value mapping to the EXP bit value from a specific IP VRF context.

- **dscp dscp_bit_value**
  
  Specifies the final DSCP bit value which is to map with the final EXP bit value in MPLS header for incoming traffic.
  
  - *dscp_bit_value* specifies the value of DSCP bit values separated in eight groups and represented with integers from 0 through 7.
  
  The default representation of DSCP value in eight groups is given in the following table:

<table>
<thead>
<tr>
<th>DSCP Marking Value</th>
<th>DSCP Map Group</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-7</td>
<td>0</td>
</tr>
<tr>
<td>8-15</td>
<td>1</td>
</tr>
<tr>
<td>16-23</td>
<td>2</td>
</tr>
<tr>
<td>24-31</td>
<td>3</td>
</tr>
<tr>
<td>32-39</td>
<td>4</td>
</tr>
<tr>
<td>40-47</td>
<td>5</td>
</tr>
<tr>
<td>48-55</td>
<td>6</td>
</tr>
<tr>
<td>56-63</td>
<td>7</td>
</tr>
</tbody>
</table>
exp exp_bit_value

Specifies the final EXP bit value in MPLS header to which the final DSCP bit value 0 to 7 (represented in eight values) coming from incoming traffic will be mapped.

exp_bit_value is the value of EXP bit in MPLS header and must be an integer between 0 through 7.

Usage

Use this command to map the final DSCP value coming from incoming IP traffic to a final EXP value in MPLS header. This mapping determines the QoS and service parameters to which the packet is assigned.

Example

The following command maps the DSCP value 3 (24 to 31) to EXP bit 3 in MPLS header:

    mpls map-dscp-to-exp dscp 3 exp 3
**mpls map-exp-to-dscp**

Maps incoming the Experimental (EXP) bit value in MPLS header to the internal differentiated services code point (DSCP) bit value in IP packet headers for outgoing traffic.

**Important:** This command has been deprecated beginning with Release 15.0.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IP VRF Context Configuration

```
configure > context context_name > ip vrf vrf_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-context-vrf)#
```

**Syntax**
```
[ no ] mpls map-exp-to-dscp exp exp_bit_value dscp dscp_bit_value
```

- **no**
  Disables the configured EXP bit value mapping to DSCP bit value from specific IP VRF context.

- **exp** `exp_bit_value`
  Specifies the incoming EXP bit value in MPLS header to which the internal DSCP bit value 0 to 7 (represented in 8 values) in IP traffic will be mapped.
  `exp_bit_value` is the value of the EXP bit in an MPLS header and must be an integer from 0 through 7.

- **dscp** `dscp_bit_value`
  Maps the DSCP bit value with the incoming EXP bit value in an MPLS header.
  `dscp_bit_value` specifies the value of the DSCP bit values separated in eight groups and represented with integers between 0 through 7.

The default representation of DSCP value in eight groups is given in the following table:

<table>
<thead>
<tr>
<th>DSCP Marking Value</th>
<th>DSCP Map Group</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-7</td>
<td>0</td>
</tr>
<tr>
<td>8-15</td>
<td>1</td>
</tr>
<tr>
<td>16-23</td>
<td>2</td>
</tr>
<tr>
<td>24-31</td>
<td>3</td>
</tr>
<tr>
<td>32-39</td>
<td>4</td>
</tr>
<tr>
<td>40-47</td>
<td>5</td>
</tr>
</tbody>
</table>
Usage
Use this command to map the incoming EXP bit value in MPLS headers to the DSCP bit value in IP traffic. This mapping determines the QoS and service parameters to which the packet is assigned.

Example
The following command maps the EXP bit value 4 to DSCP value 6 (48 to 55) in IP header:

```
mpls map-exp-to-dscp exp 4 dscp 6
```
Chapter 175
IPMS Client Configuration Mode Commands

The IPMS Client Configuration Mode is used to enable the Intelligent Packet Monitoring System (IPMS) client service on an Access Gateway and to set basic service-wide options in a context.

**Important:** This is a license enabled external application support. For more information on this product, refer to the *IPMS Installation and Administration Guide*.

**Mode**

Exec > Global Configuration > Context Configuration > IPMS Configuration

```
configure > context context_name > ipms
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-ipms)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

end

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

exit

Usage
Use this command to return to the parent configuration mode.
export keys

Enables the encryption key export in specific key exchange events to IPMS server from IPMS-enabled AGW.

**Important:** This is a license enabled customer specific command.

**Product**
IPMS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPMS Configuration

```
configure > context context_name > ipms
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-ipms)#
```

**Syntax**

```
no
```

Removes the configured source IP address from this context for IPMS client communication with IPMS server.

```
ikeyv2
```

Enables the security association (SA) key export for Internet Key Exchange (IKEv2) protocol to IPMS server.

**Usage**
Monitor subscribers which have complaints of service availability or to monitor a test user for system verification.

**Example**
The following command assigns the IP address 10.2.3.4 to the IPMS client service in context to communicate with IPMS server. This is the IP address allocated for IPMS client service on chassis.

```
source address 10.2.3.4
```
heartbeat

Configures the IPMS heartbeating between the IPMS-enabled AGW and the IPMS server.

**Product**
IPMS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPMS Configuration

`configure > context context_name > ipms`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-ipms) #
```

**Syntax**

```
heartbeat period dur [ permitted-failure no_of_failures ]
[ no | default ] heartbeat
```

---

**default**

Configures the heartbeat period and permitted number of failures to the default values of 10 seconds and 1 failure respectively.

---

**no**

Disables/removes the configured heartbeat period and permitted number of failures.

---

**period dur**

Specifies the periodicity (in seconds) between heartbeat messages as an integer from 1 through 3600. Default: 10

---

**permitted-failure no_of_failures**

Specifies the number of errors/failures allowed before declaring an IPMS server as dead/unreachable as an integer from 1 through 10. Default: 1

---

**Usage**

Use this command to configure the heartbeat message periodicity and permissible failure of heartbeat message response before declaring an IPMS server as dead or unreachable. When an IPMS server is declared down an SNMP trap is sent.

---

**Example**

Following command configures the heartbeat message periodicity to 5 second and number of failures allowed as 3 to determine an IPMS server as dead.

```
heartbeat period 5 permitted-failure 3
```
server

Configures the IPMS server address and ports on which the IPMS client on an IPMS-enabled AGW communicates. This is the IP address and port range of the IPMS server.

Product
IPMS

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPMS Configuration
configure > context context_name > ipms

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-ipms)#

Syntax

server address ip_address [ secondary ] [ start-port start_port [ end-port end_port ]][
secondary]

no server address ip_address

no

Removes the configured IPMS server IP address and port range from this context.

address ip_address

Specifies the IP address of the IPMS server to which the IPMS client service communicates in IPv4 dotted-decimal notation.
A maximum of 4 IPMS servers can be configured with this command in one context.

[ start-port start_port[ end-port end_port ]]

Default: 45001 source port
45005 end port

Specifies the range of UDP ports on which IPMS client communicates with the IPMS server.

start-port start_port: Specifies starting port number as an integer from 1 through 65535 that is less than end_port, if end-port is specified.
end-port end_port: Specifies the end port number as an integer from 1 through 65535 that is more than start_port.

secondary

The secondary keyword is used to configure the specified server address as secondary IP address on the IPMS client interface.
Usage
Use this command to configure/remove the IPMS servers. Up to 4 different IPMS servers can be configured with this command. UDP port number can also be configured with this command. IPMS client will search for this IP address to push the event and traffic logs.

Example
The following command configures IPMS server having IP address 10.2.3.4 in the IPMS client service export the event and traffic logs for intelligent packet monitoring functionality. It also specifies the UDP port range from 48000 to 48005 for communication.

server address 10.2.3.4 start-port 48000 end-port 48005
**source**

Configures the source address of the IPMS client in this context to communicate with the IPMS server. This is the IP address for IPMS client on the chassis.

**Product**

IPMS

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IPMS Configuration

```
configure > context context_name > ipms
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-ipms)#
```

**Syntax**

```
source address ip_address
```

**address ip_address**

Specifies the IP address of the IPMS client on the AGW in this context. This is the address which is bound to the IPMS client service in this context. _ip_address_ is expressed in IPv4 dotted-decimal notation.

**Usage**

Monitor subscribers which have complaints of service availability or to monitor a test user for system verification.

**Example**

The following command assigns the IP address 10.2.3.4 to the IPMS client service in context to communicate with IPMS server. This is the IP address allocated for IPMS client service on chassis.

```
source address 10.2.3.4
```
Chapter 176
IPSec Transform Set Configuration Mode Commands

The IPSec Transform Set Configuration Mode is used to configure IPSec security parameters. There are two core protocols, the Authentication Header (AH) and Encapsulating Security Payload (ESP). AH may be considered redundant as ESP can provide the same authentication services that AH does.

Mode
Exec > Global Configuration > Context Configuration > IPSec Transform Set Configuration

configure > context context_name > ipsec transform-set set_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-context-vrf)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
encryption

Configures the appropriate IPSec ESP encryption algorithm and encryption key length. AES-CBC-128 is the default.

**Product**
- ePDG
- PDIF
- SCM

**Privilege**
- Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSec Transform Set Configuration
configure > context context_name > ipsec transform-set set_name

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-context-vrf)#
```

**Syntax**

```
encryption { 3des-cbc | aes-cbc-256 | des-cbc | null }
```

**default encryption**

<table>
<thead>
<tr>
<th>Encryption Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3des-cbc</td>
<td>Data Encryption Standard Cipher Block Chaining encryption applied to the message three times using three different cypher keys (triple DES).</td>
</tr>
<tr>
<td>aes-cbc-128</td>
<td>Advanced Encryption Standard Cipher Block Chaining with a key length of 128 bits. This is the default setting for this command.</td>
</tr>
<tr>
<td>aes-cbc-256</td>
<td>Advanced Encryption Standard Cipher Block Chaining with a key length of 256 bits.</td>
</tr>
<tr>
<td>null</td>
<td>The NULL encryption algorithm represents the optional use of applying encryption within ESP. ESP can then be used to provide authentication and integrity without confidentiality.</td>
</tr>
<tr>
<td>default</td>
<td>Sets the default IPSec ESP algorithm to AES-CBC-128.</td>
</tr>
</tbody>
</table>
Usage

In cipher block cryptography, the plaintext is broken into blocks usually of 64 or 128 bits in length. In cipher block chaining (CBC) each encrypted block is chained into the next block of plaintext to be encrypted. A randomly generated vector is applied to the first block of plaintext in lieu of an encrypted block. CBC provides confidentiality, but not message integrity. Because RFC 4307 calls for interoperability between IPSec and IKEv2, the IKEv2 confidentiality algorithms must be the same as those configured for IPsec in order for there to be an acceptable match during the IKE message exchange. In IKEv2, there is no NULL option.

Example

The following command configures the encryption to be the default aes-cbc-128:

```bash
default encryption
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
**group**

Configures the appropriate key exchange cryptographic strength and activate Perfect Forward Secrecy by applying a Diffie-Hellman group.

**Product**
- ePDG
- PDIF
- SCM

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > IPSec Transform Set Configuration

**Syntax**

```plaintext
configure > context context_name > ipsec transform-set set_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-context-vrf)#
```

**Syntax**

```plaintext
group { 1 | 2 | 5 | 14 | none }
```

- **default group**
  
  Configures the default crypto strength to be `none` and disables Perfect Forward Secrecy.

- **1**
  
  Configures crypto strength at the Group 1 level. Lowest security.

- **2**
  
  Configures crypto strength at the Group 2 level. Medium security.

- **5**
  
  Configures crypto strength at the Group 5 level. Higher security.

- **14**
  
  Configures crypto strength at the Group 14 level. Highest security.

- **none**
  
  Applies no group and disables Perfect Forward Secrecy. This is the default.

- **default**
  
  Sets the default Diffie-Hellman group algorithm to none. This also deactivates PFS.
Usage

Diffie-Hellman groups are used to determine the length of the base prime numbers used during the key exchange process. The cryptographic strength of any key derived depends, in part, on the strength of the Diffie-Hellman group upon which the prime numbers are based. Group 1 provides 768 bits of keying strength, Group 2 provides 1024 bits, Group 5 provides 1536 bits and Group 14 2048 bits. Selecting a group automatically activates Perfect Forward Secrecy. The default value is none, which disables PFS.

Example

This command configures security at Group 2 and activates PFS:

```
    group 2
```
hmac

Configures the IPsec ESP integrity algorithm using a Hash-based Message Authentication Code (HMAC).

**Product**
- ePDG
- PDIF
- SCM

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSec Transform Set Configuration

```
configure > context context_name > ipsec transform-set set_name
```

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-context-vrf)#
```

**Syntax**

```
hmac { aes-xcbc-96 | md5-96 | none | null | sha1-96 }
```

**default hmac**

```
default hmac
```

Sets the default IPSec hashing algorithm to SHA1-96.

**aes-xcbc-96**

AES-XCBC-96 uses a 128-bit secret key and produces a 128-bit authenticator value.

**md5-96**

MD5-96 uses a 128-bit secret key and produces a 128-bit authenticator value.

**null**

Configures the HMAC value to be null. The NULL encryption algorithm represents the optional use of applying encryption within ESP. ESP can then be used to provide authentication and integrity without confidentiality.

**sha1-96**

SHA-1 uses a 160-bit secret key and produces a 160-bit authenticator value. This is the default setting for this command.

**Usage**

HMAC is an encryption technique used by IPsec to make sure that a message has not been altered. A keyed-Hash-based Message Authentication Code (HMAC), is a type of message authentication code that is calculated using a cryptographic hash function in combination with a secret key to verify both data integrity
and message authenticity. A hash takes a message of any size and transforms it into a message of a fixed size: the authenticator value. This is truncated to 96 bits and transmitted. The authenticator value is reconstituted by the receiver and the first 96 bits are compared for a 100 percent match.

Example

The following command configures the default HMAC value (SHA1-96):

```
default hmac
```
mode

Configures the security of IP datagrams based on header placement. Tunnel mode applies security to a completely encapsulated IP datagram, while Transport does not. Default is Tunnel mode.

Product

- ePDG
- PDIF
- SCM

Privilege

- Security Administrator, Administrator

Mode

- Exec > Global Configuration > Context Configuration > IPSec Transform Set Configuration
- `configure > context context_name > ipsec transform-set set_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-context-vrf)#
```

Syntax

```
mode { transport | tunnel }
```

**default mode**

transport

In Transport mode, the IPSec header is applied only over the IP payload, not over the IP header in front of it. The AH and/or ESP headers appear between the original IP header and the IP payload, as follows:
- Original IP header, IPSec headers (AH and/or ESP), IP payload (including transport header).
- Transport mode is used for host-to-host communications and is generally unsuited to PDIF traffic.

---

tunnel

In Tunnel mode, the original IP header is left intact, so a complete IP datagram is encapsulated, forming a virtual tunnel between IPSec-capable devices. The IP datagram is passed to IPSec, where a new IP header is created ahead of the AH and/or ESP IPSec headers, as follows:
- New IP header, IPSec headers (AH and/or ESP), old IP header, IP payload.
- Tunnel mode is used for network-to-network communications (secure tunnels between routers) or host-to-host communications over the Internet.
- This is the default setting for this command.

---

**default mode**

Sets the default IPSec Mode to Tunnel.

---

**Usage**

IPSec modes are closely related to the function of the two core protocols, the Authentication Header (AH) and Encapsulating Security Payload (ESP). Both of these protocols provide protection by adding to a datagram a header (and possibly other fields) containing security information. The choice of mode does not
affect the method by which each generates its header, but rather, changes what specific parts of the IP datagram are protected and how the headers are arranged to accomplish this.

**Example**

The following command configures the default Tunnel mode:

```
default mode
```
Chapter 177
IPSG RADIUS Server Configuration Mode Commands

The IP Services Gateway (IPSG) RADIUS Server Configuration Mode is used to create and configure IPSG RADIUS Server/eWAG services in the current context. This mode enables configuring the system to receive RADIUS accounting requests as if it is a RADIUS accounting server, and reply after accessing those requests for subscriber information.

Mode

Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-server)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
accounting-context

This command allows you to specify the GTPP accounting context.

Product
eWAG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-server)#

Syntax

accounting-context context_name

no accounting-context

no

If previously configured, removes the accounting context configuration.

context_name

Specifies name of the GTPP accounting context.
context_name must be an alphanumeric string of 1 through 79 characters in length.

Usage

Use this command to specify the GTPP accounting context.

Example

The following command specifies to use the GTPP accounting context context12 for the eWAG service:

accounting-context context12
associate sgtp-service

This command allows you to associate an SGTP service with the current eWAG service.

**Product**
eWAG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

```shell
configure > context context_name > ipsg-service service_name mode radius-server
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipsg-service-radius-server)#
```

**Syntax**

```bash
associate sgtp-service sgtp_service_name [ context sgtp_context_name ]
```

**no associate sgtp-service**

If previously configured, removes the service association from the configuration.

**sgtp-service sgtp_service_name**

Specifies name of the SGTP service to associate with this service.

*sgtp_service_name* must be the name of an SGTP service, and must be an alphanumeric string of 1 through 63 characters in length.

**context sgtp_context_name**

Specifies name of the context in which the SGTP service is configured.

*sgtp_context_name* must be the name of the context, and must be an alphanumeric string of 1 through 63 characters in length.

If a context is not specified, the current context is used.

**Usage**

Use this command to associate an SGTP service with the IPSG service. This enables the GTP functionality for eWAG supporting GTP-C (GTP Control Plane) messaging and GTP-U (GTP User Data Plane) messaging between eWAG and GGSN over the Gn' interface.

**Important:** Any change to this configuration will result in restart of the eWAG service.

**Example**

The following command associates an SGTP service named *service1*, configured in the context named *context2*, with the IPSG service:
associate sgtp-service service1 context context2

**bind**

This command allows you to bind the current IPSG/eWAG service to a logical AAA interface, and specify the number of subscriber sessions allowed.

**Product**
eWAG
IPSG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-server)#

**Syntax**

```bash
bind accounting-proxy address ipv4/ipv6_address [ max-subscribers max_sessions | port port_number | source-context source_context ]

bind address ipv4/ipv6_address [ disconnect-message [ src-port source_port_number ] | max-subscribers max_sessions | port port_number | source-context source_context ]+

bind authentication-proxy address ipv4/ipv6_address [ acct-port port_number | auth-port port_number | max-subscribers max_sessions | source-context source_context ]

no bind
```

**no**

If previously configured, removes the binding for the service.

```bash
bind accounting-proxy address ipv4/ipv6_address [ max-subscribers max_sessions | port port_number | source-context source_context ]

• accounting-proxy address ipv4/ipv6_address: Specifies the IP address of the interface where accounting proxy requests are received by this service in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

• max-subscribers max_sessions: Specifies the maximum number of subscriber sessions allowed for the service. If this option is not configured, the system defaults to the license limit.

  In StarOS 9.0 and later releases, max_sessions must be an integer from 0 through 4000000.

  In StarOS 8.3 and earlier releases, max_sessions must be an integer from 0 through 3000000.

• port port_number: Specifies the port number of the interface where accounting requests are received by this service.

  port_number must be an integer from 1 through 65535.

  Default: 1813
```
**source-context** *source_context*: Specifies the source context where RADIUS accounting requests are received.

*source_context* must be an alphanumeric string of 1 through 79 characters.

This keyword should be configured if the source of the RADIUS requests is in a different context than the IPSG service. If this keyword is not configured, the system will default to the context in which the IPSG service is configured.

```
bind address ipv4/ipv6_address [ disconnect-message [ src-port source_port_number ] | max-subscribers max_sessions | port port_number | source-context source_context ]+
```

- **address** *ipv4/ipv6_address*: Specifies the IP address of the interface where accounting requests are received by this service in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

- **disconnect-message** [ *src-port* source_port_number ]: Specifies to send RADIUS disconnect message to the configured RADIUS accounting client in call failure scenarios.

  *src-port* *source_port_number*: Specifies the port number to which the disconnect message must be sent.

  *source_port_number* must be an integer from 1 through 65535.

- **max-subscribers** *max_sessions*: Specifies the maximum number of subscriber sessions allowed for the service. If this option is not configured, the system defaults to the license limit.

  In StarOS 9.0 and later releases, *max_sessions* must be an integer from 0 through 4000000.

  In StarOS 8.3 and earlier releases, *max_sessions* must be an integer from 0 through 3000000.

- **port** *port_number*: Specifies the port number of the interface where accounting requests are received by this service.

  *port_number* must be an integer from 1 through 65535.

  Default: 1813

- **source-context** *source_context*: Specifies the source context where RADIUS accounting requests are received.

  *source_context* must be an alphanumeric string of 1 through 79 characters.

  This keyword should be configured if the source of the RADIUS requests is in a different context than the IPSG service. If this keyword is not configured, the system will default to the context in which the IPSG service is configured.

```
bind authentication-proxy address ipv4/ipv6_address [ acct-port port_number | auth-port port_number | max-subscribers max_sessions | source-context source_context ]
```

- **authentication-proxy address** *ipv4/ipv6_address*: Specifies the IP address of the interface where authentication proxy requests are received by this service in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

**Important**: Enabling authentication proxy also enables accounting proxy.

- **acct-port** *port_number*: Specifies the port number of the interface where accounting proxy requests are received by this service.

  *port_number* must be an integer from 0 through 65535.
Default: 1813

• **auth-port** *port_number*: Specifies the port number of the interface where authentication proxy requests are received by this service.

  *port_number* must be an integer from 0 through 65535.

  Default: 1812

• **max-subscribers** *max_sessions*: Specifies the maximum number of subscriber sessions allowed for the service. If this option is not configured, the system defaults to the license limit.

  In StarOS 9.0 and later releases, *max_sessions* must be an integer from 0 through 4000000.

  In StarOS 8.3 and earlier releases, *max_sessions* must be an integer from 0 through 3000000.

• **source-context** *source_context*: Specifies the source context where RADIUS accounting requests are received.

  *source_context* must be an alphanumeric string of 1 through 79 characters.

  This keyword should be configured if the source of the RADIUS requests is in a different context then the IPSG service. If this keyword is not configured, the system will default to the context in which the IPSG service is configured.

### Usage

Use this command to bind the IPSG RADIUS Server/eWAG service to a logical AAA interface and specify the number of allowed subscriber sessions. If the AAA interface is not located in this context, configure the **source-context** parameter.

Use the accounting and authentication proxy settings to enable RADIUS proxy server functionality on the IPSG. These commands are used when the NAS providing the RADIUS request messages is incapable of sending them to two separate devices. The IPSG in RADIUS Server mode proxies the RADIUS request and response messages while performing the user identification task in order to provide services to the session.

### Example

The following command binds the service to a AAA interface with and IP address of 10.2.3.4 located in the source context named **aaa ingress**:

```shell
bind address 10.2.3.4 source-context aaa_ingress
```
connection authorization

This command allows you to configure the RADIUS authorization password that must be matched by the RADIUS accounting requests received by the current IPSG service.

Product

IPSG

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration
configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-server)#

Syntax

connection authorization [ encrypted ] password password

no connection authorization

no

Deletes the RADIUS authorization from the current IPSG RADIUS Server service.

[ encrypted ] password password

- encrypted: Specifies that the RADIUS authorization password is encrypted.
- password password: Specifies the password that must be matched by incoming RADIUS accounting requests.

In StarOS 12.2 and later releases, password with encryption must be an alphanumeric string of 1 through 132 characters, and without encryption an alphanumeric string of 1 through 63 characters.

In StarOS 12.1 and earlier releases, password must be an alphanumeric string of 1 through 63 characters.

Usage

The IPSG RADIUS server service does not terminate RADIUS user authentication so the user password is unknown.

Use this command to configure the authorization password that the RADIUS accounting requests must match in order for the service to examine and extract user information.

Example

The following command sets the RADIUS authorization password that must be matched by the RADIUS accounting requests sent to this service. The password is encrypted, and the password used in this example is “secret”.

connection authorization encrypted password secret
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

`exit`

**Usage**

Use this command to return to the parent configuration mode.
gtp max-contexts-per-imsi

This command allows you to configure multiple primary contexts having the same IMSI number.

Product eWAG
Privilege Security Administrator, Administrator
Mode Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:
[context_name]host_name(config-ipsg-service-radius-server)#

Syntax

```
gtp max-contexts-per-imsi max_value min-nsapi min_nsapi_value
default gtp max-contexts-per-imsi
```

**default gtp max-contexts-per-imsi**

```
default
Configures this command to disable use of multiple primary contexts. Only one PDP context per user is allowed.
max-contexts-per-imsi: 1
min-nsapi: 15
```

**max-contexts-per-imsi max_value**

Specifies the limit for the maximum number of contexts per IMSI.
```
max_value must be an integer from 1 through 11.
```

**min-nsapi min_nsapi_value**

Specifies the range of NSAPI values to be assigned to different PDP context of the same subscriber.
```
min_nsapi_value must be an integer from 5 through 15.
```

**Usage**

Use this command to configure the maximum number of contexts per IMSI, and the range of NSAPI values to be assigned to different PDP context.

**Example**

The following command configures the maximum contexts per IMSI to 5 and specify the range of values NSAPI value to 7.
```
gtp max-context-per-imsi 5 min-nsapi 7
```
**gtp peer-ip-address**

This command allows you to configure GGSN IP address under the eWAG service.

**Product**
eWAG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

```
configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

```
/context_name/host_name(config-ipsg-service-radius-server)#
```

**Syntax**

```
gtp peer-ip-address ipv4_address

no gtp peer-ip-address
```

**Usage**

Use this command to configure the GGSN IP address under the eWAG service.

This command replaces the hidden mode command

```
[ no ] ggsn-ip-address ipv4_address
```

**Example**

The following command configures the GGSN IP address 1.2.3.4 under the current eWAG service.

```
gtp peer-ip-address 1.2.3.4
```
ip

This command enables you to configure IP parameters for the current eWAG service.

• qci 6 allocation-retention-priority 3: ef
• qci 7 allocation-retention-priority 1: af21
• qci 7 allocation-retention-priority 2: af21
• qci 7 allocation-retention-priority 3: af21
• qci 8 allocation-retention-priority 1: af21
• qci 8 allocation-retention-priority 2: af21
• qci 8 allocation-retention-priority 3: af21

no

Resets configured value for specified QCI with its default setting.

gnp-qos-dscp

Specifies, for uplink direction, the DiffServ Code Point marking to be used for sending packets of a particular 3GPP QoS class.

qos-dscp

Specifies, for downlink direction, the DiffServ Code Point marking to be used for sending packets of a particular 3GPP QoS class.

qci { 1 | 2 | 3 | 4 | 9 }

Specifies the QCI attribute of QoS.

• 1: QCI 1 attribute of QoS
• 2: QCI 2 attribute of QoS
• 3: QCI 3 attribute of QoS
• 4: QCI 4 attribute of QoS
• 9: QCI 9 attribute of QoS

qci { 5 | 6 | 7 | 8 } allocation-retention-priority { 1 | 2 | 3 }

Specifies the QCI attribute of QoS with ARP.

• 5: QCI 5 attribute of QoS
• 6: QCI 6 attribute of QoS
• 7: QCI 7 attribute of QoS
• 8: QCI 8 attribute of QoS

allocation-retention-priority { 1 | 2 | 3 }: Specifies the ARP.

af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | ef | pt

Specifies the Per-Hop Forwarding Behavior (PHB) to use.

• af11: Assured Forwarding 11 PHB
• af12: Assured Forwarding 12 PHB
• af13: Assured Forwarding 13 PHB
- af21: Assured Forwarding 21 PHB
- af22: Assured Forwarding 22 PHB
- af23: Assured Forwarding 23 PHB
- af31: Assured Forwarding 31 PHB
- af32: Assured Forwarding 32 PHB
- af33: Assured Forwarding 33 PHB
- af41: Assured Forwarding 41 PHB
- af42: Assured Forwarding 42 PHB
- af43: Assured Forwarding 43 PHB
- be: Best Effort Forwarding PHB
- ef: Expedited Forwarding PHB
- pt: Pass Through (do not modify the ToS)

Usage
Use this command to configure IP parameters for the eWAG service.

Example
The following command specifies to configure the DiffServ Code Point marking to be used for sending packets specifying QCI as 1 and Assured Forwarding 11 PHB:

```
ip gnp-qos-dscp qci 1 af11
```
map ue-mac-to-imei

This command allows you to map the UE MAC received in the Calling-Station-Id RADIUS attribute to IMEIsV in order to forward it in the GTP CPC message to the GGSN.

Product

eWAG

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-server)#

Syntax

[ default | no ] map ue-mac-to-imei

default

If previously configured, disables mapping of UE MAC address to IMEIsV IE of GTP message in order to forward it to GGSN.
Default: Mapping is disabled.

no

If previously configured, disables mapping of UE MAC address to IMEIsV IE of GTP message in order to forward it to GGSN.

Usage

Use this command to enable or disable mapping of UE MAC address to IMEIsV IE of GTP message in order to forward it to GGSN.
overlapping-ip-address

This command allows you to enable or disable overlapping of IP addresses which enables multiple users to use the same IP address.

Product
IPSG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration
configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-server)#

Syntax

[ default | no ] overlapping-ip-address

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>If previously configured, disables IPSG support of overlapping IP addresses. Using overlapping IP addresses is disabled by default.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
<tbody>
<tr>
<td>If previously configured, disables IPSG support of overlapping IP addresses.</td>
</tr>
</tbody>
</table>

Usage
Use this command to enable or disable overlapping IP addresses for subscribers on different networks that are independent of each other.

Example
The following command enables IPSG overlapping of IP addresses:

overlapping-ip-address
plmn id

This command allows you to configure Public Land Mobile Network (PLMN) identifier for the current eWAG service.

Product

eWAG

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-server)#

Syntax

plmn id mcc mcc_number mnc mnc_number

no plmn id

If previously configured, deletes the PLMN ID configuration.

mcc mcc_number

Specifies the mobile country code (MCC) part of the PLMN identifier for the eWAG service. mcc_number must be a three-digit number ranging from 200 to 999.

mnc mnc_number

Specifies the mobile network code (MNC) part of the PLMN identifier for the eWAG service. mnc_number must be a two- or three-digit number ranging from 00 to 999.

Usage

Use this command to configure the location-specific mobile network identifiers included in the Routing Area Identity (RAI) field of the PDP Create Request messages sent to the GGSN.

Important: Any change to this configuration will result in restart of the eWAG service.

Example

The following command configures the PLMN identifier for the eWAG service as MCC 333 and MNC 99:

plmn id mcc 333 mnc 99
profile

This command allows you to configure the IPSG/eWAG service to use APN or subscriber profile.

**Important:** In release 14.0, eWAG service uses only the APN profile. In release 15.0, ReWAG uses the APN profile and DeWAG uses the subscriber profile. Whereas, the IPSG service uses both APN and subscriber profiles.

**Product**

eWAG

**IPSG**

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipsg-service-radius-server)#
```

**Syntax**

```
profile { APN [ default-apn apn_name ] | subscriber }
```

**default profile**

```
default
```

Configures this command with its default setting.

Default: APN

**APN**

Specifies to use APN profile for the service.

```
default-apn apn_name
```

**Important:** This option is supported only for the eWAG service.

Specifies the default APN to be used for the eWAG service.

`apn_name` must be the name of an APN, it must be an alphanumeric string of 1 through 62 characters in length, and can consist only of the alphabetic characters (A–Z and a–z), digits (0–9), dot (.), and the hyphen (-).

**subscriber**

**Important:** This option is supported only for the IPSG RADIUS Server service, and in release 15.0 for DeWAG service. For the DeWAG service, this command must be configured with the `subscriber` option. This is because
DeWAG will operate based on subscriber template profile selection only for connecting users. If the APN profile selection is configured, the DeWAG service will not be started.

Specifies to use subscriber profile for the service.

Usage
Use this command to set the service to support APN profiles (supporting Gx through the enabling of `ims-auth-service`) or for basic subscriber profile lookup.
For the DeWAG service, this command must be configured with the `subscriber` option. This is because DeWAG will operate based on subscriber template profile selection only for connecting users. If the APN profile selection is configured, the DeWAG service will not be started.

Example
The following command specifies to use the subscriber profile:

```
profile subscriber
```
radius accounting

This command allows you to specify the IP address and shared secret of the RADIUS accounting client from which RADIUS accounting requests are received. The RADIUS client can be either the access gateway or the RADIUS accounting server depending on which device is sending accounting requests.

Product
- eWAG
- IPSG

Privilege
- Security Administrator
- Administrator

Mode
- Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration
- configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-server)#

Syntax

radius accounting { client { ipv4/ipv6_address | ipv4/ipv6_address/mask } [ encrypted ] key key [ acct-onoff [ aaa-context aaa_context_name ] [ aaa-group aaa_server_group_name ] [ clear-sessions ] + ] [ dictionary dictionary ] [ disconnect-message [ release-on-acct-stop acct_stop_wait_timeout ] [ dest-port destination_port_number ] + ] [ interim create-new-call | validate-client-ip ]

no radius accounting { client { ipv4/ipv6_address | ipv4/ipv6_address/mask } | interim create-new-call | validate-client-ip }

default radius accounting { interim create-new-call | validate-client-ip }

no

If previously configured, removes the specified configuration.

ipv4/ipv6_address | ipv4/ipv6_address/mask

Specifies the IP address, and optionally subnet mask of the RADIUS client from which RADIUS accounting requests are received.

ipv4/ipv6_address/ipv4/ipv6_address/mask must be in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

A maximum of 16 IP addresses can be configured.

[ encrypted ] key key

- **encrypted**: Specifies that the shared key between the RADIUS client and this service is encrypted.
- **key key**: Specifies the shared key between the RADIUS client and this service.

In StarOS 12.2 and later releases, **key** with encryption must be an alphanumeric string of 1 through 236 characters, and without encryption an alphanumeric string of 1 through 127 characters. Note that **key** is case sensitive.
radius accounting

In StarOS 12.1 and earlier releases, key must be an alphanumerical string of 1 through 127 characters and is case sensitive.

```
acct-onoff [ aaa-context aaa_context_name ] [ aaa-group aaa_server_group_name ] [ clear-sessions ] +
```

**Important:** In release 12.3 and earlier releases, this option is applicable only to the IPSG Proxy Mode.

**Important:** In release 14.0 and later releases, this option is applicable to the IPSG Proxy and Server Modes.

Specifies to proxy accounting On/Off messages to AAA server.
- **aaa-context aaa_context_name**: Specifies the context to find AAA server groups. If not specified, by default, the AAA context will be the source context.
  
  `aaa_context_name` must be the name of a AAA context, and must be an alphanumerical string of 1 through 79 characters.

- **aaa-group aaa_server_group_name**: Specifies the AAA server group. If not specified, by default, the AAA server group will be `default`.
  
  `aaa_server_group_name` must be the name of AAA server group, and must be an alphanumerical string of 1 through 63 characters.

- **clear-sessions**: Specifies to clear eWAG or IPSG sessions on receiving accounting On/Off messages.

- **+**: Indicates that more than one of the preceding options may be specified in a single command.

**dictionary dictionary**

Specifies the dictionary to use.

**Important:** In this release, eWAG supports only the `starent-vas1` dictionary.

**dictionary** can be one of the following:

<table>
<thead>
<tr>
<th>Dictionary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3gpp2</td>
<td>This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835-A.</td>
</tr>
<tr>
<td>3gpp2-835</td>
<td>This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835.</td>
</tr>
<tr>
<td>customX</td>
<td>These are customized dictionaries. For information on custom dictionaries, please contact your Cisco account representative. X is the integer value of the custom dictionary.</td>
</tr>
<tr>
<td>standard</td>
<td>This dictionary consists only of the attributes specified in RFC 2865, RFC 2866, and RFC 2869.</td>
</tr>
<tr>
<td>starent</td>
<td>This dictionary consists of all of the attributes in the starent-vas1 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the dictionaries supported by the system.</td>
</tr>
</tbody>
</table>
Dictionary | Description
--- | ---
starent-835 | This dictionary consists of all of the attributes in the starent-va1-835 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the -835 dictionaries supported by the system.

Important: In StarOS 12.0 and later releases, no new attributes can be added to the starent-va1 dictionary. If there are new attributes to be added, you can only add them to the starent dictionary. For more information, please contact your Cisco account representative.

starent-va1 | This dictionary consists not only of the 3GPP2 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0–255). This is the default dictionary.

Important: For information on the specific dictionary to use for your deployment contact your Cisco account representative.

starent-va1-835 | This dictionary consists not only of the 3GPP2-835 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0–255). This is the default dictionary.

### disconnect-message

```
[ release-on-acct-stop acct_stop_wait_timeout ] [ dest-port destination_port_number ]
```

Specifies to send RADIUS disconnect message to the configured RADIUS accounting client in call failure scenarios.

- **release-on-acct-stop acct_stop_wait_timeout**: Specifies to wait for the accounting stop request after sending the Packet of Disconnect (PoD) to the client for the specified time. This keyword is disabled by default.
  - `acct_stop_wait_timeout` must be an integer from 10 through 300 seconds. This indicates the time to wait to clear the call in case IPSG does not receive any accounting stop for the subscriber after sending the PoD.
  - This keyword is configured on a per RADIUS accounting client basis and not for the entire service.

- **dest-port destination_port_number**: Specifies the port number to which the disconnect message must be sent.
  - `destination_port_number` must be an integer from 1 through 65535.

### interim create-new-call

**Important**: This option does not apply to the IPSG Proxy Mode.

Specifies to create a new session upon receipt of a RADIUS interim message.

Default: Disabled

---

**validate-client-ip**

Specifies to enable the ipsgmgr to validate RADIUS accounting messages from different configured RADIUS client IP address, and forward requests to the session manager.
Default: The RADIUS client IPs are validated.

Usage

Use this command to configure the communication parameters for the RADIUS client from which RADIUS accounting requests are received.

Example

The following command configures the service to communicate with a RADIUS client with an IP address of 10.2.3.4 and an encrypted shared secret of key1234:

```
radius accounting client 10.2.3.4 encrypted key key1234
```
radius dictionary

This command allows you to specify the RADIUS dictionary for the current IPSG/eWAG service.

Product
- eWAG
- IPSG

Privilege
- Security Administrator
- Administrator

Mode
- Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration
- configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

Syntax

radius dictionary  dictionary_name

default radius dictionary

default
- Specifies to use the default dictionary.
- Default: starent-vsa1

dictionary  dictionary_name
- Specifies the dictionary to use.

Important: In 15.0 and later releases, for DeWAG use the starent dictionary.

dictionary_name must be one of the following.

<table>
<thead>
<tr>
<th>Dictionary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3gpp2</td>
<td>This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835-A.</td>

This is the default dictionary.</td>
</tr>
</tbody>
</table>

**Important:** For information on the specific dictionary to use for your deployment contact your Cisco account representative.

**Usage**

Use this command to specify the RADIUS dictionary to use for the IPSG RADIUS Server/eWAG service.

**Example**

The following command specifies to use the `custom10` RADIUS dictionary:

```
radius dictionary custom10
```
**sess-replacement**

This command allows you to enable/disable the Session Replacement feature for eWAG and IPSG services.

**Product**
- eWAG
- IPSG

**Privilege**
- Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

```bash
configure > context context_name > ipsg-service service_name mode radius-server
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipsg-service-radius-server)#
```

**Syntax**

```bash
 sess-replacement { with-diff-acct-sess-id | with-diff-ip | with-diff-key [ with-diff-acct-sess-id ] }

{ default | no } sess-replacement
```

- **default**
  - Configures this command with its default setting.
  - Default: Disabled.

- **no**
  - If previously configured, deletes the configuration.

- **with-diff-acct-sess-id**
  - Specifies to replace current session when a new session request comes with same IP address and same user name/IMSI but different accounting session ID.

- **with-diff-ip**
  - Specifies to replace current session when a new session request comes with same user name/IMSI but different IP address.

- **with-diff-key**
  - Specifies to replace current session when a new session request comes with same IP address but different user name/IMSI.

For IPSG, you can also use a combination of replacement options of different key and different account session ID.
Usage
Use this command to enable/disable the Session Replacement feature. By default, the Session Replacement feature is disabled.

Example
The following command enables session replacement specifying to replace the current session when a new session request comes with same user name/IMSI but different IP address:

```
sess-replacement with-diff-ip
```
setup-timeout

This command allows you to configure a timeout for session setup attempts for the current IPSG/eWAG service.

**Product**
eWAG
IPSG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

```
configure > context context_name > ipsg-service service_name mode radius-server
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipsg-service-radius-server)#
```

**Syntax**

```
setup-timeout setup_timeout_seconds
```

**default setup-timeout**

```
default
```

Configures this command with its default setting.
Default: 60 seconds

```
setup_timeout_seconds
```

Specifies the time period, in seconds, for which a session setup attempt is allowed to continue before being terminated.

`setup_timeout_seconds` must be an integer from 1 through 1000000.

**Usage**

Use this command to configure a timeout for IPSG/eWAG session setup attempts.

**Example**

The following command configures the timeout for session setup attempts to 30 seconds:

```
setup-timeout 30
```
w-apn

This command allows you to configure the W-APNs that can be connected through DeWAG, and the default-gateway IP addresses to be used by the UEs for connecting to the W-APN network.

Product:
eWAG

Privilege:
Security Administrator, Administrator

Mode:
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration
configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-server)#

Syntax:

w-apn apn_name default-gw ipv4/ipv6_address/maskbits +

no w-apn apn_name

If previously configured, removes the specified configuration.

apn-name apn_name

Specifies the APN name.

apn_name must be the name of an APN and must be a string of 1 to 62 characters in length consisting of alphabetic characters (A-Z and a-z), digits (0-9), dot(.) and the dash (-). This value is compared against the subscribed APN returned by the AAA server or locally configured APN in the subscriber-template configuration to find the default-gateway IP address to be used in DHCP signaling packets.

default-gw ipv4/ipv6_address/maskbits

Specifies the IP address of the default gateway to be used by UE for W-APN access. You can configure a maximum of four default gateways per W-APN. Multiple default-gateways are possible as the APN can have different pools of different subnet with different default-gateway IP addresses.

ipv4/ipv6_address/maskbits must be an IPv4/IPv6 address and subnet-mask, for example 192.168.1.1/24.

This value should be in the same subnet as that of UE allocated IP address from GGSN for the W-APN. GGSN does not supply subnet-mask along with IP address. Therefore, the identification of whether GGSN-allocated IP address is in same subnet or not is done with the help of configured “/maskbits”. This default-gateway value is sent to the UE as default-gateway IP address using “Router” option in DHCP-OFFER message. The maskbits is sent to the UE as subnet-mask using the “Subnet Mask” option in DHCP-OFFER message.
Usage

Use this command to configure the list of W-APN names that can be connected through DeWAG and the default-gateway IP addresses to be used by UE for connecting to the W-APN network. During DHCP signaling the configured default-gateway value will be notified to UE as the router. This command also configures the subnet-mask to be used for the respective default-gateway IP address in order to find the network prefix of the default-gateway.

Note that DeWAG will be acting as 'default-gateway' for the UE in its connected network.

Important: This command can be configured a maximum of four times to configure four different APNs and the corresponding default-gateways.

Example

The following command configures an APN named apn123 with the default gateway IP address and mask 192.168.1.1/24:

```
  w-apn apn123 default-gw 192.168.1.1/24
```
Chapter 178
IPSG RADIUS Snoop Configuration Mode Commands

The IP Services Gateway (IPSG) RADIUS Snoop Configuration Mode is used to create and configure IPSG services within the current context. The IPSG RADIUS Snoop Mode configures the system to inspect RADIUS accounting requests on the way to the RADIUS accounting server and extract user information.

Mode

Exec > Global Configuration > Context Configuration > IPSG RADIUS Snoop Configuration

```
configure > context context_name > ipsg-service service_name mode radius-snoop
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipsg-service-radius-snoop)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
bind

This command allows you to configure the service to accept data on any interface configured in the context. Optionally, you can also configure the system to limit the number of sessions processed by this service.

Product
IPSG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPSG RADIUS Snoop Configuration
configure > context context_name > ipsg-service service_name mode radius-snoop

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-snoop)#

Syntax

bind [ max-subscribers max_sessions ]

no bind

If previously configured, deletes the binding configuration for the service.

max-subscribers max_sessions

Specifies the maximum number of subscriber sessions allowed for the service. If this option is not configured, the system defaults to the license limit.
In StarOS 9.0 and later releases, max_sessions must be an integer from 0 through 4000000.
In StarOS 8.3 and earlier releases, max_sessions must be an integer from 0 through 3000000.

Usage

Use this command to initiate the service and begin accepting data on any interface configured in the context.

Example

The following command prepares the system to receive subscriber sessions on any interface in the context and limits the sessions to 10000:

    bind max-subscribers 10000
connection authorization

This command allows you to configure the RADIUS authorization password that must be matched by the RADIUS accounting requests “snooped” by this service.

**Product**
IPSG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSG RADIUS Snoop Configuration

```
configure > context context_name > ipsg-service service_name mode radius-snoop
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipsg-service-radius-snoop)#
```

**Syntax**

```
connection authorization [ encrypted ] password password

no connection authorization
```

- **no**

  Deletes the RADIUS connection authorization configuration from the current IPSG RADIUS snoop service.

  ```
  [ encrypted ] password password
  ```

- **encrypted**: Specifies that the received RADIUS authorization password is encrypted.

- **password password**: Specifies the password that must be matched by incoming RADIUS accounting requests.

  In StarOS 12.2 and later releases, `password` with encryption must be an alphanumeric string of 1 through 132 characters, and without encryption an alphanumeric string of 1 through 63 characters.

  In StarOS 12.1 and earlier releases, `password` must be an alphanumeric string of 1 through 63 characters.

**Usage**

RADIUS accounting requests being examined by the IPSG RADIUS snoop service are destined for a RADIUS Accounting Server. Since the “snoop” service does not terminate user authentication, the user password is unknown.

Use this command to configure the authorization password that the RADIUS accounting requests must match in order for the service to examine and extract user information.

**Example**

The following command sets the RADIUS authorization password that must be matched by the RADIUS accounting requests “snooped” by this service. The password is encrypted, and the password used in this example is “secret”.

```
connection authorization encrypted password secret
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**
Use this command to return to the parent configuration mode.
profile

This command allows you to configure the service to use APN or subscriber profile.

Product
IPSG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPSG RADIUS Snoop Configuration

configure > context context_name > ipsg-service service_name mode radius-snoop

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-snoop)#

Syntax

profile { APN | subscriber }

default profile

default

Configures this command with its default setting.

APN

Specifies the service to support APN configuration required to enable Gx support.

subscriber

Specifies the service to support subscriber profile lookup.

Usage

Use this command to set the service to support APN profiles (supporting Gx through the enabling of ims-auth-service) or for basic subscriber profile lookup.

Example

The following command specifies to use the subscriber profile:

    profile subscriber
radius

This command allows you to specify the RADIUS accounting servers where accounting requests are sent after being “inspected” by this service.

**Product**
IPSG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSG RADIUS Snoop Configuration

```
configure > context context_name > ipsg-service service_name mode radius-snoop
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipseg-service-radius-snoop)#
```

**Syntax**

```
[ no ] radius { accounting server ipv4/ipv6_address [ port port_number | source-context context_name ] } | dictionary { 3gpp2 | 3gpp2-835 | custom XX | standard | starent | starent-835 | starent-vsai | starent-vsai-835 }
```

- **no**
  Removes the RADIUS accounting server identifier from this service.

- **radius accounting server ipv4/ipv6_address**
  Specifies the IP address of a RADIUS accounting server where accounting requests are sent after being “snooped” by this service in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation. Up to 16 addresses can be configured.

- **port port_number**
  Specifies the port number of the RADIUS Accounting Server where accounting requests are sent after being “snooped” by this service.
  
  `port_number` must be an integer from 1 through 65535.
  
  Default: 1813

- **source-context context_name**
  Specifies the source context where RADIUS accounting requests are received.
  
  `context_name` must be an alphanumeric string of 1 through 79 characters.
  
  If this keyword is not configured, the system will default to the context in which the IPSG service is configured.

- **dictionary { 3gpp2 | 3gpp2-835 | custom XX | standard | starent | starent-835 | starent-vsai | starent-vsai-835 }**
  Specifies what dictionary to use. The possible values are described in the following table:

<table>
<thead>
<tr>
<th>Dictionary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Dictionary Description

<table>
<thead>
<tr>
<th>Dictionary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3gpp</td>
<td>This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in 3GPP 32.015.</td>
</tr>
<tr>
<td>3gpp2</td>
<td>This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835-A.</td>
</tr>
<tr>
<td>3gpp2-835</td>
<td>This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835.</td>
</tr>
</tbody>
</table>
| customXX     | These are customized dictionaries. For information on custom dictionaries, please contact your Cisco account representative.  
XX is the integer value of the custom dictionary. |
| standard     | This dictionary consists only of the attributes specified in RFC 2865, RFC 2866, and RFC 2869.                                                |
| starent      | This dictionary consists of all of the attributes in the starent-vsa1 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the dictionaries supported by the system. |
| starent-835  | This dictionary consists of all of the attributes in the starent-vsa1-835 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the -835 dictionaries supported by the system. |
| starent-vsa1 | This dictionary consists not only of the 3gpp2 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0–255). This is the default dictionary. |
| starent-vsa1-835 | This dictionary consists not only of the 3gpp2-835 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0–255). This is the default dictionary. |

### Usage
Use this command to specify the RADIUS Accounting Servers where accounting requests are sent after being snooped by this service.

### Example
The following command specifies the IP address (10.2.3.4) of a RADIUS Accounting Server whose accounting requests are to be “snooped”, and the source context (aaa_ingress) where the requests are received on the system:

```
radius accounting server 10.2.3.4 source-context aaa_ingress
```
sess-replacement

This command allows you to enable/disable session replacement.

Important: This command is not supported in this release. The Session Replacement feature is under development for future use.

Product
IPSG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPSG RADIUS Snoop Configuration
configure > context context_name > ipsg-service service_name mode radius-snoop

Entering the above command sequence results in the following prompt:

/context_name>host_name(config-ipsg-service-radius-snoop)#

Syntax

```
(sess-replacement { with-diff-acct-sess-id | with-diff-ip | with-diff-key }
{ default | no } sess-replacement
```

- **default**
  Configures this command with its default setting.
  Default: Disabled.

- **no**
  If previously configured, deletes the configuration.

- **with-diff-acct-sess-id**
  Specifies to replace current session when a new session request comes with same IP address and same user name/IMSI but different accounting session ID.

- **with-diff-ip**
  Specifies to replace current session when a new session request comes with same user name/IMSI but different IP address.

- **with-diff-key**
  Specifies to replace current session when a new session request comes with same IP address but different user name/IMSI.
Usage
Use this command to enable/disable session replacement. By default, session replacement is disabled.

Example
The following command enables session replacement specifying to replace the current session when a new session request comes with same user name/IMSI but different IP address:

```
sess-replacement with-diff-ip
```
setup-timeout

This command allows you to configure the timeout value for IPSG session setup attempts.

Product
IPSG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPSG RADIUS Snoop Configuration

configure > context context_name > ipsg-service service_name mode radius-snoop

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-snoop)#

Syntax

setup-timeout setup_timeout

default setup-timeout

setup_timeout

Specifies the period of time (in seconds) the IPSG session setup is allowed to continue before the setup attempt is terminated.

setup_timeout must be an integer from 1 through 1000000.

Default: 60

Usage

Use this command to prevent IPSG session setup attempts from continuing without termination.

Example

The following command configures the session setup timeout setting to 20 seconds:

setup-timeout 20
Chapter 179
IPSP Configuration Mode Commands

The IPSP Configuration Mode is used to configure properties for the IP Pool Sharing Protocol (IPSP). System-based HA services use IPSP during an offline-software upgrade to avoid the assignment of duplicate IP addresses to sessions while allowing them to maintain the same address, and to preserve network capacity.

**Important:** For information on configuring and using IPSP refer to the *System Administration Guide*.

Exec > Global Configuration > Context Configuration > Ethernet Interface Configuration > IP Pool Sharing Protocol Configuration

```plaintext
configure > context context_name > interface interface_name broadcast > pool-share-protocol { primary ip_address | secondary ip_address }
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
dead-interval

Configures the retry time to connect to the remote system for the IP Pool Sharing Protocol.

Product

- PDSN
- HA

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > Ethernet Interface Configuration > IP Pool Sharing Protocol Configuration

```
configure > context context_name > interface interface_name broadcast > pool-share-protocol { primary ip_address | secondary ip_address }
```

Syntax

```
dead-interval seconds

[ no | default ] dead-interval
```

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
</table>
| Disables the dead interval. On loss of connectivity to the remote system, no retries are attempted and the remote system is marked dead immediately on failure.

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
</table>
| Resets the dead interval to the default of 3600 seconds.

<table>
<thead>
<tr>
<th>seconds</th>
</tr>
</thead>
</table>
| Default: 3600 seconds
| The amount of time in seconds to wait before retrying the remote system. seconds must be an integer from 25 through 259200.

Usage

Use this command to set the amount of time to wait before retrying to connect with the remote system for the IP pool sharing protocol.

Example

Use the following command to set the interval to 180 seconds (3 minutes):

```
dead-interval 180
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

exit

**Usage**

Use this command to return to the parent configuration mode.
reserved-free-percentage

This command is used to set the amount of free addresses reserved for use on the primary HA.

Product
PDSN
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Ethernet Interface Configuration > IP Pool Sharing Protocol Configuration

configure > context context_name > interface interface_name broadcast > pool-share-protocol { primary ip_address | secondary ip_address }

Syntax
reserved-free-percentage value

default reserved-free-percentage

value
Default: 100
value specifies the percentage of free addresses reserved for the use on the primary HA for IP pool sharing during upgrade. It must be an integer from 0 through 100.

Usage
This command is used with pool-sharing-protocol active mode on the primary HA. Before using this command, pool-sharing-protocol in the Ethernet Interface Configuration Mode must be configured. For more information, refer to the Ethernet Interface Configuration Mode Commands chapter in this guide.

Example
To reserve 40 percent of free addresses in primary HA for IP pool sharing, enter the following command:

reserved-free-percentage 40
Chapter 180
IPv6 ACL Configuration Mode Commands

The IPv6 Access Control List Configuration Mode is used to create and manage IPv6 access privileges.

Mode

Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
deny/permit (by source IP address masking)

Used to filter subscriber sessions based on the IPv6 address mask sent by the source to the mobile node or the network.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
{ deny | permit } [ log ] source_address source_wildcard
after { deny | permit } [ log ] source_address source_wildcard
before { deny | permit } [ log ] source_address source_wildcard
no { deny | permit } [ log ] source_address source_wildcard
```

- **after**
  
  Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

- **before**
  
  Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

- **Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

- **no**
  
  Removes the rule which exactly matches the options specified.

- **deny | permit**
  
  Specifies the rule is either block (deny) or an allow (permit) filter.

- **Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.
- **deny**: Indicates the rule, when matched, drops the corresponding packets.
- **permit**: Indicates the rule, when matched, allows the corresponding packets.

**log**

Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

**source_address**

The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important**: The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**Usage**

Define a rule when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rules as it does not require a rule for each source and destination pair.

**Important**: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Example**

The following command defines two rules with the second logging filtered packets:

```
permit 2001:4A2B::1f3F
deny log 2001:4A2B::1f3F
```

The following sets the insertion point to before the first rule defined above:

```
before permit 2001:4A2B::1f3F
```

The following command sets the insertion point after the second rule defined above:

```
after deny log 2001:4A2B::1f3F
```
The following deletes the first rule defined above:

```
no permit 2001:4A2B::1f3F
```
deny/permit (any)

Used to filter subscriber sessions based on any packet received. This command is also used to set the access control list insertion point.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

{ deny | permit } [ log ] any

after { deny | permit } [ log ] any

before { deny | permit } [ log ] any

no { deny | permit } [ log ] any

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.
deny | permit

Specifies the rule is either block (deny) or an allow (permit) filter.

- **deny**: Indicates the rule, when matched, drops the corresponding packets.
- **permit**: Indicates the rule, when matched, allows the corresponding packets.

log

Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

any

Indicates all packets will match the filter regardless of source and/or destination.

---

**Usage**

Define a catch all rule to place at the end of the list of rules.

**Important**: It is suggested that any rule which is added to be a catch all should also have the `log` option specified. The logged packets may be used to determine if the current list of rules is adequate or needs modification to ensure proper security. The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Example**

The following command defines two rules with the second logging filtered packets:

```bash
permit any
deny log any
```

The following sets the insertion point to before the first rule defined above:

```bash
before permit any
```

The following command sets the insertion point after the second rule defined above:

```bash
after deny log any
```

The following deletes the first rule defined above:

```bash
no permit any
```
deny/permit (by host IP address)

Used to filter subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
{ deny | permit } [ log ] host source_host_address
after { deny | permit } [ log ] host source_host_address
before { deny | permit } [ log ] host source_host_address
no { deny | permit } [ log ] host source_host_address
```

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.
deny | permit

Specifies the rule is either block (deny) or an allow (permit) filter.

- **deny**: Indicates the rule, when matched, drops the corresponding packets.
- **permit**: Indicates the rule, when matched, allows the corresponding packets.

log

Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

### Usage

Define a rule when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rules to be very clear and concise.

**Important**: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*.

### Example

The following command defines two rules with the second logging filtered packets:

```
permit host 2001:4A2B::1f3F
deny log host 2001:4A2B::1f3F
```

The following sets the insertion point to before the first rule defined above:

```
before permit host 2001:4A2B::1f3F
```

The following command sets the insertion point after the second rule defined above:

```
after deny log host 2001:4A2B::1f3F
```

The following deletes the first rule defined above:

```
no permit host 2001:4A2B::1f3F
```
deny/permit (by source ICMP packets)

Used to filter subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

{ deny | permit } [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

after { deny | permit } [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

before { deny | permit } [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

no { deny | permit } [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

- **no**
  Removes the rule which exactly matches the options specified.

- **deny | permit**
  Specifies the rule is either block (deny) or an allow (permit) filter.
  - **deny**: Indicates the rule, when matched, drops the corresponding packets.
  - **permit**: Indicates the rule, when matched, allows the corresponding packets.

- **log**
  Default: packets are not logged.
  Indicates all packets which match the filter are to be logged.

- **source_address**
  The IP address(es) from which the packet originated.
  This option is used to filter all packets from a specific IP address or a group of IP addresses.
  When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the **sourceWildcard** parameter.

- **sourceWildcard**
  This option is used in conjunction with the **source_address** option to specify a group of addresses for which packets are to be filtered.
  The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the **source_address** parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the **source_address** parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

- **any**
  Specifies that the rule applies to all packets.

- **host**
  Specifies that the rule applies to a specific host as determined by its IP address.

- **sourceHost_address**
  The IP address of the source host to filter against expressed in IPv6 hexadecimal-colon-separated notation.

- **destHost_address**
  The IP address of the destination host to filter against expressed in IPv6 hexadecimal-colon-separated notation.
**dest_address**

The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.

**dest_wildcard**

This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**icmp_type**

Specifies that all ICMP packets of a particular type are to be filtered. The type is an integer from 0 through 255.

**icmp_code**

Specifies that all ICMP packets of a particular code are to be filtered. The type is an integer from 0 through 255.

**Usage**

Define a rule to block ICMP packets which can be used for address resolution and possible be a security risk. The IP filtering allows flexible controls for pairs of individual hosts or groups by IP masking which allows the filtering of entire subnets if necessary.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*.

**Example**

The following command defines two rules with the second logging filtered packets:

```
permit icmp host 2001:4A2B::1f3F4 any 168
```

```
deny log icmp 2001:4A2B::1f3F 2001:4a2b::1f00 host fe80::a02:410 168 11
```

The following sets the insertion point to before the first rule defined above:

```
before permit icmp host 2001:4A2B::1f3F any 168
```

The following command sets the insertion point after the second rule defined above:
deny/permit (by source ICMP packets)

```
  after deny log icmp 2001:4A2B::1f3F 2001:4a2b::1f00 host fe80::a02:410
  168 11

  The following deletes the first rule defined above:

  no permit icmp host 2001:4A2B::1f3F any 168
```
deny/permit (by IP packets)

Used to filter subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)\#`

**Syntax**

```
{ deny | permit } [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocolnum ]
```

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
deny/permit (by IP packets)

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Removes the rule which exactly matches the options specified.</td>
</tr>
<tr>
<td>deny</td>
<td>permit</td>
</tr>
<tr>
<td>log</td>
<td>Default: packets are not logged. Indicates all packets which match the filter are to be logged.</td>
</tr>
<tr>
<td>source_address</td>
<td>The IP address(es) form which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the source_wildcard parameter.</td>

<tr>
<td>source_host_address</td>
<td>The IP address of the source host to filter against expressed in IPv6 colon notation.</td>
</tr>
<tr>
<td>dest_host_address</td>
<td>The IP address of the destination host to filter against expressed in IPv6 colon notation.</td>
</tr>
</tbody>
</table>

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.
IPv6 ACL Configuration Mode Commands

deny/permit (by IP packets)

---

**dest_address**

The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the `dest_wildcard` parameter.

---

**dest_wildcard**

This option is used in conjunction with the `dest_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be ignored.

---

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

---

**fragment**

Indicates packet filtering is to be applied to IP packet fragments only.

---

**protocol num**

Indicates that the packet filtering is to be applied to a specific protocol number. `num` can be any integer ranging from 0 to 255.

---

**Usage**

Block IP packets when the source and destination are of interest.

---

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

---

**Example**

The following command defines two rules with the second logging filtered packets:

```plaintext
permit ip host 2001:4A2B::1f3F any fragment
deny log ip 2001:4A2B::1f3F 2001:4a2b::1f00 host fe80::a02:410
```

The following sets the insertion point to before the first rule defined above:

```plaintext
before permit ip host 2001:4A2B::1f3F any fragment
```

The following command sets the insertion point after the second rule defined above:

```plaintext
after deny log ip 2001:4A2B::1f3F 2001:4a2b::1f00 host fe80::a02:410
```

The following deletes the first rule defined above:

```plaintext
no permit ip host 2001:4A2B::1f3F any fragment
```
deny/permit (by TCP/UDP packets)

Used to filter subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
{ deny | permit } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port ] }
```

```
{ { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port ] }
```

```
{ { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port ] }
```

```
{ deny | permit } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port ] }
```

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.
before
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

no
Removes the rule which exactly matches the options specified.

deny | permit
Specifies the rule is either block (deny) or an allow (permit) filter.
  *deny:* Indicates the rule, when matched, drops the corresponding packets.
  *permit:* Indicates the rule, when matched, allows the corresponding packets.

log
Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

tcp | udp
Specifies the filter is to be applied to IP-based transmission control protocol or the user datagram protocol.
  *tcp:* Filter applies to TCP packets.
  *udp:* Filter applies to UDP packets.

source_address
The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the source wildcard parameter.

source wildcard
This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
  *Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
  *One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

any
Specifies that the rule applies to all packets.
host
Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address
The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

eq source_port
Specifies a single, specific source TCP port number to be filtered.
source_port must be configured to an integer from 0 through 65535.

gt source_port
Specifies that all source TCP port numbers greater than the one specified are to be filtered.
source_port must be configured to an integer from 0 through 65535.

lt source_port
Specifies that all source TCP port numbers less than the one specified are to be filtered.
source_port must be configured to an integer from 0 through 65535.

neq source_port
Specifies that all source TCP port numbers not equal to the one specified are to be filtered.
source_port must be configured to an integer from 0 through 65535.

dest_address
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

dest_wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

eq dest_port
Specifies a single, specific destination TCP port number to be filtered.
**deny/permit (by TCP/UDP packets)**

`dest_port` must be configured to an integer from 0 through 65535.

---

`gt dest_port`

Specifies that all destination TCP port numbers greater than the one specified are to be filtered.
`dest_port` must be configured to an integer from 0 through 65535.

---

`lt dest_port`

Specifies that all destination TCP port numbers less than the one specified are to be filtered.
`dest_port` must be configured to an integer from 0 through 65535.

---

`neq dest_port`

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered.
`dest_port` must be configured to an integer from 0 through 65535.

---

**Usage**

Block IP packets when the source and destination are of interest but for only a limited set of ports.

---

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

---

**Example**

The following command defines four rules with the second and fourth rules logging filtered packets:

```plaintext
permit tcp host 2001:4A2B::1f3F any
deny log udp 2001:4A2B::1f3F 2001:4a2b::1f00 host fe80::a02:410
permit tcp host 2001:4A2B::1f3F gt 1023 any
```

The following sets the insertion point to before the first rule defined above:

```plaintext
before permit tcp host 2001:4A2B::1f3F any
```

The following command sets the insertion point after the second rule defined above:

```plaintext
after deny log udp 2001:4A2B::1f3F 2001:4a2b::1f00 host fe80::a02:410
```

The following deletes the third rule defined above:

```plaintext
no permit tcp host 2001:4A2B::1f3F gt 1023 any
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
dend
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

`exit`

**Usage**

Use this command to return to the parent configuration mode.
readdress server

Alter the destination address and port number in TCP or UDP packet headers to redirect packets to a different server.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```bash
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

`after`
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

`before`
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

`no`
Removes the rule which exactly matches the options specified.

`redirect_address`
The IP address to which the IP packets are redirected. TCP or UDP packet headers are rewritten to contain the new destination address. This must expressed in IPv6 colon-separated-hexadecimal notation.

`port port_number`
The number of the port at the redirect address where the packets are sent. TCP or UDP packet headers are rewritten to contain the new destination port number.
IPv6 ACL Configuration Mode Commands

**tcp | udp**

Specifies the redirect is to be applied to the IP-based transmission control protocol or the user datagram protocol.

- **tcp**: Redirect applies to TCP packets.
- **udp**: Redirect applies to UDP packets.

**source_address**

The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**any**

Specifies that the rule applies to all packets.

**host**

Specifies that the rule applies to a specific host as determined by its IP address.

**source_host_address**

The IP address of the source host to filter against expressed in IPv6 colon notation.

**dest_host_address**

The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**eq source_port**

Specifies a single, specific source TCP port number to be filtered. `source_port` must be configured to an integer from 0 through 65535.

**gt source_port**

Specifies that all source TCP port numbers greater than the one specified are to be filtered. `source_port` must be configured to an integer from 0 through 65535.

**lt source_port**

Specifies that all source TCP port numbers less than the one specified are to be filtered. `source_port` must be configured to an integer from 0 through 65535.

**neq source_port**

Specifies that all source TCP port numbers not equal to the one specified are to be filtered. `source_port` must be configured to an integer from 0 through 65535.

**dest_address**

The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the `dest_wildcard` parameter.
**eq dest_port**

Specifies a single, specific destination TCP port number to be filtered. `dest_port` must be configured to an integer from 0 through 65535.

**gt dest_port**

Specifies that all destination TCP port numbers greater than the one specified are to be filtered. `dest_port` must be configured to an integer from 0 through 65535.

**lt dest_port**

Specifies that all destination TCP port numbers less than the one specified are to be filtered. `dest_port` must be configured to an integer from 0 through 65535.

**neq dest_port**

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered. `dest_port` must be configured to an integer from 0 through 65535.

**Usage**

Use this command to define a rule that redirects packets to a different destination address. The TCP and UDP packet headers are modified with the new destination address and destination port.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule that redirects packets to the server at `fe80::c0a8:a04`, UDP packets coming from any host with a destination of any host are matched:

```
readdress server fe80::c0a8:a04 udp any any
```

The following sets the insertion point to before the rule defined above:

```
before readdress server fe80::c0a8:a04 udp any any
```

The following deletes the rule defined above:

```
no readdress server fe80::c0a8:a04 udp any any
```
redirect context (by IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect context context_id [ log ] source_address source_wildcard

after redirect context context_id [ log ] source_address source_wildcard

before redirect context context_id [ log ] source_address source_wildcard

no redirect context context_id [ log ] source_address source_wildcard
```

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.
IPv6 ACL Configuration Mode Commands

redirect context (by IP address masking)

context context_id
Specifies the context identification number of the context to which packets are redirected. At the executive
mode prompt, use the show context all command to display context names and context IDs.

log
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

source_address
Filters by the IP address(es) from which the packet originated. This option filters all packets from a specific
IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then
be configured using the source_wildcard parameter.

source_wildcard
Filters packets for a group of addresses specified in conjunction with the source_address option.
The mask must be entered as a complement:
• Zero-bits in this parameter mean that the corresponding bits configured for the source_address
  parameter must be identical.
• One-bits in this parameter mean that the corresponding bits configured for the source_address
  parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

Usage
Define a rule when any packet from the IP addresses which fall into the group of addresses matching the IP
address masking. This allows the reduction of redirect rules as it does not require a rule for each source and
destination pair.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is
to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also
note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific
context.

Example
The following command defines a rule that redirects packets to the context with the context ID of 23 and the
source IP and wildcard of 2002::c6a2:1600 and 2002::c6a2:1600:

   redirect context 23 2002::c6a2:1600 2002::c6a2:1600

The following sets the insertion point to before the first rule defined above:

   before redirect context 23 2002::c6a2:1600 2002::c6a2:1600

The following command sets the insertion point after the second rule defined above:

   after redirect context 23 2002::c6a2:1600 2002::c6a2:1600
The following deletes the first rule defined above:

```
no redirect context 23 2002::c6a2:1600 2002::c6a2:1600
```
redirect context (any)

Used to redirect subscriber sessions based on any packet received. This command is also used to set the access control list insertion point.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```plaintext
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect context context_id [ log ] any
after redirect context context_id [ log ] any
before redirect context context_id [ log ] any
no redirect context context_id [ log ] any
```

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.
redirect context (any)

context context_id
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

log
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

any
Indicates all packets will match the redirect regardless of source and/or destination.

Usage
Define a catch all rule to place at the end of the list of rules to provide explicit handling of rules which do not fit any other criteria.

Important: It is suggested that any rule which is added to be a catch all should also have the log option specified. The logged packets may be used to determine if the current list of rules is adequate or needs modification to ensure proper security. The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example
The following command defines a rule that redirects packets to the context with the context ID of 23 and any source IP:

```
redirect context 23 any
```

The following sets the insertion point to before the first rule defined above:

```
before redirect context 23 any
```

The following command sets the insertion point after the second rule defined above:

```
after redirect context 23 any
```

The following deletes the first rule defined above:

```
no redirect context 23 any
```
redirect context (by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```bash
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```bash
redirect context context_id [ log ] host source_ip_address
after redirect context context_id [ log ] host source_ip_address
before redirect context context_id [ log ] host source_ip_address
no redirect context context_id [ log ] host source_ip_address
```

*after*
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

*before*
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

*no*
Removes the rule which exactly matches the options specified.
`context context_id`

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

`log`

Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

`host`

Specifies that the rule applies to a specific host as determined by its IP address.

`source_host_address`

The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

### Usage

Define a rule when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rules to be very clear and concise.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the `Engineering Rules` appendix in the `System Administration Guide`. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

### Example

The following command defines a rule that redirects packets to the context with the context ID of 23 and a host IP address of `fe80::c0a8:c80b`:

```
redirect context 23 host fe80::c0a8:c80b
```

The following sets the insertion point to before the first rule defined above:

```
before redirect context 23 host fe80::c0a8:c80b
```

The following command sets the insertion point after the second rule defined above:

```
after redirect context 23 host fe80::c0a8:c80b
```

The following deletes the first rule defined above:

```
no redirect context 23 host fe80::c0a8:c80b
```
redirect context (by source ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

        configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

        [context_name]host_name(config-ipv6-acl)#

Syntax

    redirect context context_id [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

    after redirect context context_id [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

    before redirect context context_id [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

    no redirect context context_id [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

    after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

    before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.

**context context_id**
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

**log**
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**source_address**
The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `sourceWildcard` parameter.

**sourceWildcard**
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**any**
Specifies that the rule applies to all packets.

**host**
Specifies that the rule applies to a specific host as determined by its IP address.

**source_host_address**
The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**dest_host_address**
The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.
**dest_address**

The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.

**dest_wildcard**

This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**icmp_type**

Specifies that all ICMP packets of a particular type are to be filtered. Type is an integer from 0 through 255.

**icmp_code**

Specifies that all ICMP packets of a particular code are to be filtered. Type is an integer from 0 through 255.

**Usage**

Define a rule to block ICMP packets which can be used for address resolution and possibly be a security risk.
The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule that redirects packets to the context with the context ID of 23, and ICMP packets coming from the host with the IP address 2002::c6a2:6419:

```
redirect context 23 icmp host 2002::c6a2:6419
```

The following sets the insertion point to before the first rule defined above:

```
before redirect context 23 icmp host 2002::c6a2:6419
```

The following command sets the insertion point after the second rule defined above:

```
after redirect context 23 icmp host 2002::c6a2:6419
```
The following deletes the first rule defined above:

```
no redirect context 23 icmp host 2002:c6a2:6419
```
redirect context (by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect context context_id [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]
```

```
after redirect context context_id [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]
```

```
before redirect context context_id [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]
```

```
oredirect context context_id [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]
```

**after**

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

- **no**
  Removes the rule which exactly matches the options specified.

- **context context_id**
  The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

- **log**
  Default: packets are not logged.
  Indicates all packets which match the redirect are to be logged.

- **source_address**
  The IP address(es) from which the packet originated.
  This option is used to filter all packets from a specific IP address or a group of IP addresses.
  When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source wildcard` parameter.

- **source wildcard**
  This option is used in conjunction with the `source address` option to specify a group of addresses for which packets are to be filtered.
  The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the `source address` parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the `source address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

- **any**
  Specifies that the rule applies to all packets.

- **host**
  Specifies that the rule applies to a specific host as determined by its IP address.

- **source_host_address**
  The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

- **dest_host_address**
  The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.
IPv6 ACL Configuration Mode Commands

**redirect context (by IP packets)**

**dest_address**

The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.

**dest_wildcard**

This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**fragment**

Indicates packet redirection is to be applied to IP packet fragments only.

**protocol** **num**

Indicates that the packet filtering is to be applied to a specific protocol number. **num** is an integer from 0 through 255.

**Usage**

Block IP packets when the source and destination are of interest.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule that redirect packets to the context with the context ID of 23, and IP packets coming from the host with the IP address 2002::c6a2:6419, and fragmented packets for any destination are matched:

```
redirect context 23 ip host 2002::c6a2:6419 any fragment
```

The following sets the insertion point to before the first rule defined above:

```
befor redirect context 23 ip host 198.162.100.25 any fragment
```

The following command sets the insertion point after the second rule defined above:

```
afte redirect context 23 ip host 2002::c6a2:6419 any fragment
```
The following deletes the first rule defined above:

```plaintext
do redirect context 23 ip host 2002::c6a2:6419 any fragment
```
Redirect context (by TCP/UDP packets)

Redirect context is used to redirect subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

**Product**: All

**Privilege**: Security Administrator, Administrator

**Mode**: Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect context context_id [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }
```

```
after redirect context context_id [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }
```

```
before redirect context context_id [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }
```

```
no redirect context context_id [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }
```

**Important**: If the options specified do not exactly match an existing rule, the insertion point does not change.
**IPv6 ACL Configuration Mode Commands**

### redirect context (by TCP/UDP packets)

#### before
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

---

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

---

#### no
Removes the rule which exactly matches the options specified.

---

#### context context_id
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

---

#### log
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

---

#### tcp | udp
Specifies the redirect is to be applied to IP-based transmission control protocol or the user datagram protocol.
- **tcp**: Redirect applies to TCP packets.
- **udp**: Redirect applies to UDP packets.

---

#### source_address
The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source wildcard` parameter.

---

#### source wildcard
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

---

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

---

#### any
Specifies that the rule applies to all packets.
host
Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address
The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

eq source_port
Specifies a single, specific source TCP port number to be filtered.
source_port must be configured to an integer from 0 through 65535.

gt source_port
Specifies that all source TCP port numbers greater than the one specified are to be filtered.
source_port must be configured to an integer from 0 through 65535.

lt source_port
Specifies that all source TCP port numbers less than the one specified are to be filtered.
source_port must be configured to an integer from 0 through 65535.

neq source_port
Specifies that all source TCP port numbers not equal to the one specified are to be filtered.
source_port must be configured to an integer from 0 through 65535.

dest_address
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

dest_wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
  ● Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
  ● One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

eq dest_port
Specifies a single, specific destination TCP port number to be filtered.
IPv6 ACL Configuration Mode Commands

redirect context (by TCP/UDP packets)

---

dest_port must be configured to an integer from 0 through 65535.

---

**gt dest_port**

Specifies that all destination TCP port numbers greater than the one specified are to be filtered.

*dest_port* must be configured to an integer from 0 through 65535.

---

**lt dest_port**

Specifies that all destination TCP port numbers less than the one specified are to be filtered.

*dest_port* must be configured to an integer from 0 through 65535.

---

**neq dest_port**

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered.

*dest_port* must be configured to an integer from 0 through 65535.

---

**Usage**

Block IP packets when the source and destination are of interest but for only a limited set of ports.

---

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

---

**Example**

The following command defines a rule that redirects packets to the context with the context ID of 23, and UDP packets coming from any host are matched:

```
redirect context 23 udp any
```

The following sets the insertion point to before the rule defined above:

```
before redirect context 23 udp any
```

The following command sets the insertion point after the rule defined above:

```
after redirect context 23 udp any
```

The following deletes the rule defined above:

```
no redirect context 23 udp any
```
redirect css delivery-sequence

This is a restricted command. In StarOS 9.0 and later, this command is obsoleted.
**redirect css service (any)**

Used to redirect subscriber sessions based on any packet received with Content Service Steering (CSS) enabled. This command is also used to set the access control list insertion point.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl) #
```

**Syntax**

```
redirect css service svc_name [ log ] any
after redirect css service svc_name [ log ] any
before redirect css service svc_name [ log ] any
no redirect css service svc_name [ log ] any
```

**after**
Indicates all rule definitions defined subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definitions which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**
Removes the rule definition which exactly matches the options specified.
**redirect css service (any)**

css service *svc_name*

The name of the CSS service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services. *svc_name* must be a string of 1 through 15 characters.

log

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

any

Indicates all packets will match the redirect regardless of source and/or destination.

**Usage**

Define a catch all rule definitions to place at the end of the list of rule definitions to provide explicit handling of rule definitions which do not fit any other criteria.

**Important:** It is suggested that any rule definition which is added to be a catch all should also have the `log` option specified. The logged packets may be used to determine if the current list of rule definitions is adequate or needs modification to ensure proper security.

**Important:** A maximum of 16 rule definitions can be configured per ACL.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the CSS service with the name `css-svcl` and any source IP:

```
redirect css service css-svcl any
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service css-svcl any
```

The following command sets the insertion point after the second rule definitions above:

```
after redirect css service css-svcl any
```

The following deletes the first rule definition above:

```
no redirect css service css-svcl any
```
redirect css service (by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

redirect css service svc_name [ log ] host source_host_address
after redirect css service svc_name [ log ] host source_host_address
before redirect css service svc_name [ log ] host source_host_address
no redirect css service svc_name [ log ] host source_host_address

after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no
Removes the rule definition which exactly matches the options specified.
**redirect css service (by host IP address)**

**css service svc_name**

The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services. `svc_name` must be an alphanumeric string of 1 through 15 characters.

**log**

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**host**

Specifies that the rule definition applies to a specific host as determined by its IP address.

**source_host_address**

The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**Usage**

Define a rule definition when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rule definitions to be very clear and concise.

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the CSS service with the name `css-svcl` and a host IP address of `fe80::c0a8:c80b`:

```
redirect css service css-svcl host fe80::c0a8:c80b
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service css-svcl host fe80::c0a8:c80b
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service css-svcl host fe80::c0a8:c80b
```

The following deletes the first rule definition above:

```
no redirect css service css-svcl host fe80::c0a8:c80b
```
redirect css service (by ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

**Syntax**

```plaintext
redirect css service svc_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]

after redirect css service svc_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]

before redirect css service svc_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]

no redirect css service svc_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]
```

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```plaintext
after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

before
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.
```
**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```plaintext
no
```
Removes the rule definition which exactly matches the options specified.

```plaintext
css service svc_name
```
The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured charging services.

*svc_name* must be an alphanumeric string of 1 through 15 characters.

```plaintext
log
```
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

```plaintext
source_address
```
The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source wildcard* parameter.

```plaintext
source wildcard
```
This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

```plaintext
any
```
Specifies that the rule definition applies to all packets.

```plaintext
host
```
Specifies that the rule definition applies to a specific host as determined by its IP address.

```plaintext
source host address
```
The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.
IPv6 ACL Configuration Mode Commands

redirect css service (by ICMP packets)

**dest_host_address**
The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**dest_address**
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

**dest_wildcard**
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

<table>
<thead>
<tr>
<th>Important:</th>
<th>The mask must contain a contiguous set of one-bits from the least significant bit (LSB).</th>
</tr>
</thead>
</table>

**icmp_type**
Specifies that all ICMP packets of a particular type are to be filtered. The type can be an integer value from 0 through 255.

**icmp_code**
Specifies that all ICMP packets of a particular code are to be filtered. The type is an integer from 0 through 255.

**Usage**
Define a rule definition to block ICMP packets which can be used for address resolution and possibly be a security risk.
The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

<table>
<thead>
<tr>
<th>Important:</th>
<th>A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.</th>
</tr>
</thead>
</table>

**Example**
The following command defines a rule definition that redirects packets to the CSS service named css-svc1, and ICMP packets coming from the host with the IP address 2002::c6a2:6419:

```
redirect css service css-svc1 icmp host 2002::c6a2:6419
```

The following sets the insertion point to before the first rule definition above:
before redirect css service css-svcl icmp host 2002::c6a2:6419

The following command sets the insertion point after the second rule definition above:

after redirect css service css-svcl icmp host 2002::c6a2:64195

The following deletes the first rule definition above:

no redirect css service css-svcl icmp host 2002::c6a2:6419
redirect css service (by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

**Syntax**

- `redirect css service svc_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]`

- `after redirect css service svc_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]`

- `before redirect css service svc_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]`

- `no redirect css service svc_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]`

**after**
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important**: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.
redirect css service (by IP packets)

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

- **no**
  Removes the rule definition which exactly matches the options specified.

- **css service svc_name**
  The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services.
  `svc_name` must be an alphanumeric string of 1 through 15 characters.

- **log**
  Default: packets are not logged.
  Indicates all packets which match the redirect are to be logged.

- **source_address**
  The IP address(es) from which the packet originated.
  This option is used to filter all packets from a specific IP address or a group of IP addresses.
  When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

- **source_wildcard**
  This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
  The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

- **any**
  Specifies that the rule definition applies to all packets.

- **host**
  Specifies that the rule definition applies to a specific host as determined by its IP address.

- **source_host_address**
  The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.
**dest_host_address**

The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**dest_address**

The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.

**dest_wildcard**

This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**fragment**

Indicates packet redirection is to be applied to IP packet fragments only.

**Usage**

Block IP packets when the source and destination are of interest.

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the CSS service named **css-svc1**, and IP packets coming from the host with the IP address 2002::c6a2:6419, and fragmented packets for any destination are matched:

```
redirect css service css-svc1 ip host 2002::c6a2:6419 any fragment
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service css-svc1 ip host 2002::c6a2:6419 any fragment
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service css-svc1 ip host 2002::c6a2:6419 any fragment
```
The following deletes the first rule definition above:

```
no redirect css service css-svc1 ip host 2002::c6a2:6419 any fragment
```
redirect css service (by source IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

redirect css service svc_name [ log ] source_address source_wildcard

after redirect css service svc_name [ log ] source_address source_wildcard

before redirect css service svc_name [ log ] source_address source_wildcard

no redirect css service svc_name [ log ] source_address source_wildcard

after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no
Removes the rule definition which exactly matches the options specified.
The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services. `svc_name` must be an alphanumeric string of 1 through 15 characters.

Indicates all packets which match the filter are to be logged.

The IP address(es) form which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

Define a rule definition when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rule definitions as it does not require a rule definition for each source and destination pair.

A maximum of 16 rule definitions can be configured per ACL.

The following command defines a rule definition to redirect packets to a CSS service named `css-svc1`:

```
redirect css service css=svc1 2002::c6a2:6419
```
redirect css service (by TCP/UDP packets)

Used to redirect subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl) #
```

**Syntax**

```
redirect css service svc_name [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }
```

```
after redirect css service svc_name [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }
```

```
after redirect css service svc_name [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }
```

```
o redirect css service svc_name [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }
```

```
after
```

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.
**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**

Removes the rule definition which exactly matches the options specified.

**css service svc_name**

The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured charging services. `svc_name` must be an alphanumeric string of 1 through 15 characters.

**log**

Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

**tcp | udp**

Specifies the redirect is to be applied to IP-based transmission control protocol or the user datagram protocol.

- **tcp**: Redirect applies to TCP packets.
- **udp**: Redirect applies to UDP packets.

**source_address**

The IP address(es) form which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `sourceWildcard` parameter.

**sourceWildcard**

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.
**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

- **any**
  Specifies that the rule definition applies to all packets.

- **host**
  Specifies that the rule definition applies to a specific host as determined by its IP address.

- **source_host_address**
  The IP address of the source host to filter against expressed in IPv6 colon notation.

- **dest_host_address**
  The IP address of the destination host to filter against expressed in IPv6 colon notation.

- **eq source_port**
  Specifies a single, specific source TCP port number to be filtered.
  `source_port` must be configured to an integer from 0 to 65535.

- **gt source_port**
  Specifies that all source TCP port numbers greater than the one specified are to be filtered.
  `source_port` must be configured to an integer from 0 to 65535.

- **lt source_port**
  Specifies that all source TCP port numbers less than the one specified are to be filtered.
  `source_port` must be configured to an integer from 0 to 65535.

- **neq source_port**
  Specifies that all source TCP port numbers not equal to the one specified are to be filtered.
  `source_port` must be configured to an integer from 0 to 65535.

- **range start_source_port end_source_port**
  Specifies that all source TCP ports within a specific range are to be filtered.
  `start_source_port` is the initial port in the range and `end_source_port` is the final port in the range.
  Both `start_source_port` and `end_source_port` can be configured to an integer from 0 to 65535.

- **dest_address**
  The IP address(es) to which the packet is to be sent.
  This option is used to filter all packets to a specific IP address or a group of IP addresses.
  When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the `dest_wildcard` parameter.

- **dest_wildcard**
  This option is used in conjunction with the `dest_address` option to specify a group of addresses for which packets are to be filtered.
  The mask must be entered as a complement:
IPv6 ACL Configuration Mode Commands

redirect css service (by TCP/UDP packets)

- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

### Important:
The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

<table>
<thead>
<tr>
<th>Command</th>

</tr>
</tbody>
</table>

### Usage
Block IP packets when the source and destination are of interest but for only a limited set of ports.

### Important:
A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

### Example
The following command defines a rule definition that redirects packets to the CSS service named css-svcl, and UDP packets coming from any host are matched:

```
redirect css service css-svcl udp any
```

The following sets the insertion point to before the rule definition above:

```
before redirect css service css-svcl udp any
```

The following command sets the insertion point after the rule definition above:

```
```
after redirect css service css-svcl udp any

The following deletes the rule definition above:

no redirect css service css-svcl udp any
**redirect css service (for downlink, any)**

Used to redirect subscriber sessions based on any packet received in the downlink (from the Mobile Node) direction. This command is also used to set the access control list insertion point.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect css service svc_name [ log ] downlink any

after redirect css service svc_name [ log ] downlink any

before redirect css service svc_name [ log ] downlink any

no redirect css service svc_name [ log ] downlink any
```

**after**
Indicates all rule definitions defined subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important**: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important**: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**
Removes the rule definition which exactly matches the options specified.
**css service svc_name**

The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services.

`svc_name` must be an alphanumeric string of 1 through 15 characters.

**downlink**

Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

**log**

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**any**

Indicates all packets will match the redirect regardless of source and/or destination.

**Usage**

Define a catch all rule definition to place at the end of the list of rule definitions to provide explicit handling of rule definitions which do not fit any other criteria.

**Important:** It is suggested that any rule definition which is added to be a catch all should also have the `log` option specified. The logged packets may be used to determine if the current list of rule definitions is adequate or needs modification to ensure proper security.

**Important:** A maximum of 16 rule definitions can be configured per ACL.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the CSS service with the name `css-svcl` and any source IP:

```plaintext
redirect css service css-svcl downlink any
```

The following sets the insertion point to before the first rule definition above:

```plaintext
before redirect service css-svcl downlink any
```

The following command sets the insertion point after the second rule definition above:

```plaintext
after redirect service css-svcl downlink any chgsvcl downlink any
```

The following deletes the first rule definition above:

```plaintext
no redirect service css-svcl downlink any
```
redirect css service (for downlink, by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address in the downlink (from the Mobile Node) direction.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

- `redirect css service svc_name [ log ] downlink host source_host_address`
- `after redirect css service svc_name [ log ] downlink host source_host_address`
- `before redirect css service svc_name [ log ] downlink host source_host_address`
- `no redirect css service svc_name [ log ] downlink host source_host_address`

**after**
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**
Removes the rule definition which exactly matches the options specified.
**css service svc_name**

The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services.

`svc_name` must be an alphanumeric string of 1 through 15 characters.

**downlink**

Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

**log**

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**host**

Specifies that the rule definition applies to a specific host as determined by its IP address.

**source_host_address**

The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**Usage**

Define a rule definition when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rule definitions to be very clear and concise.

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the charging service with the name `css-svc1` and a host IP address of `fe80::c0a8:c80b`:

```
redirect service css-svc1 downlink host fe80::c0a8:c80b
```

The following sets the insertion point to before the first rule definition above:

```
before redirect service css-svc1 downlink host fe80::c0a8:c80b
```

The following command sets the insertion point after the second rule definition above:

```
after redirect service css-svc1 downlink host fe80::c0a8:c80b
```

The following deletes the first rule definition above:

```
no redirect service css-svc1 downlink host fe80::c0a8:c80b
```
redirect css service (for downlink, by ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets in the downlink (from the Mobile Node) direction.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-ipv6-acl) #
```

**Syntax**

```
redirect css service svc_name [ log ] downlink icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]
```

```
after redirect css service svc_name [ log ] downlink icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]
```

```
before redirect css service svc_name [ log ] downlink icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]
```

```
no redirect css service svc_name [ log ] downlink icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]
```

---

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```
before
```

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.
**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

- **no**
  Removes the rule definition which exactly matches the options specified.

- **css service svc_name**
  The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services.
  `svc_name` must be an alphanumeric string of 1 through 15 characters.

- **downlink**
  Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

- **log**
  Default: packets are not logged.
  Indicates all packets which match the redirect are to be logged.

- **source_address**
  The IP address(es) from which the packet originated.
  This option is used to filter all packets from a specific IP address or a group of IP addresses.
  When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

- **source_wildcard**
  This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
  The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

- **any**
  Specifies that the rule definition applies to all packets.

- **host**
  Specifies that the rule definition applies to a specific host as determined by its IP address.

- **source_host_address**
  The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.
IPv6 ACL Configuration Mode Commands

- **redirect css service** (for downlink, by ICMP packets)

**dest_host_address**
- The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**dest_address**
- The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.

**dest_wildcard**
- This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**icmp_type**
- Specifies that all ICMP packets of a particular type are to be filtered. The type can be an integer value from 0 through 255.

**icmp_code**
- Specifies that all ICMP packets of a particular code are to be filtered. The type can be an integer value from 0 through 255.

**Usage**
- Define a rule definition to block ICMP packets which can be used for address resolution and possibly be a security risk.
- The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the charging service named **css-svcl**, and ICMP packets coming in the downlink (from the Mobile Node) direction from the host with the IP address **2002::c6a2:6419**:

```
redirect css service css-svcl downlink icmp host 2002::c6a2:6419
```

The following sets the insertion point to before the first rule definition above:
IPv6 ACL Configuration Mode Commands

redirect cs service (for downlink, by ICMP packets)

before redirect cs service cs-svcl downlink icmp host 2002::c6a2:6419

The following command sets the insertion point after the second rule definition above:

after redirect cs service cs-svcl downlink icmp host 2002::c6a2:6419

The following deletes the first rule definition above:

no redirect cs service cs-svcl downlink icmp host 2002::c6a2:6419
redirect css service (for downlink, by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets in the downlink (from the Mobile Node) direction.

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

redirect css service svc_name [ log ] downlink ip { any | host source_host_address | source_address sourceWildcard } { any | host dest_host_address | dest_address destWildcard } [ fragment ]

after redirect css service svc_name [ log ] downlink ip { any | host source_host_address | source_address sourceWildcard } { any | host dest_host_address | dest_address destWildcard } [ fragment ]

before redirect css service svc_name [ log ] downlink ip { any | host source_host_address | source_address sourceWildcard } { any | host dest_host_address | dest_address destWildcard } [ fragment ]

no redirect css service svc_name [ log ] downlink ip { any | host source_host_address | source_address sourceWildcard } { any | host dest_host_address | dest_address destWildcard } [ fragment ]

after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before
Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.
**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```plaintext
no
```

Removes the rule definition which exactly matches the options specified.

```plaintext
css service svc_name
```

The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services. `svc_name` must be a string of 1 through 15 characters.

```plaintext
downlink
```

Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

```plaintext
log
```

Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

```plaintext
source_address
```

The IP address(es) form which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source wildcard` parameter.

```plaintext
source wildcard
```

This option is used in conjunction with the `source address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

```plaintext
any
```

Specifies that the rule definition applies to all packets.

```plaintext
host
```

Specifies that the rule definition applies to a specific host as determined by its IP address.
source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

dest_wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

fragment
Indicates packet redirection is to be applied to IP packet fragments only.

Usage
Block IP packets when the source and destination are of interest.

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example
The following command defines a rule definition that redirects packets to the charging service named css-svc1, and downlink IP packets coming from the host with the IP address 2002::c6a2:6419, and fragmented packets for any destination are matched:

```
redirect css service css-svc1 downlink ip host 2002::c6a2:6419 any fragment
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service css-svc1 downlink ip host 2002::c6a2:6419 any fragment
```

The following command sets the insertion point after the second rule definition above:
after redirect css service css-svc1 downlink ip host 2002::c6a2:6419 any fragment

The following deletes the first rule definition above:

no redirect css service css-svc1 downlink ip host 2002::c6a2:6419 any fragment
redirect css service (for downlink, by source IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source in the downlink (from the Mobile Node) direction.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

- `redirect css service svc_name [ log ] downlink source_address source_wildcard`
- `after redirect css service svc_name [ log ] downlink source_address source_wildcard`
- `before redirect css service svc_name [ log ] downlink source_address source_wildcard`
- `no redirect css service svc_name [ log ] downlink source_address source_wildcard`

**after**
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.
no
Removes the rule definition which exactly matches the options specified.

css service svc_name
The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services. `svc_name` must be an alphanumeric string of 1 through 15 characters.

downlink
Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

log
Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

source_address
The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

source_wildcard
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

Usage
Define a rule definition when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rule definitions as it does not require a rule definition for each source and destination pair.

**Important:** A maximum of 16 rule definitions can be configured per ACL.

Example
The following command defines a rule definition to redirect packets to a charging service named `css-svcl`:

```
redirect css service css-svcl downlink fe80::c0a8:a04
```
redirect css service (for downlink, by TCP/UDP packets)

Used to redirect subscriber sessions to a charging service based on the transmission control protocol/user datagram protocol packets in the downlink (from the Mobile Node) direction.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

redirect css service svc_name [ log ] downlink { tcp | udp } { { source_address
source_wildcard | any | host source_host_address } { eq source_port | gt source_port | lt
source_port | neq source_port | range start_source_port end_source_port } } { {
dest_address dest_wildcard | any | host dest_host_address } { eq dest_port | gt dest_port
| lt dest_port | neq dest_port | range start_dest_port end_dest_port } }

after redirect css service svc_name [ log ] downlink { tcp | udp } { { source_address
source_wildcard | any | host source_host_address } { eq source_port | gt source_port | lt
source_port | neq source_port | range start_source_port end_source_port } } { {
dest_address dest_wildcard | any | host dest_host_address } { eq dest_port | gt dest_port
| lt dest_port | neq dest_port | range start_dest_port end_dest_port } }

no redirect css service svc_name [ log ] downlink { tcp | udp } { { source_address
source_wildcard | any | host source_host_address } { eq source_port | gt source_port | lt
source_port | neq source_port | range start_source_port end_source_port } } { {
dest_address dest_wildcard | any | host dest_host_address } { eq dest_port | gt dest_port
| lt dest_port | neq dest_port | range start_dest_port end_dest_port } }

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.
**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**
Removes the rule definition which exactly matches the options specified.

**css service svc_name**
The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services.
svc_name must be an alphanumeric string of 1 through 15 characters.

**downlink**
Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

**log**
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**tcp | udp**
Specifies the redirect is to be applied to IP-based transmission control protocol or the user datagram protocol.
- **tcp**: Redirect applies to TCP packets.
- **udp**: Redirect applies to UDP packets.

**source_address**
The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

- `any` Specifies that the rule definition applies to all packets.
- `host` Specifies that the rule definition applies to a specific host as determined by its IP address.
  - `source_host_address` The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.
  - `dest_host_address` The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.
- `eq source_port` Specifies a single, specific source TCP port number to be filtered.
  - `source_port` must be configured to an integer value from 0 to 65535.
- `gt source_port` Specifies that all source TCP port numbers greater than the one specified are to be filtered.
  - `source_port` must be configured to an integer value from 0 to 65535.
- `lt source_port` Specifies that all source TCP port numbers less than the one specified are to be filtered.
  - `source_port` must be configured to an integer value from 0 to 65535.
- `neq source_port` Specifies that all source TCP port numbers not equal to the one specified are to be filtered.
  - `source_port` must be configured to an integer value from 0 to 65535.
- `range start_source_port end_source_port` Specifies that all source TCP ports within a specific range are to be filtered.
  - `start_source_port` is the initial port in the range and `end_source_port` is the final port in the range.
  - Both `start_source_port` and `end_source_port` can be configured to an integer value from 0 to 65535.
- `dest_address` The IP address(es) to which the packet is to be sent.
  - This option is used to filter all packets to a specific IP address or a group of IP addresses.
  - When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the `dest_wildcard` parameter.
**IPv6 ACL Configuration Mode Commands**

**redirect css service (for downlink, by TCP/UDP packets)**

---

**dest_wildcard**

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

---

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

---

**eq dest_port**

Specifies a single, specific destination TCP port number to be filtered. *dest_port* must be configured to an integer value from 0 to 65535.

---

**gt dest_port**

Specifies that all destination TCP port numbers greater than the one specified are to be filtered. *dest_port* must be configured to an integer value from 0 to 65535.

---

**lt dest_port**

Specifies that all destination TCP port numbers less than the one specified are to be filtered. *dest_port* must be configured to an integer value from 0 to 65535.

---

**neq dest_port**

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered. *dest_port* must be configured to an integer value from 0 to 65535.

---

**range start_dest_port end_dest_port**

Specifies that all destination TCP ports within a specific range are to be filtered. *start_dest_port* is the initial port in the range and *end_dest_port* is the final port in the range. Both *start_dest_port* and *end_dest_port* can be configured to an integer value from 0 to 65535.

---

**Usage**

Block IP packets when the source and destination are of interest but for only a limited set of ports.

---

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

---

**Example**

The following command defines a rule definition that redirects packets to the charging service named *css-svcl*, and UDP packets coming from any host are matched:

```
redirect css service css-svcl downlink udp any
```

The following sets the insertion point to before the rule definition above:

---

Cisco ASR 5x00 Command Line Interface Reference
before redirect css service css-svcl downlink udp any

The following command sets the insertion point after the rule definition above:

after redirect css service css-svcl downlink udp any

The following deletes the rule definition above:

no redirect css service css-svcl downlink udp any
redirect css service (for uplink, any)

Used to redirect subscriber sessions based on any packet received in the uplink (to the Mobile Node) direction. This command is also used to set the access control list insertion point.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect css service svc_name [ log ] uplink any
after redirect css service svc_name [ log ] uplink any
before redirect css service svc_name [ log ] uplink any
no redirect css service svc_name [ log ] uplink any
```

**after**
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**
Removes the rule definition which exactly matches the options specified.
**css service svc_name**

The name of the Content Service steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services. `svc_name` must be an alphanumeric string of 1 through 15 characters.

**uplink**

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

**log**

Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

**any**

Indicates all packets will match the redirect regardless of source and/or destination.

**Usage**

Define a catch all rule definition to place at the end of the list of rule definitions to provide explicit handling of rule definitions which do not fit any other criteria.

**Important:** It is suggested that any rule definition which is added to be a catch all should also have the `log` option specified. The logged packets may be used to determine if the current list of rule definitions is adequate or needs modification to ensure proper security.

**Important:** A maximum of 16 rule definitions can be configured per ACL.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the charging service with the name `css-svc1` and any source IP:

```
redirect css service css-svc1 uplink any
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service css-svc1 uplink any
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service css-svc1 uplink any
```

The following deletes the first rule definition above:

```
no redirect css service css-svc1 uplink any
```
redirect css service (for uplink, by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address in the uplink (to the Mobile Node) direction.

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

redirect css service svc_name [ log ] uplink host source_host_address
after redirect css service svc_name [ log ] uplink host source_host_address
before redirect css service svc_name [ log ] uplink host source_host_address
no redirect css service svc_name [ log ] uplink host source_host_address

uplink
Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

after
Indicates all rule definitions defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.
redirect css service (for uplink, by host IP address)

no
Removes the rule definition which exactly matches the options specified.

css service svc_name
The name of the Content service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the show css service all command to display the names of all configured CSS services.
svc_name must be an alphanumeric string of 1 through 15 characters.

uplink
Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

log
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

host
Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

Usage
Define a rule definition when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rule definitions to be very clear and concise.

Important: A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example
The following command defines a rule definition that redirects packets to the charging service with the name css-svc1 and a host IP address of fe80::c0a8:c80b:

    redirect service css-svc1 uplink host fe80::c0a8:c80b

The following sets the insertion point to before the first rule definition above:

    before redirect service css-svc1 uplink host fe80::c0a8:c80b

The following command sets the insertion point after the second rule definition above:

    after redirect service css-svc1 uplink host fe80::c0a8:c80b

The following deletes the first rule definition above:

    no redirect service css-svc1 uplink host fe80::c0a8:c80b
redirect css service (for uplink, by ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets in the uplink (to the Mobile Node) direction.

Product

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

redirect css service svc_name [ log ] uplink icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]

after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no
Removes the rule definition which exactly matches the options specified.
css service svc_name

The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the show css service all command to display the names of all configured CSS services. svc_name must be an alphanumeric string of 1 through 15 characters.

uplink

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

log

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the source_wildcard parameter.

source_wildcard

This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
• Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
• One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

any

Specifies that the rule definition applies to all packets.

host

Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

dest_address

The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

**dest_wildcard**

This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**icmp_type**

Specifies that all ICMP packets of a particular type are to be filtered. The type can be an integer value from 0 through 255.

**icmp_code**

Specifies that all ICMP packets of a particular code are to be filtered. The type can be an integer value from 0 through 255.

**Usage**

Define a rule definition to block ICMP packets which can be used for address resolution and possibly be a security risk. The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the charging service named chgsvc1, and ICMP packets in the uplink (to the Mobile Node) direction from the host with the IP address 198.162.100.25:

```
redirect css service chgsvc1 uplink icmp host 198.162.100.25
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service chgsvc1 uplink icmp host 198.162.100.25
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service chgsvc1 uplink icmp host 198.162.100.25
```

The following deletes the first rule definition above:
no redirect css service chgsvcl uplink icmp host 198.162.100.25
redirect css service (for uplink, by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets in the uplink (to the Mobile Node) direction.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect css service svc_name [ log ] uplink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

after redirect css service svc_name [ log ] uplink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

before redirect css service svc_name [ log ] uplink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

no redirect css service svc_name [ log ] uplink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]
```

- **after**
  
  Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
  
  This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

- **before**
  
  Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
  
  This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

---

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.
redirect css service (for uplink, by IP packets)

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```plaintext
no
Removes the rule definition which exactly matches the options specified.
```

```plaintext
css service svc_name
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services.
`svc_name` must be a string of 1 through 15 characters.
```

```plaintext
uplink
Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.
```

```plaintext
log
Default: packets are not logged. Indicates all packets which match the redirect are to be logged.
```

```plaintext
source_address
The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.
```

```plaintext
source_wildcard
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.
```

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

```plaintext
any
Specifies that the rule definition applies to all packets.
```

```plaintext
host
Specifies that the rule definition applies to a specific host as determined by its IP address.
```
IPv6 ACL Configuration Mode Commands

redirect css service (for uplink, by IP packets)

source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address
The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

dest_wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

fragment
Indicates packet redirection is to be applied to IP packet fragments only.

Usage
Block IP packets when the source and destination are of interest.

Example
The following command defines a rule definition that redirects packets to the charging service named chgsvcl, and uplink IP packets going to the host with the IP address 198.162.100.25, and fragmented packets for any destination are matched:

   redirect css service chgsvcl uplink ip host 198.162.100.25 any fragment

The following sets the insertion point to before the first rule definition above:

   redirect css service chgsvcl uplink ip host 198.162.100.25 any fragment

The following command sets the insertion point after the second rule definition above:

   after redirect css service chgsvcl uplink ip host 198.162.100.25 any fragment

The following deletes the first rule definition above:

   no redirect css service chgsvcl uplink ip host 198.162.100.25 any fragment
redirect css service (for uplink, by source IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source in the uplink (to the Mobile Node) direction.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:
```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect css service svc_name [ log ] uplink source_address source_wildcard
```

**after**
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**no**
Removes the rule definition which exactly matches the options specified.

**css service svc_name**
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services.

`svc_name` must be a string of 1 through 15 characters.

**uplink**
Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

**log**
Default: packets are not logged.
Indicates all packets which match the filter are to be logged.
source_address

The IP address(es) form which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the source_wildcard parameter.

source_wildcard

This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

Usage

Define a rule definition when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rule definitions as it does not require a rule definition for each source and destination pair.

Example

The following command defines a rule definition to redirect packets to a charging service named chgsvc1:

```
redirect css service chgsvc1 uplink 1:1:1:1:1:1:1:1
```
redirect css service (for uplink, by TCP/UDP packets)

Used to redirect subscriber sessions to a charging service based on the transmission control protocol/user datagram protocol packets in the uplink (to the Mobile Node) direction.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```bash
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-ipv6-acl)#
```

**Syntax**

```bash
redirect css service svc_name [ log ] uplink { tcp | udp } { { source_address source_wildcard | any | source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }
```

- **after redirect css service svc_name [ log ] uplink { tcp | udp } { { source_address source_wildcard | any | source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

- **before redirect css service svc_name [ log ] uplink { tcp | udp } { { source_address source_wildcard | any | source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

- **no redirect css service svc_name [ log ] uplink { tcp | udp } { { source_address source_wildcard | any | source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

**after**

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.
IPv6 ACL Configuration Mode Commands

redirect css service (for uplink, by TCP/UDP packets)

before
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

no
Removes the rule definition which exactly matches the options specified.

css service svc_name
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the show active-charging service all command to display the names of all configured charging services. svc_name must be a string of 1 through 15 characters.

uplink
Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

log
Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

tcp | udp
Specifies the redirect is to be applied to IP-based transmission control protocol or the user datagram protocol.

• tcp: Redirect applies to TCP packets.
• udp: Redirect applies to UDP packets.

source_address
The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the source_wildcard parameter.

source_wildcard
This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

• Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
• One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

any
Specifies that the rule definition applies to all packets.
**IPv6 ACL Configuration Mode Commands**

- **host**
  Specifies that the rule definition applies to a specific host as determined by its IP address.

- **source_host_address**
  The IP address of the source host to filter against expressed in IPv6 colon notation.

- **dest_host_address**
  The IP address of the destination host to filter against expressed in IPv6 colon notation.

- **eq source_port**
  Specifies a single, specific source TCP port number to be filtered. **source_port** must be configured to an integer value from 0 to 65535.

- **gt source_port**
  Specifies that all source TCP port numbers greater than the one specified are to be filtered. **source_port** must be configured to an integer value from 0 to 65535.

- **lt source_port**
  Specifies that all source TCP port numbers less than the one specified are to be filtered. **source_port** must be configured to an integer value from 0 to 65535.

- **neq source_port**
  Specifies that all source TCP port numbers not equal to the one specified are to be filtered. **source_port** must be configured to an integer value from 0 to 65535.

- **range start_source_port end_source_port**
  Specifies that all source TCP ports within a specific range are to be filtered. **start_source_port** is the initial port in the range and **end_source_port** is the final port in the range. Both **start_source_port** and **end_source_port** can be configured to an integer value from 0 to 65535.

- **dest_address**
  The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.

- **dest_wildcard**
  This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.
eq dest_port
Specifies a single, specific destination TCP port number to be filtered.
dest_port must be configured to an integer value from 0 to 65535.

gt dest_port
Specifies that all destination TCP port numbers greater than the one specified are to be filtered.
dest_port must be configured to an integer value from 0 to 65535.

lt dest_port
Specifies that all destination TCP port numbers less than the one specified are to be filtered.
dest_port must be configured to an integer value from 0 to 65535.

neq dest_port
Specifies that all destination TCP port numbers not equal to the one specified are to be filtered.
dest_port must be configured to an integer value from 0 to 65535.

range start_dest_port end_dest_port
Specifies that all destination TCP ports within a specific range are to be filtered.
start_dest_port is the initial port in the range and end_dest_port is the final port in the range.
Both start_dest_port and end_dest_port can be configured to an integer value from 0 to 65535.

Usage
Block IP packets when the source and destination are of interest but for only a limited set of ports.

Example
The following command defines a rule definition that redirects packets to the charging service named chgsvcl, and UDP packets coming from any host are matched:

   redirect css service chgsvcl uplink udp any

The following sets the insertion point to before the rule definition above:

   before redirect css service chgsvcl uplink udp any

The following command sets the insertion point after the rule definition above:

   after redirect css service chgsvcl uplink udp any

The following deletes the rule definition above:

   no redirect css service chgsvcl uplink udp any
redirect nexthop (by IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

**Syntax**

\[
\text{redirect nexthop } \text{nexthop_addr \{ context context_id | interface interface_name \} [ log ]}
\]

\[
\text{source_address source_wildcard}
\]

\[
\text{after redirect nexthop } \text{nexthop_addr \{ context context_id | interface interface_name \} [ log ]}
\]

\[
\text{source_address source_wildcard}
\]

\[
\text{before redirect nexthop } \text{nexthop_addr \{ context context_id | interface interface_name \} [ log ]}
\]

\[
\text{source_address source_wildcard}
\]

\[
\text{no redirect nexthop } \text{nexthop_addr \{ context context_id | interface interface_name \} [ log ]}
\]

\[
\text{source_address source_wildcard}
\]

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

\[
\text{after}
\]

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

\[
\text{before}
\]

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Removes the rule which exactly matches the options specified.</td>
</tr>
<tr>
<td><code>nexthop nexthop_addr</code></td>
<td>The IP address to which the IP packets are redirected.</td>
</tr>
<tr>
<td><code>context context_id</code></td>
<td>The context identification number of the context to which packets are redirected. At the executive mode prompt, use the <code>show context all</code> command to display context names and context IDs.</td>
</tr>
<tr>
<td><code>interface interface_name</code></td>
<td>The name of the logical interface to which the packets should be redirected. <code>interface_name</code> must be an alpha and/or numeric string from 1 to 79 characters.</td>
</tr>
<tr>
<td>log</td>
<td>Default: packets are not logged. Indicates all packets which match the redirect are to be logged.</td>
</tr>
<tr>
<td><code>source_address</code></td>
<td>The IP address(es) form which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the <code>source_wildcard</code> parameter.</td>
</tr>
</tbody>
</table>
| `source_wildcard` | This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:  
  * Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.  
  * One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.  

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.  

**Usage**  
Define a rule when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of redirect rules as it does not require a rule for each source and destination pair.  

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also
note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the next hop host at 192.168.10.4, the context with the context ID of 23 and the source IP and wildcard of 198.162.22.0 and 0.0.0.31:

```
redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31
```

The following sets the insertion point to before the first rule defined above:

```
before redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31
```

The following command sets the insertion point after the second rule defined above:

```
after redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31
```

The following deletes the first rule defined above:

```
no redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31
```
redirect nexthop (any)

Used to redirect subscriber sessions based on any packet received. This command is also used to set the access control list insertion point.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

>[context_name]host_name(config-ipv6-acl)#

Syntax

redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] any

after redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] any

before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] any

no redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] any

after
 Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before
 Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.
redirect nexthop (any)

no
Removes the rule which exactly matches the options specified.

nexthop nexthop_addr
The IP address to which the IP packets are redirected.

context context_id
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the show context all command to display context names and context IDs.

interface interface_name
The name of the logical interface to which the packets should be redirected. interface_name must be an alpha and/or numeric string from 1 to 79 characters.

log
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

any
Indicates all packets will match the redirect regardless of source and/or destination.

Usage
Define a catch all rule to place at the end of the list of rules to provide explicit handling of rules which do not fit any other criteria.

Important: It is suggested that any rule which is added to be a catch all should also have the log option specified. The logged packets may be used to determine if the current list of rules is adequate or needs modification to ensure proper security. The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example
The following command defines a rule that redirects packets to the next hop host at 192.168.10.4, the context with the context ID of 23 and any source IP:

   redirect nexthop 192.168.10.4 context 23 any

The following sets the insertion point to before the first rule defined above:

   before redirect nexthop 192.168.10.4 context 23 any

The following command sets the insertion point after the second rule defined above:

   after redirect nexthop 192.168.10.4 context 23 any

The following deletes the first rule defined above:
no redirect nexthop 192.168.10.4 context 23 any
redirect nexthop (by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] host source_ip_address

after redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] host source_ip_address

before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] host source_ip_address

no redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] host source_ip_address

**after**

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.
no
Removes the rule which exactly matches the options specified.

nexthop  nexthop_addr
The IP address to which the IP packets are redirected.

context  context_id
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the show context all command to display context names and context IDs.

interface  interface_name
The name of the logical interface to which the packets should be redirected. interface_name must be an alpha and/or numeric string from 1 to 79 characters.

log
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

host
Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

Usage
Define a rule when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rules to be very clear and concise.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example
The following command defines a rule that redirects packets to the next hop host at 192.168.10.4, the context with the context ID of 23 and a host IP address of 192.168.200.11:

    redirect nexthop 192.168.10.4 context 23 host 192.168.200.11

The following sets the insertion point to before the first rule defined above:

    before redirect nexthop 192.168.10.4 context 23 host 192.168.200.11

The following command sets the insertion point after the second rule defined above:

    after redirect nexthop 192.168.10.4 context 23 host 192.168.200.11
The following deletes the first rule defined above:

```
no redirect nexthop 192.168.10.4 context 23 host 192.168.200.11
```
redirect nexthop (by source ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] icmp { source_address source_wildcard | any | host source_host_address }{ dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

after redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] icmp { source_address source_wildcard | any | host source_host_address }{ dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] icmp { source_address source_wildcard | any | host source_host_address }{ dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

no redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] icmp { source_address source_wildcard | any | host source_host_address }{ dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]
```

**after**

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
**redirect nexthop (by source ICMP packets)**

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

<tr>
<td><strong>host</strong></td>
<td>Specifies that the rule applies to a specific host as determined by its IP address.</td>
</tr>
</tbody>
</table>
source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter.
The range can then be configured using the dest_wildcard parameter.

dest_wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

icmp_type
Specifies that all ICMP packets of a particular type are to be filtered. The type can be an integer value from 0 through 255.

icmp_code
Specifies that all ICMP packets of a particular code are to be filtered. The type can be an integer value from 0 through 255.

**Usage**

Define a rule to block ICMP packets which can be used for address resolution and possible be a security risk.
The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used.
For more information, refer to the Engineering Rules appendix in the System Administration Guide.
Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule that redirects packets to the next hop host at `fe80::c0a8:a04`, the context with the context ID of 23, and ICMP packets coming from the host with the IP address `2002::c6a2:64195`:
redirect nexthop fe80::c0a8:a04 context 23 icmp host 2002::c6a2:6419

The following sets the insertion point to before the first rule defined above:

before redirect nexthop fe80::c0a8:a04 context 23 icmp host 2002::c6a2:6419

The following command sets the insertion point after the second rule defined above:

after redirect nexthop fe80::c0a8:a04 context 23 icmp host 2002::c6a2:6419

The following deletes the first rule defined above:

no redirect nexthop fe80::c0a8:a04 context 23 icmp host 2002::c6a2:6419
redirect nexthop (by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

Syntax

redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
ip { source_address source wildcard | any | host source_host_address } { dest_address dest wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]

after
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no
Removes the rule which exactly matches the options specified.

nexthop nexthop_addr
The IP address to which the IP packets are redirected.
**context context_id**

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

**interface interface_name**

The name of the logical interface to which the packets should be redirected. `interface_name` must be an alphanumeric string from 1 through 79 characters.

**log**

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**source_address**

The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**any**

Specifies that the rule applies to all packets.

**host**

Specifies that the rule applies to a specific host as determined by its IP address.

**source_host_address**

The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**dest_host_address**

The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**dest_address**

The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the `dest_wildcard` parameter.

`dest_wildcard`

This option is used in conjunction with the `dest_address` option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be ignored.

**Important**: The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

`fragment`

Indicates packet redirection is to be applied to IP packet fragments only.

`protocol num`

Indicates that the packet filtering is to be applied to a specific protocol number. `num` can be an integer from 0 through 255.

**Usage**

Block IP packets when the source and destination are of interest.

**Important**: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.
redirect nexthop (by TCP/UDP packets)

Used to redirect subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }

after redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }

before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }

no redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

> Important: If the options specified do not exactly match an existing rule, the insertion point does not change.
IPv6 ACL Configuration Mode Commands

redirect next-hop (by TCP/UDP packets)

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.

**nexthop**  
**nexthop_addr**
The IP address to which the IP packets are redirected.

**context**  
**context_id**
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

**interface**  
**interface_name**
The name of the logical interface to which the packets should be redirected. `interface_name` must be an alphanumeric string from 1 through 79 characters.

**log**
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**tcp** | **udp**
Specifies the redirect is to be applied to IP-based transmission control protocol or the user datagram protocol.
- **tcp**: Redirect applies to TCP packets.
- **udp**: Redirect applies to UDP packets.

**source_address**
The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.
<table>
<thead>

</tr>
<tr>
<td></td>
<td>• One-bits in this parameter mean that the corresponding bits configured for the <code>dest_address</code> parameter must be ignored.</td>
</tr>
</tbody>
</table>
**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

---

**eq dest_port**

Specifies a single, specific destination TCP port number to be filtered. 
`dest_port` must be configured to an integer value from 0 to 65535.

**gt dest_port**

Specifies that all destination TCP port numbers greater than the one specified are to be filtered. 
`dest_port` must be configured to an integer value from 0 to 65535.

**lt dest_port**

Specifies that all destination TCP port numbers less than the one specified are to be filtered. 
`dest_port` must be configured to an integer value from 0 to 65535.

**neq dest_port**

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered. 
`dest_port` must be configured to an integer value from 0 to 65535.

---

**Usage**

Block IP packets when the source and destination are of interest but for only a limited set of ports.

---

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

---

**Example**

The following command defines a rule that redirects packets to the next hop host at `fe80::c0a8:a04`, the context with the context ID of 23, and UDP packets coming from any host are matched:

```
redirect nexthop fe80::c0a8:a04 context 23 udp any
```

The following sets the insertion point to before the rule defined above:

```
before redirect nexthop fe80::c0a8:a04 context 23 udp any
```

The following command sets the insertion point after the rule defined above:

```
after redirect nexthop fe80::c0a8:a04 context 23 udp any
```

The following command deletes the first rule defined above:

```
no redirect nexthop fe80::c0a8:a04 context 23 udp any
```
Chapter 181
IPv6 to IPv4 Tunnel Interface Configuration Mode Commands

The IPv6 to IPv4 Tunnel Interface Configuration Mode is used to create and manage the IP interface for addresses, address resolution options, etc.

Mode

Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > IPv6 to IPv4 Tunnel Interface Configuration

configure > context context_name > interface interface_name tunnel > tunnel-mode ipv6ip

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-if-tunnel-ipv6ip)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
destination address

Configures the destination of the tunneled packets for a manual tunnel.

Product
All

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > IPv6 to IPv4 Tunnel Interface Configuration
configure > context context_name > interface interface_name tunnel > tunnel-mode ipv6ip

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-if-tunnel-ipv6ip)#

Syntax

destination address address

no destination address

no

Removes configuration for the specified keyword.

address

Specifies the IP address of the destination device. address must be specified in IPv4 dotted decimal or IPv6 colon-separated-hexadecimal notation.

Usage

Use this command to configure the IP address of the destination end of the tunnel.

Example

The following command sets the destination address for packets on this tunneled interface to 10.2.3.4:

destination address 10.2.3.4
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

exit

**Usage**

Use this command to return to the parent configuration mode.
mode

Configures the mode of IPv6 to IPv4 tunneling. The default is set to manual mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > IPv6 to IPv4 Tunnel Interface Configuration
configure > context context_name > interface interface_name tunnel > tunnel-mode ipv6ip

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-if-tunnel-ipv6ip)#
```

**Syntax**

```
mode { 6to4 | manual }
```

default mode

**6to4**

Configures automatic IPv6-to-IPv4 (6to4) tunnels as specified in RFC 3056.

**manual**

Configures point-to-point manual IPv6-to-IPv4 tunnels by specifying the IPv4 address of the tunnel remote end.

**default**

Resets the mode of IPv6-to-IPv4 tunneling to manual mode.

**Usage**

There can be only one IPv6-to-IPv4 tunnel possible in a context. Once an IPv6-to-IPv4 tunnel is configured, all subsequent tunnels will be configured as manual tunnels.

**Example**

The following command configures the mode to IPv6-to-IPv4 (6to4).

```
mode 6to4
```

The following command configures the mode to 6to4.

```
mode manual
```
source

Configures the source of tunneled packets.

Product

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > IPv6 to IPv4 Tunnel Interface Configuration

configure > context context_name > interface interface_name tunnel > tunnel-mode ipv6ip

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-if-tunnel-ipv6ip)#

Syntax

source { address ip_address | interface interface_name }

no source { address | interface } 

address ip_address

Specifies the IPv4 address to use as the source address of the tunnel.

ip_address must be expressed in IPv4 dotted-decimal notation.

interface interface_name

Specifies the name of a non-tunnel IPv4 interface, whose address is used as the source address of the tunnel. interface must be an alphanumeric string of 1 through 79 characters.

no source { address | interface } 

Removes configuration for the specified keyword.

Usage

Configures the source IPv4 address of the tunnel by either specifying the IP address (host address) or by specifying another configured non-tunnel IPv4 interface. The source address must be an existing interface address before it is used. State of source address will affect the operational state of the tunnel.

Example

The following command configures the source address of the tunnel.

source address 10.2.3.4

The following command specifies the source interface as testsource1.

source interface testsource1
tos

Configures the type of service (TOS) settings of the outer IPv4 header of the tunneled packets.

**Product**

PDSN

HA

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > IPv6 to IPv4 Tunnel Interface Configuration

```
configure > context context_name > interface interface_name tunnel > tunnel-mode ipv6ip
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-if-tunnel-ipv6ip)#
```

**Syntax**

```
tos { copy | value tos_value }
```

**default tos**

```
copy
```

Copies the DC octet of the IPv6 packet to the TOS octet of IPv4 packet.

```
default
```

Configures default setting for the specified keyword.

```
value tos_value
```

Configures the raw TOS value ranging from 0 to 255. The default is 0.

**Usage**

Sets the TOS parameter to be used in the tunnel transport protocol or copies the TOS value from the original IPv6 DC byte to the TOS value of the encapsulating IPv4 header.

**Example**

The following command sets the tos value to 1:

```
tos value 1
```
ttl

Configures the TTL (Time to live) value of the outer IPv4 header of the tunneled packets.

**Product**

- PDSN
- HA

**Privilege**

Security Administrator, Administrator

**Mode**

- Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > IPv6 to IPv4 Tunnel Interface Configuration

```
configure > context context_name > interface interface_name tunnel > tunnel-mode ipv6ip
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-if-tunnel-ipv6ip)#
```

**Syntax**

```
ttl value ttl_value
```

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Configures default setting for the specified keyword.</td>
</tr>
<tr>
<td>value ttl_value</td>
<td>ttl_value is an integer from 1 through 255. The default is 16.</td>
</tr>
</tbody>
</table>

**Usage**

Configures the TTL parameter to be used in the tunnel transport protocol.

**Example**

The following command sets the TTL value to 25.

```
ttl value 25
```
Chapter 182
ISAKMP Configuration Mode Commands

The ISAKMP Configuration Mode is used to configure Internet Security Association Key Management Protocol (ISAKMP) policies that are used to define Internet Key Exchange (IKE) security associations (SAs).

Modification(s) to an existing ISAKMP policy configuration will not take effect until the related security association has been cleared. Refer to the `clear crypto security-association` command described in the Exec Mode (A–C) Commands chapter for more information.

Mode

Exec > Global Configuration > Context Configuration > ISAKMP Configuration

`configure > context context_name > isakmp policy policy_number`

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
authentication

Configures the ISAKMP policy authentication mode.

**Product**
- PDSN
- HA
- GGSN

**Privilege**
- Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ISAKMP Configuration

`configure > context context_name > isakmp policy policy_number`

**Syntax**

```
authentication preshared-key
[ default | no ] authentication
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default authentication</td>
<td>Restores the default setting of this parameter. This command is enabled by default.</td>
</tr>
<tr>
<td>no authentication</td>
<td>Disables the preshared key authentication mode.</td>
</tr>
<tr>
<td>preshared-key</td>
<td>Specifies that the policy will be authenticated through the use of the pre-shared key.</td>
</tr>
</tbody>
</table>

**Usage**
When the system is configured to use ISAKMP-type crypto maps for establishing IPSec tunnels, this command is used to indicate that the policy will be authenticated through the use of the pre-shared key configured in the ISAKMP crypto map.

**Example**
The following command sets policy authentication mode to use a pre-shared key:

```
authentication preshared-key
```
encryption

Configures the encryption protocol to use to protect subsequent IKE SA negotiations.

**Product**

PDSN
HA
GGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > ISAKMP Configuration

`configure > context context_name > isakmp policy policy_number`

**Syntax**

```
encryption { 3des-cbc | aes-cbc-128 | aes-cbc-256 | des-cbc }
[ default | no ] encryption
```

---

**default encryption**

Restores the default setting of this parameter.

**no encryption**

Removes a previously configured encryption type.

**3des-cbc**

Specifies that the encryption protocol is Triple Data Encryption Standard (3DES) in chain block (CBC) mode.

**aes-cbc-128**

Specifies that the encryption protocol is Advanced Encryption Standard (AES) in CBC mode with a 128-bit key.

**aes-cbc-256**

Specifies that the encryption protocol is Advanced Encryption Standard (AES) in CBC mode with a 256-bit key.

**des-cbc**

Specifies that the encryption protocol is DES in CBC mode. This is the default setting.

**Usage**

Once the D-H exchange between the system and the security gateway has been successfully completed, subsequent IKE SA negotiations will be protected using the protocol specified by this command.

**Example**

The following command sets the IKE encryption method to 3des-cbc:

```
encryption 3des-cbc
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
**group**

Configures the Oakely group (also known as the Diffie-Hellman [D-H] group) in which the D-H exchange occurs.

**Product**

PDSN
HA
GGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > ISAKMP Configuration

cfgure > context context_name > isakmp policy policy_number

**Syntax**

```
group { 1 | 2 | 5 }
[ default | no ] group
```

---

**default group**

Restores the default setting of this parameter.

---

**no group**

Removes a previously configured group.

---

{ 1 | 2 | 5 }

Default: 1

Specifies the number of the Oakley group. The following groups are allowed:

- **1**: Enables Oakley Group 1 using a 768-bit modp as defined in RFC 2409.
- **2**: Enables Oakley Group 2, using a 1024-bit modp as defined in RFC 2409.
- **5**: Enables Oakley Group 5, using a 1536-bit modp as defined in RFC 3526.

---

**Usage**

Specifies the Oakley group that determine the length of the base prime numbers that are used during the key exchange process.

**Example**

The following command sets the group to 5 which specifies 1536-bit base prime numbers:

```
group 5
```
hash

Confirms the IKE hash protocol to use during IKE SA negotiations.

Product
- PDSN
- HA
- GGSN

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration > Context Configuration > ISAKMP Configuration
- configure > context context_name > isakmp policy policy_number

Syntax
hash { md5 | sha1 }
[ default | no ] hash

default
Restores the default setting of this parameter.

no
Removes a previously configured hash algorithm.

md5
Specifies that the hash protocol is Message Digest 5 truncated to 96 bits.

sha1
Specifies that the hash protocol is Secure Hash Algorithm-1 truncated to 96 bits. This is the default setting for this command.

Usage
Use this command to configure the hash algorithm used during key negotiation.

Example
Set the hash algorithm to Message-Digest 5 by entering the following command:

hash md5
**lifetime**

Configures the lifetime of the IKE Security Association (SA).

**Product**
- PDSN
- HA
- GGSN

**Privilege**
- Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ISAKMP Configuration

```bash
configure > context context_name > isakmp policy policy_number
```

**Syntax**

```bash
lifetime seconds
```

**default lifetime**

```bash
default lifetime
```

**Usage**
Use this command to set the time that an ISAKMP SA will be valid. The lifetime is negotiated with the peer and the lowest configured lifetime duration is used.

**Example**
The following command sets the SA lifetime to 100 seconds:

```bash
lifetime 100
```
Chapter 183
IuPS Service Configuration Mode Commands

The IuPS Service configuration mode is used to define properties for the IuPS service which controls the Iu-PS interface connections to Radio Network Controllers (RNCs) of the UMTS Terrestrial Radio Access Network (UTRAN).

Mode

Exec > Global Configuration > Context Configuration > IuPS Service Configuration

configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

⚠️ **Important**: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**access-protocol**

This command configures the access protocol parameters for the IuPS service.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```bash
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```bash
access-protocol sccp-network sccp_net_id

no access-protocol sccp-network
```

**Usage**

Use this command to configure access protocol parameters for the current IuPS service.

**Example**

The following command specifies that the current Iu-PS service should use SCCP 1:

```bash
access-protocol sccp-network 1
```
associate

This command associates a configured DSCP marking template with this IuPS service and associated Iu interface.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
associate dscp-template downlink dscp_template_name

no associate dscp-template downlink
```

- **no**
  - Removes a previously configured association.

- **dscp_template_name**
  - Specifies a DSCP marking template that was previously configured with the commands in the DSCP Template configuration mode.
  - `dscp_template_name` - Enter an alphanumeric string of 1 to 64 characters, including dots (.), dashes (-), and forward slashes (/), to identify a unique instance of a DSCP marking template.

**Usage**

Use this command to associate a specific DSCP marking template with this IuPS service and associated Iu interface. The DSCP template provides a mechanism for differentiated services code point (DSCP) marking of control packets and signaling messages at the SGSN’s M3UA level on the Iu interface. This DSCP marking enables the SGSN to perform classifying and managing of network traffic and to determine quality of service (QoS) for the interface to the IP network.

**Example**

The following command associates a DSCP marking template named `dscptempl1` with the Iu interface:

```
associate dscp-template downlink dscptempl1
```

The following command disassociates a previously associated DSCP marking template named `template4` with this IuPS service configuration:

```
no associate dscp-template downlink
```
blacklist-timeout-gtpu-bind-addresses

This command specifies the time period that a GTP-U bind address (loopback address) will not be used (is blacklisted) in RAB-Assignment requests after a RAB assignment request, with that GTP-U bind address, has been rejected by an RNC with the cause - Unspecified Error. This is a failure at the RNC’s GTP-U IP interface.

Product

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration
configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax

blacklist-timeout-gtpu-bind-addresses seconds

default blacklist-timeout-gtpu-bind-addresses

default
Resets the blacklist time to 60 seconds.

seconds
Number of seconds that the GTP-U bind (loopback) address will not be used in a RAB-Assignment request.
seconds: Must be an integer from 1 to 1800.

Usage
Use this command to configure the blacklist period.

Example
The following command specifies a 15 minutes (460 seconds) blacklist period.

blacklist-timeout-gtpu-bind-addresses 460
empty-cr

This command allows the operator to determine how empty Connection Request messages will be handled.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

**Syntax**

empty-cr procedure reject

[ default | no ] empty-cr procedure reject

```
default | no
```

Using either `default` or `no` with the command disables the rejection function and returns the system to the default behavior, which is to ignore receipt of the empty CRs.

**Usage**

Use this command to enable/disable the procedure for handling empty (not containing dataparameters) Connection Request (CR) messages.

This feature can be used in the following scenario: During 4G to 3G handovers, some Connection Requests from mobile subscribers might be ignored by the SGSN, even though their UE would display that the WCDMA was available. The RNC would send an SCCP Connection Request (CR) over the Iu interface to the SGSN. Normally, this message contains a RANAP message and GMM, but according to 3GPP and ITU Q.713 standards, it is permissible to send an SCCP CR without any data parameters. In such a situation, normally the SGSN would ignore these SCCP CR messages, because without these data parameters the SGSN would be unable to derive the DeMux key which is the basis for determining the Session Manager instance to be used for a subscriber. Using this feature allows the SGSN to send a Reject to the mobile subscriber when an “empty” SCCP CR is sent from their UE.

Fields have been added to the output of the following CLI show commands to track the receipt and rejection of Connect Request (CR) messages:

- `show gmm-sm statistics`
- `show gmm-sm statistics verbose`

**Example**

The following command enables the empty CR handling procedure:

```
empty-cr procedure reject
```

The following command disables the empty CR handling procedure:
default empty-cr procedure reject
end

Exits the current configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the previous configuration mode, the context configuration mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Return to the context configuration mode.
force-authenticate consecutive-security-failure

Disable/enable authentication when the MS/UE security fails and configures the procedures and frequency for authentication

Product
SGSN

Privilege
Security Administrator, Administrator, Operator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration
configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax

force-authenticate consecutive-security-failure { inter-sgsn-rau | local-messages count frequency | non-local-messages count frequency }

[ default | no ] force-authenticate consecutive-security-failure { inter-sgsn-rau | local-messages | non-local-messages }

default

Resets the values to defaults. Forced authentication is enabled for all the types of event procedures with the default values for determining frequency for authentication.

no

Disables the specified authentication configuration.

inter-sgsn-rau

Default: enabled
Enables/disables authentication for inter-SGSN RAU.
The SGSN does not remember previous inter-SGSN-RAU failures for a P-TMSI/RAI because the SGSN clears all contexts on the occurrence of an inter-SGSN-RAU security failure. So the next inter-SGSN-RAU can only be authenticated forcefully if it comes before the previous context is cleared. This type of forced authentication is enabled by default because this type of failure is fairly common.

local-messages count frequency

Default: 5
Enables/disables authentication for local messages (such as local RAUs, Service Requests, Detach Requests, etc). Consecutive security failures is fairly rare for local messages so the default count frequency is fairly high, 5. Setting the count frequency enables the feature and sets the number of consecutive local message security failures that must occur prior to authentication being forced.

frequency: Enter an integer from 1 to 10.
**force-authenticate consecutive-security-failure**

`non-local-messages count count`

Default: 1

Enables/disables authentication for non-local messages (such as inter-RAT RAUs and all types of attaches). Consecutive security failures for non-local messages is fairly common so the default count frequency is 1. Setting the count frequency enables the feature and sets the number of consecutive non-local message security failures that must occur prior to authentication being forced.

*frequency:* Enter an integer from 1 to 10.

**Usage**

GMM authentication is optional for UMTS. When GMM authentication is skipped, the SGSN and the MS continue to re-use the latest keys exchanged during the most recent GMM authentication procedure. This can result in the SGSN and the MS going out of sync with the CK and IK currently in use. If a mismatch occurs when the MS continues to use the correct parameters (e.g., cksn or P-TMSI signature) in the next Iu and if the SGSN skips authentication on the Iu, then, usually, the security mode will timeout or be rejected because the MS will not be able to decipher or perform an integrity check on the network messages. This scenario results in a lot of useless signaling in the network. This command allows the operator to enable a forced GMM authentication that will either resolve this type of problem or avoid it. As well, the operator can configure a frequency of authentication that best meets their needs.

**Example**

The following command enables forced authentication after every 3rd local message security failure:

```
force-authenticate consecutive-security-failure local-messages count 3
```
gtpu

This command configures parameters for the GTP user (GTP-U) dataplane.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```bash
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```bash
gtpu { bind ip_addr | echo-interval seconds | max-retransmissions number | retransmission-timeout seconds | sync-echo-with-peer }
no gtpu { bind address ip_addr | echo-interval | max-retransmissions | retransmission-timeout | sync-echo-with-peer }
default gtpu { echo-interval | max-retransmissions | retransmission-timeout | sync-echo-with-peer }

```

---

**no**

Removes the configured parameter value.

---

**default**

Sets the specified parameter to its default setting.

---

**bind address ip_addr**

This command binds the specified IP address to the Iu-PS GTP-U endpoint.

*ip_addr*: Must be an IP v4 IP address in dotted decimal notation.

---

**echo-interval seconds**

Default: 60

Configures the rate, in seconds, at which GTP-U echo packets are sent to the UTRAN over the Iu-PS interface.

*seconds*: Must be an integer from 60 through 3600.

---

**max-retransmissions number**

Default: 5

Configures the maximum number of transmission retries for GTP-U packets.

*number*: Must be an integer from 0 through 15.
retransmission-timeout seconds

Default: 5
Configures the retransmission timeout for GTPU packets in seconds.
seconds: Must be an integer from 1 through 20.

sync-echo-with-peer

This keyword is applicable to the SGSN only.
This keyword enables the SGSN to synchronize path management procedures with the peer after a GTP service restart recovery.
After GTP service recovery, the SGSN restarts the timers for GTP echo transmission, hence a drift in echo request transmission time (from the pre-recovery time) can occur causing the SGSN to be out of sync with the peer. By using this keyword, when the SGSN receives the first Echo Request (GTPC or GTPU) from the peer after the GTP service restart, in addition to replying with an ECHO Response, the SGSN transmits an ECHO Request to the peer and the SGSN restarts the timers associated with the path management procedures. This causes the path management procedure at SGSN to synchronize with the peer node.
Default: Enabled

Usage

Use this command to configure GTP-U parameters for the Iu-PS interface.

Example

The following command binds the IP address 192.168.0.10 to the Iu-PS interface for communication with the UTRAN:

```
gtpu bind address 192.168.0.10
```
inter-rnc-procedures

This command enables the processing of SRNS relocation when the source RNC is behaving as the target RNC.

**Product**

SGSN

Insert product and tag this paragraph appropriately.

**Mode**

Exec > Global Configuration > Context Configuration > IuPS Service Configuration

configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
[no] inter-rnc-procedures source-rnc-as-target-rnc
```

Configures the SGSN to complete SRNS relocation when the source RNC is behaving as the target RNC. For example, in the case of a Femtocell-to-Femtocell handoff - the femtocell gateway may act both as the source and target RNC to the femtocells, although from the SGSN’s perspective it is the same RNC.

```
no
```

Disables SRNS relocation when the source RNC is behaving as the target RNC. This is the default setting.

**Usage**

Use this command to enable/disable SRNS relocation when the source RNC is behaving as the target RNC.

**Example**

Enter this command to enable SRNS relocation for those scenarios where the source RNC is behaving as the target RNC:

```
inter-rnc-procedures source-rnc-as-target-rnc
```
iu-hold-connection

Defines the type and duration of the Iu hold connection.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
iu-hold-connection [ always | requested-by-ms ] [ hold-time seconds ]
default iu-hold-connection
no iu-hold-connection
```

---

**default**

 Resets the Iu hold connection parameters to requested-by-ms and 100 second duration.

---

**no**

 Removes the configuration information for the specified Iu hold connection parameter.

---

**always**

 Specifies that there is always to be an Iu hold connection procedure.

---

**requested-by-ms**

 Specifies that there is only an Iu hold connection procedure if requested by the MS/UE. This is the default setting for Iu-hold-connection.

---

**hold-time time**

 This variable configures the interval (in seconds) that the SGSN holds the Iu connection.

 | time: must be an integer from 1 to 3600. 
 | time: must be an integer from 10 to 3600.

**Important:** It is recommended to use a minimum value of “10” seconds. If a value less than “10” seconds is used, more collisions may be observed. If the minimum value of “1” is set, after a re-load, INTRA-RAU (with unknown ptmsi, old-rai known) will be released in “1” second if the Identity Rsp does not come within “1” second.

Default is 100.
Usage
Define the amount of time the Iu connection will be held open.

Example
Instruct the SGSN to hold the Iu connection open for 120 seconds

    iu-hold-connection always hold-time 120
**Important:** This command has been deprecated and is no longer available.

**Product**
SGSN

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```
**iu-release-complete-timeout**

Configures the SGSN’s timer for waiting for an Iu Release Complete message from the RNC.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```plaintext
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```plaintext
iu-release-complete-timeout time
```

**default iu-release-complete-timeout**

- **default**
  - Resets the timer to its default setting.

- **time**
  - This variable defines the amount of time (in seconds) that the SGSN waits to receive an ‘Iu Release Complete’ message from the RNC.
  - Default: 10.
  - `time`: Must be an integer from 1 to 60.

**Usage**
Configure the number of seconds that the SGSN waits to receive the Iu Release Complete message.

**Example**

Set the SGSN to wait 20 seconds for Iu-Release-Complete:

```plaintext
iu-release-complete-timeout 20
```
loss-of-radio-coverage ranap-cause

This command sets the detection cause included in the Iu Release message. This command is unique to releases 9.0 and higher.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration
configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

**Syntax**

```
loss-or-radio-coverage ranap-cause cause_number

default loss-of-radio-coverage ranap-cause
```

**Usage**

By defining a cause code, the SGSN knows to detect the LORC state of the mobile from Iu Release messages it receives for the subscriber. This configuration also instructs the SGSN to include the defined cause code for the LORC state in the IE portion of various messages sent to the GGSN and optionally the peer SGSN. This command is one of the two commands required to enable the SGSN to work with the GGSN and, optionally the peer SGSN, to implement the Overcharging Protection feature (see the SGSN Overview in the SGSN Administration Guide for feature details. The other command needed to implement the Overcharging Protection feature is the `gtp private extension` command explained in the SGSN APN Policy Configuration Mode chapter of the Command Line Interface Reference.

**Example**

Use the following command to set the cause code to indicate that there are no radio resources available in the target cell, cause 53.

```
loss-or-radio-coverage ranap-cause 53
```
mbms

This command is in development for future use so the command and keywords that you might see are not currently supported.
network-sharing cs-ps-coordination

Enables/disables the SGSN service to perform a CS-PS coordination check.

**Important:** With the release of 15.0, both 2G and 3G MOCN functionality is license controlled and the license is required to use all previously available network sharing SGSN configuration commands. For additional information, contact your Cisco Account Representative.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IuPS Service Configuration

configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

**Syntax**

```plaintext
network-sharing cs-ps-coordination [ homer | roamer ]

default network-sharing cs-ps-coordination

no network-sharing cs-ps-coordination
```

**Usage**

Use this command to facilitate the network sharing functionality. With this command, the SGSN can be instructed to perform a check to determine if CS-PS coordination is needed.

3GPP TS 25.231 section 4.2.5 describes the functionality of the SGSN to handle CS-PS (circuit-switching/packet-switching) coordination for attached networks not having a Gs-interface. In compliance with the standard, the SGSN rejects an Attach in a MOCN configuration with cause 'CS-PS coordination
required', after learning the IMSI, to facilitate the RNC choosing the same operator for both CS and PS domains.

**Example**

Use the following syntax to disable the CS-PS coordination check:

```
no network-sharing cs-ps-coordination
```

Use the following command to enable the CS-PS coordination check only for UEs from outside the home network:

```
no network-sharing cs-ps-coordination roamer
```
network-sharing failure-code

Configure the reject cause code to included in network-sharing Reject messages.

Important: With the release of 15.0, both 2G and 3G MOCN functionality is now license controlled and the license is required to use all previously available network sharing SGSN configuration commands. For additional information, contact your Cisco Account Representative.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration
configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax

network-sharing failure failure_code

default network-sharing failure

default

Resets the SGSN service to use the default cause code,14 (GPRS services not allowed in this PLMN).

failure_code

Enter one of the GMM failure cause codes listed below (from section 10.5.5.14 of the 3GPP TS 124.008 v7.2.0 R7):

- 2 - IMSI unknown in HLR
- 3 - Illegal MS
- 6 - Illegal ME
- 7 - GPRS services not allowed
- 8 - GPRS services and non-GPRS services not allowed
- 9 - MSID cannot be derived by the network
- 10 - Implicitly detached
- 11 - PLMN not allowed
- 12 - Location Area not allowed
- 13 - Roaming not allowed in this location area
- 14 - GPRS services not allowed in this PLMN
- 15 - No Suitable Cells In Location Area
• 16 - MSC temporarily not reachable
• 17 - Network failure
• 20 - MAC failure
• 21 - Synch failure
• 22 - Congestion
• 23 - GSM authentication unacceptable
• 40 - No PDP context activated
• 48 to 63 - retry upon entry into a new cell
• 95 - Semantically incorrect message
• 96 - Invalid mandatory information
• 97 - Message type non-existent or not implemented
• 98 - Message type not compatible with state
• 99 - Information element non-existent or not implemented
• 100 - Conditional IE error
• 101 - Message not compatible with the protocol state
• 111 - Protocol error, unspecified

Usage

Use this command to determine which failure code will be included in Reject messages sent by the SGSN when there is a network-sharing failure.

Example

Use the following syntax to indicate that roaming is not allowed (# 13) as the cause for the network-sharing failure:

```
network-sharing failure 13
```
network-sharing non-shared

This command allows non-shared area access when network-sharing is enabled.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
network-sharing non-shared

[ default | no ] network-sharing non-shared
```

```
default

Resets the default to disable non-shared access.
```

**Usage**
When non-shared area access is enabled, the SGSN sends the selected-plmn value in Attach/RAU accept if LAI is having one of the selected-plmn and "selected-plmn" or "Redirect-attempt flag" IEs are not included in the request message.

**Example**
Disable non-shared area access if it has already been configured:

```
no network-sharing non-shared
```
plmn

Configures the PLMN (public land mobile network) related parameters for the IuPS service. This command is applicable to releases 8.1 and higher.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax

plmn id mcc mcc_num mnc mnc_num [ network-sharing common-plmn mcc mcc_num mnc mnc_num [ plmn-list mcc mcc_num mnc mnc_num [ mcc mcc_num mnc mnc_num+ ] ] ]

no plmn id

no

Removes the PLMN ID from the configuration.

id

Creates a PLMN configuration instance based on the PLMN ID (comprised of the MCC and MNC). In accordance with TS 25.413, the SGSN supports up to 32 PLMN configurations for shared networks.

mcc mcc_num

Specifies the mobile country code (MCC) portion of the PLMN’s identifier.

mcc_num: The PLMN MCC identifier and can be configured to any integer value between 100 and 999.

mnc mnc_num

Specifies the mobile network code (MNC) portion of the PLMN’s identifier.

mnc_num: The PLMN MNC identifier and can be configured to any 2-digit or 3-digit value between 00 and 999.

network-sharing common-plmn mcc mcc_num mnc mnc_num

When network sharing is employed, this set of keywords is required to define the PLMN Id of the common PLMN. The common PLMN is usually not the same as the local PLMN.

Important: With the release of 15.0, both 2G and 3G MOCN functionality is now license controlled and the license is required to use all previously available network sharing SGSN configuration commands. For additional information, contact your Cisco Account Representative.
**plmn-list mcc mcc_num mnc mnc_num**

When network sharing is employed and more than two PLMNs are available, then use the `plmn-list` keyword to begin a list of all additional PLMNs.

---

**Usage**

Use this command to configure the PLMN associated with the SGSN. There can only be one PLMN associated with an SGSN unless one of the following features is enabled and configured: network sharing or multiple PLMN.

For network sharing, use of the `network-sharing` keywords make it possible to identify more than one PLMN. Including the PLMN identified initially. None have precedence. They are all treated equally but they must each be unique. In a MOCN configuration, the PLMN list will not be used as there would only be one local PLMN.

For multiple PLMN support, the SGSN can support up to 8 Iu-PS configurations for PLMNs. These Iu-PS service configurations must be associated with the SGSN via the `ran-protocol` command in the SGSN Service configuration mode.

**Example**

Use the following command to identify a PLMN by the MCC 313 and MNC 23 and instruct the SGSN to perform network sharing with a single common PLMN identified by MCC 404 and MNC 123:

```
plmn id mcc 313 mnc 23 network-sharing common-plmn mcc 404 mnc 123
```
rab-assignment-response-timeout

Configures the RAB assignment timer.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

Syntax

rab-assignment-response-timeout time

default rab-assignment-response-timeout

default
Resets the timer to its default setting.

time
This variable configures the amount of time (in seconds) that the SGSN waits to receive a RAB assignment from the RNC.
time: must be an integer from 1 to 60.
Default: 8.

Usage
This command defines time the SGSN waits for the completion of the RAB assignment procedure.

Example
Change the timer setting to 11 seconds.

rab-assignment-response-timeout 11
radio-network-controller

This command creates an instance of an RNC configuration to associate with the IuPS service for the SGSN. This command is only available in release 8.0; use the rnc command for releases 8.1 and higher.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax

radio-network-controller id rnc_id mcc mcc_num mnc mnc_num

no radio-network-controller id rnc_id mcc mcc_num mnc mnc_num

no

Removes the configuration information for the specified RNC.

id rnc_id

Define the instance number of the RNC configuration.

rnc_id: Must be an integer from 0 to 4095.

mcc mcc_num

Specifies the mobile country code (MCC).

mcc_num: Must be an integer between 100 and 999.

mnc mnc_num

Specifies the mobile network code (MNC).

mnc_num: Must be an integer between 00 and 999.

Usage

Use this command to configure information for the IuPS service to use to contact specific RNCs. This command also provides access to the RNC configuration mode.

Example

The following command creates or accesses RNC configuration instance #1 with MCC of 131 and MNC of 22:

radio-network-controller id 1 mcc 131 mnc 22
relocation.alloc.timeout

This command defines the amount of time the SGSN waits for a Relocation Request message.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration
configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax

relocation.alloc.timeout  timeout_value

default relocation.alloc.timeout

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resets the configuration to a 5 second wait time.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>timeout_value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time in seconds that the SGSN waits to receive a Relocation Request message.</td>
</tr>
<tr>
<td>timeout_value: Must be an integer from 1 to 60.</td>
</tr>
<tr>
<td>Default: 5 seconds.</td>
</tr>
</tbody>
</table>

Usage

Use this command to configure the number of seconds the SGSN will wait for a Relocation Request message to be received. This timeout needs to be set with sufficient time so that SRNS procedure aborts can be avoided if the peer fails to respond in a timely fashion in the case of a hard handoff.

Example

The following command sets the wait time to 10 seconds.

relocation.alloc.timeout 10
relocation-complete-timeout

This command specifies the maximum time for the SGSN to wait for a Relocation Completion from the core network.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
relocation-complete-timeout timeout_value
```

```
default relocation-complete-timeout
```

```
default
  Resets the configuration to a 5 second wait time.
```

```
timeout_value
  Time in seconds that the SGSN waits for relocation to be completed.
  timeout_value: Must be an integer from 1 to 60.
  Default: 5 seconds.
```

**Usage**

Use this command to configure the number of seconds the SGSN will wait for a relocation to be completed. This timeout needs to be set with sufficient time so that SRNS procedure aborts can be avoided if the peer fails to respond in a timely fashion in the case of a hard handoff.

**Example**

The following command sets the wait time for 10 seconds.

```
relocation-complete-timeout 10
```
reset

Defines the configuration specific to the RESET procedure.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
reset { ack-timeout time | guard-timeout time | max-retransmissions retries | sgsn-initiated }
```

```
default reset { ack-timeout | guard-timeout | max-retransmissions | sgsn-initiated }
```

```
no reset sgsn-initiated
```

---

**default**

Returns to the default settings for the Reset procedure.

**no**

Removes the SGSN-initiated reset procedure from the configuration.

**ack-timeout** *time*

Configures the interval (in seconds) for which the SGSN waits for RESET-ACK from the RNC.

*time* must be an integer from 5 to 60.
Default: 20.

**guard-timeout**

Configures the interval (in seconds) after which the SGSN sends RESET-ACK to the RNC.

*time* must be an integer from 5 to 60.
Default: 10

**max-retransmissions**

Configures maximum retries for RESET message.

*retries* must be an integer from 0 to 2.
Default: 1.

**sgsn-initiated**

Enables SGSN initiated RESET procedure.
Default: disabled.

Usage

Configures the parameters that determine a RESET.

Example

Use the following to have the SGSN initiate the RESET procedure:

```
reset sgsn-initiated
```
**rnc**

This command creates or accesses an instance of an RNC (radio network controller) configuration.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IuPS Service Configuration

configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

- **rnc id rnc_id**
- **no rnc id rnc_id**

**Usage**

Use this command to configure information for the IuPS service to use to contact specific RNCs. This command also provides access to the RNC configuration mode.

**Example**

The following command creates an RNC configuration instance 3442:

```
rnc id 3442
```
security-mode-complete-timeout

This command configures the security mode timer.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

`configure > context context_name > iups-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
security-mode-complete-timeout time

default security-mode-complete-timeout
```

- **default**

  Resets the timer configuration to the default settings.

- **time**

  Configures the interval (in seconds) the SGSN waits for the security mode from the MS to complete.
  
  *time* must be an integer from 1 to 60.
  
  Default is 5

**Usage**

Use this command to configure the timer that determines how long the SGSN waits for a Security Mode Complete message from the MS (mobile station).

**Example**

Instruct the SGSN to wait 7 seconds:

```
security-mode-complete-timeout 7
```
service-request-follow-on

Instructs the SGSN not to release an Iu immediately.

Product
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration
configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax

[ default | no ] service-request-follow-on

---

**default**

Resets the configuration to the default, this function is enabled.

---

**no**

Disables this function so that Iu is released without waiting for the Iu-Hold-Timer to expire.

---

Usage

For an Iu established as the result of a Service Request (signaling), the SGSN, by default, waits for the Iu-Hold-Timer to expire.

Use this command with the ‘no’ prefix to disable this function.

Use this command with the ‘default’ prefix or without any prefix if the configuration was modified previously with by no service-request-follow-on.

Example

Disable this function to wait for the Iu-Hold-Timer to expire:

no service-request-follow-on

Enable this function if it was previously disabled:

service-request-follow-on
srns-context-response-timeout

This command configures the SGSN context response timer.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax

srns-context-response-timeout time

default srns-context-response-timeout

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resets the timer configuration to the default setting.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configures the interval (in seconds) for which the SGSN waits for an SRNS Context Request message.</td>
</tr>
</tbody>
</table>

| time must be an integer from 1 to 60. |
| Default: 5. |

Usage

Configures the time to wait before the SGSN sends a response to the SRNS Context-Request message.

Example

Configure the SGSN to wait 7 seconds for an SRNS Context-Request response:

srns-context-response-timeout 7
tigoc-timeout

This command configures the TigOc interval.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax

tigoc-timeout time
default tigoc-timeout

default

Resets the timer configuration to the default setting.

time

This command sets the time in seconds.

time: Must be an integer from 1 to 60.
Default: 5.

Usage

Define the amount of time that the SGSN ignores any overload messages for TigOc interval after receiving one overload message from the RNC.

Example

Use the following command to change the default TigOc interval to 4 seconds:

tigoc-timeout 4
tintc-timeout

This command configures the TinTc interval..

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax

tintc-timeout time

default tintc-timeout

default

Resets the timer configuration to the default setting.

time

Set the number of seconds to wait.

time: Must be an integer from 1 to 60.
Default: 30.

Usage

Define 4 as the number of seconds that the SGSN waits before decrementing (by one) the traffic level of the RNC.

Example

tintc-timeout 4
Chapter 184
LAC Service Configuration Mode Commands

The LAC Service Configuration Mode is used to create and manage L2TP services within contexts on the system. L2TP Access Concentrator (LAC) services facilitate tunneling to peer L2TP Network Servers (LNSs).

Mode

Exec > Global Configuration > Context Configuration > LAC Service Configuration

configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lac-service)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
allow

This command configure the system to allow different attributes in the LAC Hostname Attribute Value Pair (AVP) and Called-Number AVP for L2TP messages exchanged between LAC and LNS.

Product
GGSN
PDSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LAC Service Configuration
configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lac-service)#

Syntax

allow { aaa-assigned-hostname | called-number value apn | calling-number value imsi }

default allow { aaa-assigned-hostname | called-number value apn }

no allow { aaa-assigned-hostname | called-number value apn | calling-number }

no

Disable the configured attribute and returns to the behavior that uses the LAC-Service name as the HostName AVP.

aaa-assigned-hostname

When enabled if AAA assigns a valid Tunnel-Client-Auth-ID attribute for the tunnel, it is used as the HostName AVP in the L2TP tunnel setup message.
This keyword works in conjunction with the local-hostname hostname keyword applied via the tunnel l2tp command in APN Configuration mode.
When Tunnel parameters are not received from the RADIUS Server, Tunnel parameters configured in an APN are considered for the LNS peer selection. When APN configuration is selected, the local-hostname configured with the tunnel l2tp command in the APN for the LNS peer will be used as an LAC Hostname.

called-number value apn

Configures the system to send the APN name in the Called-Number AVP as a part of ICRQ message sent to the LNS. If this keyword is not configured, Called-Number AVP will not be included in ICRQ message sent to the LNS.
allow calling-number value imsi  

Configures the system to allow the IMSI to be used as Calling-Number as a part of ICRQ message sent to the LNS. If this keyword is not configured, then MSISDN will be used as Calling-Number.

**Important:** This is a customer-specific keyword available for PDSN. Please contact your local Cisco sales representative for more information.

**Usage**

Use this command to configure the attribute for the HostName AVP for L2TP messages exchanged between LAC and LNS. LAC Hostname will be different for the subscribers corresponding to the different corporate APNs. In the absence of a AAA assigned HostName, the LAC-Service name is used as HostName. By default the LAC-Service name is used as the HostName AVP.

**Example**

The following command enables the use of the value of Tunnel-Client-Auth-ID attribute for the HostName AVP:

```
allow aaa-assigned-hostname
```

Use the following command to reset the behavior so that the LAC-Service uses the LAC-Service name as the HostName AVP:

```
no allow aaa-assigned-hostname
```
bind

This command assigns a local end point address to the LAC service in the current context.

Product
GGSN
PDSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LAC Service Configuration
configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lac-service)#

Syntax
bind ip_address [ max-subscribers ]
no bind ip_address

Usage
Use this command to bind a local end point IP address to the LAC service.

Example
The following command binds the local end point IP address 10.10.10.100 to the LAC service in the current context:

    bind 10.10.10.100

The following command removes the binding of the local end point to the LAC service:

    no bind
**data sequence-number**

Enables data sequence numbering for sessions that use the current LAC service. Data sequence numbering is enabled by default.

**Product**
- GGSN
- PDSN
- P-GW
- SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LAC Service Configuration

`configure > context context_name > lac-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lac-service)#
```

**Syntax**

```
[ no ] data sequence-number
```

- **no**
  Disables data sequence numbering for sessions.

**Usage**

An L2TP data packet header has an optional data sequence numbers field. The data sequence number may be used to ensure ordered delivery of data packets. This command is used to re-enable or disable the use of the data sequence numbers for data packets.

**Example**

Use the following command to disable the use of data sequence numbering:

```
no data sequence-number
```

Use the following command to re-enable data sequence numbering:

```
data sequence-number
```
**default**

This command sets the specified LAC service parameter to its default value or setting.

**Product**

- GGSN
- PDSN
- P-GW
- SAEGW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > LAC Service Configuration

```
configure > context context_name > lac-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lac-service)#
```

**Syntax**

```
default { data sequence-number | hide-attributes | keepalive-interval | load-balancing | local-receive-window | max-retransmission | max-session-per-tunnel | max-tunnel-challenge-length | max-tunnels | proxy-lcp-authentication | retransmission-timeout-first | retransmission-timeout-max | trap all | tunnel-authentication }
```

---

**data sequence-number**

Enables data sequence numbering for sessions.

**hide-attributes**

Disables hiding attributes in control messages sent from the LAC to the LNS.

**keepalive-interval**

Sets the interval for send L2TP Hello keepalive if there is no control or data transactions to the default value of 60 seconds.

**load-balancing**

Sets the load balancing algorithm to be used when many LNS peers have been configured to the default of round robin.

**local-receive-window**

Sets the window size to be used for the local side for the reliable control transport to the default of 16.

**max-retransmission**

Sets the maximum number of retransmissions to the default of 5.
max-session-per-tunnel
Sets the maximum number of sessions per tunnel at any point in time to the default of 512.

max-tunnel-challenge-length
Sets the maximum length of the tunnel challenge to the default of 16 bytes.

max-tunnels
Sets the maximum number of tunnels for this service to the default of 32000.

proxy-lcp-authentication
Sets sending of proxy LCP authentication parameters to the LNS to the default state of enabled.

retransmission-timeout-first
Sets the first retransmit interval to the default of 1 second.

retransmission-timeout-max
Sets the maximum retransmit interval to the default of 8 seconds.

tunnel-authentication
Sets tunnel authentication to the default state of enabled.

Usage
Use the default command to set LAC service parameters to their default states.

Example
Use the following command to set the keep alive interval to the default value of 60 seconds:

    default
    keepalive-interval

Use the following command to set the maximum number of sessions per tunnel to the default value of 512:

    default max-session-per-tunnel
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
end

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
hide-attributes

Enables hiding certain attributes (such as proxy-auth-name and proxy-auth-rsp) in control messages sent from the LAC to the LNS. The LAC hides such attributes only if tunnel authentication is enabled between the LAC and the LNS.

**Product**
- GGSN
- PDSN
- P-GW
- SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LAC Service Configuration

```
configure > context context_name > lac-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lac-service)#
```

**Syntax**
```
[ no ] hide-attributes
```  

```
no
```

Disable hiding attributes.

**Usage**
Use this command to hide certain attributes from control messages when tunnel authentication is enabled between the LAC and the LNS.

**Example**
The following command enables hiding attributes:

```
hide-attributes
```
keepalive-interval

This command specifies the amount of time to wait before sending a Hello keep alive message.

Product
GGSN
PDSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LAC Service Configuration
configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lac-service)#

Usage
Use this command to set the amount of time to wait before sending a Hello keep alive message or disable the generation of Hello keep alive messages completely. A keepalive mechanism is employed by L2TP in order to differentiate tunnel outages from extended periods of no control or data activity on a tunnel. This is accomplished by injecting Hello control messages after a specified period of time has elapsed since the last data or control message was received on a tunnel. As for any other control message, if the Hello message is not reliably delivered then the tunnel is declared down and is reset. The transport reset mechanism along with the injection of Hello messages ensures that a connectivity failure between the LNS and the LAC is detected at both ends of a tunnel.

Example
Use the following command to set the Hello keepalive message interval to 120 seconds:

    keepalive-interval 120

Use the following command to disable the generation of Hello keepalive messages:

    no keepalive-interval
no keepalive-interval
load-balancing

Configures how LNSs are selected for this LAC service.

Product
GGSN
PDSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LAC Service Configuration
configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lac-service)#

Syntax

load-balancing { balanced | prioritized | random }

<table>
<thead>
<tr>
<th>balanced</th>
</tr>
</thead>
<tbody>
<tr>
<td>LNS selection is made without regard to prioritization, but in a sequential order that balances the load across the total number of LNS nodes available.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>prioritized</th>
</tr>
</thead>
<tbody>
<tr>
<td>LNS selection is made based on the priority assigned in the Tunnel-Preference attribute. An example of this method is three LNS nodes, with preferences of 1, 2, and 3 respectively. In this example, the RADIUS server always tries the tunnel with a preference of 1 before using any of the other LNS nodes.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>random</th>
</tr>
</thead>
</table>
| Default: Enabled
LNS selection is random in order, wherein the RADIUS server does not use the Tunnel-Preference attribute in determining which LNS to select. |

Usage
Use this command to configure the load-balancing algorithm that defines how the LNS node is selected by the LAC when there are multiple peer LNSs configured in the LAC service.

Example
The following command sets the LAC service to connect to LNSs in a sequential order;

load-balancing balanced

The following command sets the LAC service to connect to LNSs according to the priority assigned through the Tunnel-Preference attribute:
load-balancing prioritized
local-receive-window

Specifies the number of control messages the remote peer LNS can send before waiting for an acknowledgement.

Product
GGSN
PDSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LAC Service Configuration

configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lac-service)#

Syntax

local-receive-window integer

integer
Default: 4
Specifies the number of control messages to send before waiting for an acknowledgement. The number can be configured to an integer from 1 to 256.

Usage
Use this command to set the size of the control message receive window being offered to the remote peer LNS. The remote peer LNS may send the specified number of control messages before it must wait for an acknowledgment.

Example
The following command sets the local receive window to 10 control messages:

local-receive-window 10
max-retransmission

Sets the maximum number of retransmissions of a control message to a peer before the tunnel and all sessions within it are cleared.

**Product**
- GGSN
- PDSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > LAC Service Configuration

```
configure > context context_name > lac-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-lac-service)#
```

**Syntax**

```
max-retransmission integer
```

- **integer**
  - Default: 5
  - Specifies the maximum number of retransmissions of a control message to a peer. This value must be an integer from 1 through 10.

**Usage**

Each tunnel maintains a queue of control messages to be transmitted to its peer. After a period of time passes without acknowledgement, a message is retransmitted. Each subsequent retransmission of a message employs an exponential backoff interval. For example; if the first retransmission occurs after 1 second, the next retransmission occurs after 2 seconds has elapsed, then the next after 4 seconds. If no peer response is detected after the number of retransmissions set by this command, the tunnel and all sessions within are cleared.

Use this command to set the maximum number of retransmissions that the LAC service sends before closing the tunnel and all sessions within it.

**Example**

The following command sets the maximum number of retransmissions of a control message to a peer to 7:

```
max-retransmissions 7
```
max-session-per-tunnel

Sets the maximum number of sessions that can be facilitated by a single a tunnel at any time.

**Product**
- GGSN
- PDSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LAC Service Configuration
configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lac-service)#
```

**Syntax**

```
max-sessions-per-tunnel integer
```

<table>
<thead>
<tr>
<th>integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 512</td>
</tr>
<tr>
<td>The maximum number of sessions expressed as an integer from 1 through 65535.</td>
</tr>
</tbody>
</table>

**Usage**
Use this command to set the maximum number of sessions you want to allow in a tunnel.

**Example**
The following command sets the maximum number of sessions in a tunnel to 5000:

```
max-sessions-per-tunnel 5000
```
max-tunnel-challenge-length

Sets the maximum length of the tunnel challenge in bytes. The challenge is used for tunnel authentication purposes during tunnel creation.

**Product**

GGSN
PDSN
P-GW
SAEGW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > LAC Service Configuration

```bash
configure > context context_name > lac-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-lac-service)#
```

**Syntax**

```
max-tunnel-challenge-length bytes
```

- `bytes`

  Default: 16

  Specifies the maximum length (in bytes of the tunnel challenge. This must be an integer from 4 through 32.

**Usage**

Use this command to set the maximum length (in bytes) for the tunnel challenge that is used during tunnel creation.

**Example**

The following command sets the maximum length of the tunnel challenge to 32 bytes:

```
max-tunnel-challenge-length 32
```
max-tunnels

The maximum number of tunnels that the current LAC service can support.

**Product**
- GGSN
- PDSN
- P-GW
- SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LAC Service Configuration

```config
configure > context context_name > lac-service service_name
```

Entering the above command sequence results in the following prompt:

```config
[context_name]host_name(config-lac-service)>
```

**Syntax**

```
max-tunnels integer
```

integer
Default: 32000
The maximum number of tunnels expressed as an integer from 1 through 32000.

**Usage**
Use this command to set the maximum number tunnels that this LAC service can support at any on time.

**Example**
Use the following command to set the maximum number of tunnels for the current LAC service to 20000:

```
max-tunnels 20000
```
peer-lns

Adds a peer LNS address for the current LAC service. Up to eight peer LNSs can be configured for each LAC service.

**Product**

GGSN  
PDSN  
P-GW  
SAEGW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > LAC Service Configuration  
`configure > context context_name > lac-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lac-service)#
```

**Syntax**

```
peer-lns ip_address [ encrypted ] secret secret [ crypto-map map_name { [ encrypted ] isakmp-secret secret } ] [ description text ] [ preference integer ]
```

```
no peer-lns ip_address
```

**Description**

```
no peer-lns ip_address
```

Deletes the peer LNS at the IP address specified by `ip_address`. **ip_address** must be entered in IPv4 dotted-decimal notation.

```
ip_address
```

The IP address of the peer LNS for the current LAC service. **ip_address** must be entered in IPv4 dotted-decimal notation.

```
[ encrypted ] secret secret
```

Designates the secret which is shared between the current LAC service and the peer LNS. **secret** must be an alphanumeric string of 1 through 256 characters that is case sensitive.

**encrypted secret secret**: Specifies that encryption should be used when communicating the secret with the peer LNS.

```
crypto-map map_name { [ encrypted ] isakmp-secret secret }
```

**map_name** is the name of a crypto map that has been configured in the current context. **map_name** must be an alphanumeric string of 1 through 127 characters that is case sensitive.

**isakmp-secret secret**: The pre-shared key for IKE. **secret** must be an alphanumeric string of 1 through 127 characters that is case sensitive.

**encrypted isakmp-secret secret**: The pre-shared key for IKE. Encryption must be used when sending the key. **secret** must be an alphanumeric string of 1 through 127 characters.
description text

Specifies the descriptive text to use to describe the specified peer LNS. text must be an alphanumeric string of 0 through 79 characters.

preference integer

This sets the priority of the peer LNS if multiple peer LNSs are configured. integer must be an integer from 1 through 128.

Usage

Use this command to add a peer LNS address for the current LAC service.

Example

The following command adds a peer LNS to the current LAC service with the IP address of 10.10.10.100, sets encryption on, specifies the shared secret to be 1b34nnf5d, and sets the preference to 3:

```
peer-lns 10.10.10.100 encrypted secret 1b34nnf5d preference 3
```

The following command removes the peer LNS with the IP address of 10.10.10.200 for the current LAC service:

```
no peer-lns 10.10.10.200
```
proxy-lcp-authentication

Enables and disables the sending of proxy LCP authentication parameters to the LNS.

**Product**
- GGSN
- PDSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LAC Service Configuration
configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lac-service)#
```

**Syntax**

```
[ no ] proxy-lcp-authentication
```

- **no**
  - Disables the sending of proxy LCP authentication parameters to the LNS.

- **proxy-lcp-authentication**
  - Default: Enabled
  - Enables the sending of proxy LCP authentication parameters to the LNS.

**Usage**

Use this feature in situations where the peer LNS does not understand the proxy LCP Auth AVPs that the system sends and does not do an LCP renegotiation and tears down the call.

**Example**

Use the following command to disable the sending of proxy LCP authentication parameters to the LNS:

```
no proxy-lcp-authentication
```

Use the following command to re-enable the sending of proxy LCP authentication parameters to the LNS:

```
proxy-lcp-authentication
```
retransmission-timeout-first

Each tunnel maintains a queue of control messages to transmit to its peer. After a period of time passes without acknowledgement, a message is retransmitted. This command sets the initial timeout for retransmission of control messages.

Product
- GGSN
- PDSN
- P-GW
- SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LAC Service Configuration
configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lac-service)#

Syntax

retransmission-timeout-first integer

integer
Default: 1
The amount of time to wait (in seconds) before sending the first control message retransmission. This must be an integer from 1 through 100.

Usage
Use this command to set the initial timeout before retransmitting control messages to the peer.

Example
The following command sets the initial retransmission timeout to 3 seconds:

retransmission-timeout-first 3
retransmission-timeout-max

Configures maximum amount of time between two retransmission of control messages.

**Product**
- GGSN
- PDSN
- P-GW
- SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LAC Service Configuration

```
configure > context context_name > lac-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lac-service)#
```

**Syntax**

```
retransmission-timeout-max integer
```

- `integer`
- Default: 8
- `integer` is the maximum time (in seconds) to wait before retransmitting control messages expressed as an integer from 1 through 100.

**Usage**

Use this command to set the maximum amount of time that can elapse before retransmitting control messages.

Each tunnel maintains a queue of control messages to transmit to its peer. After a period of time passes without acknowledgement, a message is retransmitted. Each subsequent retransmission of a message employs an exponential backoff interval.

**Example**

The following command sets the maximum retransmission time-out to 10 seconds:

```
retransmission-timeout-max 10
```
**single-port-mode**

This command enables/disables the L2TP LAC service always to use standard L2TP port 1701 as source port for all L2TP control and data packets originated from LAC node.

**Product**

GGSN
PDSN
P-GW
SAEGW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > LAC Service Configuration

`configure > context context_name > lac-service service_name`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-lac-service)#`

**Syntax**

```
[ default | no ] single-port-mode
```

- **default**
  
  Default: Enabled
  
  Sets this command to its default state of disabled. By default single source port configuration for L2TP LAC packets is disabled.

- **no**
  
  Disables the configured single source port configuration from this LAC service.

**Usage**

Use this command to enable or disable the single port mode for L2TP LAC service.

If this feature is enabled, then L2TP LAC service will always use standard L2TP port 1701 as source port for all L2TP control/data packets originated from LAC (instead of the default scheme in which each L2TPMgr uses a dynamic source port). L2TPMgr instance 1 will handle all L2TP calls for the service.

⚠️ **Caution:** Changing this configuration, while the service is already running, will cause restart of the service.

**Example**

The following command enables the LAC service to use port 1701 as source port for all L2TP control and data packets:

```
single-port-mode
```
snoop framed-ip-address

When enabled, this feature allows the LAC to detect IP Control Protocol (IPCP) packets exchanged between the mobile node and the LNS and extract the framed-ip-address assigned to the mobile node. The address will be reported in accounting start/stop messages and displayed for subscriber sessions.

Product
GGSN
PDSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LAC Service Configuration

configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lac-service)#

Syntax

[ default | no ] snoop framed-ip-address

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Disabled.</td>
</tr>
<tr>
<td>no</td>
<td>Disables the feature. Accounting start/stop will occur before the PPP session is established and the framed IP address field will be reported as 0.0.0.0.</td>
</tr>
</tbody>
</table>

Usage

This feature is available to address simple IP roaming scenarios. If this feature is enabled, the Accounting Start will be sent only after the framed-ip-address is detected. If the framed-ip-address is not detected within 16 seconds, an Accounting Start will be sent for the session with the 0.0.0.0 address. If the session is disconnected during the detection attempt, Accounting Start/Stop will be sent for the session. If the session renegotiates IPCP, an Accounting Stop will be generated with a framed-ip-address from the old session, and an Accounting Start will be generated with an IP address for the new session. IPv6 address detection is not supported.

**Important:** When this feature is enabled and the show subscribers all command is invoked, the framed-IP-address is displayed for the PDSN Simple IP subscriber in the output display.
trap

This command generates SNMP traps.

**Product**
- GGSN
- PDSN
- P-GW
- SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LAC Service Configuration

```bash
configure > context context_name > lac-service service_name
```

Entering the above command sequence results in the following prompt:

```bash
[context_name]host_name(config-lac-service)#
```

**Syntax**

```
[ no ] trap all
```

- `no`

Disables SNMP traps.

**Usage**

Use this command to enable/disable all supported SNMP traps.

**Example**

To enable all supported SNMP traps, enter the following command:

```
trap all
```
tunnel selection-key

Enables the creation of tunnels between an L2TP service and an LNS server on the basis of a key received from AAA server.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > LAC Service Configuration
  - `configure > context context_name > lac-service service_name`
  - Entering the above command sequence results in the following prompt:
    
    `[context_name]host_name(config-lac-service)#`

**Syntax**

```
tunnel selection-key { none | tunnel-client-auth-id | tunnel-server-auth-id }
```

**default tunnel selection-key**

```
default
```

**default**

Disables the creation of tunnel between LAC service and LNS based on a key value received from AAA server.

```
none
```

**none**

Default: Enabled

This keyword disables the creation of multiple tunnels between a pair of LAC service and LNS server. LAC will not make use of the key to choose a tunnel with LNS in this setup.

```
tunnel-client-auth-id
```

**tunnel-client-auth-id**

Default: Disabled

This keyword enables the creation of tunnels between LAC service and an LNS server on the basis of domain attribute “Tunnel-Client-Auth-ID” value received from AAA server.

```
tunnel-server-auth-id
```

**tunnel-server-auth-id**

Default: Disabled

This keyword enables the creation of tunnels between LAC service and an LNS server on the basis of domain attribute “Tunnel-Server-Auth-ID” value received from AAA server.

**Usage**

Use this command to enable or disable the creation of additional L2TP tunnels between LAC service and LNS server on the basis of “Tunnel-Client-Auth-ID” or “Tunnel-Server-Auth-ID” attribute value received
from AAA Server in Access-Accept message. This value of attribute is treated as a key for tunnel selection and creation.

When the LAC needs to establish a new L2TP session, it first checks for an existing L2TP tunnel with the peer LNS based on the value of the key configured. If no such tunnel exists for the key, it will create a new tunnel with the LNS.

The default configuration has the selection-key as none. Hence, LAC will not make use of key to choose a tunnel with LNS in default setup.

The maximum number of sessions, as configured via the max-sessions-per-tunnel command, is applicable for each tunnel created through this command. By default, each tunnel supports 512 sessions.

If the LAC service needs to establish a new tunnel for a new L2TP session with LNS and the tunnel create request fails because maximum tunnel creation limit is reached, LAC will try other LNS addresses received from AAA server in Access-Accept message for the APN/subscriber. If all available peer-LNS are exhausted, LAC service will reject the call.

**Example**

The following command enables the use of “Tunnel-Server-Auth-ID” attribute value received from AAA Server in Access-Accept message as a key for tunnel selection and creation:

```
tunnel selection-key tunnel-server-auth-id
```
**tunnel-authentication**

Enables tunnel authentication. When tunnel authentication is enabled, a configured shared secret is used to ensure that the LAC service is communicating with an authorized peer LNS. The shared secret is configured by the `peer-lns` command in the LAC Service Configuration mode, the `tunnel l2tp` command in the Subscriber Configuration mode, or the **Tunnel-Password** attribute in the subscribers RADIUS profile.

**Product**
- GGSN
- PDSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LAC Service Configuration
configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lac-service)#
```

**Syntax**

```
[ no ] tunnel-authentication
```

**Usage**

Disable or enable the usage of secrets to authenticate a peer LNS when setting up a tunnel.

**Example**

To disable tunnel authentication, use the following command:

```
no tunnel-authentication
```

To re-enable tunnel authentication, use the following command:

```
tunnel-authentication
```
Chapter 185
Line Configuration Mode Commands

The Line Configuration Mode is used to manage the terminal line characteristics for output formatting.

Mode

Exec > Global Configuration > Line Configuration
configure > line

Entering the above command sequence results in the following prompt:

[local]host_name(config-line)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
default

Restores the default length or width for the output to the display terminal.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Line Configuration
configure > line
Entering the above command sequence results in the following prompt:

[local]host_name(config-line)#

Syntax

default { length | width }

length | width
length: restores the default value for the number of rows (length) of the output for display.
width: restores the default value for the number of columns (width) of the output for display as the number of characters.

Usage
Reset the output display properties if they had been changed during a session.

Example

default length
default width
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

end

Usage
Use this command to return to the Exec mode.
**exit**

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
length

Configures the output for the display's length (number of rows).

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Line Configuration

configure > line

Entering the above command sequence results in the following prompt:

[local] host_name(config-line) #

Syntax

length number

number

Specifies the number of rows (lines) of output that can be displayed at one time for the display (output) terminal. number must be 0 or an integer from 5 through 512, where the special value 0 implies an infinite number of rows.

Usage

Set the current session's display terminal has different display characteristics than the defaults. The special infinite value (0) is typically used when logging the output of a session from a remote machine since this will result in no pagination of output.

Example

The following commands set the length of the display to infinite and 33, respectively.

length 0

length 33
**width**

Configures the output for the displays width (number of columns/characters wide).

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Line Configuration

```
configure > line
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-line)#
```

**Syntax**

```
width number
```

*number*

Specifies the number of columns (characters) of output that can be displayed at one time for the display (output) terminal. *number* must be an integer from 5 through 512.

**Usage**

Set the current session’s display terminal has different display characteristics than the defaults.

**Example**

```
width 160
```
Chapter 186
Link Configuration Mode Commands

The Link configuration mode defines the MTP3 link parameters for a specific link in a linkset of an SS7 routing domain instance.

**Mode**

Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration

configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
arbitration

This command configures link arbitration.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration

configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id

Entering the above command sequence results in the following prompt:

[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#

Syntax

arbitration { active | passive }

no arbitration

Syntax Table

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arbitration { active</td>
<td>passive }</td>
</tr>
<tr>
<td>no arbitration</td>
<td>Removes the arbitration configuration for the link.</td>
</tr>
</tbody>
</table>

Usage

The SSCOP initiates the transmission of PDUs.

Example

arbitration active
end

Exits the current configuration mode and returns to the Exec mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

end

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
mtp2-aerm-emergency-threshold

Configure the alignment error rate monitor (AERM) emergency threshold value. This command is only available for a lowspeed-narrowband link-type.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration

configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id

Entering the above command sequence results in the following prompt:

[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#

**Syntax**

mtp2-aerm-emergency-threshold value

default mtp2-aerm-emergency-threshold

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resets the parameter to the default value of 1.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>value: Enter an integer from 1 to 50. Default: 1.</td>
</tr>
</tbody>
</table>

**Usage**
This command sets the emergency threshold for the MTP2 alignment error rate monitor.

**Example**
Set the emergency AERM threshold to 17:

mtp2-aerm-emergency-threshold 17
mtp2-aerm-normal-threshold

Configure the alignment error rate monitor (AERM) normal threshold value. This command is only available for a lowspeed-narrowband link-type.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id

Entering the above command sequence results in the following prompt:

[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#

Syntax

mtp2-aerm-normal-threshold value

default mtp2-aerm-normal-threshold

default

 Resets the parameter to the default value of 4.

value

value: Enter an integer from 4 to 100. Default: 4.

Usage

This command sets the normal threshold for the MTP2 alignment error rate monitor.

Example

Set the normal AERM threshold to 55:

mtp2-aerm-normal-threshold 55
mtp2-eim-decrement

Configure the errored interval monitor (EIM) emergency decrement value. This command is only available for a highspeed-narrowband link-type.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration

configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id

Entering the above command sequence results in the following prompt:

[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#

Syntax

mtp2-eim-decrement value

default mtp2-eim-decrement

default

Resets the parameter to the default value of 11.

value

value: Enter an integer from 1 to 63. Default: 11.

Usage

This command sets the emergency decrement value for the EIM.

Example

Reset the EIM emergency decrement to 1:

default mtp2-eim-decrement
mtp2-eim-increment

Configure the errored interval monitor (EIM) emergency increment value. This command is only available for a highspeed-narrowband link-type.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration
configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id

Entering the above command sequence results in the following prompt:

[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#

Syntax

mtp2-eim-increment value

default mtp2-eim-increment

default
Resets the parameter to the default value of 198.

value

value: Enter an integer from 1 to 1023. Default: 198.

Usage

This command sets the emergency increment value for the EIM.

Example

Set the EIM emergency increment to 2:

mtp2-eim-increment 2
mtp2-eim-threshold

Configure the errored interval monitor (EIM) emergency threshold value. This command is only available for a highspeed-narrowband link-type.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration
configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id

Entering the above command sequence results in the following prompt:

[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#

Syntax

mtp2-eim-threshold value

default mtp2-eim-threshold

default

Resets the parameter to the default value of 794.

value

value: Enter an integer from 1 to 65535. Default: 794.

Usage

This command sets the emergency threshold value for the EIM.

Example

Set the EIM emergency threshold to 154:

mtp2-eim-threshold 154
mtp2-error-correction

Configure the error correction method to be used. This command is only available for lowspeed or highspeed narrowband link-types.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration
configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id

Entering the above command sequence results in the following prompt:

[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#

Syntax

mtp2-error-correction { basic | preventive-cyclic-retransmission }

default mtp2-error-correction

default
Resets the parameter to the default value.

basic
Basic error correction (BEC) is a positive / negative acknowledgement method that uses backwards retransmission. This method is best for links with less than 30 ms one-way propagation delays.

preventive-cyclic-retransmission
PCR is recommended for links with 125 ms, or higher, propagation delays.

Usage
Set the method of MTP2 layer error correct to be used on the link.

Example
Set error correction for a link with 15 ms propagation delay:

mtp2-error-correction basic
mtp2-Issu-len

This command sets the length of the link status signal unit (LSSU) which carries link status information used to manage link alignment and indicate the status of the signaling points to each other. This command is only available for lowspeed or highspeed narrowband link-types.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration

configure > ss7-routing-domain  domain_id  variant  var_type  > linkset id  linkset_id  > link id  link_id

Entering the above command sequence results in the following prompt:

[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#

Syntax

mtp2-Issu-len  #_octets

default mtp2-Issu-len

default

Using this keyword with the command resets the length to the default of 1 octet.

#_octets

Sets the number of octets for the length of the LSSU.

#_octets: Must be either 1 or 2.

Usage

Use this command to define the maximum amount of link status information that is to be shared between signaling points.

Example

You can use the following command to set the LSSU length to 2 octets - the maximum length:

mtp2-Issu-len  2
**mtp2-max-outstand-frames**

This command sets the maximum number of outstanding packets to be sent by the link manager (linkmgr) - applicable for both high speed (HSL) and low speed (LSL) narrowband links.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration

```bash
configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#
```

**Syntax**

```
 mtp2-max-outstand-frames #_bytes
 default mtp2-max-outstand-frames
```

- **default**
  
  Using this keyword with the command resets number of packets to the default of 7 bytes.

- **#_bytes**
  
  Sets the maximum number of packets sent by the linkmgr that can be allowed to be outstanding.
  
  #_bytes: Must be an integer from 5 to 10.

**Usage**

The linkmgr (MTP2) sends data at a higher rate, than the narrowband (NB) E1 link speed, when in congestion and performing retransmission. This can lead to more congestion leading to more time taken for the link to come out of congestion. If using a value of 10 during congestion, then linkmgr pumps data at a rate higher than 2.5 mbps. To avoid this problem, a lower value is usually considered optimal. This configuration holds good for both HSL and LSL.

**Example**

Use the following command to reset the default number of outstanding packets sent by the LinkMgr:

```
 default mtp2-max-outstand-frames
```

Set the maximum number of outstanding packets the linkmgr can send to 6:

```
 mtp2-max-outstand-frames 6
```
mtp2-suerm-threshold

Configure the signal unit error rate monitor (SUERM) threshold. This command is only available for lowspeed-narrowband link-types.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration
configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id

Entering the above command sequence results in the following prompt:

[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#

Syntax

mtp2-suerm-threshold value

default mtp2-suerm-threshold

default

Resets the parameter to the default value.

value

Defines the threshold for number of bad frames
value: Enter an integer from 64 to 1023. Default is 64.

Usage
Sets the threshold for link monitoring of bad frames.

Example
Set a new link monitoring bad frames (SEURM) threshold of 256:

mtp2-suerm-threshold 256
**mtp3-discard-priority**

Configure MTP3 message discard priority.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration

`configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#
```

**Syntax**

```plaintext
mtp3-discard-priority priority

default mtp3-discard-priority

default

Resets the priority to the default value.

priority

priority: must be an integer between 0 and 3.
Default is 0.
```

**Usage**
Use this command to manage MTP3 messaging.

**Example**

```plaintext
mtp3-discard-priority 2
```
mtp3-max-slt-try

Configure maximum number of times to retry SLT (signaling link test).

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration

```bash
configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#
```

**Syntax**

```
mtp3-max-slt-try retries

default mtp3-max-slt-try
```

**default mtp3-max-slt-try**

```
default
Resets the number of retries to the default value.
```

```
retries
retries: must be an integer between 1 to 65535.
Default is 10.
```

**Usage**
Use this command to troubleshoot MTP3 link mismatch.

**Example**

```
mtp3-max-slt-try 35
```
mtp3-msg-priority

Configures the priority for sending MTP3 management messages.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration

configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id

Entering the above command sequence results in the following prompt:

[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#

Syntax

mtp3-msg-priority priority

default mtp3-msg-priority

---------------------
default

Resets the number of priority to the default value.

priority

priority: must be an integer from 0 to 3.
Default: 0

Usage

Use this command to set the priority for sending MTP3 management messages.

Example

Use the following to set the message priority to 3:

mtp3-msg-priority 3
mtp3-msg-size

Configures the size of messages from layer 3 to layer 2.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration
configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#
```

**Syntax**

```
mtp3-msg-size size

default mtp3-msg-size
```

**default**

Resets the size to the default value which is 4096 (for q.2140) or 272 (for MTP2)

**size**

- **size:** must be an integer from 1 to 272 for high-speed or low-speed narrowband SS7 links.
- **size:** must be an integer from 1 to 4096 for ATM broadband links.

**Usage**

Use this command to set the maximum message size, in bytes.

**Example**

Use this command to set the MTP3 message size to 4096 bytes:

```
mtp3-msg-size 4096
```
mtp3-p1-qlen

Configure the size for the MTP3 p1 queue length.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration
configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id

Entering the above command sequence results in the following prompt:
[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#

Syntax

mtp3-p1-qlen size

default mtp3-p1-qlen

default

Resets the number of size of the priority 1 queue to the default value.

size

size: integer from 1 to 65535. Size should be less than MTP3 p2 qlen and p3 qlen.
Default: 1024

Usage

Use this command to configure the queue length threshold for raising the congestion priority to level 1.

Example

Use this command to set the queue length priority to 128:

mtp3-p1-qlen 128
**mtp3-p2-qlen**

Configure the size of the priority 2 queue.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration  
configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id  

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#
```

**Syntax**

```
mtp3-p2-qlen size

default mtp3-p2-qlen
```

**default mtp3-p2-qlen**

```
default

Resets the number of size of the priority 2 queue to the default value.

size

size: integer from 1 to 65535. Size should be less than MTP3 p3 qlen and greater than p1 qlen.  
Default: 1024
```

**Usage**

Use this command to configure the queue length threshold for raising the congestion priority to level 2.

**Example**

Use this command to set the queue length threshold to 256:

```
mtp3-p2-qlen 256
```
mtp3-p3-qlen

Configure the size of the priority 3 queue.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration

```
configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#
```

**Syntax**

```
mtp3-p3-qlen size
```

**default mtp3-p3-qlen**

- **default**
  Resets the number of size of the priority 3 queue to the default value.

- **size**
  
  *size:* integer from 1 to 65535. Size should be greater than MTP3 p1 qlen and p2 qlen .
  Default: 1024

**Usage**

Use this command to configure the queue length threshold for raising the congestion priority to level 3.

**Example**

```
mtp3-p3-qlen 1024
```
mtp3-test-pattern

Configures the character string for the test message.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration

configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id

Entering the above command sequence results in the following prompt:

[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#

Syntax

mtp3-test-pattern pattern

default mtp3-test-pattern

default

Resets the pattern to the default value.

pattern

pattern: 1 to 15 alphanumeric characters.
Default: SGSN-ORIGINATED

Usage

Use this command to define a test pattern string for the signalling link test match (SLTM).

Example

mtp3-test-pattern TEST1-HomeOffice
priority

Configures the MTP3 Link Priority.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration

configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id

Entering the above command sequence results in the following prompt:

[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#

Syntax

priority pri_value

no priority

no

Removes the priority configuration.

pri_value

pri_value: 0 represents highest priority and 15 represents the lowest priority.

Usage

Use this command to configure the link priority within the MTP3 link set.

Example

priority 2
signaling-link-code

Configures the signaling link code (SLC).

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration

configure > ss7-routing-domain *domain_id* variant *var_type* > linkset id *linkset_id* > link id *link_id*

Entering the above command sequence results in the following prompt:

[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#

**Syntax**

```
signaling-link-code code

no signaling-link-code
```

**Usage**

Removes the SLC configuration.

```
code

code: integer from 0 to 15.
```

**Example**

Use this command to uniquely identify the signaling link to be used for MTP3 management messages.

```
signaling-link-code 4
```
**sscf-nni-n1**

Configures the SSCF NNI N1. This command is only available for ATM-broadband link-types.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration

```
configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#
```

**Syntax**

```
sscf-nni-n1 value

no scsf-nni-n1
```

**Default**
Removes the scsf-nni-n1 configuration.

**Value**

```
value

value: integer from 1 to 65535.
Default: 1000
```

**Usage**
Use this command to identify the network-to-node interface (NNI) between the MTP3 and SSCOP layers.

**Example**

```
sscf-nni-n1 4064
```
**sscop-max-cc**

Configure the maximum value for the SSCOP connection control (CC) state variable. This command is only available for ATM-broadband link-types.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration
configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#
```

**Syntax**

```
sscop-max-cc value

no sscop-max-cc
```

**Usage**
Use this command as part of the configuration responsible for managing the SSCOP connection. This command sets the number of times retries.

**Example**

```
sscop-max-cc 256
```
**sscop-max-pd**

Configures the maximum acceptable value for the SSCOP state variable VT(PD). This command is only available for ATM-broadband link-types.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration

```
configure > ss7-routing-domain  domain_id  variant  var_type  > linkset_id  linkset_id  > link_id  link_id
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#
```

**Syntax**

```
sscop-max-pd  value

no sscop-max-pd
```

- **default**
  - Removes the sscop-max-pd configuration.

- **value**
  - value: integer from 1 to 65535.
  - Default: 500

**Usage**

Use this command to define the maximum number of data PDUs transmitted between POLL PDUs.

**Example**

```
sscop-max-pd  2500
```
**sscop-max-stat**

Configures the maximum number of elements included in a status PDU. This command is only available for ATM-broadband link-types.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration

```
configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#
```

**Syntax**

```
sscop-max-stat value

no sscop-max-stat
```

**default**

Removes the sscop-max-stat configuration.

**value**

*value*: integer from 3 to 65535. This parameter should be an odd integer greater than or equal to 3. Default: 67

**Usage**

Received in response to a POLL PDU, the STAT PDU includes information about the number of SD PDUs that have been received.

**Example**

```
sscop-max-stat 56000
```
**timeout**

This command enables configuration of an array of signaling and flow control timers - for MTP, SSCF, and SSCOP.

**Product**  
SGSN

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration > Link Configuration

```bash
configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id > link id link_id
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-ss7-rd-linkset-linkset_id-link-link_id)#
```

**Syntax**

```bash
[ no ] timeout timer timer_value
```

- **no**  
  Adding **no** to the **timeout** command removes the timer configuration.

- **timer timer_value**  
  Select the timer and enter a value from the range.
  For timers having different ranges for highspeed and lows speed links or for different variants, the appropriate ranges will be displayed based on the link-type configured.

**Important:** Currently, the China variant uses ITU values.

</tbody>
</table>

**Usage**

For a single link and specified link-type (highspeed or lowspeed), this command sets the timer values listed above. The SS7 variant is determined when the SS7 routing domain is first defined from the Global Configuration mode.

Repeat the `timeout` command (one timer and value per entry) as needed to configure all required timers.

**Important:** Currently, the China variant uses the same timers, values, and defaults as the ITU variant.

**Example**

```
timeout timer timer_value
```
Chapter 187
Linkset Configuration Mode Commands

The Linkset configuration mode defines the MTP3 linkset parameters for a specific SS7 routing domain instance.

Mode

Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration

configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id

Entering the above command sequence results in the following prompt:

[local]host_name(config-ss7-rd-linkset-linkset_id)#

⚠️ Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
adjacent-point-code

This command defines the point-code for the adjacent (next) network element in the SS7 network.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration

```
configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ss7-rd-linkset-linkset_id)#
```

**Syntax**

```
adjacent-point-code point-code

no adjacent-point-code
```

**point-code**

Point-code is an SS7 address for an element in the SS7 network. Point-codes must be defined in dotted-decimal format in a string of 1 to 11 digits. Format options include:

- 0.0.1 to 7.255.7 for point-code in the ITU range.
- 0.0.1 to 255.255.255 for point-code in the ANSI range.
- 0.0.1 to 15.31.255 for point-code in the TTC range.
- A string of 1 to 11 digits in dotted-decimal to represent a point-code in a different range.

**no**

Removes the adjacent-point-code configuration for this linkset in the SS7 routing domain

**Important:** Removing the linkset configuration will result in the termination of all of the links within the linkset.

**Usage**

Use this command to define the point-code for the adjacent element in the SS7 network.

**Example**

```
adjacent-point-code 6.202.7
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
link

This command creates an MTP3 link configuration for the SS7 linkset and enters the Link configuration mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration

configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id

Entering the above command sequence results in the following prompt:

[local]host_name(config-ss7-rd-linkset-linkset_id)#

Syntax

link id id [ link-type [ atm-broadband | highspeed-narrowband | lowspeed-narrowband ]

no link id id

no
Disables the specified link configuration.

**Important:** Removing the link configuration will result in the termination of traffic on the specified link.

#_octets
Sets the number of octets for the length of the LSSU.

id
This number uniquely identifies the link in the linkset.
id: an integer between 1 and 16.

**link-type**
Identifies the signalling type for this link; options include:

- ATM broadband -- ATM AAL5 over an optical line card (OLC2)
- high speed-narrowband -- 64 kbps over a channelized optical line card (CLC2)
- low speed-narrowband -- 4.8 kbps over a channelized optical line card (CLC2)

**Important:** Be default link-type is ATM-broadband. To support narrowband SS7, one of the other options must be set.
**Usage**

Access the Link configuration mode to configure the parameters for the link.

**Example**

Access configuration for link 4:

```
link id 4
```
**self-point-code**

This command defines the SS7 network point-code to identify this SGSN.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > SS7 Routing Domain Configuration > Linkset Configuration

```
configure > ss7-routing-domain domain_id variant var_type > linkset id linkset_id
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ss7-rd-linkset-linkset_id)#
```

**Syntax**

```
self-point-code point-code
no self-point-code
```

- **point-code**
  
  Point-code is an SS7 address for an element in the SS7 network. Point-codes must be defined in dotted-decimal format in a string of 1 to 11 digits. Format options include:
  
  - 0.0.1 to 7.255.7 for point-code in the ITU range.
  - 0.0.1 to 255.255.255 for point-code in the ANSI range.
  - 0.0.1 to 15.31.255 for point-code in the TTC range.
  - a string of 1 to 11 digits in dotted-decimal to represent a point-code in a different range.

- **no**

  Removes the self-point-code configuration for this linkset in the SS7 routing domain.

**Important:** Removing the self-point-code will result in the termination of all traffic on this link.

**Usage**

Use this command to define the SS7 point-code to identify this system.

**Example**

```
self-point-code 6.192.7
```
Chapter 188
LMA Service Configuration Mode Commands

The LMA Service Configuration Mode is used to create and manage the Local Mobility Anchor configuration supporting Proxy Mobile IP on a PDN Gateway in an eHRPD and E-UTRAN/EPC network.

Mode

Exec > Global Configuration > Context Configuration > LMA Service Configuration

configure > context context_name > lma-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lma-service)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
aaa accounting

Enables the LMA to send AAA accounting information for subscriber sessions.

Product
P-GW
SAEGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > LMA Service Configuration

configure > context context_name > lma-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lma-service)#

Syntax

[ default | no ] aaa accounting

- default
  Sets the command to the default condition of enabled.

- no
  Disables the ability of the LMA to send AAA accounting information.

Usage

Use this command to enable the LMA service to send all accounting data (start, stop, and interim) to the configured AAA servers.

Important: In order for this command to function properly, AAA accounting must be enabled for the context in which the LMA service is configured using the `aaa accounting subscriber radius` command.

Example

The following command disables aaa accounting for the LMA service:

`no aaa accounting`
bind address

Binds the LMA service to a logical IP interface serving as the S2a (HSGW) or S5/S8 (S-GW) interface and specifies the maximum number of subscribers that can access this service over the configured interface.

**Product**
- P-GW
- SAEGW

**Privilege**
- Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > LMA Service Configuration

configure > context context_name > lma-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lma-service)#
```

**Syntax**

```
bind address ipv6_address [ ipv4-address ipv4_address ] [ max-subscribers num ]
```

**no bind address**

- **no**
  - Removes the interface binding from this service.

- **address ipv6_address**
  - Specifies the IPv6 address of the interface configured as the S2a or S5/S8 interface. `ipv6_address` is specified in colon separated notation.

- **ipv4-address ipv4_address**
  - Specifies optional IPv4 HA/P-GW address to support DSMIP6 session using IPv4 transport. `ipv4_address` must be entered as a standard IPv4 address in dotted decimal notation.

- **max-subscribers num**
  - Default: 3000000
  - Specifies the maximum number of subscribers that can access this service on this interface. `num` must be configured to an integer between 0 and 3,000,000.

**Important:** The maximum number of subscribers supported is dependant on the license key installed and the number of active PSCs in the system. A fully loaded system with 13 active PSCs can support 3,000,000 total subscribers. Refer to the license key command and the Usage section (below) for additional information.
bind address

Usage

Associate the LMA service to a specific logical IP address. The logical IP address or interface takes on the characteristics of an S2a or S5/S8 interface that provides the session connectivity to an HSGW (S2a) or S-GW (S5/S8). Only one interface can be bound to a service. The interface should be configured prior to issuing this command.

This command also sets a limit as to the number of simultaneous subscribers sessions that can be facilitated by the service/interface at any given time.

When configuring the **max-subscribers** option, be sure to consider the following:

- The total number of S2a or S5/S8 interfaces you will configure
- The total number of subscriber sessions that all of the configured interfaces may handle during peak busy hours
- An average bandwidth per session multiplied by the total number of sessions
- The type of physical port (10/100Base-T or 1000Base-Tx) that these interfaces will be bound to

Taking these factors into account and distributing your subscriber session across all available interfaces will allow you to configure your interfaces to optimally handle sessions without degraded performance.

Example

The following command would bind the logical IP interface with the address of 4551:0db8:85a3:08d3:3319:8a2e:0370:1344 to the LMA service and specifies that a maximum of 300,000 simultaneous subscriber sessions can be facilitated by the interface/service at any given time:

```
bind address 4551:0db8:85a3:08d3:3319:8a2e:0370:1344 max-subscribers 300000
```
end

Exits the current mode and returns to the Exec Mode.

**Product**
All

**Privilege**
Administrator

**Syntax**

**Usage**
Change the mode back to the Exec mode.
exit

Exits the current mode and returns to the previous mode.

**Product**
- All

**Privilege**
- Administrator

**Syntax**

```plaintext
exit
```

**Usage**

Return to the previous mode.
heartbeat

Configures the PMIPv6 heartbeat message interval, retransmission timeout, and max retransmission for the LMA Service.

Product
P-GW

Privilege
Administrator

Syntax

```
heartbeat { interval seconds | retransmission { max number | timeout seconds } }

default heartbeat { interval | retransmission { max | timeout } }

no heartbeat
```

- **no**

Disables the PMIPv6 heartbeat functionality. The P-GW starts sending heartbeat request to peers when the heartbeat interval is configured.

- **default**

Resets the specified parameter to the system default value.

- **interval seconds**

The interval in seconds at which heartbeat messages are sent.

Seconds is an integer from 30 through 3600.

Default: 60

- **retransmission max number**

The maximum number of heartbeat retransmissions allowed.

Number is an integer from 1 through 15.

Default: 3

- **retransmission timeout seconds**

The timeout in seconds for heartbeat retransmissions.

Seconds is an integer from 1 through 20.

Default: 3

Usage

Proxy Mobile IPv6 (PMIPv6) is a network-based mobility management protocol to provide mobility without requiring the participation of the mobile node in any PMIPv6 mobility related signaling. The Local Mobility Anchor (LMA) service sets up tunnels dynamically to manage mobility for a mobile node.

This command provides configuration of heartbeat messages between the LMA and MAG services to know the reachability of the peers, to detect failures, quickly inform peers in the event of a recovery from node failures, and allow a peer to take appropriate action.
Example

The following command enables PMIPv6 heartbeat messaging to known LMA service peers and sets the heartbeat interval to 160 seconds.

```
    heartbeat interval 160
```
mobility-option-type-value

Changes the mobility option type value used in mobility messages.

Product
P-GW
SAEGW

Privilege
Administrator

Syntax

mobility-option-type-value { custom1 | custom2 | standard }

default mobility-option-type-value

default
Sets the command to the default value of custom1.

custom1
( Default ) Non-standard type values used before they were defined by IANA.

custom2
Standard type values, as defined by IANA, and some customer-specific message formats.

standard
Standard type values as defined by IANA. In addition, standard option uses type values defined in RFC 5844 for HoA options for PMIPv6 PBU/PBA/revocation message.

Usage
Use this command to change the mobility option type value used in mobility messages.

Example

The following command changes the mobility option type value to standard:

    mobility-option-type-value standard
refresh-advice-option

Configures inclusion of a refresh advice option in the binding acknowledgement message sent by the LMA.

**Product**
P-GW
SAEGW

**Privilege**
Administrator

**Syntax**

```
[ default | no ] refresh-advice-option
```

- **default**
  Returns the command setting to the default setting of disabled.

- **no**
  Disables the inclusion of the refresh advice option in the binding acknowledgement message sent by the LMA

**Usage**

Use this command to enable the LMA to include this option in a binding acknowledgment sent to the requesting MAG. The option provides a “hint” to the MAG of when it should refresh the binding. As defined in RFC 3775 “Mobility Support in IPv6”, the binding refresh advice option can only be present in the binding acknowledgement sent from the mobile node’s home agent in reply to a registration request. A refresh interval parameter determines the amount of time until the mobile node must send a new registration to the home agent to avoid de-registration and loss of session.

**Important:** Refer to the refresh-interval-percent and reg-lifetime commands for a complete understanding of registration (binding) lifetimes and refresh intervals.
**refresh-interval-percent**

Configures percentage of the granted registration lifetime to be used in the refresh interval mobility option in a binding acknowledgement message sent by the LMA service.

**Product**

P-GW

SAEGW

**Privilege**

Administrator

**Syntax**

```
refresh-interval-percent number
```

```
default refresh-interval-percent
```

```
default
```

Resets the command value to the default setting of 75.

```
number
```

Default: 75

Sets the percent value for session lifetimes for this service.

`number` must be an integer value from 1 to 99.

**Usage**

Use this command to configure the amount of the granted registration lifetime to be used in the refresh interval mobility option in the binding acknowledgement message sent by the LMA service to the requesting MAG.

Refreshing a binding or registration is based on the granted registration lifetime. Since a refresh request must be within the granted range of a registration lifetime, this command provides a method of setting the interval of when a refresh request is sent.

As described in RFC 3775 “Mobility Support in IPv6”, if a binding refresh advice option is present in the binding acknowledgement, the refresh interval field in the option must be a value less than the binding lifetime (also returned in the binding acknowledgement). The mobile node then should attempt to refresh its registration at the shorter refresh interval. The home agent will still honor the registration for the lifetime period, even if the mobile node does not refresh its registration within the refresh period.

**Important**: Refer to the refresh-advice-option and reg-lifetime commands for a complete understanding of registration (binding) lifetimes and refresh intervals.

**Example**

The following command sets the refresh interval percent to 90:

```
refresh-interval-percent 90
```
reg-lifetime

Configures the Mobile IPv6 session registration lifetime for this service.

Product
- P-GW
- SAEGW

Privilege
Administrator

Syntax

```
reg-lifetime seconds

default reg-lifetime
```

- **default**
  Resets the command value to the default setting of 600.

- **seconds**
  Default: 600
  Sets the time value for session lifetimes for this service.
  `seconds` must be an integer value from 1 to 262140.

Usage

Use this command to limit PMIPv6 lifetime on this service. If the PBU contains a lifetime shorter than what is specified, it is granted. If the lifetime is longer, then HA service will limit the granted lifetime to the configured value.

**Important:** Refer to the refresh-interval-percent and refresh-advice-option commands for a complete understanding of registration (binding) lifetimes and refresh intervals.

Example

The following command sets the registration lifetime for Mobile IPv6 sessions using this service to 1200 seconds (20 minutes):

```
reg-lifetime 1200
```
revocation

Enables the MIP revocation feature and configures revocation parameters.

**Product**
P-GW
SAEGW

**Privilege**
Administrator

**Syntax**

```
revocation { enable | max-retransmission number | retransmission-timeout msecs }
```

```
default revocation { enable | max-retransmission | retransmission-timeout }
```

```
no revocation enable
```

---

**default**

Resets the keyword to its default value.

---

**no**

Disables revocation for this service.

---

**enable**

Default: disabled

Enables the MIP registration revocation feature for the LMA service. When enabled, if revocation is negotiated with a MAG and a MIP binding is terminated, the LMA can send a Revocation message to the MAG. This feature is disabled by default.

---

**max-retransmission number**

Default: 3

The maximum number of retransmissions of a Revocation message before the revocation fails. *number* must be an integer value from 0 through 10.

---

**retransmission-timeout msecs**

Default: 3000

The number of milliseconds to wait for a Revocation Acknowledgement from the MAG before retransmitting the Revocation message. *msecs* must be an integer value from 500 through 10000.

---

**Usage**

Use this command to enable or disable the MIP revocation feature on the LMA or to change settings for this feature.

---

**Example**

The following command sets the maximum number of retries for a Revocation message to 6:

```
revocation max-retransmission 6
```
The following command sets the timeout between retransmissions to 10:

```plaintext
revocation retransmission-timeout 10
```
sequence-number-validate

Configures sequence number validation of the received MIPv6 control packets by the LMA service according to RFC 3775.

Product
P-GW
SAEGW

Privilege
Administrator

Syntax

[ default | no ] sequence-number-validate

- **default**
  Resets the command value to the default setting of enabled.

- **no**
  Disables the feature.

Usage

Use this command to configure the sequence number validation of the received MIPv6 control packets (PBUs) by the LMA service. This feature validates MIPv6 control packets and insures that any incoming packets with a sequence number prior to the last number received is consider invalid.

If this service has no cache entry of the home address included in the PBU, it will accept any sequence value in the initial PBU from the mobile node.
setup-timeout

The maximum amount of time allowed for session setup.

Product
P-GW
SAEGW

Privilege
Administrator

Syntax

```
setup-timeout seconds
```

```
default setup-timeout
```

```
default
Reset the command value to the default setting of 60.
```

```
seconds
Default: 60 seconds
The maximum amount of time, in seconds, to allow for setup of a session in this service. seconds must be an integer value from 1 through 100000.
```

Usage

Use this command to set the maximum amount of time allowed for setting up a session.

Example

The following command sets the maximum time allowed for setting up a session to 5 minutes (300 seconds):

```
setup-timeout 300
```
**signalling-packets**

Enables the DSCP marking feature for IP headers carrying outgoing signalling packets.

**Product**
P-GW
SAEGW

**Privilege**
Administrator

**Syntax**

```
signalling-packets ip-header-dscp value

{ default | no } signalling-packets ip-header-dscp
```

- **default**
  Restores the specified parameter to its default setting of 0x0.

- **no**
  Disables the specified functionality.

- **ip-header-dscp value**
  Used to configure the QoS Differentiated Services Code Point (DSCP) marking for IP header encapsulation. 
  *value*: Represents the DSCP setting. It represents the first six most-significant bits of the ToS field. It can be configured to any hex value from 0x0 through 0x3F. Default is 0x0.

**Usage**

Use this command to enable or disable the DSCP marking feature for IP headers carrying outgoing signalling packets. DSCP marking is disabled by default.

**Example**

The following command configures the HSGW service to support DSCP marking for IP headers carrying outgoing signalling packets:

```
signalling-packets ip-header-dscp 0x21
```
simul-bindings

Specifies the maximum number of “care-of” addresses that can simultaneously be bound for the same user as identified by NAI and Home address.

Product
P-GW
SAEGW

Privilege
Administrator

Syntax

simul-bindings number

default simul-bindings

default

Resets the command value to the default setting of 1.

number

Default: 1
Configures maximum number of “care of” addresses that can be simultaneously bound for the same user as identified by their NAI and home address. \textit{number} must be an integer value between 1 and 3.

Usage
Per RFC 5213 (and 3775), the LMA service creates a binding record known as a binding cache entry (BCE) for each subscriber session it is facilitating. Each BCE is associated with a care-of address. As the mobile node roams, it is possible that the session will be associated with a new care of address. Typically, the LMA service will delete an old binding and create a new one when the information in the registration request changes. However, the mobile node could request that the LMA maintains previously stored BCEs. This command allows you to configure the maximum number of BCEs that can be stored per subscriber if more than one is requested.

Example
The following command configures the service to support up to 2 addresses per subscriber:

\texttt{simul-bindings 2}
standalone

Configures the LMA service to start in standalone mode.

**Product**
P-GW
SAEGW

**Privilege**
Administrator

**Syntax**

```
[ default | no ] standalone
```

- **default**
  Resets the command value to the default setting.

- **no**
  Disables the feature.

**Usage**

Use this command to start the LMA service in standalone mode.
**timestamp-option-validation**

Configures validation of timestamp option in binding update messages. By default, timestamp option is mandatory.

**Product**
- P-GW
- SAEGW

**Privilege**
Administrator

**Syntax**

```
[ default | no ] timestamp-option-validation
```

- **default**
  Resets the command value to the default setting of enabled.

- **no**
  Disables the feature.

**Usage**

Use this command to configure timestamp validation in binding update messages.
timestamp-replay-protection

Designates timestamp replay protection scheme as per RFC 4285.

**Product**
P-GW
SAEGW

**Privilege**
Administrator

**Syntax**

```
timestamp-replay-protection tolerance seconds
{ default | no } timestamp-replay-protection tolerance
```

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resets the command value to the default setting of 7.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disables the timestamp replay protection feature.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>tolerance seconds</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 7</td>
</tr>
<tr>
<td>Defines the acceptable difference in timing (between timestamps) before rejecting packet, in seconds.</td>
</tr>
<tr>
<td>seconds must be an integer value between 0 and 65535.</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to define the acceptable difference in timing (between timestamps) before rejecting packet.

**Example**

The following command sets the acceptable difference for timestamps to 10 seconds:

```
timestamp-replay-protection tolerance 10
```
Chapter 189
LNS Service Configuration Mode Commands

The LNS Service Configuration Mode is used to create and manage L2TP services within contexts on the system. L2TP Network Server (LNS) services facilitate tunneling with peer L2TP Access Concentrators (LACs).

Mode

Exec > Global Configuration > Context Configuration > LNS Service Configuration

configure > context context_name > lns-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ns-service)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
aaa accounting

Enables the sending of authentication, authorization, and accounting (AAA) accounting information by the LNS.

Product
PDSN
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LNS Service Configuration
configure > context context_name > lns-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lns-service)#

Syntax

aaa accounting [ roaming ]

[ no ] aaa accounting

no
Disables this option.

roaming

Enables the sending of AAA accounting information by the LNS only for roaming subscribers.

Usage
Use this command to enable the sending of AAA accounting information by the LNS. By default this is enabled.

Example

The following command enables the sending of AAA accounting information by the LNS:

    aaa accounting
**authentication**

Configures the type of subscriber authentication for PPP sessions terminated at the current LNS.

**Product**
- PDSN
- GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LNS Service Configuration

```
configure > context context_name > lns-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lns-service)#
```

**Syntax**

```
authentication { [ allow-noauth ] [ chap chap_priority ] [ mschap mschap_priority ] [ pap pap_priority ] } | msid-auth }
```

---

**allow-noauth**

Default: Disabled

Configures the LNS to allow PPP sessions access even though they have not been authenticated. This command issued by itself causes the LNS not to attempt authentication for any PPP sessions.

When the `allow-noauth` option is used in conjunction with commands specifying other authentication protocols and priorities to use, then if attempts to use those protocols fail, the system treats the `allow-noauth` option as the lowest priority.

If no authentication is allowed, the system constructs an Network Access Identifier (NAI) to provide accounting records for the PPP session.

---

**chap chap_priority**

Default: 1

Configures the LNS to attempt to use Challenge Handshake Authentication Protocol (CHAP) to authenticate the PPP session.

A `chap_priority` must be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on.

`chap_priority` must be an integer from 1 through 1000. The lower the integer, the higher the preference. CHAP is enabled by default as the highest preference.

---

**mschap mschap_priority**

Default: Disabled

Configures the LNS to attempt to use the Microsoft Challenge Handshake Authentication Protocol (MSCHAP) to authenticate the PPP session.

A `mschap_priority` must be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on.

`mschap_priority` must be an integer from 1 through 1000. The lower the integer, the higher the preference.
**pap pap_priority**

Default: 2

This option configures the LNS to attempt to use the Password Authentication Protocol (PAP) to authenticate the PPP session. A *pap_priority* must be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on. *pap_priority* must be an integer from 1 through 1000. The lower the integer, the higher the preference. PAP is enabled by default as the second highest preference.

**msid-auth**

Default: Disabled

This option configures the LNS to attempt to authenticate the PPP session based on the Mobile Station Identity (MSID).

**Usage**

Use to specify how the LNS service should handle authentication and what protocols to use. The flexibility is given to configure this option to accommodate the fact that not every mobile will implement the same authentication protocols.

By default LNS authentication options are set as follows:
- *allow-noauth* disabled
- *chap* enabled with a priority of 1
- *mschap* disabled
- *msid-auth* disabled
- *pap* enabled with a priority of 2

**Important:** At least one of the keywords must be used to complete the command.

**Example**

The following command configures the LNS service to allow no authentication for PPP sessions and would perform accounting using the default NAI-construct of *username*@*domain*:

```
authentication allow-noauth
```

The following command configures the system to attempt authentication first using CHAP, then MSCHAP, and finally PAP. If the allow-noauth command was also issued, when all attempts to authenticate the subscriber using these protocols failed, then the subscriber would be allowed access:

```
authentication chap 1 mschap 2 pap 3
```
avp map called-number apn

This command maps an incoming Attribute Value Pair (AVP) to a GGSN Access Point Name (APN) for authentication and authorization of the call.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LNS Service Configuration

```
configure > context context_name > lns-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ins-service)#
```

**Syntax**

```
[ default | no ] avp map called-number apn
```

- **default**
  Disables mapping.

- **no**
  Disables mapping.

**Usage**
For LNS calls received through a LAC, the ICRQ message includes an APN name in the Called Number AVP. This mapping function enables a GGSN system to provide RADIUS authentication/authorization via a defined APN in place of an LNS configuration. If the mapped APN has not been defined within the GGSN configuration then the call will be rejected.

**Example**
Enter the following command to enable mapping:

```
   avp map called-number apn
```

Enter the following command to disable mapping:

```
   no avp map called-number apn
```
bind

This command assigns the IP address of an interface in the current context to the LNS service.

Product

- PDSN
- GGSN

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > LNS Service Configuration
configure > context context_name > lns-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lns-service)#

Syntax

bind ip_address [ max-subscribers max_value ]
no bind ip_address

no

Unassign, or unbind, the local end point to the LNS service.

ip_address

Specifies the IP address of an interface in the current context. This must be a valid IP address entered using IPV4 dotted-decimal notation.

max-subscribers max_value

Default: 10000
Specifies the maximum number of subscribers that can be connected to this service at any time. max_value must be an integer from 1 through 2500000.

Usage

Use this command to bind the IP address of an interface in the current context to the LNS service.

Example

The following command binds the current context interface IP address 192.168.100.10 to the current LNS service:

bind 192.168.100.10

The following command removes the binding of the IP address from the LNS service:

no bind
data sequence-number

Enables data sequence numbering for sessions that use the current LNS service. Data sequence numbering is enabled by default.

**Product**
PDSN
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LNS Service Configuration

```
configure > context context_name > lns-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lns-service)#
```

**Syntax**

```
[ no ] data sequence-number
```

- **no**

  Disables data sequence numbering for sessions.

**Usage**

An L2TP data packet header has an optional data sequence numbers field. The data sequence number may be used to ensure ordered delivery of data packets. This command is used to re-enable or disable the use of the data sequence numbers for data packets.

**Example**

Use the following command to disable the use of data sequence numbering:

```
no data sequence-number
```

Use the following command to re-enable data sequence numbering:

```
data sequence-number
```
**default**

This command sets the specified LAC service parameter to its default value or setting.

**Product**
- PDSN
- GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LNS Service Configuration

```
configure > context context_name > lns-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lns-service)#
```

**Syntax**

```
default { authentication | data sequence-number | ip source-violation | keepalive-interval | load-balancing | local-receive-window | max-retransmission | max-session-per-tunnel | max-tunnel-challenge-length | max-tunnels | proxy-lcp-authentication | retransmission-timeout-first | retransmission-timeout-max | setup-timeout| single-port-mode | subscriber| trap all tunnel-authentication}
```

---

**authentication**

Sets the authentication parameters for PPP sessions to the following defaults:
- allow-noauth disabled
- chap enabled with a priority of 1
- mschap disabled
- msid-auth disabled
- pap enabled with a priority of 2

---

**data sequence-number**

Enables data sequence numbering for sessions.

---

**ip source-violation**

Sets the IP source violation parameters to the following defaults:
- drop-limit 10
- period 120 seconds
- reneg-limit 5

---

**keepalive-interval**

Sets the interval for send L2TP Hello keepalive if there is no control or data transactions to the default value of 60 seconds.
**local-receive-window**
Sets the window size to be used for the local side for the reliable control transport to the default of 4.

**max-retransmission**
Sets the maximum number of retransmissions to the default of 5.

**max-session-per-tunnel**
Sets the maximum number of sessions per tunnel at any point in time to the default of 65535.

**max-tunnel-challenge-length**
Sets the maximum length of the tunnel challenge to the default of 16 bytes.

**max-tunnels**
Sets the maximum number of tunnels for this service to the default of 32000.

**proxy-lcp-authentication**
Sets sending of proxy LCP authentication parameters to the LNS to the default state of enabled.

**retransmission-timeout-first**
Sets the first retransmit interval to the default of 1 second.

**retransmission-timeout-max**
Sets the maximum retransmit interval to the default of 8 seconds.

**setup-timeout**
Sets the maximum time allowed for session setup to the default of 60 seconds.

**single-port-mode**
Disables assignment of only port 1107 for incoming tunnels and allows dynamic assignment of ports.

**subscriber**
Sets the name of the default subscriber configuration to use.

**tunnel-authentication**
Sets tunnel authentication to the default state of enabled.

**trap all**
Generates all supported SNMP traps.

**tunnel-switching**
Sets the ability of the LNS to create subsequent tunnels to the default of enabled.
Usage

Use the default command to set LAC service parameters to their default states.

Example

Use the following command to set the keepalive interval to the default value of 60 seconds:

```
default keepalive-interval
```

Use the following command to set the maximum number of sessions per tunnel to the default value of 512:

```
default max-session-per-tunnel
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

`end`

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
**ip source-violation**

This command configures settings related to IP source-violation detection.

**Product**
- PDSN
- GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LNS Service Configuration
configure > context context_name > lns-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lns-service)#
```

**Syntax**

```
ip source-violation { clear-on-valid-packet | drop-limit num | period secs | reneg-limit num }
no ip source-violation clear-on-valid-packet
```

---

**clear-on-valid-packet**
Default: disabled
Configures the service to reset the reneg-limit and drop-limit counters after receipt of a properly addressed packet.

**drop-limit num**
Default: 10
Sets the number of allowed source violations within a detection period before forcing a call disconnect. If `num` is not specified, the value is set to the default. `num` can be an integer from 1 through 1000000.

**period secs**
Default: 120
The length of time (in seconds) for a source violation detection period to last. drop-limit and reneg-limit counters are decremented each time this value is reached.

The counters are decremented in this manner: reneg-limit counter is reduced by one (1) each time the period value is reached until the counter is zero (0); drop-limit counter is halved each time the period value is reached until the counter is zero (0). If `secs` is not specified, the value is set to the default. `secs` can be an integer from 1 through 1000000.

**reneg-limit num**
Default: 5
Sets the number of allowed source violations within a detection period before forcing a PPP renegotiation. If `num` is not specified, the value is set to the default.
**Usage**

This function allows the operator to configure a network to prevent problems such as when a user gets handed back and forth between two PDSNs a number of times during a handoff scenario. When a subscriber packet is received with a source address violation, the system increments both the IP source-violation reneg-limit and drop-limit counters and starts the timer for the IP-source violation period. Every subsequent packet received with a bad source address during the IP-source violation period causes the reneg-limit and drop-limit counters to increment.

For example, if reneg-limit is set to 5, the system allows five packets with a bad source address (source violations), but on the fifth packet, it re-negotiates PPP. If the drop-limit is set to 10, the above process of receiving five source violations and renegotiating PPP occurs only once. After the second 5-source violation, the call is dropped. The period timer continues to count throughout this process.

If at any time before the call is dropped, the configured source-violation period is exceeded, the counters for drop-limit is decremented by half and reneg-limit is decremented by 1. See period definition above.

**Example**

To set the maximum number of source violations before dropping a call to 100, enter the following command:

```
ip source-violation drop-limit 100
```
**keepalive-interval**

This command specifies the amount of time to wait before sending a Hello keepalive message.

**Product**
- PDSN
- GGSN

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > LNS Service Configuration

```
configure > context context_name > ins-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ins-service)#
```

**Syntax**

```
keepalive-interval seconds

no keepalive-interval
```

- **no**
  - Disables the generation of Hello keepalive messages on the tunnel.

- **seconds**
  - Default: 60
  - Specifies the number of seconds to wait before sending a Hello keepalive message as an integer from 30 through 2147483648.

**Usage**

Use this command to set the amount of time to wait before sending a Hello keepalive message or disable the generation of Hello keepalive messages completely. A keepalive mechanism is employed by L2TP in order to differentiate tunnel outages from extended periods of no control or data activity on a tunnel. This is accomplished by injecting Hello control messages after a specified period of time has elapsed since the last data or control message was received on a tunnel. As for any other control message, if the Hello message is not reliably delivered then the tunnel is declared down and is reset. The transport reset mechanism along with the injection of Hello messages ensures that a connectivity failure between the LNS and the LAC is detected at both ends of a tunnel.

**Example**

Use the following command to set the Hello keepalive message interval to 120 seconds:

```
keepalive-interval 120
```

Use the following command to disable the generation of Hello keepalive messages:

```
no keepalive-interval
```
local-receive-window

Specifies the number of control messages the remote peer LAC can send before waiting for an acknowledgement.

**Product**
- PDSN
- GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LNS Service Configuration

```bash
configure > context context_name > lns-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lns-service)#
```

**Syntax**

```bash
local-receive-window integer
```

- **integer**
  - Default: 4
  - Specifies the number of control messages to send before waiting for an acknowledgement as an integer from 1 through 256.

**Usage**

Use this command to set the size of the control message receive window being offered to the remote peer LAC. The remote peer LAC may send the specified number of control messages before it must wait for an acknowledgment.

**Example**

The following command sets the local receive window to 10 control messages:

```bash
local-receive-window 10
```
max-retransmission

Sets the maximum number of retransmissions of a control message to a peer before the tunnel and all sessions within it are cleared.

Product
- PDSN
- GGSN

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration > Context Configuration > LNS Service Configuration
- configure > context context_name > lns-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lns-service)#

Syntax

```
max-retransmission integer
```

- `integer`

  Default: 5
  Specifies the maximum number of retransmissions of a control message to a peer as an integer from 1 through 10.

Usage

Each tunnel maintains a queue of control messages to be transmitted to its peer. After a period of time passes without acknowledgement, a message is retransmitted. Each subsequent retransmission of a message employs an exponential backoff interval. For example; if the first retransmission occurs after 1 second, the next retransmission occurs after 2 seconds has elapsed, then the next after 4 seconds. If no peer response is detected after the number of retransmissions set by this command, the tunnel and all sessions within are cleared.

Use this command to set the maximum number of retransmissions that the LAC service sends before closing the tunnel and all sessions within it.

Example

The following command sets the maximum number of retransmissions of a control message to a peer to 7:

```
max-retransmissions 7
```
max-session-per-tunnel

Sets the maximum number of sessions that can be facilitated by a single tunnel at any time.

**Product**
PDSN
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LNS Service Configuration

```
configure > context context_name > lns-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lns-service)#
```

**Syntax**

```
max-sessions-per-tunnel integer
```

integer
Default: 512
Specifies the maximum number of sessions as an integer from 1 through 65535.

**Usage**
Use this command to set the maximum number of sessions you want to allow in a tunnel.

**Example**
The following command sets the maximum number of sessions in a tunnel to 5000:

```
max-sessions-per-tunnel 5000
```
**max-tunnel-challenge-length**

Sets the maximum length of the tunnel challenge in bytes. The challenge is used for authentication purposes during tunnel creation.

**Product**
- PDSN
- GGSN

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > LNS Service Configuration

```
configure > context context_name > lns-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lns-service)#
```

**Syntax**

```
max-tunnel-challenge-length bytes
```

- `bytes` - Specifies the number of bytes to set the maximum length of the tunnel challenge as an integer from 4 through 32.

  - Default: 16

**Usage**

Use this command to set the maximum length, in bytes, for the tunnel challenge that is used during tunnel creation.

**Example**

The following command sets the maximum length of the tunnel challenge to 32 bytes:

```
max-tunnel-challenge-length 32
```
max-tunnels

The maximum number of tunnels that the current LNS service can support.

**Product**
- PDSN
- GGSN

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > LNS Service Configuration
- `configure > context context_name > lns-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lns-service)#
```

**Syntax**

```
max-tunnels integer
```

- `integer`
  - Default: 32000
  - Specifies the maximum number of tunnels as an integer from 1 through 32000.

**Usage**

Use this command to set the maximum number tunnels that this LNS service can support at any one time.

**Example**

Use the following command to set the maximum number of tunnels for the current LNS service to 20000:

```
max-tunnels 20000
```
nai-construction domain

Designates the alias domain name to use for Network Access Identifier (NAI) construction.

Product

PDSN
GGSN

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > LNS Service Configuration
configure > context context_name > lns-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lns-service)#

Syntax

nai-construction domain domain_name { @ | % | - | \ | # | / }

no nai-construction domain

no

Deletes the NAI construction domain alias.

domain_name { @ | % | - | \ | # | / }

Specifies the desired domain name alias followed immediately by a separator from the valid list. domain_name must be an alphanumeric string of from 1 through 79 characters.

Usage

Use this command to specify the domain alias and separator to use for NAI construction. The specified domain name must be followed by a valid separator (@ | % | - | \ | # | /).

Example

To specify a domain alias of mydomain@ with a separator of @, enter the following command:

    nai-construction domain mydomain@

To delete the current setting for the NAI construction domain alias, enter the following command:

    no nai-construction domain
newcall

Configures new call related behavior.

Product

PDSN
GGSN

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > LNS Service Configuration

configure > context context_name > lns-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lns-service)#

Syntax

newcall duplicate-subscriber-requested-address { accept | reject }

default newcall duplicate-subscriber-requested-address

---

default

Sets or restores default value assigned for specified parameter

duplicate-subscriber-requested-address

Configures how duplicate sessions with same address request are handled.

Example

The following command configures new call with duplicate address request to accept:

```
newcall duplicate-subscriber-requested-address accept
```
peer-lac

Adds a peer LAC address for the current LNS service. Up to eight peer LACs can be configured for each LNS service.

**Product**
PDSN
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LNS Service Configuration

`configure > context context_name > lns-service service_name`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-Ins-service)#`

**Syntax**

```
peer-lac { ip_address | ip_address/mask } [ encrypted ] secret secret [ description text ]
```

**no peer-lac ip_address**

```
no peer-lac ip_address
```

Deletes the peer LAC IP address specified by `ip_address`. `ip_address` must be entered using IPv4 dotted-decimal notation.

**ip_address**

The IP address of a specific peer LAC for the current LNS service. `ip_address` must be entered using IPv4 dotted-decimal notation.

**ip_address/mask**

A network prefix and mask enabling communication with a group of peer LACs. `ip_address` is the network prefix expressed in IPv4 dotted-decimal notation. `mask` is the number of bits that defines the prefix.

**encrypted**

Specifies the encrypted shared key between the LAC and the LNS service. This keyword is intended only for use by the system while saving configuration scripts. The system displays the encrypted keyword in the configuration file as a flag that the variable following the secret keyword is the encrypted version of the plain text secret. Only the encrypted secret is saved as part of the configuration file.

**secret secret**

Designates the secret which is shared between the current LNS service and the peer LAC. `secret` must be an alphanumeric string of 1 through 127 characters that is case-sensitive.
**description text**

Specifies the descriptive text to use to describe the specified peer LAC. text must be an alphanumeric string of 0 through 79 characters.

**Usage**

Use this command to add a peer LAC address for the current LNS service. Specific peer LACs can be configured by specifying their individual IP addresses. In addition, to simplify configuration, communication with a group of peer LACs can be enabled by specifying a network prefix and a mask.

**Example**

The following command adds a peer LAC to the current LNS service with the IP address of 10.10.10.100, and specifies the shared secret to be 1b34nnf5d:

```
peer-lac 10.10.10.100 secret 1b34nnf5d
```

The following command enables communication with up to 16 peer LACs on the 192.168.1.0 network each having a secret of abc123:

```
peer-lac 92.168.1.0/28 secret abc123
```

The following command removes the peer LAC with the IP address of 10.10.10.200 for the current LNS service:

```
no peer-lac 10.10.10.200
```
proxy-lcp-authentication

Enables/disables proxy LCP authentication.

Product
- PDSN
- GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LNS Service Configuration

configure > context context_name > lns-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lns-service)#

Syntax

[ no ] proxy-lcp-authentication

no
Disables the processing of proxy LCP authentication parameters from the LAC.

proxy-lcp-authentication
Default: Enabled
Enables the processing proxy LCP authentication parameters from the LAC.

Usage
When enabled, if proxy LCP authentication parameters are received from the LAC and are acceptable, the LNS resumes the PPP session from the authentication phase and goes to the IPCP phase.
When disabled, PPP is always started from the LCP phase, ignoring and discarding any proxy LCP authentication parameters received from the LAC. Disable this feature in situations where accept proxy LCP Auth AVPs that the peer LAC sends should not be expected.

Example
Use the following command to disable the processing of proxy LCP authentication parameters from the LAC:

    no proxy-lcp-authentication

Use the following command to re-enable the processing of proxy LCP authentication parameters from the LAC:

    proxy-lcp-authentication
retransmission-timeout-first

Configures the initial timeout for the retransmission of control messages to the peer LAC.

**Product**
- PDSN
- GGSN

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > LNS Service Configuration
- configure > context context_name > lns-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lns-service)#
```

**Syntax**

```
retransmission-timeout-first integer
```

- `integer`
  
Default: 1

Specifies the amount of time (in seconds) to wait before sending the first control message retransmission. This value is an integer from 1 through 100.

**Usage**

Each tunnel maintains a queue of control messages to transmit to its peer. After a period of time passes without acknowledgement, a message is retransmitted.

**Example**

The following command sets the initial retransmission timeout to 3 seconds:

```
retransmission-timeout-first 3
```
retransmission-timeout-max

Configures the maximum amount of time that can elapse before retransmitting control messages to the peer LAC.

Product
- PDSN
- GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LNS Service Configuration
configure > context context_name > lns-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ins-service)#

Syntax

retransmission-timeout-max integer

integer
Default: 8
Specifies the maximum time (in seconds) to wait before retransmitting control messages. If this limit is reached, the tunnel, and all sessions within it, is cleared. This value is an integer from 1 through 100.

Usage
Each tunnel maintains a queue of control messages to transmit to its peer. After a period of time passes without acknowledgement, a message is retransmitted. Each subsequent retransmission of a message employs an exponential backoff interval. For example; if the first retransmission occurs after 1 second, the next retransmission occurs after 2 seconds has elapsed, then the next after 4 seconds. This continues until the limit set by this command is reached. If this limit is reached, the tunnel, the tunnel, and all sessions within it, is cleared.

Example
Use the following command to set the maximum retransmission time-out to 10 seconds:

retransmission-timeout-max 10
setup-timeout

Configures the maximum amount of time, in seconds, allowed for session setup.

**Product**
- PDSN
- GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LNS Service Configuration

```
configure > context context_name > lns-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lns-service)#
```

**Syntax**

```
setup-timeout seconds
```

- `seconds`

Default: 60
- Specifies the maximum time (in seconds) to wait for the setup of a session. `seconds` must be an integer from 1 through 100000.

**Usage**

This command controls the amount of time allowed for tunnel establishment with a peer LAC. If this timer is exceeded the tunnel setup is aborted.

**Example**

The following command configures a maximum setup time of 120 seconds:

```
setup-timeout 120
```
single-port-mode

When enabled, this command sets the LNS to use only the default local UDP port (port 1701) for the life of a tunnel.

Product
PDSN
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LNS Service Configuration

Syntax

[ default | no ] single-port-mode

no
Disable single port mode

Usage
Use this command to control the L2TP LNS tunnel local UDP port assignment mode. If single-port-mode is enabled, the LNS-service uses the standard UDP port (port 1701) for the life of the incoming tunnel. Otherwise, it assigns a new local UDP port number for a tunnel when it responds to a tunnel create request received on the standard port number. This is done for load distributing the tunnel processing between multiple tasks within the system to increase the capacity and performance. Even though all L2TP LACs are required to support such dynamic port assignments during tunnel establishments, there exist some LACs that do not support port assignment other than port 1701. This single-port-mode feature can be enabled to support such LAC peers. This configuration must be applied for the LNS-Service before the bind command is executed.

Example

The following command enables single port mode for the current LNS service:

    single-port-mode
**trap**

This command generates SNMP traps.

**Product**

PDSN

GGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > LNS Service Configuration

```
configure > context context_name > lns-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lns-service)#
```

**Syntax**

```
[ no ] trap all
```

no

Disables SNMP traps.

**Usage**

Use this command to enable/disable all supported SNMP traps.

**Example**

To enable all supported SNMP traps, enter the following command;

```
trap all
```
tunnel-authentication

Enables/disables L2TP tunnel authentication for the LNS service.

Product
PDSN
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LNS Service Configuration

configure > context context_name > lns-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lns-service)#

Syntax

[ no ] tunnel-authentication

no

Disables tunnel authentication
Tunnel authentication is enabled by default.

Usage
When tunnel authentication is enabled, a configured shared secret is used to ensure that the LNS service is communicating with an authorized peer LAC. The shared secret is configured by the peer-lac command, the tunnel l2tp command in the Subscriber Configuration mode, or the Tunnel-Password attribute in the subscribers RADIUS profile.

Example
To disable tunnel authentication, use the following command:

    no tunnel-authentication

To re-enable tunnel authentication, use the following command:

    tunnel-authentication
tunnel-switching

Enables or disables the LNS service from creating tunnels to another LAC for an existing tunnel.

**Product**
- PDSN
- GGSN

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > LNS Service Configuration
- `configure > context context_name > lns-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ns-service)#
```

**Syntax**

```
[ no ] tunnel-switching
```

- `no`
  - Disable tunnel switching.
  - Tunnel switching is enabled by default.

**Usage**

Tunnel switching is when the LNS has a tunnel connected to a LAC and creates a tunnel to a different LAC and routes the data from the original LAC through the new tunnel to the other LAC.

**Example**

To disable tunnel switching in the LNS, enter the following command;

```
no tunnel-switching
```
Chapter 190
Local Policy Actiondef Configuration Mode Commands

The Local Policy Actiondef Configuration Mode is used to define the action definitions to be used for local QoS policies.

Mode

Exec > Global Configuration > Local Policy Service Configuration > Local Policy Actiondef Configuration

configure > local-policy-service service_name > actiondef actiondef_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-local-policy-actiondef)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**action**

This command configures the action priority for an actiondef.

**Product**

P-GW  
SAEGW  

**Privilege**

Security Administrator, Administrator  

**Mode**

Exec > Global Configuration > Local Policy Service Configuration > Local Policy Actiondef Configuration  
configure > local-policy-service service_name > actiondef actiondef_name  

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-local-policy-actiondef)＃
```

**Syntax**

```
action priority priority action_name arguments
no action priority priority
```

---

### priority  priority

Specifies a priority for the specified action.  
**priority** must be a unique integer from 1 to 2048.

```
action_name arguments
```

The following actions are supported. **arguments** specify a set of parameters to be used when invoking the action.

- **activate-ambr uplink bandwidth downlink bandwidth**
  
  Sets the aggregated maximum bit rate (AMBR) for the APN.  
  Configures uplink and downlink bandwidth. **bandwidth** must be an integer from 1 to 1000000000.

- **activate-flow-detection { initiation | termination } ruledef ruledef_name**
  
  Detects a flow and takes action.  
  **initiation ruledef**: Checks for flow initiation and adds a rule definition.  
  **termination ruledef**: Checks for flow termination and adds a rule definition.  
  **ruledef_name** must be an existing ruledef.

- **activate-policy-group**
  
  This keyword is not supported in this release.

- **activate-rule name rule_name**
  
  Activates a rule within ECS rulebase for a subscriber.  
  **rule_name** must be an existing rule within this local QoS policy service expressed as an alphanumeric string of 1 through 63 characters.
• activate-rulebase name rulebase_name
  Associates the session with a specific rulebase.
  rulebase_name must be an existing rulebase within this local QoS policy service expressed as an alphanumeric string of 1 through 63 characters.

• allow-requested-qos
  Allow a specific UE initiated QoS request.

• allow-session
  Allows the session to continue.

• create-bearer qci value arp value uplink-mbr mbr_rate downlink-mbr mbr_rate [ uplink-gbr gbr_rate ] downlink-gbr gbr_rate
  Creates a bearer with a specific QCI and BANDWIDTH.
  qci value must be an integer from 1 through 254.
  arp value must be an integer from 1 through 15 (StarOS v12.1 and earlier) or 1 through 127 (StarOS v12.2 and later).
  uplink-mbr: Uplink maximum bitrate. mbr_rate must be an integer from 1 through 1000000000.
  downlink-mbr: Downlink maximum bitrate. mbr_rate must be an integer from 1 through 1000000000.
  uplink-gbr: Uplink guaranteed bitrate. gbr_rate must be an integer from 1 through 1000000000.
  downlink-gbr: Downlink guaranteed bitrate. gbr_rate must be an integer from 1 through 1000000000.

• deactivate-ambr
  Removes AMBR control for the specific session.

• deactivate-flow-detection { initiation | termination } ruledef ruledef_name
  Deactivates detection of flow and takes action.
  initiation ruledef: Checks for flow initiation and adds a rule definition.
  termination ruledef: Checks for flow termination and adds a rule definition.
  ruledef_name must be an existing ruledef.

• deactivate-policy-group
  This keyword is not supported in this release.

• deactivate-rule name rule_name
  Deactivates a rule within ECS.
  rule_name must be an existing rule within this local QoS policy service expressed as an alphanumeric string of 1 through 63 characters.

• deactivate-rulebase name rulebase_name
  Disassociates the rulebase from a session.
  rulebase_name must be an existing rulebase within this local QoS policy service expressed as an alphanumeric string of 1 through 63 characters.

• default-qos qci value arp value
  Sets the default QoS parameters for the session
**Local Policy Actiondef Configuration Mode Commands**

qci  value must be an integer from 1 through 254.

arp  value must be an integer from 1 through 15 (StarOS v12.1 and earlier) or 1 through 127 (StarOS v12.2 and later).

*delete-bearer qci  value  arp  value*

Deletes a bearer.

qci  value must be an integer from 1 through 254.

arp  value must be an integer from 1 through 15 (StarOS v12.1 and earlier) or 1 through 127 (StarOS v12.2 and later).

*reconnect-to-server*

Reconnects to the PCRF server to handle fallback scenario. That is, when the session falls back to local policy, this action specifies to retry connecting to the PCRF server.

*reject-requested-qos*

Rejects UE QoS resource request.

*retry-count  value*

Retry action. This applies to start-timer/activate-rule/activate-ruledef.

value must be an integer from 0 through 65535.

*start-timer  name  duration  value  retry-count  value*

Starts a named timer. On expiry of this timer, the local policy engine is contacted to initiate the appropriate action, such as termination of a session.

duration  value: Enter a timer duration from 0 through 28800 seconds. A value of 0 can be used to leave the local policy until the subscriber disconnects. Default timer value is 14400 (seconds).

retry-count specifies the maximum number of times the server will be retried before terminating the call.

retry-count  value must be an integer from 0 through 65535. Default retry count is 3.

*stop-timer  name*

Stops the designated timer.

*terminate-session*

Terminates the session.

no action priority  priority

Deletes the specified action.

**Usage**

Use this command to enable the setting of parameters to be used when invoking actions. Actions are a series of operations that are triggered by activated rules.

This command can be entered multiple times to configure multiple actions for an actiondef. The actions are examined in priority order until a match is found and the corresponding action is applied.

**Example**

The following command creates an action to allow a session to continue with priority set to 125:

```
action priority 125 allow-session
```
end

Exits the current configuration mode and returns to the Exec mode.

Chapter 191
Local Policy Eventbase Configuration Mode Commands

The Local Policy Eventbase Configuration Mode is used to configure the events to be used for local QoS policies.

Mode

Exec > Global Configuration > Local Policy Service Configuration > Local Policy Eventbase Configuration
configure > local-policy-service service_name > eventbase eventbase_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-local-policy-eventbase)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
**exit**

Exits the current mode and returns to the parent configuration mode.

**Product**

Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**
Use this command to return to the parent configuration mode.
rule

This command enables the setting of event rules. An event is something that occurs in the system which would trigger a set of actions to take place, such as new-call or rat-change.

Product
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Local Policy Service Configuration > Local Policy Eventbase Configuration
configure > local-policy-service service_name > eventbase eventbase_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-local-policy-eventbase)#

Syntax

```
rule priority priority [ event list_of_events ] ruledef ruledef_name actiondef actiondef_name [ continue ]

no rule priority priority
```

<table>
<thead>
<tr>
<th>priority priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies a priority for the specified rule.</td>
</tr>
<tr>
<td>priority must be unique and an integer from 1 to 2048.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>event list_of_events</th>
</tr>
</thead>
<tbody>
<tr>
<td>The event is defined by any of the following events. Upon triggering the event, the rules specified in the eventbase are executed.</td>
</tr>
<tr>
<td>•default-qos-change: The event is triggered as a result of a default QoS change.</td>
</tr>
<tr>
<td>•fallback: This event is triggered as a result of fallback from PCRF.</td>
</tr>
<tr>
<td>•location-change: The event is triggered as a result of any change relating to location.</td>
</tr>
<tr>
<td>•new-call: This event is initiated when a new call is established.</td>
</tr>
<tr>
<td>•out-of-credit: This event is initiated on out of OCS credit.</td>

<th>ruledef ruledef_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Associates the rule with a specific ruledef.</td>
</tr>
</tbody>
</table>
ruledef_name must be an existing ruledef within this local QoS policy service.

actiondef actiondef_name
Associates the rule with a specific actiondef. actiondef_name must be an existing actiondef within this local QoS policy service expressed as an alphanumeric string of 1 through 63 characters.

continue
Subsequent rules are also matched; otherwise, rule evaluation is terminated on first match.

no rule priority priority
Deletes the specified rule.

Usage
Use this command to create, configure, or delete event rules. The rules are executed in priority order, and if the rule is matched the action specified in the actiondef is executed. If an event qualifier is associated with a rule, the rule is matched only for that specific event. If a qualifier of continue is present at the end of the rule, the subsequent rules are also matched; otherwise, rule evaluation is terminated on first match. This command can be entered multiple times to configure multiple rules for an eventbase.

Important: A maximum 256 rules are suggested in an eventbase for performance reasons.

Example
The following command creates a rule with priority set to 2 and associated with ruledef rule5 and actiondef action7:

   rule priority 2 ruledef rule5 actiondef action7
Chapter 192
Local Policy Ruledef Configuration Mode Commands

The Local Policy Ruledef Configuration Mode is used to configure the rule definitions to be used for local QoS policies.

Mode
Exec > Global Configuration > Local Policy Service Configuration > Local Policy Ruledef Configuration
configure > local-policy-service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-local-policy-ruledef)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**condition**

This command is used to configure the conditions which trigger the ruledef event.

**Product**
- P-GW
- SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Local Policy Service Configuration > Local Policy Ruledef Configuration

```bash
configure local-policy-service service_name ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-local-policy-ruledef)#
```

**Syntax**

```bash
condition priority priority \{ variable \{ eq | ge | gt | le | lt | match | ne | nomatch \} regex | string_value | int_value | set \}

no condition priority priority
```

**priority priority**

Specifies a priority for the specified condition.

**variable**

The following variables are supported:

- **apn**
  The APN associated with the current session expressed as an alphanumeric string of 1 through 63 characters.

- **arp**
  The APN associated with the current session expressed as an integer from 1 through 15.

- **bandwidth**
  Total bandwidth associated with the QCI and ARP value associated with the request, expressed as an integer from 0 through 1000000000.

- **bsid**
  Base Station Identifier associated with the subscriber as expressed as an alphanumeric string of 1 through 63 characters.

- **cause-code**
  Failure Cause Code associated with the subscriber as expressed as an alphanumeric string of 1 through 63 characters.

- **cgi**
Cell Global Identification associated with the subscriber as expressed as an alphanumeric string of 1 through 63 characters.

**Important:** This variable is available only in 15.0 and earlier releases. In 16.0 and later releases, it is deprecated.

- **date**
  Date value to match. <Clock in format YYYYY-MM-DD>

- **day-of-month**
  The day of the month to match the rule to, expressed as an integer from 1 through 31.

- **day-of-week**
  Sunday...Saturday, expressed as an integer from 1 to 7.

- **ecgi**
  E-UTRAN Cell Global Identification associated with the subscriber as expressed as an alphanumeric string of 1 through 63 characters.

**Important:** This variable is available only in 15.0 and earlier releases. In 16.0 and later releases, it is deprecated.

- **imeisv**
  IMEISV of the user equipment expressed as an alphanumeric string of 1 through 63 characters.

- **imsi**
  IMSI associated with the subscriber expressed as an alphanumeric string of 1 through 63 characters.

- **meid**
  MEID associated with the subscriber expressed as an alphanumeric string of 1 through 63 characters.

- **month-of-year**
  Jan, Feb....Dec, expressed as an integer from 1 through 12.

- **msisdn**
  MSISDN associated with the session expressed as an alphanumeric string of 1 through 63 characters.

- **nai**
  NAI associated with the session expressed as an alphanumeric string of 1 through 63 characters.

- **pdn-type**
  Type of PDNs associated with the same APN.
  - **IPV4**: IPv4 PDN Type
  - **IPV4V6**: IPv4v6 PDN Type
  - **IPV6**: IPv6 PDN Type

- **qci**
  QCI associated with the current event expressed as an integer from 1 through 254.

- **radio-access-technology**
Radio access technology associated with the subscriber:

- **cdma-lxrtt**: CDMA 1X RTT radio access technology
- **cdma-evdo**: CDMA-EVDO radio access technology
- **cdma-evdo-reva**: CDMA EVDO REVA radio access technology
- **cdma-other**: Other CDMA radio access technologies
- **ehrpdp**: EHRPD radio access technology
- **eutan**: EUTRAN radio access technology
- **gan**: GAN radio access technology
- **gprs-geran**: GPRS GERAN radio access technology
- **gprs-other**: Other GPRS radio access technology
- **hsapa**: HSPA radio access technology
- **unknown**: Unknown radio access technology
- **wcdma-utran**: WCDMA UTRAN radio access technology
- **wimax**: WiMax radio access technology
- **wireless-lan**: Wireless LAN radio access technology

- **rai**
  
  Routing Area Identification associated with the subscriber as expressed as an alphanumeric string of 1 through 63 characters.

- **sai**
  
  Serving Area Identification associated with the subscriber as expressed as an alphanumeric string of 1 through 63 characters.

**Important**: This variable is available only in 15.0 and earlier releases. In 16.0 and later releases, it is deprecated.

- **serving-node-address**
  
  IP address associated with the current node serving the subscriber entered using IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

- **serving-plmn**
  
  PLMN associated with the current node serving the subscriber expressed as an alphanumeric string of 1 through 63 characters.

- **tai**
  
  Tracking Area Identification associated with the subscriber as expressed as an alphanumeric string of 1 through 63 characters.

**Important**: This variable is available only in 15.0 and earlier releases. In 16.0 and later releases, it is deprecated.

- **time-of-day**
  
  Time associated with the change. <Clock in format HH:mm:ss or HH:mm>
**timer**

Timer name as expressed as an alphanumeric string of 1 through 63 characters.

---

**Important:** This variable is available only in 15.0 and earlier releases. In 16.0 and later releases, it is deprecated.

---

```
| eq | ge | gt | le | lt | match | ne | nomatch |
---|----|----|----|----|-------|----|---------|

**eq:** Operation equal to

**ge:** Operation greater than or equal to

**gt:** Operation greater than

**le:** Operation less than or equal to

**lt:** Operation less than

**match:** Operation match

**ne:** Operation not equal to

**nomatch:** Operation nomatch
```

---

```
no condition priority priority
```

Deletes the specified condition.

---

**Usage**

Use this command to configure the conditions which trigger the ruledef event. A ruledef represents a set of matching conditions. This command can be entered multiple times to configure multiple conditions for a ruledef. The conditions are examined in priority order until a match is found and the corresponding condition is applied.

---

**Example**

The following command creates a condition with priority set to 5 and configured match apn myapn*:

```
condition priority 5 apn match myapn*
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

exit

**Usage**
Use this command to return to the parent configuration mode.
The Local Policy Service Configuration Mode is used to configure the local QoS policy for one or more services.

**Important:** A maximum of 16 local QoS policy services are supported.

**Mode**

Exec > Global Configuration > Local Policy Service Configuration

```bash
configure > local-policy-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-local-policy-service)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
actiondef

This command enables creating, configuring, or deleting action definitions for an event.

**Product**

P-GW
SAEGW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Local Policy Service Configuration

```
configure > local-policy-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-local-policy-service)#
```

**Syntax**

```
actiondef actiondef_name [ -noconfirm ]

no actiondef actiondef_name
```

---

**no**

Deletes the specified actiondef from the local QoS policy service.

```
actiondef_name
```

Specifies name of the actiondef.

*actiondef_name* must be unique within the service expressed as an alphanumeric string of 1 through 63 characters. If the named actiondef does not exist, it is created, and the CLI mode changes to the Local Policy Actiondef Configuration Mode wherein the actiondef can be configured. If the named actiondef already exists, the CLI mode changes to the Local Policy Actiondef Configuration Mode for that actiondef.

---

**-noconfirm**

Specifies that the command must execute without prompting for confirmation.

---

**Usage**

Use this command to create, configure, or delete an actiondef. The actiondef configuration is used to configure the action definitions for an event. The event ruledef will have one or more rules and associated action(s).

This command can be entered multiple times to specify multiple actiondefs.

---

**Important:** A maximum of 256 actiondefs are suggested in a local QoS policy service for performance reasons. An actiondef can be referenced by multiple eventbases.
Entering this command results in the following prompt:

```
[context_name]hostname(config-local-policy-actiondef)#
```

Local Policy Actiondef Configuration Mode commands are defined in the *Local Policy Actiondef Configuration Mode Commands* chapter.

**Example**

The following command creates an actiondef named `actiondef1` and enters the Local Policy Actiondef Configuration Mode:

```
actiondef actiondef1
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
eventbase

This command enables creating, configuring, or deleting an eventbase.

**Product**

P-GW
SAEGW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Local Policy Service Configuration
configure > local-policy-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-local-policy-service)#
```

**Syntax**

```
eventbase eventbase_name [ -noconfirm ]
no eventbase eventbase_name
```

-no

Deletes the specified eventbase from the local QoS policy service.

```
eventbase_name
```

Specifies name of the eventbase.

`eventbase_name` must be unique within the service expressed as an alphanumeric string of 1 through 63 characters.

**Important:** Currently, only one eventbase is supported, and it must be named “default”.

If the named eventbase does not exist, it is created, and the CLI mode changes to the Local Policy Eventbase Configuration Mode wherein the eventbase can be configured.

If the named eventbase already exists, the CLI mode changes to the Local Policy Eventbase Configuration Mode for that eventbase.

-noconfirm

Specifies that the command must execute without prompting for confirmation.

**Usage**

Use this command to create, configure, or delete an eventbase.

Entering this command results in the following prompt:

```
[context_name]host_name(config-local-policy-eventbase)#
```
Local Policy Eventbase Configuration Mode commands are defined in the *Local Policy Eventbase Configuration Mode Commands* chapter.

**Example**

The following command creates an eventbase named *default* and enters the Local Policy Eventbase Configuration Mode:

```
eventbase default
```
**ruledef**

This command enables creating, configuring, or deleting a rule definition.

**Product**

P-GW
SAEGW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Local Policy Service Configuration

`configure > local-policy-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-local-policy-service)#
```

**Syntax**

```
ruledef  ruledef_name  [  -noconfirm  ]

no  ruledef  ruledef_name
```

- **no**
  
  Deletes the specified ruledef from the local QoS policy service.

  ```
  ruledef_name
  ```

  Specifies name of the ruledef.

  `ruledef_name` must be unique within the service expressed as an alphanumeric string of 1 through 63 characters.

  If the named ruledef does not exist, it is created, and the CLI mode changes to the Local Policy Ruledef Configuration Mode wherein the ruledef can be configured.

  If the named ruledef already exists, the CLI mode changes to the Local Policy Ruledef Configuration Mode for that ruledef.

  ```
  -noconfirm
  ```

  Specifies that the command must execute without prompting for confirmation.

**Usage**

Use this command to create, configure, or delete a ruledef. A ruledef represents a set of matching conditions. This command can be entered multiple times to specify multiple ruledefs.

**Important:** A maximum 256 ruledefs are suggested in a local QoS policy service for performance reasons.

Entering this command results in the following prompt:

```
[context_name]host_name(config-local-policy-ruledef)#
```
Local Policy Ruledef Configuration Mode commands are defined in the *Local Policy Ruledef Configuration Mode Commands* chapter.

**Example**

The following command creates a ruledef named `rule5` and enters the Local Policy Ruledef Configuration Mode:

```
ruledef rule5
```
Chapter 194
Location Service Configuration Mode Commands

The Location Service Configuration Mode is used to manage Location Services (LCS). Using LCS, the system (MME or SGSN) can collect and use or share location (geographical position) information for connected UEs in support of a variety of location services.

Mode

Exec > Global Configuration > Context Configuration > Location Service Configuration

configure > context context_name > location-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-location-service)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
associate

Associates or disassociates supportive interfaces or services with this location service instance.

Product
MME
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > Location Service Configuration
configure > context context_name > location-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-location-service)#

Syntax

associate { diameter { dictionary standard | endpoint } | map-service map_svc_name }
default associate diameter dictionary
no associate { diameter endpoint | map-service }

---

default
Returns the command to its default value of ‘standard’.

---

no
Disassociates a previously associated interface or service with this location service.

---

diameter dictionary standard
Associates a Diameter dictionary with this location service. The standard dictionary contains definitions per the 3GPP definition.

diameter endpoint endpoint_name
Specifies the Diameter endpoint for this location service, which includes the hostname, peer configuration, and other Diameter base configuration.

---

map-service map_svc_name
Associates a Mobile Application Part (MAP) service with this location service. This keyword is applicable for SGSN only.

map_sv_svc_name specifies the name for a pre-configured MAP service to associate with this location service.
Usage
Use this command to specify the Diameter dictionary and endpoint to be used for this location service, or associate supportive services with this location service.
The location service provides SLg (MME) interface support or Lg (SGSN) interface support via the Diameter protocol between the MME or SGSN and the GLMC.

Example
The following command associates a pre-configured Diameter endpoint named test12 to this location service:

```
associate diameter endpoint test12
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
end

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```bash
exit
```

Usage
Use this command to return to the parent configuration mode.
timeout

Configures the timers used to control various location service procedures.

Product
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > Location Service Configuration

configure > context context_name > location-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-location-service)#

Syntax

[ default ] timeout { area-event-invoke-timer aietimer_seconds | lcsn lcns_seconds | periodic-event-invoke-timer peitimer_seconds | ue-available-guard-timer ueagtimer_seconds

default

Resets the specified timer to the default value.

area-event-invoke-timer aietimer_seconds

This timer, set in seconds, is used to guard the area event invoke procedure.

aietimer_seconds is an integer from 10 through 20. Default is 15.

lcsn lcns_seconds

Sets the NAS location service notification timer defining how long the SGSN will wait (in seconds) before aborting the Location Service Request, and release all resources allocated for the transaction.

lcns_seconds is an integer from 10 through 20. Default is 15.

periodic-event-invoke-timer peitimer_seconds

This timer, set in seconds, is used to guard the period location invoke procedure.

peitimer_seconds is an integer from 10 to 20. Default is 15.

ue-available-guard-timer ueagtimer_seconds

This timer, set in seconds, is used to guard the packet-switched deferred location request (UE available event) procedures.

ueagtimer_seconds is an integer from 10 to 600. Default is 600.

Usage
Use this command to set the amount of time the SGSN waits to perform various location service procedures.

Example
The following command can be used to set the time the SGSN will wait, for example 12 seconds, before aborting the Location Service Request:

```
timeout lcns 12
```

The following command can be used to set the timeout for the UE available guard timer to 460 seconds:

```
timeout ue-available-guard-timer 460
```
Chapter 195
Logical eNode Configuration Mode Commands

The Logical eNodeB configuration option enables the configuration of one or more logical eNodeBs within the HeNB-GW. The Logical eNodeB configuration can be used to support load balancing within a pool of TAI.

Mode

Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration > Logical eNodeB Configuration

configure > context context_name > henbgw-network-service service_name > logical-enb
  global-enb-id plmn-id mcc mcc_id mnc mnc_id { home-enb-id henb_id | macro-enb-id menb_id }

Entering the above command sequence results in the following prompt:

[context_name]host_name(logical-enb)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
associate mme-pool

Associates a previously configured MME pool to this logical eNodeB. An MME pool must be configured in LTE Policy Configuration mode before using this configuration.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration > Logical eNodeB Configuration

```bash
configure > context context_name > hnbgw-network-service service_name > logical-enb global-enb-id plmn_id mcc mcc_id mnc mnc_id { home-enb-id henb_id | macro-enb-id menb_id }
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(logical-enb)#
```

Syntax

```bash
associate mme-pool pool_name

no associate mme-pool
```

`no`
Removes the associated MME pool from this logical eNodeB configuration.

`pool_name`
Identifies the name of the pre-configured MME pool to associate with this logical eNodeB. `pool_name` is an alphanumeric string of 1 through 63 characters.

Usage

Use this command to bind/associate a pre-configured MME pool to the this logical eNodeB. The MME pool can be configured in LTE Policy configuration mode. The associate configuration is used to establish associations with other helper services in general. Each logical eNodeB can connect up to 8 MMEs. Since 8 logical eNodeBs can be configured per HeNB-GW Network service, a total of 64 associations can be established between HeNB-GW and MME.

Example

Following command associates an MME pool named `mme_pool` with specific logical eNodeB:

```
associate mme-pool mme_pool
```
associate tai-list-db

Associates a previously configured TAI database name to this logical eNodeB. A TAI database name for TAI configuration must be configured in LTE Policy Configuration mode before using this configuration.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration > Logical eNodeB Configuration
configure > context context_name > hembgw-network-service service_name > logical-enb global-enb-id plmn_id mcc_id mcc_id nnc_id { home-enb-id henb_id | macro-enb-id mcnb_id }

Entering the above command sequence results in the following prompt:

[context_name]host_name (logical-enb) #

Syntax

associate tai-list-db tai_db_name

no associate tai-list-db

no

Removes the associated TAI database from this logical eNodeB configuration.

tai_db_name

Identifies the name of the pre-configured TAI database to associate with this logical eNodeB. tai_db_name is an alphanumeric string of 1 through 63 characters.

Usage

Use this command to bind/associate a pre-configured TAI database to the this logical eNodeB. The MME pool can be configured in LTE Policy configuration mode. The associate configuration is used to establish associations with other helper services in general.

A maximum number of 8 TAI databases are supported. Each TAI database can accommodate up to 256 configurations of Tracking Area Codes (TACs). Therefore a total of 2048 TACs are supported.

Example

Following command associates a TAI database named henb_tai_db with specific logical eNodeB:

associate tai-list-db henb_tai_db
**bind s1-mme**

Binds the pre configured Local SCTP IP Address for S1 association to MME.

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration > Logical eNodeB Configuration

```
configure > context context_name > hnbgw-network-service service_name > logical-enb
global-enb-id plmn_id mcc mcc_id mnc mnc_id { home-enb-id henb_id | macro-enb-id menb_id }
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(logical-enb)#
```

**Syntax**

```
bind s1-mme { ipv4-address } ip_addr

no bind s1-mme
```

**Usage**

```
no
```

Removes the binding of S1-MME interface from this logical eNodeB configuration.

```
ip_addr
```

Identifies the IP address of the S1-MME interface to associate with this HeNB-GW Network service.

`addr_val` must be entered in the IPv4 (dotted decimal notation) or IPv6 (`/::` notation).

**Example**

Use this command to bind the pre configured IPv4/IPv6 address of the S1-MME interface to the logical eNodeB.

Following command binds the S1-MME interface having `192:168:100:101` IP address with specific logical eNodeB.

```
bind s1-mme ipv6-address 192:168:100:101
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
s1-mme ip qos-dscp

This command configures the quality of service (Do's) differentiated service code point (DSCP) marking for IP packets sent out on the S1-MME interface, from the HeNB-GW to the MME(s).

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration > Logical eNodeB Configuration

```
configure > context context_name > henhbgw-network-service service_name > logical-enb
global-enb-id pimn_id mcc mcc_id mnc mnc_id {home-enb-id henhbgw | macro-enb-id menb_id}
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(logical-enb)#
```

Syntax

```
s1-mme ip qos-dscp { af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41
| af42 | af43 | be | cs0 | cs1 | cs2 | cs3 | cs4 | cs5 | cs6 | cs7 | ef }

default s1-mme ip qos-dscp
```

```
qos-dscp { af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41
| af42 | af43 | be | cs0 | cs1 | cs2 | cs3 | cs4 | cs5 | cs6 | cs7 | ef }
```

Default: af11

Specifies the DSCP for the specified QoS traffic pattern. qos-dscp can be configured to any one of the following:

- `af11`: Assured Forwarding 11 per-hop-behavior (PHB)
- `af12`: Assured Forwarding 12 PHB
- `af13`: Assured Forwarding 13 PHB
- `af21`: Assured Forwarding 21 PHB
- `af22`: Assured Forwarding 22 PHB
- `af23`: Assured Forwarding 23 PHB
- `af31`: Assured Forwarding 31 PHB
- `af32`: Assured Forwarding 32 PHB
- `af33`: Assured Forwarding 33 PHB
- `af41`: Assured Forwarding 41 PHB
- `af42`: Assured Forwarding 42 PHB
- `af43`: Assured Forwarding 43 PHB
- `be`: Best effort forwarding PHB
- `cs0`: Designates use of Class Selector 0 PHB. This is same as DSCP Value BE
- `cs1`: Designates use of Class Selector 1 PHB
- `cs2`: Designates use of Class Selector 2 PHB
- `cs3`: Designates use of Class Selector 3 PHB
- `cs4`: Designates use of Class Selector 4 PHB
cs5: Designates use of Class Selector 5 PHB
cs6: Designates use of Class Selector 6 PHB
cs7: Designates use of Class Selector 7 PHB
ef: Expedited forwarding PHB

Usage

DSCP levels can be assigned to specific traffic patterns to ensure that data packets are delivered according to the precedence with which they are tagged. The diffserv markings are applied to the IP header of every subscriber data packet transmitted over the S1-MME interface(s).

Example

The following command sets the DSCP-level for data traffic sent over the S1-MME interface to af12:

```
s1-mme ip qos-dscp af12
```
s1-mme sctp port

This command configures the local Stream Control Transmission Protocol (SCTP) port used for binding the SCTP socket to communicate with the MMEs over S1-MME interface.

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration > Logical eNodeB Configuration

```
configure > context context_name > hengw-network-service service_name > logical-enb
  global-enb-id plmn_id mcc mcc_id mnc mnc_id { home-enb-id henb_id | macro-enb-id menb_id }
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(logical-enb)#
```

**Syntax**

```
s1-mme sctp port port_num

default s1-mme sctp port
```

**default s1-mme sctp port**

- **default**
  
  Sets the SCTP port to the default value of 36412 to communicate with the MMEs using S1-MME interface.

- **port_num**
  
  Specifies the SCTP port number to communicate with the HeNBs using S1-MME interface as an integer from 1 through 65535. Default: 36412

**Usage**

Use this command to assign the SCTP port with SCTP socket to communicate with the HeNB using S1AP. Only one SCTP port can be associated with one MME service.

**Example**

The following command sets the default SCTP port number 699 for to interact with Home eNodeB using S1AP on S1-MME interface:

```
default s1-mme sctp port
```
Chapter 196
Loopback Interface Configuration Mode Commands

Use the Loopback Interface Configuration mode to create and manage loopback interfaces that provide IP addresses that are always available and reachable from any interface within a given context.

**Mode**

Exec > Global Configuration > Context Configuration > Loopback Interface Configuration

```
configure > context context_name > interface interface_name loopback
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-if-loopback)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**crypto-map**

Applies the specified IPSec crypto-map to this interface.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Loopback Interface Configuration

```
configure > context context_name > interface interface_name loopback
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-if-loopback)#
```

**Syntax**

```
crypto-map map_name [ secondary-address sec_ip_addr ]
```

- **no**
  Deletes the application of the crypto map on this interface.

- **map_name**
  Specifies the name of the crypto map being applied. The name is an alphanumeric string of 1 through 127 characters that is case sensitive.

- **secondary-address sec_ip_addr**
  Applies the crypto map to the secondary address for this interface that is specified by `sec_ip_addr`. `sec_ip_addr` must be specified using the IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

**Usage**

In order for ISAKMP and/or manual crypto maps to work, they must be applied to a specific interface using this command. Dynamic crypto maps should not be applied to interfaces. The crypto map must be configured in the same context as the interface.

**Example**

To apply the IPSec crypto map named cmap1 to this interface, use the following command:

```
crypto-map cmap1
```
**description**

Use this command to configure the descriptive text for the current interface.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > Loopback Interface Configuration  
configure > context context_name > interface interface_name loopback

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-if-loopback)#
```

**Syntax**

```
description text
no description
```

**Usage**

Set the description to provide any useful information on the interface’s primary function, services, end users.

**Example**

```
description sampleInterfaceDescriptiveText
```
end

Exits the current configuration mode and returns to the Exec mode.

All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Loopback Interface Configuration

configure > context context_name > interface interface_name loopback

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-if-loopback)#

Syntax

ip address { ip_address ip_mask | ip_address/bitmask } [ secondary | srp-activate ]
no ip address ip_address

ip ranged-address { ip_address ip_mask | ip_address/bitmask}
no ip ranged-address

no

Deletes the IP address or range of IP address you specify from the interface configuration.

address {ip_address ip_mask | ip_address/bitmask} [ secondary | srp-activate ]

Configures the IP address and network mask for the interface.

Enter an ip_address ip_mask to specify an IP address and the subnet mask pair that identifies the IP address of the interface. ip_address is entered in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation. Currently, the only value accepted for ip_mask is 255.255.255.255 (IPv4) or 120 (IPv6).

For the network mask, ip_address/net_mask, enter the IP address and the length in bits of the network mask. For example, 192.168.1.0/32 (IPv4) or fe80::c0a8:100/32 (IPv6). Currently, the only value accepted for bit_mask is 32.

Use the secondary keyword ito configure a secondary IP address on the interface. This is referred to as multi-homing of the interface.

Use the srp-activate keyword to activate the IP address for Interchassis Session Recovery (ICSR).

range-address ip_address ip_mask | ip_address/bitmask

Configures the range or group of IP address for the loopback interface. This support is provided to enable the support of multiple Enterprise HA in one HA service.

ip_address specifies the IP address for the loopback interface and must be specified in IPv4 dotted-decimal notation.

ip_mask specifies the number of subnet bits, representing the subnet mask in CIDR notation and must be a value between 1 to 32 and bitmask specifies the subnet mask in IPv4 dotted-decimal notations.
**Important:** This interface configuration is allowed only for IPv4 addresses and MUST be bound to the HA Service.

**Usage**
Create and manage loopback interfaces for the current context.
IP range support is provided through `range-address` keyword. This keyword is added to provide Enterprise HA support on HA service to connect enhanced number of enterprise nodes. Refer *HA Administration Guide* for more information.

This IP address range configuration must meet the following criteria:
- The ranged address MUST be a primary address.
- The ranged-address MUST be unique across the interface configuration.
- The ranged-address MUST be unique across the Context.
- The address specified in the ranged address MUST NOT be part of any other interface.
- The ranged-address can be a SRP-activated address and the behavior is the same as with any SRP-activated address.

**Example**
The following command configures IP address to associate with the interface:

```
ip address 1.2.3.4 255.255.255.255
```

The following command removes the associated IP address for the interface:

```
no ip address 10.2.3.4
```

The following command configures the range of IP addresses for over this interface to be used with HA service configuration for Enterprise HA support:

```
ip range-address 10.2.3.0/24
```
ip vrf

Use this command to configure the IP VPN Routing Forwarding (VRF) instance for the current interface.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Loopback Interface Configuration

configure > context context_name > interface interface_name loopback

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-if-loopback)#

Syntax

ip vrf forwarding vrf_name

no vrf forwarding

no

Deletes the IP VRF instance you specify from the interface configuration.

vrf_name

Specifies the preconfigured IP VRF instance name to be used with this interface.

For vrf_name, enter a VRF instance name that was preconfigured via the ip vrf forwarding command in Context Configuration mode.

Usage

Use this command to associate a preconfigured IP VRF instance for the current interface.

Example

The following command associates a preconfigured IP VRF instance named vrf_1 with this interface:

ip vrf forwarding vrf_1
**ipv6 address**

Use this command to configure the IPv6 options for the current interface.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > Loopback Interface Configuration
configure > context context_name > interface interface_name loopback

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-if-loopback)#
```

**Syntax**

```
ipv6 address ipv6_address ip_mask [ srp-activate ]

no ipv6 address ipv6_address
```

**Usage**

Create and manage loopback interfaces for the current context and enable Session Redundancy Protocol (SRP) when appropriate.

**Example**

The following command configures an IPv6 address to associate with the interface and enables SRP:

```
ipv6 address 2001:268:2008:b::1021/128 srp-activate
```
Chapter 197
LTE Emergency Profile Configuration Mode Commands

This mode configures parameters supporting the IP Multimedia Subsystem (IMS) emergency bearer services. Connectivity to an emergency Packet Data Network (PDN) is statically configured in this mode.

**Mode**

Exec > Global Configuration > LTE Policy Configuration > LTE Emergency Profile Configuration

```
configure > lte-policy > lte-emergency-profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(lte-emergency-profile) #
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
ambr

Configures the maximum aggregated uplink and downlink bitrate values for this profile.

Product
MME

Privilege
Administrator

Mode
Exec > Global Configuration > LTE Policy Configuration > LTE Emergency Profile Configuration

configure > lte-policy > lte-emergency-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(lte-emergency-profile)#

Syntax

ambr max-\ul bitrate max-\dl bitrate

no ambr

no

Removes the aggregated maximum bitrate (AMBR) configuration for this emergency profile.

max-\ul bitrate

Configures the maximum aggregated bitrate value for the uplink as an integer from 0 through 1410065408.

max-\dl bitrate

Configures the maximum aggregated bitrate value for the downlink as an integer from 0 through 1410065408.

Usage

Use this command to configure uplink and downlink maximum aggregated bitrate values to be shared across all non-guaranteed bitrate bearers established for the emergency session.

Example

The following example configures the uplink AMBR value to 2000 bps and the downlink AMBR value to 2000 bps:

    ambr max-\ul 2000 max-\dl 2000
apn

Configures the name and PDN type of the access point name (APN) used for emergency PDN connections.

**Product**
MME

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > LTE Policy Configuration > LTE Emergency Profile Configuration

configure > lte-policy > lte-emergency-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(lte-emergency-profile)#

**Syntax**

```
apn apn_name pdn-type { ipv4 | ipv4v6 | ipv6 }
no apn
```

**no apn**

Removes the selected APN from the profile.

```
apn_name
```

*apn_name* specifies the name of a pre-configured APN profile to associate with this LTE emergency profile. For more information on APNs, refer to the *apn* command in the *Context Configuration Mode Commands* chapter.

```
pdn-type { ipv4 | ipv4v6 | ipv6 }
```

Configures the packet data network type supported by the APN and this profile.

*ipv4*: Specifies that the PDN supports IPv4 network traffic.

*ipv4v6*: Specifies that the PDN supports both IPv4 and IPv6 network traffic.

*ipv6*: Specifies that the PDN supports IPv6 network traffic.

**Usage**
Use this command to select the APN to be used for emergency bearer services. APNs are configured through the APN Configuration mode. For more information regarding APN configuration mode commands, refer to the *APN Configuration Mode Commands* chapter.

**Example**
The following command specifies that the APN named *apn-3.com* is to be used for emergency bearer services and that the PDN supports IPv4 traffic only:

```
apn apn-3.com pdn-type ipv4
```
associate

 Associates a location service with this LTE emergency profile.

 **Product**
 MME

 **Privilege**
 Administrator

 **Mode**
 Exec > Global Configuration > LTE Policy Configuration > LTE Emergency Profile Configuration

 configure > lte-policy > lte-emergency-profile profile_name

 Entering the above command sequence results in the following prompt:

 [local]host_name(lte-emergency-profile)#

 **Syntax**

 associate location-service location_svc_name

 no associate location-service

 no

 Disassociates a previously associated location service with this LTE emergency profile.

 location-service location_svc_name

 Associates a location service with this LTE emergency profile. Only one location service can be associated with an LTE emergency profile.

 location_svc_name specifies the name for a pre-configured location service to associate with the LTE emergency profile as an alphanumeric string of 1 through 63 characters.

 **Usage**

 Use this command to associate a pre-configured location service with an LTE emergency profile. This enables the associated location service to provide location information of emergency calls to the GMLC.

 For more information about Location Services (LCS), refer to the location-service command in the Context Configuration Mode Commands chapter as well as the Location Services Configuration Mode Commands chapter.

 Further details can be found in the Location Services chapter of the MME Administration Guide.
end

Exits the current configuration mode and returns to the Exec mode.

pgw

Statically configures a P-GW to support emergency bearer services for this profile.

Product
MME

Privilege
Administrator

Mode
Exec > Global Configuration > LTE Policy Configuration > LTE Emergency Profile Configuration
configure > lte-policy > lte-emergency-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(lte-emergency-profile)#

Syntax

pgw fqdn fqdn

pgw ip-address address protocol { both | gtp | pmip } weight value

no pgw { fqdn | ip-address address }

no fqdn
Removes the specified P-GW Fully Qualified Domain Name (FQDN) or IP address from this profile.

fqdn fqdn
Specifies the domain name of the P-GW as an alphanumeric string of 1 through 256 characters.

**Important:** A maximum of one P-GW FQDN configuration is allowed per profile.

ip-address address
Specifies the IP address for the P-GW in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

**Important:** A maximum of four P-GW IP address configurations are allowed per profile.

protocol { both | gtp | pmip }
Specifies the protocol the P-GW supports. Options are:

• **both:** Specifies that both the GTP and PMIP protocols are supported.
• **gtp:** Specifies that only GTP is supported.
• **pmip:** Specifies that only PMIP is supported.
weight value
Assigns a weight to P-GW IP address to use as a preferred P-GW as an integer from 1 through 100. Lowest value has the least preference.

Usage
Use this command to statically configure the P-GW used to support emergency bearer services through this profile.

Example
The following command configures the P-GW supporting emergency bearer services for this profile as pdn-911.gov:

```
pgw fqdn P-GW FQDN
```

The following command configures the P-GW supporting emergency bearer services for this profile as having an IPv4 address of 10.2.3.4, supporting GTP only, and having a weight of 10:

```
pgw ip-address 10.2.3.4 protocol gtp weight 10
```
qos

Configures the quality of service (QoS) parameters for the emergency bearer service.

**Product**
MME

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > LTE Policy Configuration > LTE Emergency Profile Configuration

```bash
configure > lte-policy > lte-emergency-profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(lte-emergency-profile)#
```

**Syntax**

```bash
qos qci qci arp arp_value preemption-capability { may | shall-not } vulnerability { not-preemptable | preemptable }

no qos
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>qci qci</code></td>
<td>Specifies the QoS Class Identifier (QCI) for the emergency bearer profile as an integer from 0 through 255.</td>
</tr>
<tr>
<td><code>arp arp_value</code></td>
<td>Defines the address retention priority value as an integer from 1 through 15.</td>
</tr>
</tbody>
</table>
| `preemption-capability { may | shall-not }` | Specifies the preemption capability flag. Options are:  
  - `may`: Bearer may be preempted  
  - `shall-not`: Bearer shall not be preempted |
| `vulnerability { not-preemptable | preemptable }` | Specifies the vulnerability flag. Options are:  
  - `not-preemptable`: Bearer cannot be preempted.  
  - `preemptable`: Bearer can be preempted. |

**Usage**

Use this command to set the QoS ARP and QCI parameters for the emergency bearer configuration.

**Example**

The following command sets the QCI number to 7, the ARP value to 2, the preemption capability to “may”, and the vulnerability flag to “pre-emptable”:

```bash
qos qci 7 arp 2 preemption-capability may vulnerability preemptable
```
ue-validation-level

Configures the type of user equipment (UE) that can use the emergency bearer service through the profile.

**Product**
MME

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > LTE Policy Configuration > LTE Emergency Profile Configuration

```
configure > lte-policy > lte-emergency-profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(lte-emergency-profile)#
```

**Syntax**

```
ue-validation-level { auth-only | full | imsi | none }
```

```
default ue-validation-level
```

```
default
```

Returns the command to its default setting of “none”.

```
{ auth-only | full | imsi | none }
```

Specifies the type of UE allowed to use the emergency bearer service. Options are:

- **auth-only**: Specifies that UEs that have been authenticated are allowed to use the emergency bearer service. These UEs may be in a limited service state in that they may be in an area with restricted service or where they are restricted from services. Enabling this option also causes subscription and location validation to be bypassed.
- **full**: Specifies that only UEs that have been authenticated and have successfully passed subscription and location validation are allowed to use the emergency bearer service. Enabling this option indicates that only UEs that are capable of normal attach procedures will be allowed to use the emergency bearer service.
- **imsi**: Specifies that UEs with an International Mobile Subscriber Identity (IMSI) are allowed to use the emergency bearer service regardless of authentication. Even if authentication fails, the UE is granted access.
- **none**: Specifies that all UEs are allowed to use the service. This is the default value for the command.

**Usage**

Use this command to indicate which UEs can use the emergency bearer service through this profile.

**Example**

The following command configures the type of UE allowed to use the emergency bearer service to “IMSI required, authentication optional”:

```
ue-validation-level imsi
```
Chapter 198
LTE Forbidden Location Area Configuration Mode Commands

The LTE Forbidden Location Area Configuration Mode is used to create and manage forbidden 3G location area code (LAC) configurations.

Mode

Exec > Global Configuration > LTE Policy Configuration > LTE HO Restriction List Configuration > LTE Forbidden Location Area Configuration

```
configure > lte-policy > ho-restrict-list list_name > forbidden location-area plmnid plmn_id
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(forbidden_la)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**
Use this command to return to the parent configuration mode.
**lac**

Configures a 3G location area code (LAC) or area codes where a UE, associated with this LTE policy, is restricted from participating in a handover scenario.

**Product**
MME

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > LTE Policy Configuration > LTE HO Restriction List Configuration > LTE Forbidden Location Area Configuration

```bash
configure > lte-policy > ho-restrict-list list_name > forbidden location-area plmn_id
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(forbidden_la)#
```

**Syntax**

```
[ no ] lac { area_code } +
```

*no*

Removes a configured forbidden handover area code or area codes from this policy. If no location area code is specified, then all location area codes are removed.

*area_code*

Specifies an area code or area codes from which UEs are restricted from participating in a handover as an integer from 0 through 65535. Multiple area codes can be entered (up to 128 in a single line, separated by spaces).

**Usage**

Use this command to configure 3G location-based area codes that will be forbidden to UEs associated with this LTE policy.

**Example**

The following command configures eight location-based area codes (1, 2, 3, 4, 5, 6, 7, 8) where a UE, associated with this LTE policy, is restricted from participating in a handover scenario:

```
lac 1 2 3 4 5 6 7 8
```
Chapter 199
LTE Forbidden Tracking Area Configuration Mode
Commands

The LTE Forbidden Tracking Area Configuration Mode is used to create and manage forbidden tracking area code (TAC) configurations.

Mode
Exec > Global Configuration > LTE Policy Configuration > LTE HO Restriction List Configuration > LTE Forbidden Tracking Area Configuration
configure > lte-policy > ho-restrict-list list_name > forbidden tracking-area plmnid plmn_id

Entering the above command sequence results in the following prompt:

[local]host_name(forbidden_ta)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

**Product**

<tbody>
<tr>
<td>Specifies a tracking area code or area codes from which UEs are restricted from participating in a handover as an integer from 0 to 65535. Multiple area codes can be entered (up to 128 in a single line, separated by spaces).</td>
</tr>
</tbody>
</table>

Usage
Use this command to configure tracking area codes that will be forbidden to UEs associated with this LTE policy.

Example
The following command configures two tracking area codes (1, 2, 3, 4, 5, 6, 7, 8) where a UE, associated with this LTE policy, is restricted from participating in a handover scenario:

    tac 1 2 3 4 5 6 7 8
Chapter 200
LTE Foreign PLMN GUTI Management Database
Configuration Mode Commands

The LTE Foreign PLMN GUTI Management Database Configuration Mode is used to create restrictions on foreign PLMNs, thereby avoiding DNS request attempts to foreign PLMNs.

**Mode**

Exec > Global Configuration > LTE Policy Configuration > Foreign PLMN GUTI Management Database

```plaintext
configure > lte-policy > foreign-plmn-guti-mgmt-db
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(foreign-plmn-guti-mgmt-db)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

```

**Usage**
Use this command to return to the parent configuration mode.
plmn

Configures a foreign Public Land Mobile Network (PLMN) entry in the Foreign PLMN GUTI management database. This optional configuration is used to control the acceptance or immediate reject of Attach Requests and TAU Requests containing a GUTI from this PLMN.

Product
MME

Privilege
Administrator

Mode
Exec > Global Configuration > LTE Policy Configuration > Foreign PLMN GUTI Management Database
configure > lte-policy > foreign-plmn-guti-mgmt-db

Entering the above command sequence results in the following prompt:

[local]host_name(foreign-plmn-guti-mgmt-db)#

Syntax

plmn mcc { mcc_value | any } mnc { mnc_value | any } [ allow | reject ]

plmn mcc mcc_value mnc mnc_value

no

Removes the specified PLMN entry from the Foreign PLMN GUTI management database.

mcc mcc_value mnc mnc_value

mcc { mcc_value | any } : Specifies the mobile country code (MCC) portion of the PLMN identifier as an integer from 100 through 999. Use the optional any keyword to specify a wildcard, representing any MCC.
mnc { mnc_value | any } : Specifies the mobile network code (MNC) portion of the PLMN identifier a 2- or 3-digit integer from 00 through 999. Use the optional any keyword to specify a wildcard, representing any MNC.

Note: The any keyword can only be used for the MNC value when a specific MCC value is given. For example, the follow command is not allowed:
plmn mcc any mnc 456 allow

allow

Configures the MME to allow foreign GUTIs from this PLMN.

reject

Configures the MME to reject foreign GUTIs from this PLMN.
Usage

Use this command to create and configures a foreign Public Land Mobile Network (PLMN) entry in the Foreign PLMN GUTI management database. This optional configuration is used to control the acceptance or immediate reject of Attach Requests and TAU Requests containing a GUTI from this PLMN.

If the configured action is Reject, the MME takes the following actions:

- Attach Requests: a NAS Identity Request is sent to the UE to determine its IMSI, and no DNS lookup is performed to find a peer MME or SGSN.
- TAU Requests: a TAU Reject message is sent immediately with cause code 9 (UE Identity cannot be derived by the network), and no DNS lookup is performed to find a peer MME or SGSN.

If the configured action is Allow, the MME continues processing the Attach Request or TAU Request, and a DNS request may be made.

A maximum of 16 foreign PLMN entries can be added to a Foreign PLMN GUTI management database.

Example

The following command creates a plmn entry in the foreign PLMN GUTI management database. The entry specifies that GUTIs from PLMNs with the MCC of 123 and any MNC be rejected.

```
plmn mcc 123 mnc any reject
```
Chapter 201
LTE Handover Restriction List Configuration Mode Commands

The LTE Handover Restriction List Configuration Mode is used to create and manage the LTE handover restriction lists for LTE/SAE networks. Handover restriction lists are used to restrict user equipment (UE) from participating in specified handovers. The MME creates the handover restriction lists as part of its local policy and provides them to the eNobeB where the restrictions are enforced.

Mode

Exec > Global Configuration > LTE Policy Configuration > LTE HO Restriction List Configuration

configure > lte-policy > ho-restrict-list list_name

Entering the above command sequence results in the following prompt:

[local]host_name(ho-restrict-list)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
forbidden

Configures the handover restriction lists provided to eNodeBs where handover restrictions are enforced for UEs.

Product
MME

Privilege
Administrator

Mode
Exec > Global Configuration > LTE Policy Configuration > LTE HO Restriction List Configuration

configure > lte-policy > ho-restrict-list list_name

Entering the above command sequence results in the following prompt:

[local]host_name(ho-restrict-list)#

Syntax

[ no ] forbidden { inter-rat { all | cdma2000 | geran | utran } | location-area plmnid id | tracking-area plmnid id }

default forbidden inter-rat

Remove the forbidden inter-RAT configuration from the LTE policy.

no

Removes the forbidden configuration from the LTE policy.

inter-rat { all | cdma2000 | geran | utran }

Specifies that one or all Radio Access Technology (RAT) handovers are to be prohibited for UEs associated with the LTE policy.

all: Specifies that all inter-RAT handovers are to be prohibited for UEs associated with the LTE policy.

cdma2000: Specifies that all CDMA2000 handovers are to be prohibited for UEs associated with the LTE policy.

geran: Specifies that all GSM EDGE Radio Access Network (GERAN) handovers are to be prohibited for UEs associated with the LTE policy.

utran: Specifies that all UMTS Terrestrial Radio Access Network (UTRAN) handovers are to be prohibited for UEs associated with the LTE policy.

location-area plmnid id

Specifies that handovers to 3G location area codes defined through this keyword and subsequent configuration mode are to be prohibited for UEs associated with the LTE policy. Enters the LTE Forbidden Location Area Configuration Mode. id must be a valid PLMN ID expressed as an integer comprised of an MCC (Mobile Country Code) and MNC (Mobile Network Code) [five-digit minimum, six-digit maximum].

Important: Up to 16 forbidden location area PLMN IDs can be configured per handover restriction list.
Entering this command results in the following prompt:

```
[context_name]hostname(forbidden_la)#
```

LTE Forbidden Location Area Configuration Mode commands are defined in the *LTE Forbidden Location Area Configuration Mode Commands* chapter.

```
tracking-area plmnid id
```

Specifies that handovers to 4G tracking area codes defined through this keyword and subsequent configuration mode are to be prohibited for UEs associated with the LTE policy. Enters the LTE Forbidden Tracking Area Configuration Mode. *id* must be a valid PLMN ID and be an integer value comprising an MCC and MNC (five-digit minimum, six-digit maximum).

**Important:** Up to 16 forbidden tracking area PLMN IDs can be configured per handover restriction list.

```
[context_name]hostname(forbidden_ta)#
```

LTE Forbidden Tracking Area Configuration Mode commands are defined in the *LTE Forbidden Tracking Area Configuration Mode Commands* chapter.

### Usage

Use this command to create the list of restricted handover types that apply to all UEs associated with the LTE policy.

### Example

The following command prohibits UEs associated with this LTE policy from participating in a handover to a GERAN network type:

```
forbidden inter-rat geran
```

The following command prohibits UEs, associated with this LTE policy and a mobile network with a PLMN ID of 12345, from participating in a handover to location area codes defined in the Location Area Configuration Mode:

```
forbidden location-area plmnid 12345
```
Chapter 202
LTE Network Global MME ID Management Database Configuration Mode Commands

The LTE Network Global MME ID Management Database Configuration Mode is used to create associations between PLMN IDs and MME group ID ranges.

Mode

Exec > Global Configuration > LTE Policy Configuration > LTE Network Global MME ID Management Database Configuration

configure > lte-policy > network-global-mme-id-mgmt-db

Entering the above command sequence results in the following prompt:

[local]host_name(network-global-mme-id-mgmt-db)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
exit
```

Usage
Use this command to return to the parent configuration mode.
**plmn**

Configures associations between public land mobile network (PLMN) IDs and ranges of MME group IDs. On the S4-SGSN, this command allows the operators to configure a custom list of MME group IDs if networks have been configured with LACs in the 32768-65535 range for UMTS and GPRS coverage.

**Product**
MME
SGSN

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > LTE Policy Configuration > LTE Network Global MME ID Management Database Configuration

configure > lte-policy > network-global-mme-id-mgmt-db

Entering the above command sequence results in the following prompt:

```
[local]host_name(network-global-mme-id-mgmt-db)#
```

**Syntax**

```
[ no ] plmn mcc mcc_value mnc mnc_value mme-group-id-range first id last id
```

- **no**
  - Removes the selected PLMN ID to MME group ID range from the MME ID management database.

```
mcc mcc_value mnc mnc_value
```

- **mcc mcc_value**: Specifies the mobile country code (MCC) portion of the PLMN identifier as an integer from 100 through 999.
- **mnc mnc_value**: Specifies the mobile network code (MNC) portion of the PLMN identifier as a 2- or 3-digit integer from 00 through 999.

```
mme-group-id-range first id last id
```

- Specifies the range of MME group IDs to apply to the PLMN ID as an integer from 0 to 65535.

**Usage**

Use this command to create associations between PLMN IDs and a range of MME group IDs. On the S4-SGSN, use this command to create a custom list of MME group IDs on the S4-SGSN if networks have been configured with LACs in the 32768-65535 range for UMTS and GPRS coverage. The S4-SGSN will use this custom list to identify whether the received LAC is a native LAC or a LAC mapped from a globally unique temporary identifier (i.e., an MME group code part of GUTI). Once the **plmn** configuration is completed, operators must associate the configuration with the GPRS and/or SGSN services configured on the S4-SGSN using the **associate network-global-mme-id-mgmt-db** command. Refer to the **SGSN Service Configuration Mode** and **GPRS Service Configuration Mode** chapters in the **GPRS/UMTS Command Line Reference** for a description of this command.

**Example**

Cisco ASR 5x00 Command Line Interface Reference
The following command creates an association between a PLMN ID of 12323 and a set of MME group IDs with a range of 500 through 575:

```
plmn mcc 12323 mnc 23 mme-group-id-range first 500 last 575
```
Chapter 203
LTE Paging Map Configuration Mode Commands

The LTE Paging Map Configuration Mode is used to create and manage the LTE paging maps supporting MME configurations on the system.

Mode

Exec > Global Configuration > LTE Policy Configuration > LTE Paging Map Configuration

```
configure > lte-policy > paging-map map_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(paging-map)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
precedence

Enables the operator to apply a priority for different paging-profiles based on traffic type. When the MME service is associated with a paging map, the system checks the profile map to determine which paging-profile to adopt for a given paging trigger.

Product
MME

Privilege
Administrator

Mode
Exec > Global Configuration > LTE Policy Configuration > LTE Paging Map Configuration

configure > lte-policy > paging-map <map_name>

Entering the above command sequence results in the following prompt:

[local]host_name(paging-map)#

Syntax

precedence priority traffic-type { cs | ps } paging-profile <paging_profile_name>

no precedence precedence

no

Remove the paging map from the system.

precedence priority

precedence: For StarOS releases 16.5 and higher, enter an integer from 1 to 19, where 1 is the highest priority and 19 is the lowest priority. For StarOS releases prior to 16.5, enter an integer from 1 to 7, where 1 is the highest priority and 7 is the lowest priority.

traffic-type { cs | ps}

Defines the type of traffic of the incoming call.

- **cs** (Circuit Switched) - All data and control activities that involve CSFB. Paging requests from the MSC for mobile-terminated calls alone are treated as CS type. Paging requests for SMS are treated as PS type.
  
  If a sub-traffic-type is not configured then paging-profile configured for CS (with no sub traffic-type qualification) is applied. If no such entry exists, then default heuristics based paging behavior is applied.

- **ps** (Packet Switched) - All data and control activities that involve packet services. SRVCC is also mapped to this traffic-type as the voice is carried using PS service.

paging-profile <paging_profile_name>

The paging-profile to apply for paging UE.
**Important:** If the associated paging-map does not exist or does not have an entry matching the paging-trigger, the MME performs paging as outlined in 'Default Heuristics Paging Behavior' in the *Heuristic and Intelligent Paging* chapter in the MME Administration Guide.

**Usage**

Use this command to apply different paging-profiles based on traffic types. The command defines the order (1 - highest, 7 - lowest) in which the MME checks the entries in this paging-map. If the paging trigger (like Downlink Data Notification or MSC request) matches the traffic-type of that entry, then the corresponding paging-profile is used for paging the UE. If the paging trigger does not match, then the next entry in the precedence order is picked and checked for a match. If no match is found in the entire paging-map table then default heuristic paging profile is adopted.

If the MME receives another paging trigger (for example from the MSC for CSFB) while paging is already in progress, the MME checks whether a higher precedence paging profile can be applied. If the new trigger has a paging-map entry with a higher precedence, the MME restarts the paging process using the paging-profile associated with the new map entry.

Paging is typically triggered when either the MSC indicates that there is an incoming call to the UE (Call Service, CS), or when the S-GW sends a Downlink Data Notification (Packet Service, PS) to the MME, or when there is a bearer/PDN request coming from the P-GW/S-GW.

Refer to the *Heuristic and Intelligent Paging* chapter in the MME Administration Guide for more information.

**Related Commands**

Refer to the `paging-profile` command in the LTE Policy Configuration Commands chapter to create the paging profiles used in this command.
Chapter 204
LTE Paging Profile Configuration Mode Commands

The LTE Paging Map Configuration Mode is used to create and manage the paging profiles that control the different stages of paging for MME configurations on the system.

Mode

Exec > Global Configuration > LTE Policy Configuration > LTE Paging Profile Configuration

configure > lte-policy > paging-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(paging-profile)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
end

**Usage**

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**
Use this command to return to the parent configuration mode.
paging-stage

Enables the operator to configure different stages of paging in the order of desired execution with parameters that control the pace, volume, and behavior of a given paging stage.

Product
MME

Privilege
Administrator

Mode
Exec > Global Configuration > LTE Policy Configuration > LTE Paging Profile Configuration

configure > lte-policy > paging-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(paging-profile)#

Syntax

[ no ] paging-stage level match-criteria { ue-contact-time seconds | all } action { last-n-enb-last-tai max-n-enb value | all-enb-last-tai | all-enb-all-tai } t3413-timeout
seconds max-paging-attempts attempts

no

Remove the paging-stage from the system.

level

Defines different levels of paging-stages, each with a different match-criteria and different action. level must be a value 1 through 5.

match-criteria

Specifies the criteria for selecting a given paging stage.

•ue-contact-time seconds - Number of seconds elapsed since the MME last heard from UE. This time, if set, acts as an upper time limit to consider a given paging-stage for paging purposes. seconds must be a value from 0 through 86400.

•all - No criteria. Operator can use this match-criteria for the final paging stage.

action

Defines how the paging request should be formulated.

•last-n-enb-last-tai max-n-enb value - Send paging request to the last known number of eNodeBs (configured using max-n-enb value) and to the last known TAI. value must be a value from 1 through 5.

•all-enb-last-tai - Send paging request to all eNodeBs and to last known TAI.

•all-enb-all-tai - Send paging request to all eNodeBs and to all TAIs.
**t3413-timeout** *seconds*

Defines the time-interval in seconds between paging requests. The MME uses this timer for retransmission of an S1 Paging request to UE for PS paging. *timeout* must be a value from 0 through 20.

CS triggered S1 Paging requests are transmitted only once by the MME (no retransmission). For a CS paging to be sent again, another SGs paging request needs to be sent by MSC/VLR towards MME.

**max-paging-attempts** *attempts*

Defines the number of paging requests to be sent out during this paging-stage.

*attempts* must be a value from 0 through 5.

**Usage**

Use this command to configure paging procedure stages, which in turn control the pace, volume, and behavior of paging for each stage.

**Related Commands**

Refer to the **paging-map** command in the *LTE Policy Configuration Commands* chapter to assign a priority for this paging profile based on traffic type.
Chapter 205
LTE Peer Map Configuration Mode Commands

The LTE Peer Map Configuration Mode enables the operator to map LTE Policy to a peer profile based on matching criteria and precedence for the criteria.

**Mode**

Exec > Global Configuration > LTE Policy Configuration > LTE Peer Map Configuration

`configure > lte-policy > peer-map map_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(peer-map)#
```

**Important:** Available commands or keywords/variables vary based on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

**precedence**

Configures the matching criteria and precedence for mapping an LTE Policy with a peer profile.

**Product**

P-GW
SAEGW
S-GW

**Privilege**

Administrator

**Mode**

Exec > Global Configuration > LTE Policy Configuration > LTE Peer Map Configuration

```
configure > lte-policy > peer-map map_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(peer-map) #
```

**Syntax**

```
precedence priority match-criteria { all peer-profile-name profile_name | peer-ip-address { ip_address | ip_address/mask } [ serving-plmnid mcc mcc mcc mcc ] peer-profile-name profile_name | serving-plmnid mcc mcc mcc mcc [ peer-ip-address { ip_address | ip_address/mask } ] peer-profile-name profile_name }
```

```
no precedence priority
```

Removing the selected precedence priority number from the peer map.

**priority**

(priority must be an integer from 1 to 1024.

**match-criteria**

Defines the criteria to be used to match peer nodes.

**all**

Specifies that all peer nodes are to be associated with the peer map.
To map a peer to a profile when there is no specific criteria required, use the all keyword.

**peer-profile-name profile_name**

Sets the peer profile with which the matching criteria is associated.

**profile_name** must be an existing peer profile expressed as an alphanumeric string of 1 through 64 characters.
**peer-ip-address ip_address | ip_address/mask**

Specifies the IP address of the peer node.

- `ip_address` must be specified using the standard IPv4 dotted decimal notation or colon notation for IPv6.
- `ip_address/mask` must be specified using the standard IPv4 dotted decimal notation or colon notation for IPv6, followed by the mask.

**serving-plmnid mcc mcc mnc mnc**

Specifies serving nodes with criteria matching the PLMN ID (MCC and MNC) are to be associated with a specified peer map.

- `mcc`: Specifies the mobile country code (MCC) portion of the PLMN ID. `mcc` must be a three-digit number between 100 and 999.
- `mnc`: Specifies the mobile network code (MNC) portion of the PLMN ID. `mnc` must be a two- or three-digit number between 00 and 999.

**Usage**

Use this command to map LTE Policy to a peer profile based on matching criteria and precedence for the criteria.

A maximum of 1024 precedence entries can be configured.

**Example**

The following command associates the peer profile named pp5 with peers associated with a serving node PLMN ID MCC of 111 and an MNC of 222:

```
precedence 100 match-criteria serving-plmnid mcc 111 mnc 222 peer-profile-name pp5
```
Chapter 206
LTE Policy Configuration Mode Commands

The LTE Policy Configuration Mode is used to create and manage the LTE policies supporting ePDG, MME, S-GW, SAEGW, SGSN and HeNBGW configurations on the system.

Mode

Exec > Global Configuration > LTE Policy Configuration
configure > lte-policy

Entering the above command sequence results in the following prompt:

[local]host_name(lte-policy)#

Important: Available commands or keywords/variables vary based on platform type, product version, and installed license(s).
cause-code-group

 Creates a new cause code group, or specifies an existing cause code group and enters the Cause Code Group Configuration Mode.

Product
MME

Privilege
Administrator

Mode
Exec > Global Configuration > LTE Policy Configuration

configure > lte-policy

Entering the above command sequence results in the following prompt:

[local]host_name(lte-policy)#

Syntax

cause-code-group group_name protocol s1ap

no cause-code-group group_name

no

Removes the specified cause code group with all related configuration from the LTE Policy.

 group_name

Specify a name of a cause-code-group to create, modify, or remove. This name must be an alphanumeric string of 1 through 16 characters. Each new cause-code-group must have a unique name.

A maximum of 4 cause code groups can be defined across all services (MME+GPRS+SGSN).

protocol

Specifies the protocol for the cause code group being created/accessed. Options include:

• S1-AP

Usage

Use this command to create or modify a group of cause codes.

Entering this command results in a prompt, with the protocol ID included, similar to the following:

[context_name]host_name(s1ap-cause-code)#

Depending upon the protocol you have selected, the Cause Code Group configuration commands are defined in the

• S1AP Cause Code Configuration Mode Commands chapter of this guide.

Example

The following command creates an S1-AP cause code group named move-ue-to-idle.
cause-code-group move-ue-to-idle protocol slap
congestion-action-profile

Creates an action profile for MME or ePDG critical, major and minor congestion thresholds. The profile defines the action to be taken when these thresholds are exceeded.

Product
- ePDG
- HeNBGW
- MME

Privilege
- Administrator

Mode
- Exec > Global Configuration > LTE Policy Configuration
  - configure > lte-policy

Entering the above command sequence results in the following prompt:

[local]host_name(lte-policy)#

Syntax

[ no ] congestion-action-profile profile_name

no

Removes the specified profile from the system.

profile_name

Specifies the name of the action profile. If the entered name does not refer to an existing profile, a new profile is created. profile_name is an alphanumeric string of 1 through 64 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use this command to establish MME or ePDG action profiles to be associated with critical, major and minor congestion thresholds. This command is also used to remove an existing profile.

For information on setting the action to be taken within this profile, see the Congestion Action Profile Configuration Mode Commands chapter in this guide, and the Congestion Control chapter in the System Administration Guide.

Example

The following command creates a major congestion action profile named mme_major_profile and moves to the Congestion Action Profile Configuration mode:

congestion-action-profile mme_major_profile
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
**foreign-plmn-guti-mgmt-db**

Creates a new, or enters the existing Foreign PLMN GUTI management database.

**Product**

MME

**Privilege**

Administrator

**Mode**

Exec > Global Configuration > LTE Policy Configuration

`configure > lte-policy`

Entering the above command sequence results in the following prompt:

```
[local]host_name(lte-policy)#
```

**Syntax**

```
foreign-plmn-guti-mgmt-db  db_name  [  -noconfirm  ]

no foreign-plmn-guti-mgmt-db  db_name
```

- **no**
  
  Remove the specified management database from the system.

- **-noconfirm**
  
  Executes the command without any additional prompt and confirmation from the user.

- **db-name**
  
  Specifies the name of the management database. If the name does not refer to an existing database, a new database is created.
  
  *db_name* is an alphanumeric string of 1 through 64 characters.

**Usage**

Use this command to create a new, or enter the existing Foreign PLMN GUTI management database. This management database allows for the optional configuration of foreign PLMNs for which Attach Requests or TAU Requests containing a GUTI from such a PLMN can either be allowed or immediately rejected.

A maximum of four separate Foreign PLMN GUTI management databases can be configured.

Entering this command results in the following prompt:

```
{context_name}hostname(foreign-plmn-guti-mgmt-db)#
```

Global MME ID management database commands are defined in the *LTE Foreign PLMN GUTI Management Database Configuration Mode Commands* chapter.

**Example**

The following command creates a Foreign PLMN GUTI management database named *fguti-db1*.

```
foreign-plmn-guti-mgmt-db  fguti-db1  -noconfirm
```
**henbgw mme-pool**

Creates or configures a specified MME or MME pool to which the HeNB-GW is to communicate and enters the MME pool configuration mode.

**Product**
HeNB-GW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > LTE Policy Configuration
configure > lte-policy

Entering the above command sequence results in the following prompt:

```
[local]host_name(lte-policy)#
```

**Syntax**

```
[ no ] henbgw mme-pool pool_name [ -noconfirm ]
```

- **no**
  Removes an already configured MME or MME pool from the system.

- **pool_name**
  Specifies the name of the MME pool being created or accessed. If the pool name does not refer to an existing profile, a new pool is created. *pool_name* is an alphanumeric string of 1 through 63 characters.

- **-noconfirm**
  Executes the command without any additional prompt and confirmation from the user.

**Usage**

Use this command to enter the MME Pool Configuration Mode for an existing pool or for a newly defined MME pool. This command is also used to remove an existing MME pool.

**Important:** A maximum of eight MME pools are allowed per system.

Entering this command results in the following prompt:

```
[context_name]hostname(mme-pool)#
```

MME Pool Configuration Mode commands are defined in the *MME Pool Configuration Mode Commands* chapter.

**Example**

The following command helps entering the MME Pool Configuration Mode for a new or existing profile named *henb_mme_pool*.
mme pool henb_mme_pool
**henbgw overload-control**

Configures HeNBGW overload control parameters.

**Product**
HeNBGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > LTE Policy Configuration

configure > lte-policy

Entering the above command sequence results in the following prompt:

[local]host_name(lte-policy)#

**Syntax**

```
henbgw overload-control [ load-reduction-indicator percentage_value | ochl-guard-time minutes ]
```

```
default henbgw overload-control [ load-reduction-indicator | ochl-guard-time ]
```

---

default

Sets/Restores the default values assigned to HeNBGW overload control parameters. The default value of load Reduction indication is 99 percent.

---

**load-reduction-indicator** percentage_value

Designates the percentage of HeNBs to relay overload start message if traffic load Reduction indication IE is not present in the overload start message.

*percentage_value* is the percentage value, which is an integer between 1 and 99.

---

**ochl-guard-time** minutes

Designates the guard timeout value for sending overload stop messages if overload stop message is not received from MME to all the HeNBs in corresponding MME’s overload control HeNBs list.

*minutes* is the number of minutes, which is an integer between 0 and 2147483647.

**Usage**

Use this command to configure HeNBGW overload control parameters.

**Example**

The following command configures HeNBGW overload control parameter *ochl-guard-time* as 45 minutes:

```
henbgw overload-control ochl-guard-time 45
```
ho-restrict-list

Creates a handover (HO) restriction list or specifies an existing HO restriction list and enters the Handover Restriction List Configuration Mode.

Product
- MME
- ePDG
- SAEGW
- S-GW

Privilege
Administrator

Mode
Exec > Global Configuration > LTE Policy Configuration
configure > lte-policy

Entering the above command sequence results in the following prompt:

[local]hostname(lte-policy)#

Syntax

[ no ] ho-restrict-list  list_name  [ -noconfirm ]

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
<tbody>
<tr>
<td>Removes the specified restriction list from the system.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>-noconfirm</th>
</tr>
</thead>
<tbody>
<tr>
<td>Executes the command without any additional prompt and confirmation from the user.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>list_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the name of the HO restriction list. If the entered list name does not refer to an existing list, a new list is created. list_name is an alphanumeric string of 1 through 64 characters.</td>
</tr>
</tbody>
</table>

Usage

Use this command to enter the Handover Restriction List Configuration Mode for an existing list or for a newly defined list. This command is also used to remove an existing list.

Entering this command results in the following prompt:

[context_name]hostname(ho-restrict-list)#

Handover Restriction List Configuration Mode commands are defined in the LTE Handover Restriction List Configuration Mode Commands chapter.

Example

The following command enters the Handover Restriction List Configuration Mode for a new or existing list named ho_restrict_list1:
ho-restrict-list ho_restrict_list1
**lte-emergency-profile**

Creates an LTE emergency profile or specifies an existing emergency profile and enters the LTE Emergency Profile Configuration Mode.

**Product**
- MME
- ePDG
- SAEGW
- S-GW

**Privilege**
Adminstrator

**Mode**
Exec > Global Configuration > LTE Policy Configuration
   `configure > lte-policy`

Entering the above command sequence results in the following prompt:

```
[local]host_name(lte-policy)#
```

**Syntax**

```
[ no ] lte-emergency-profile profile_name [ -noconfirm ]
```

- **no**
  Removes an LTE emergency profile from the system.

- **profile_name**
  Specifies the name of the LTE emergency profile being created or accessed. If the profile name does not refer to an existing profile, a new profile is created. `profile_name` is an alphanumeric string of 1 through 64 characters.

- **-noconfirm**
  Executes the command without any additional prompt and confirmation from the user.

**Usage**

Use this command to enter the LTE Emergency Profile Configuration Mode for an existing profile or for a newly defined profile. This command is also used to remove an existing profile.

**Important:** A maximum of four LTE emergency profiles are allowed per system.

Entering this command results in the following prompt:

```
[context_name]hostname(lte-emergency-profile)#
```
LTE Emergency Profile Configuration Mode commands are defined in the LTE Emergency Profile Configuration Mode Commands chapter.

**Example**

The following command enters the LTE Emergency Profile Configuration Mode for a new or existing profile named `emergency_profile3`:

```
lte-emergency-profile emergency_profile3
```
mme paging cache

Enable or disables caching of the MME’s paging and provides the operator configurable paging cache controls.

Product
MME

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > LTE Policy Configuration
configure > lte-policy

Entering the above command sequence results in the following prompt:

[local]host_name(lte-policy)#

Syntax

mme paging cache { size cache_size | timeout time }

default mme paging cache { size | timeout }

default

Resets either the paging cache size or the paging cache timer to default settings.

size cache_size

cache_size: Enter an integer from 0 to 10000 to specify the maximum number of Tracking Area Code (TAC) entries to be cached.

Entering the ‘0’ value disables caching and should be followed by use of the mme paging cache clear command (in the Exec mode).

Default cache size = 5000 TAC entries per SessMgr.

timeout time

time: Enter an integer from 1 to 1440 to specify the number of minutes that each Tracking Area Code (TAC) entry remains valid.

A lower cache timeout helps to refresh the cache frequently and enables this functionality to quickly adapt to changes in the network. We recommend the timeout value be less than the expected eNodeB flap frequency; for example, if the eNodeBs connected to the MME are expected to disconnect and reconnect every 10 minutes (due to network issues), then the timeout configuration should be less than 10 minutes.

Default timeout = 5 minutes.

Usage

Both size and timeout must be configured to enable paging cache optimization. The mme paging cache command must be entered twice, once for each parameter.

Example

Set the paging cache timeout to match the eNodeB flap frequency of 10 minutes:

mme paging cache timeout 10
Set the paging cache size to disable caching:

```
  mme paging cache size 0

  end

  mme paging cache clear { all | instance sessmgr_instance }
```
network-global-mme-id-mgmt-db

Creates a new, or enters the existing MME group ID management database.

**Product**
- MME
- ePDG
- SAEGW
- S-GW
- SGSN

**Privilege**
Administrator

**Mode**
- Exec > Global Configuration > LTE Policy Configuration
- configure > lte-policy

Entering the above command sequence results in the following prompt:

```
[local] host_name(lte-policy)#
```

**Syntax**

```
[ no ] network-global-mme-id-mgmt-db
```

**Usage**

Use this command to create a new, or enter the existing MME group ID management database. The MME group ID management database is used to create associations between PLMN IDs and ranges of MME group IDs.

On the S4-SGSN, this command enables operators to create a MME group ID management database that can be associated with an SGSN service.

**Important:** Only one MME group ID management database can be created per system.

Entering this command results in the following prompt:

```
[context_name] host_name(network-global-mme-id-mgmt-db)#
```

Global MME ID management database commands are defined in the *LTE Network Global MME ID Management Database Configuration Mode Commands* chapter.
paging-map

Creates a paging map or specifies an existing paging map and enters the Paging Map Configuration Mode.

Product
MME
ePDG

Privilege
Administrator

Mode
Exec > Global Configuration > LTE Policy Configuration
configure > lte-policy
Entering the above command sequence results in the following prompt:

[local]host_name(lte-policy)#

Syntax

[ no ] paging-map paging_map_name [ -noconfirm ]

no
Remove the paging map from the system.

paging_map_name
Specifies the name of the paging map being created or accessed. If the map name does not refer to an existing map, a new map is created. paging_map_name must be an alphanumeric string of 1 through 64 characters.

-noconfirm
Executes the command without any additional prompt and confirmation from the user.

Usage

Enter the Paging Map Configuration Mode for an existing or newly defined map. This command is also used to remove an existing map.
Entering this command results in the following prompt:

hostname(paging-map)#

Paging Map Configuration Mode commands are defined in the LTE Paging Map Configuration Mode Commands chapter.
Refer to the Heuristic and Intelligent Paging chapter in the MME Administration Guide for more information about Paging Maps.

Example

The following command enters the existing Paging Map Configuration Mode (or creates it if it does not already exist) for the map named map1:

paging-map map1
paging-profile

Creates a paging profile or specifies an existing paging profile and enters the Paging Profile Configuration Mode.

**Product**
MME
ePDG

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > LTE Policy Configuration
configure > lte-policy

The above command sequence results in the following prompt:

```
[local]host_name(lte-policy)#
```

**Syntax**

```plaintext
[ no ] paging-profile paging_profile_name [ -noconfirm ]
```

- **no**
  Remove the paging map from the system.

- **paging_profile_name**
  Specifies the name of the paging profile being created or accessed. If the profile name does not refer to an existing profile, a new profile is created. `paging_profile_name` must be an alphanumeric string of 1 through 64 characters.

- **-noconfirm**
  Executes the command without any additional prompt and confirmation from the user.

**Usage**
Enter the Paging Profile Configuration Mode for an existing or newly defined paging profile. This command is also used to remove an existing profile.

Entering this command results in the following prompt:

```
hostname(paging-profile)#
```

Paging Profile Configuration Mode commands are defined in the *LTE Paging Profile Configuration Mode Commands* chapter.

Refer to the *Heuristic and Intelligent Paging* chapter in the *MME Administration Guide* for more information about Paging Profiles.

**Example**
The following command enters the existing Paging Profile Configuration Mode (or creates it if it does not already exist) for the profile named `profile1`:

```
paging-profile profile1
```
peer-map

Creates a peer map and enters the LTE Peer Map Configuration mode.

**Product**
- P-GW
- SAEGW
- S-GW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > LTE Policy Configuration

configure > lte-policy

Entering the above command sequence results in the following prompt:

```
[local]host_name(lte-policy)#
```

**Syntax**

```
peer-map map_name [ -noconfirm ]
```

```
no peer-map map_name
```

- **map_name**
  Specify a name of a peer map to create, modify, or remove. This name must be an alphanumeric string of 1 through 64 characters. Each new peer map must have a unique name.

- **-noconfirm**
  Executes the command without any additional prompt and confirmation from the user.

**Usage**

Use this command to create or modify a peer map.

Entering this command results in the following prompt:

```
[local]host_name(peer-map)#
```

LTE Peer Map Configuration Mode commands are defined in the *LTE Peer Map Configuration Mode Commands* chapter of this guide.

**Example**

The following command creates a peer map named map5 and enters the LTE Peer Map Configuration mode:

```
peer-map map5
```
subscriber-map

Creates a subscriber map or specifies an existing subscriber map and enters the Subscriber Map Configuration Mode.

Product
- MME
- ePDG
- SAEGW
- S-GW

Privilege
- Administrator

Mode
- Exec > Global Configuration > LTE Policy Configuration
- configure > lte-policy

Entering the above command sequence results in the following prompt:

[local]host_name(lte-policy)#

Syntax

[ no ] subscriber-map map_name [ -noconfirm ]

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Removes the specified subscriber map from the system.</td>
</tr>
<tr>
<td>-noconfirm</td>
<td>Executes the command without any additional prompt and confirmation from the user.</td>
</tr>
<tr>
<td>map_name</td>
<td>Specifies the name of the subscriber map. If the map name does not refer to an existing map, a new map is created. map_name must be an alphanumeric string of 1 through 64 characters.</td>
</tr>
</tbody>
</table>

Usage

Enter the Subscriber Map Configuration Mode for an existing or newly defined map. This command is also used to remove an existing map.

Entering this command results in the following prompt:

hostname(subscriber-map)#

Subscriber Map Configuration Mode commands are defined in the LTE Subscriber Map Configuration Mode Commands chapter.

Example

The following command enters the existing Subscriber Map Configuration Mode (or creates it if it does not already exist) for the map named map1:

subscriber-map map1
**tai-list-db**

Creates or configures a list of Tracking Area Information (TAI). This list is called TAI List Database.

**Product**
HeNB-GW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > LTE Policy Configuration

```
configure > lte-policy
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(lte-policy)#
```

**Syntax**

```
[ no ] tai-list-db  db_name [ -noconfirm ]
```

---

**no**

Removes the specified TAI list database from the system.

---

**-noconfirm**

Executes the command without any additional prompt and confirmation from the user.

---

**db_name**

Specifies the name of the TAI list database. If the name does not refer to an existing database, a new database is created. `db_name` is an alphanumeric string of 1 through 64 characters.

**Usage**

Enters the TAI List Database Configuration Mode for an existing or newly defined database. This command is also used to remove an existing database.

---

Important: Maximum of eight TAI List Database instances can be created in a system.

Entering this command results in the following prompt:

```
[context_name]hostname(tai-list-db)#
```

TAI List Database Configuration Mode commands are defined in the TAI List Database Configuration Mode Commands chapter.

**Example**

The following command enters the existing TAI List Database configuration mode (or creates it if it does not already exist) for the database named `tai_db1`:

```
tai-list-db  tai_db1
```
**tai-mgmt-db**

Creates a Tracking Area Identifier (TAI) Management Database or specifies an existing database and enters the TAI Management Database Configuration mode. On an S4-SGSN, this command is used as part of configuring S-GWs and their associated RAIs to bypass DNS resolution of RAI FQDN for obtaining the S-GW address.

**Product**
- MME
- ePDG
- SAEGW
- S-GW
- SGSN

**Privilege**
Administrator

**Mode**
- `Exec > Global Configuration > LTE Policy Configuration`
- `configure > lte-policy`

Entering the above command sequence results in the following prompt:

```
[local]host_name(lte-policy)#
```

**Syntax**

```
[ no ] tai-mgmt-db db_name [ -noconfirm ]
```

- no
  Removes the specified management database from the system.

- -noconfirm
  Executes the command without any additional prompt and confirmation from the user.

- db_name
  Specifies the name of the management database. If the name does not refer to an existing database, a new database is created. `db_name` is an alphanumeric string of 1 through 64 characters.

**Usage**

Enter the TAI Management Database Configuration Mode for an existing or newly defined database. This command is also used to remove an existing database.

On the S4-SGSN, once you have created a new, or accessed an existing, TAI Management database, a TAI Management Object must be created or accessed and the S-GWs and their associated RAIs configured using the `rai` and `sgw-address` commands. Refer to the `LTE TAI Object Configuration Mode` chapter for details on these two commands.

Entering this command results in the following prompt:

```
[context_name]host_name(tai-mgmt-db)#
```
TAI Management Database Configuration Mode commands are defined in the *TAI Management Database Configuration Mode Commands* chapter.

**Example**

The following command enters the existing TAI Management Database configuration mode (or creates it if it does not already exist) for the database named *tai_db1*:

```
tai-mgmt-db tai_db1
```
Chapter 207
LTE Subscriber Map Configuration Mode Commands

The LTE Subscriber Map Configuration Mode is used to create and manage subscriber maps for applying operator policy templates to individual subscribers and/or groups of subscribers.

Subscriber mappings are ordered lists containing explicit UE matching criteria. The maps are examined for specific UE identity information such as the UE’s IMSI. The system uses the first map that matches the criteria to associate an operator policy with the UE.

Subscriber maps can be modified but will only affect future subscribers and not subscribers already attached to UEs.

Mode

Exec > Global Configuration > LTE Policy Configuration > LTE Subscriber Map Configuration

configure > lte-policy > subscriber-map subscriber_map_name

Entering the above command sequence results in the following prompt:

[local]host_name(subscriber-map)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
end

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

exit

Usage
Use this command to return to the parent configuration mode.
precedence

Sets the order of precedence, the matching criteria and the association to an operator policy for subscribers meeting the match criteria.

Product
MME
SAEGW
S-GW

Privilege
Administrator

Mode
Exec > Global Configuration > LTE Policy Configuration > LTE Subscriber Map Configuration
configure > lte-policy > subscriber-map subscriber_map_name

Entering the above command sequence results in the following prompt:

[local]host_name(subscriber-map)#

Syntax

precedence number match-criteria all operator-policy-name policy_name

precedence number match-criteria imsi mcc mcc_num mnc mnc_num [ msein first start_range last end_range | service-plmnid id ] operator-policy-name policy_name

precedence number match-criteria [ imsi mcc mcc_num mnc mnc_num ] [ service-plmnid id ] ssid id operator-policy-name policy_name

precedence number match-criteria service-plmnid id operator-policy-name policy_name

no precedence number

no
Removes the selected precedence number from the subscriber map. number must be an integer value from 1 to 1024.

number
Specifies the order of precedence for the subscriber map. 1 is the highest precedence. number must be an integer value from 1 to 1024.

match-criteria
Specifies that the keyword following this keyword is the criteria to be used to match a UE.

all
Specifies that all UEs are to be associated with the operator policy.
###imsi mcc mcc_num mnc mnc_num [msin first start_range last end_range | service-plmnid id ]###

Specifies that UEs with criteria matching the International Mobile Subscriber Identifier (IMSI) information (MCC and MNC) are to be associated with a specified operator policy.

- **mcc mcc_num**: Specifies the mobile country code (MCC) portion of the IMSI identifier as an integer value between 100 and 999.
- **mnc mnc_num**: Specifies the mobile network code (MNC) portion of the IMSI identifier as a 2- or 3-digit integer value between 00 and 999.
- **msin first start_range last end_range**: Optionally specifies a range of Mobile Subscriber Identification Numbers that further narrows the match criteria for the IMSI match configuration.
  - *start_range* and *end_range* must each be an integer value of 10 digits.
- **service-plmnid id**: Optionally specifies a local service PLMN ID number used further narrow the IMSI-based operator policy selection. *id* must be an integer value of five digits minimum and six digits maximum (the combination of the MCC and MNC).

---

###service-plmnid id###

Specifies a local service PLMN ID number used for PLMN ID-based operator policy selection. *id* must be an integer value of five digits minimum and six digits maximum (the combination of the MCC and MNC).

---

###ssid id###

Specifies a local SSID used for SSID-based operator policy selection to support the SaMOG Local Break Out (LBO) feature. The operator policy and associated call control profile are selected based on the SSID received in the Called-Station-Id attribute in Access-Request.
- *id* must be an alphanumeric string of 1 through 32 characters.
- The SaMOG LBO feature is license dependant. Contact your Cisco account representative for more information.

---

###operator-policy-name policy_name###

Sets the operator policy with which the matching criteria is associated. *policy_name* must be an existing operator policy expressed as an alphanumeric string of 1 through 64 characters. Operator policies are configured in the Operator Policy Configuration Mode. For more information about operator policies, refer to the *Operator Policy Configuration Mode Commands* chapter.

---

###Usage###

The operator policy provides mechanisms to fine tune the behavior of subsets of subscribers above and beyond the behaviors described in the user profile. It is also used to control the behavior or visiting subscribers in roaming scenarios, enforce roaming agreements, and provide a measure of local protection against foreign subscribers.

---

###Example###

The following command associates the operator policy named *op_poll* with UEs associated with an IMSI MCC of 111, an MNC of 222, and a service PLMN ID of 123456:

```plaintext
precedence 100 match-criteria imsi mcc 111 mnc 222 service-plmnid 123456
operator-policy-name op_poll
```
Chapter 208
LTE TAI Management Database Configuration Mode Commands

The LTE TAI Management Database Configuration Mode is used to create and manage the LTE Tracking Area Identifier (TAI) management database on this system.

Mode

Exec > Global Configuration > LTE Policy Configuration > LTE TAI Management Database Configuration

configure > lte-policy > tai-mgmt-db db_name

Entering the above command sequence results in the following prompt:

[local]host_name(tai-mgmt-db)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Use this command to return to the parent configuration mode.
network-name

This command configures the long (full) and short network name used in the Long and Short network name IE in the EMM Information message that is sent to the UE from the MME.

Product
MME

Privilege
Administrator

Mode
Exec > Global Configuration > LTE Policy Configuration > LTE TAI Management Database Configuration
configure > lte-policy > tai-mgmt-db \( \text{db}_\text{name} \)

Entering the above command sequence results in the following prompt:

[local] \( \text{host}_\text{name}(\text{tai-mgmt-db}) \)#

Syntax

\[
\begin{align*}
[ \text{no} ] \ & \text{network-name} \ & [ \text{full} \ & \text{full}_\text{name} \ | \ & \text{short} \ & \text{short}_\text{name} ] \\
\text{no} \\
& \text{Removes a configured network-name.} \\
\text{full} \ & \text{full}_\text{name} \\
& \text{Defines the full (long) network name. } \text{full}_\text{name} \ & \text{is an alphanumeric string of 1 through 251 characters.} \\
\text{short} \ & \text{short}_\text{name} \\
& \text{Defines the short network name. } \text{short}_\text{name} \ & \text{is an alphanumeric string of 1 through 251 characters.}
\end{align*}
\]

Usage

Use this command to configure the full and short network name on the \( \text{tai-db} \) object.
This configuration affects the actions of the MME when the MME is configured to set the UE time. If this configuration exists, and there is no interaction with an MSC that sends a EMM INFORMATION message, the MME uses the above configuration while sending an EMM INFORMATION message.
There is no default for this configuration. If this configuration does not exist at the \( \text{tai-db} \) level and \( \text{tai-mgmt-object} \) level, no network name will be signaled in a EMM Information message.
tai-custom-list

Creates a new custom TAI list, and/or enters the tai-cstm-list configuration mode.

**Product**
MME

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > LTE Policy Configuration > LTE TAI Management Database Configuration
configure > lte-policy > tai-mgmt-db  *db_name*

Entering the above command sequence results in the following prompt:

```
[local]hostname(tai-mgmt-db)#
```

**Syntax**

tai-custom-list tac  *value*  [ -noconfirm ]

```
tac  *value*
```
Specifies the Tracking Area Code portion of the TAI as an integer from 1 through 65535.  
A maximum of 1000 Custom TAI Lists can be configured per TAI Management Database.

**Usage**
Use this command to enter the Custom TAI List Configuration Mode for an existing object or for a newly defined object.  
Prior to 17.0, the MME could have a tracking area in only one tracking area list (TAI List). Consequently, the tracking area list assigned to subscribers attaching from different TAI will be same, even if the adjacency of these tracking areas is not same. This resulted in the MME getting TAUs even as subscribers moved to the adjacent area.  
With this functionality, you can configure adjacency lists as TAI Lists, thus reducing the Tracking Area Updates (TAU) received by MME. This feature enables the MME to send configured customized TAI List in ATTACH_ACCEPT/TAU_ACCEPT when a request is received from the custom or border TAI.  
Entering this command results in the following prompt:

```
[local]hostname{tai-cstm-list}#
```

Custom TAI List Configuration Mode commands are defined in the LTE Custom TAI List Configuration Mode Commands chapter.

**Example**
The following command creates a Custom TAI List for TAC 2325 and enters the Custom TAI List Configuration Mode:

```
custom-tai-list tac 2325
```
tai-mgmt-obj

Creates new, or removes/enters existing, LTE Tracking Area Identifier (TAI) object configurations. On the S4-SGSN, this command is required as part of configuring S-GWs and their associated RAIs to bypass DNS resolution of RAI FQDN for obtaining the S-GW address.

Product
MME
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration > LTE Policy Configuration > LTE TAI Management Database Configuration
configure > lte-policy > tai-mgmt-db db_name

Entering the above command sequence results in the following prompt:

[local]host_name(tai-mgmt-db)#

Syntax

[ no ] tai-mgmt-obj object_name [ -noconfirm ]

- no
Removes a configured TAI management object from the TAI management database.

- -noconfirm
Executes the command without any additional prompt and confirmation from the user.

- object_name
Specifies the name of the TAI management object and enters the LTE TAI Management Object Configuration Mode as an alphanumeric string of 1 through 64 characters.

Usage

Use this command to enter the LTE TAI Management Object Configuration Mode for an existing object or for a newly defined object. This command is also used to remove an existing object. 
On the S4-SGSN, after creating the TAI Management Object and entering TAI Management Object Configuration Mode, the rai and sgw-address commands are used to complete the S-GW for RAI configuration. Refer to the LTE TAI Management Object Configuration mode chapter for details on these commands.
Entering this command results in the following prompt:

[context_name]hostname(tai-mgmt-obj)#

LTE TAI Management Object Configuration Mode commands are defined in the LTE TAI Management Object Configuration Mode Commands chapter.
The following command creates a TAI management object called \textit{tai-obj3} and enters the LTE TAI Management Object Configuration Mode:

\texttt{tai-mgmt-obj tai-obj3}
**timezone**

Configures the timezone to be used for the UE timezone in S11 and Non Access Stratum (NAS) messages.

**Product**
MME

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > LTE Policy Configuration > LTE TAI Management Database Configuration

```bash
configure > lte-policy > tai-mgmt-db db_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(tai-mgmt-db)#
```

**Syntax**

```bash
timezone { + | - } hours value [ minutes { 0 | 15 | 30 | 45 } | daylight-savings-time-increment { 0 | 1 | 2 } ]
```

```bash
no timezone
```

Removes the timezone configuration from the management database.

**Usage**

Use this command to configure the timezone to be used for the UE timezone in S11 and NAS messages.
**Important:** Time zone configurations at the TAI Management Object level take precedence over time zone configurations at the TAI Management Database level. If neither is configured, the system defaults to the MME (system) time zone.

**Example**

The following command sets the timezone mapping for this management database to plus-3 hours and 15 minutes from UTC:

```
timezone + hours 3 minutes 15
```
Chapter 209
LTE TAI Management Object Configuration Mode Commands

The LTE TAI Management Object Configuration Mode is used to create and manage the LTE Tracking Area Identifiers for the TAI database.

Mode
Exec > Global Configuration > LTE Policy Configuration > LTE TAI Management Database Configuration > LTE TAI Management Object Configuration

```
configure > lte-policy > tai-mgmt-db db_name > tai-mgmt-objc obj_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(tai-mgmt-objc)#
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
exit
```

**Usage**
Use this command to return to the parent configuration mode.
**lai**

Configures a Location Area Identifier (LAI) for this TAI management object.

**Product**
MME

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > LTE Policy Configuration > LTE TAI Management Database Configuration > LTE TAI Management Object Configuration

`configure > lte-policy > tai-mgmt-db db_name > tai-mgmt-obj obj_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(tai-mgmt-obj)#
```

**Syntax**

```
lai mcc number mnc number lac area_code

no lai
```

**no lai**

Removes a configured LAI from the TAI management object.

```
mcc number
```

Specifies the mobile country code (MCC) portion of a PLMN identifier as an integer from 100 through 999.

```
mnc number
```

Specifies the mobile network code (MNC) portion of a PLMN identifier as a 2- or 3-digit integer from 00 through 999.

```
lac area_code
```

Specifies the Location Area Code portion of the TAI as an integer from 1 through 65535.

**Usage**

Use this command to configure an LAI for this management object.

**Example**

The following command adds an LAI to this management object with an MCC of **111**, an MNC of **22**, and a LAC of **101**:

```
lai mcc 122 mnc 22 lac 101
```
network-name

This command configures the long (full) and short network name used in the Long and Short network name IE in the EMM Information message that is sent to the UE from the MME.

Product
MME

Privilege
Administrator

Mode
Exec > Global Configuration > LTE Policy Configuration > LTE TAI Management Database Configuration > LTE TAI Management Object Configuration

configure > lte-policy > tai-mgmt-db db_name > tai-mgmt-obj obj_name

Entering the above command sequence results in the following prompt:

[local]host_name(tai-mgmt-obj)#

Syntax

[ no ] network-name [ full full_name | short short_name ]

no
Removes a configured network-name.

full full_name
Defines the full (long) network name. full_name is an alphanumeric string of 1 through 251 characters.

short short_name
Defines the short network name. short_name is an alphanumeric string of 1 through 251 characters.

Usage

Use this command to configure the full and short network name on the tai-mgmt-obj. This configuration affects the actions of the MME when the MME is configured to set the UE time. If this configuration exists, and there is no interaction with an MSC that sends an EMM INFORMATION message, the MME uses the above configuration while sending a EMM INFORMATION message. There is no default for this configuration. If this configuration does not exist at the tai-db level and tai-mgmt-object level, no network name will be signaled in a EMM Information message.
rai

Configures a Routing Area Identifier (RAI) for an associated S-GW for this TAI management object.

**Product**
SGSN

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > LTE Policy Configuration > LTE TAI Management Database Configuration > LTE TAI Management Object Configuration
configure > lte-policy > tai-mgmt-db db_name > tai-mgmt-obj obj_name

Entering the above command sequence results in the following prompt:

[local]host_name(tai-mgmt-obj)#

**Syntax**

```
rai mcc number mnc number lac area_code rac rac_value
```

```
no rai
```

**Usage**

On the S4-SGSN, use this command as part of the configuration of the selection of an SGW for RAI on the S4-SGSN for operators wishing to bypass the DNS resolution of RAI FQDN for obtaining the SGW address. Once the RAI is configured, the SGW address that serves this RAI must be configured with the `sgw-address` command. For details on this command, refer to the description of `sgw-address` in this chapter.

**Example**
The following command adds a RAI to this management object with an MCC of 111, an MNC of 22, and a LAC of 110:

```
rai mcc 111 mnc 22 lac 110
```
**sgw-address**

Configures an IP address for a Serving Gateway (S-GW), a supported S5/S8 protocol type, and selection weight used in a pool for S-GW selection. On an S4-SGSN, this command is used as part of the configuration to bypass DNS resolution of RAI FQDN for an S-GW.

**Product**

SGSN

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > LTE Policy Configuration > LTE TAI Management Database Configuration > LTE TAI Management Object Configuration

```
configure > lte-policy > tai-mgmt-db db_name > tai-mgmt-obj obj_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(tai-mgmt-obj)#
```

**Syntax**

```
sgw-address ipv4_or_ipv6_address s5-s8-protocol { both | gtp | pmip } weight number

no sgw-address ipv4_or_ipv6_address s5-s8-protocol { both | gtp | pmip }

no sgw-address ipv4_or_ipv6_address s5-s8-protocol { both | gtp | pmip }
```

Removes the configured S-GW address from this TAI management object.

```
ipv4_or_ipv6_address
```

Specifies the IP address of the S-GW in the selection pool in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

Up to 32 S-GW addresses can be configured per TAI management object.

```
s5-s8-protocol { both | gtp | pmip }
```

Specifies the S5/S8 interface type found between the configured S-GW and the P-GW.

- **both**: Specifies that both the GTP and PMIP protocols are supported over the S5/S8 interface. The **both** option is not supported on the SGSN.
- **gtp**: Specifies that the GTP protocol is supported over the S5/S8 interface. This is the only option supported by the SGSN.
- **pmip**: Specifies that the PMIP protocol is supported over the S5/S8 interface. The **pmip** option is not supported on the SGSN.

```
weight number
```

Specifies the priority or weight of the S-GW address used during weighted round-robin selection within this TAI management object. **number** must be an integer from 1 through 100.
Usage
Use this command to configure a pool of S-GW addresses used for S-GW selection.
On the S4-SGSN, use this command to complete the configuration of bypassing DNS resolution of RAI
FQDN to obtain the S-GW address. This command is not valid on the S4-SGSN until the following
commands have been executed:

- `tai-mgmt-db` in *LTE Policy Configuration Mode*
- `tai-mgmt-obj` in *LTE Management Database Configuration Mode*
- `rai` in *LTE TAI Management Object Configuration Mode*

Example
The following command configures an S-GW with an IPv4 address of 10.2.3.4, a supported S5/S8 protocol
type of GTP, and a selection weight of 3:

```
sgw-address 10.2.3.4 s5-s8-protocol gtp weight 3
```
**tai**

Configures a Tracking Area Identifier (TAI) for this TAI management object.

**Product**
MME

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > LTE Policy Configuration > LTE TAI Management Database Configuration > LTE TAI Management Object Configuration

```
configure > lte-policy > tai-mgmt-db db_name > tai-mgmt-obj obj_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(tai-mgmt-obj)#
```

**Syntax**

```
[ no ] tai mcc number  mnc number { tac value } +
```

- **no**
  Removes a configured TAI from the TAI management object.

- **mcc number**
  Specifies the mobile country code (MCC) portion of a PLMN identifier as an integer from 100 through 999.

- **mnc number**
  Specifies the mobile network code (MNC) portion of a PLMN identifier as a 2- or 3-digit integer from 00 through 999.

- **tac value +**
  Specifies the Tracking Area Code portion of the TAI as an integer from 1 through 65535. Up to 16 TAC values can be entered on a single line.

**Usage**

Use this command to configure one or more TAIs for this management object. Up to 16 TAIs can be configured per management object.

**Example**

The following command adds a TAI to this management object with an MCC of 111, an MNC of 22, and a TAC value of 1001:

```
tai mcc 122 mnc 22 tac 1001
```
timezone

Configures the timezone to be used for the UE timezone in S11 and Non-Access Stratum (NAS) messages.

Mode
Exec > Global Configuration > LTE Policy Configuration > LTE TAI Management Database Configuration > LTE TAI Management Object Configuration

configure > lte-policy > tai-mgmt-db db_name > tai-mgmt-obj obj_name

Entering the above command sequence results in the following prompt:

[local]host_name(tai-mgmt-obj)#

Syntax

timezone { + | - } hours value [ minutes { 0 | 15 | 30 | 45 } | daylight-savings-time-increment { 0 | 1 | 2 } ]

no timezone

Removes the timezone configuration from the management object.
