About this Guide

This preface describes the *Command Line Interface Reference* and its document conventions.

This reference describes how to use the command line interface (CLI) to interact with the products supported by the StarOS™. The CLI commands are organized by command modes in the code and in this reference. The command modes are presented alphabetically. The description of each command states the command’s function, describes its syntax, presents limitations when applicable, and offers an example of its usage.
# Conventions Used

The following tables describe the conventions used throughout this documentation.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Notice Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>![Information Note Icon]</td>
<td>Information Note</td>
<td>Provides information about important features or instructions.</td>
</tr>
<tr>
<td>![Caution Icon]</td>
<td>Caution</td>
<td>Alerts you of potential damage to a program, device, or system.</td>
</tr>
<tr>
<td>![Warning Icon]</td>
<td>Warning</td>
<td>Alerts you of potential personal injury or fatality. May also alert you of potential electrical hazards.</td>
</tr>
</tbody>
</table>

## Typeface Conventions

<table>
<thead>
<tr>
<th>Typeface Conventions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text represented as a screen display</td>
<td>This typeface represents displays that appear on your terminal screen, for example: Login:</td>
</tr>
<tr>
<td>Text represented as commands</td>
<td>This typeface represents commands that you enter, for example: show ip access-list This document always gives the full form of a command in lowercase letters. Commands are not case sensitive.</td>
</tr>
<tr>
<td>Text represented as a command variable</td>
<td>This typeface represents a variable that is part of a command, for example: show card slot_number slot_number is a variable representing the desired chassis slot number.</td>
</tr>
<tr>
<td>Text represented as menu or sub-menu names</td>
<td>This typeface represents menus and sub-menus that you access within a software application, for example: Click the File menu, then click New</td>
</tr>

Obtaining Documentation

The most current Cisco documentation is available on the following website:
http://www.cisco.com/cisco/web/psa/default.htm
Use the following path selections to access this documentation:
Products > Wireless > Mobile Internet> Platforms > Cisco ASR 5000 Series > Cisco ASR 5000
Contacting Customer Support

Use the information in this section to contact customer support.

Refer to the support area of http://www.cisco.com for up-to-date product documentation or to submit a service request. A valid username and password are required to access this site. Please contact your Cisco sales or service representative for additional information.
Chapter 1
Command Line Interface Overview

This chapter describes the numerous features in the command line interface (CLI). It includes information about the architecture of the CLI, its command modes and user privileges, how to obtain help within the CLI, and other key items.

The operating system (StarOS™) controls the overall system logic, control processes, and the CLI. The CLI is a multi-threaded user interface that allows you to manipulate, configure, control and query the hardware and software components that make up the system and its hosted services. In addition, the CLI can host multiple instances of management and service configuration sessions. This allows multiple users to simultaneously access and manage multiple hosted services.

This section provides the following information about the CLI:

- CLI Structure
- CLI Command Modes
- CLI Administrative Users
- CLI Contexts
- Understanding the CLI Command Prompt
- CLI Command Syntax
- Entering and Viewing CLI Commands
- Obtaining CLI Help
- Exiting the CLI and CLI Command Modes
- Accessing the CLI
- Platform Related CLI Issues
- IP Address Notation
- Alphanumeric Strings
CLI Structure

CLI commands are strings of commands or keywords and user-specified arguments that set or modify specific parameters of the system. Commands are grouped by function and the various command modes with which they are associated.

The structure of the CLI is hierarchical. All users begin at a specific entry point into the system, called the Exec (Execute) Mode, and then navigate through the CLI according to their defined user privileges (access level) by using other command modes.
CLI Command Modes

There are two primary CLI command modes:

- **Exec (Execute) Mode**: The Exec Mode is the lowest level in the CLI. The Exec Mode is where you execute basic commands such as `show` and `ping`. When you log into the CLI, you are placed in this mode by default.

- **Config (Configuration) Mode**: The Config mode is accessible only by users with administrator and security administrator privileges. If you are an administrative user, in this mode you can add and configure contexts and access the configuration sub-modes to configure protocols, interfaces, ports, services, subscribers and other service-related items.

The entry point into the CLI is called Exec Mode. In the initial CLI login, all users are placed into the default local context, which is the CLI’s default management context. From this context, administrative users can access the Config Mode and define multiple service contexts.

Refer to the mode entry-path diagrams at the beginning of each mode chapter in the *Command Line Interface Reference*.

---

**Important**: The commands or keywords/variables that are available to the user vary based on platform type, StarOS version and installed license(s).
CLI Administrative Users

This section contains information on the administrative user types and privileges supported by the system.

Administrative User Types

There are two types of administrative users supported by the system:

- **Context-level administrative users**: This user type is configured at the context-level and relies on the AAA subsystems for validating user names and passwords during login. This is true for both administrative user accounts configured locally through a configuration file or on an external RADIUS or TACACS+ server. Passwords for these user types are assigned once and are accessible in the configuration file.

- **Local-users**: This user type provides support for ANSI T1.276-2003 password security protection. Local-user account information, such as passwords, password history, and lockout states, is maintained flash memory by the Shared Configuration Task (SCT). This information is maintained in a separate file, not in configuration files used by the system. As such, the configured local-user accounts are not visible with the rest of the system configuration.

Local-user and context-level administrative accounts can be used in parallel. However, a mechanism is provided to deactivate context-level administrative user accounts, thereby providing access only to local-user accounts.

Authenticating Administrative Users with RADIUS

To authorize users via RADIUS, you must include two RADIUS attributes in the RADIUS Access-Accept message:

- RFC 2865 standard Service-Type
- Starent Vendor-Specific Attribute (VSA) SN-Admin-Permission or SN1-Admin-Permission.

RADIUS SN-Admin-Permission / SN1-Admin-Permission AVP

The possible values for SN-Admin-Permission / SN1-Admin-Permission AVP are as follows:

- None = 0
- CLI = 1
- FTP = 2
- CLI-FTP = 3
- Intercept = 4
- CLI-Intercept = 5
- CLI-Intercept-FTP = 7
- ECS = 8
- CLI-ECS = 9
- CLI-FTP-ECS = 11
- CLI-Intercept-ECS = 13
- CLI-Intercept-FTP-ECS = 15
The default value is 1 (CLI).

**RADIUS Mapping System**

RADIUS server configuration depends on the type of server used and the instructions distributed by the server manufacturer. The following table shows the supported attribute/value mapping system that is constant, regardless of server manufacturer or model:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Framed</td>
<td>2</td>
</tr>
<tr>
<td>Administrative (Administrator)</td>
<td>6</td>
</tr>
<tr>
<td>NAS_Prompt</td>
<td>7</td>
</tr>
<tr>
<td>Authenticate_Only</td>
<td>8</td>
</tr>
<tr>
<td>Authorize_Only</td>
<td>17</td>
</tr>
<tr>
<td>Inspector</td>
<td>19650516</td>
</tr>
<tr>
<td>Security_Admin</td>
<td>19660618</td>
</tr>
</tbody>
</table>

**RADIUS Privileges**

There are four RADIUS privilege roles. The following table shows the relationship between the privilege roles in the CLI configuration and RADIUS Service-Type.

<table>
<thead>
<tr>
<th>CLI Configuration Parameter</th>
<th>RADIUS Service Type</th>
<th>show admin Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>administrator</td>
<td>Security_Admin (19660618)</td>
<td>admin</td>
</tr>
<tr>
<td>config_administrator</td>
<td>Administrative (6)</td>
<td>cfgadm</td>
</tr>
<tr>
<td>operator</td>
<td>NAS_Prompt (7)</td>
<td>oper</td>
</tr>
<tr>
<td>inspector</td>
<td>Inspector (19650516)</td>
<td>inspect</td>
</tr>
</tbody>
</table>

**Authenticating Administrative Users with TACACS+**

The ASR 5x00 or StarOS virtual machine is identified as a Network Access Server (NAS) and remotely accesses the Terminal Access Controller Access Control System+ (TACACS+) server for information about users who can perform administrative operations on the system.
The NAS is defined as a client-side requesting component associated with a specific IP address. StarOS only supports one NAS with one IP address. This NAS processes TACACS+ protocol packets within the local context. Several management services may be associated with a login.

StarOS only supports multiple-connection mode with a TACACS+ server. In a multiple-connection mode, each TACACS+ session opens and maintains a separate and private TCP connection to the server. When the session ends, this connection is always closed.

TACACS+ users and their passwords are defined and stored on the TACACS+ server. They are stored in a persistent space and are always known to the server while the server is running. The users are not directly known to the NAS.

### Administrative User Privileges

Regardless of the administrative user type, the system supports four user privilege levels:

- **Inspector**: Inspectors are limited to a small number of read-only Exec Mode commands. The bulk of these are show commands for viewing a variety of statistics and conditions. The Inspector cannot execute show configuration commands and does not have the privilege to enter the Config Mode.

- **Operator**: Operators have read-only privileges to a larger subset of the Exec Mode commands. They can execute all commands that are part of the inspector mode, plus some system monitoring, statistic, and fault management functions. Operators do not have the ability to enter the Config Mode.

- **Administrator**: Administrators have read-write privileges and can execute any command in the CLI except for a few security-related commands that can only be configured by Security Administrators. Administrators can configure or modify system settings and can execute all system commands, including those available to the Operators and Inspectors.

- **Security Administrator**: Security Administrators have read-write privileges and can execute all CLI commands, including those available to Administrators, Operators, and Inspectors.

The following figure represents how user privileges are defined in the CLI configuration modes.

![User Privileges](image)

Though the privilege levels are the same regardless of user type, the corresponding user type names differ slightly. The following table displays the privilege level to administrative user type mappings:
Table 3. User Privilege to User Type Mapping

</tbody>
</table>

Configure context-level administrative users in the Context Configuration Mode with the `administrator`, `config-administrator`, `operator`, and `inspector` commands.

Configure local-user administrative users at the Global Configuration Mode with the `local-user username` command.

You can further refine administrative levels to include access to certain features with the following feature-use administrative user options:

- **Lawful Intercept (LI) Administrative User**: To configure and manage LI-related issues, configure at least one administrative user account with LI functionality privileges.

  **Important**: This privilege is available only for context-level administrative users. In addition, to ensure security in accordance with the standards, LI administrative users must access the system through the Secure Shell Protocol (SSH).

- **Enhanced Charging Service (ECS) Administrative User**: To log in and execute ECS-related commands, configure at least one administrative user account with ECS functionality privileges.

  All system users can be configured within any context. However, it is recommended that you configure users in the system’s management context called local. Refer to sections later in this chapter for additional information about contexts.

### Allowed Commands per User Type

With the exception of security administrators, all other management users are limited to a subset of the entire command list. This section defines the commands allowed for each management user type.

### Inspector Mode Commands

In the Exec Mode, system inspectors can access the following commands:

- `abort`
- `autoconfirm`
- `context`
- `crypto-group`
- `default terminal`
CLI Administrative Users

- exit
- help
- logs checkpoint
- no logging active
- no logging trace
- no reveal disabled commands
- no timestamps
- no autoconfirm
- ping
- reveal disabled commands
- show (except show snmp communities and show snmp transports)
- sleep
- start crypto security-association
- terminal length
- terminal width
- timestamps
- traceroute

Operator Mode Commands

In the Exec Mode, system operators can access all inspector mode commands plus the following commands:

- aaa test
- alarm cutoff
- bulkstats force
- card
- clear (a subset of all clear command variations)
- debug
- dhcp test
- gtpc test
- gtpp interim
- gtpp test
- gtpu test
- gtpv0 test
- host
- logging active
- logging filter
- logging trace
- monitor protocol
- monitor subscriber
- newcall
- no card
- no debug
- no newcall policy
- port
- ppp echo-test
- radius interim accounting
- radius test
- rlogin
- show access-group
- show access-list
- show access-flow
- show access statistics
- show configuration
- show snmp transports
- ssh
- telnet
- test alarm

**Administrator Mode Commands**

Administrators can access all system commands except:

- Context Configuration Mode:
  - config-administrator
  - operator
  - inspector
  - administrator
- Global Configuration Mode:
  - snmp community
  - snmp user
  - local-user
  - suspend local-user
- Exec Mode:
  - show snmp communities
  - clear (all clear command variations)
  - show local-user
  - password change local-user
Security Administrator Mode Commands

Security administrators can access all system commands.
CLI Contexts

A context is a group of configuration parameters that apply to the ports, interfaces, and protocols supported by the system. You can configure multiple contexts on the system, each of which resides as a separate, logically independent instance on the same physical device. The CLI can host multiple contexts within a single physical device.

This allows wireless service providers to use the same system to support:

- Different levels of service
- Multiple wholesale or enterprise customers or customer groups
- Different classes of customers based on defined Class of Service (CoS) parameters
- IP address pools across multiple contexts, thus saving IP address allocation
- Enhanced security

Each defined context operates independently from any other context(s) in the system. Each context contains its own CLI instance, IP routing tables, access filters, compression methods, and other configured data.

By default, a single system-wide context called “local”, is used exclusively for the management of the system. Think of the local context as the root directory of the system, since you can define and access all other contexts from this point. You cannot delete the local context.

From this location in the CLI, you can:

- Create and configure other service contexts that contain different service configurations
- Configure system-wide services such as CORBA and SNMP management interfaces, physical management ports, system messages, and others

**Important:** The system requires that you define at least one context in addition to the local context. This isolates system management functions from application or service functions.

Administrative users add contexts through the Global Configuration Mode. A substantial advantage of configuring numerous service contexts is that it allows operators to broadly distribute different subscribers across the system. This greatly enhances the performance of the system and minimizes the loss of sessions should a failure occur.
Understanding the CLI Command Prompt

The CLI provides an intuitive command prompt that informs you of:

- Exactly where you are located within the CLI
- The command mode you are using
- Your user privilege level.

The following figure shows the various components of the command prompt.

Figure 2. CLI Command Prompt
CLI Command Syntax

This section describes the components of the CLI command syntax that you should be familiar with prior to using the CLI. These include:

- **Commands**: Specific words that precede, or initiate, a specific function.
- **Keywords**: Specific words that follow a command to more clearly dictate the command’s function.
- **Variables**: Alphanumeric values that are user-supplied as part of the command syntax. Sometimes referred to as arguments, these terms further specify the command function.
- **Repetitive keywords (+)**: Specific keyword, that when followed by a plus (+) sign, indicates that more than one of the keywords can be entered within a single command.

In the following example, `port_number` and `slot_number` are the command variables for the `info` keyword:

```
show port info slot_number/
```

`port_number/slot_number` is a variable representing a particular Ethernet slot/port on an ASR 5x00 or virtualized platform. See the *System Administration Guide* specific to the platform type for actual slot/port ranges.
Entering and Viewing CLI Commands

This section describes various methods for entering commands into the CLI.
Typing each command keyword, argument, and variable can be time-consuming and increase your chance of making mistakes. The CLI therefore, supports the following features to assist you in entering commands quickly and more accurately. Other features allow you to view the display and review previously entered commands.

Entering Partial CLI Commands

In all of the modes, the CLI recognizes partially-typed commands and keywords, as long as you enter enough characters for the command to be unambiguously recognized by the system. If you do not enter enough characters for the system to recognize a unique command or keyword, it returns a message listing all possible matches for the partial entry.
If you enter the partial command `conf` and press Enter, you enter the Global Configuration Mode. If you were to enter only , the system would respond with the message:

```
Ambiguous Command
```

CLI Command Auto-completion

Use the command auto-completion feature to automatically complete unique CLI commands. Press the Tab key after entering enough characters to enable this feature.

```
[local]host_name# sho<Tab>
[local]host_name# show
```
If you do not enter enough characters to allow the CLI to determine the appropriate command to use, the CLI displays all commands that match the characters you entered with auto-completion:

```
[local]host_name# sh<Tab>
show    shutdown
[local]host_name#
```
Enter a question mark (?) after a partial command to display all of the possible matching commands, and their related help text.

```
[local]host_name# sh?
shutdown - Terminates execution of all tasks within the entire chassis
show - Displays information based on a specified argument
[local]host_name#
```
Using CLI Auto-Pagination

When you enter commands whose expected results exceed the terminal window’s vertical display, the auto-pagination function pauses the display each time the terminal window reaches its display limit. Press any key to display the next screen of results.

By default, auto-pagination functionality is disabled. To enable auto-pagination, type the pipe command: | more.

```
[local]host_name# show configuration | more
```

**Important:** When auto-pagination is enabled, if a command’s output exceeds the terminal window’s vertical display parameters, you can exit by entering "q". This returns you to the CLI prompt.

Using CLI Autoconfirmation

By default, the system is configured to prompt all administrative users with a confirmation prior to executing certain commands. This functionality serves two purposes:

- Helps ensure that you do not execute an unwanted configuration change.

For example, to save a configuration:

```
[local]host_name# save configuration
Are you sure ? [Yes | No]:
```

- Indicates potential misspellings of names during configuration. The first time you configure an element name (context, subscribers, services, etc.), the prompt is displayed. The prompt is not displayed for subsequent entries of the name. Therefore, if you see the confirmation prompt after entering the name of a previously configured element, it is likely that you misspelled the name.

You create a context named newcontext:

```
[local]host_name(config)# context newcontext
Are you sure ? [Yes | No]: yes
[newcontext]host_name(config-ctx)#
```

You revisit the context named newcontext:

```
[local]host_name(config)# context newcontext
[newcontext]host_name(config-ctx)#
```

On another occasion, you misspell the context named newcontext:

```
[local]host_name(config)# context mewcontext
Are you sure ? [Yes | No]:n
Action aborted
[local]host_name(config)#
```
After aborting the above action, you can again revisit `newcontext`:

```
[local] host_name(config)# context newcontext
[newcontext] host_name(config-ctx)#
```

You can control CLI autoconfirmation at the following levels:

- **Specific administrative user sessions**: To enable or disable autoconfirmation, use the `[no] autoconfirm` commands while in the Exec Mode.
- **All Future Sessions**: To disable or re-enable autoconfirmation for all future sessions, use the `[no] autoconfirm` commands while in the Global Configuration Mode.
- **For specific commands**: Disable autoconfirmation for various commands that support the `-noconfirm` keyword, such as the save configuration or card reboot commands.

## Regulating the Command Output

For many CLI commands, you can use `| grep` and/or `| more` keywords to regulate or control the command’s output.

### grep for Regular Expressions

Use the `| grep` keyword to filter through a command’s output for certain expressions or patterns. Only those portions of the output that contain or exclude the pattern are displayed. The `| grep` has the following syntax:

```
| grep [-E | -i | -n | -v | --extended-regexp | --ignore-case | --invert-match | --line-number] expression
```

**Table 4. grep Options**

<table>
<thead>
<tr>
<th>Alternative Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-E</td>
<td>Match using extended regular expressions (EREs). Treat each pattern specified as an ERE (“IEEE Std 1003.1-2001, Section 9.4, Extended Regular Expressions”). If any entire ERE pattern matches some part of an input line excluding terminating &lt;newline&gt;, the line shall be matched. A null ERE shall match every line.</td>
</tr>
<tr>
<td>-i</td>
<td>Perform pattern matching in searches without regard to case. Lower case matches the same as upper case.</td>
</tr>
<tr>
<td>-n</td>
<td>Precede each output line by its relative line number in the file, each file starting at line 1. The line number counter is reset for each file processed.</td>
</tr>
<tr>
<td>-v</td>
<td>Select lines not matching any of the specified patterns. If the <code>-v</code> option is not specified, selected lines shall be those that match any of the specified patterns.</td>
</tr>
<tr>
<td>--extended-regexp</td>
<td>The long form of the <code>-E</code> option.</td>
</tr>
<tr>
<td>--ignore-case</td>
<td>The long form of the <code>-i</code> option.</td>
</tr>
<tr>
<td>--invert-match</td>
<td>The long form of the <code>-v</code> option.</td>
</tr>
<tr>
<td>expression</td>
<td>Specifies the character pattern to find in the command’s output as an alphanumeric string of 1 to 256 characters.</td>
</tr>
</tbody>
</table>
A regular expression is a pattern that describes a set of strings. Regular expressions are constructed analogously to arithmetic expressions, by using various operators to combine smaller expressions. For additional information, refer to ISO/IEC/IEEE 9945:2009 Information technology – Portable Operating System Interface (POSIX®) Base Specifications, Issue 7.

**more Command**

Use the `| more` keyword to pause the terminal each time the terminal window reaches its display limit. Press any key to display the next screen. The function of this keyword is identical to the `autoless` command, except that you must manually enter it on a command-by-command basis.

**Viewing Command History**

To view a history of all commands line by line, simply scroll up or down with the `<up arrow>` and `<down arrow>` cursor keys on the keyboard.

The operating system supports EMACS-style text editing commands. This standard UNIX text editor format allows you to use keyboard-based shortcut keys for maneuvering around the CLI. The following table lists these available shortcut keys.

<table>
<thead>
<tr>
<th>Shortcut Keys</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;Ctrl + p&gt;</code> and <code>&lt;up arrow&gt;</code></td>
<td>Recalls previous command in the command history</td>
</tr>
<tr>
<td><code>&lt;Ctrl + n&gt;</code> and <code>&lt;down arrow&gt;</code></td>
<td>Recalls next command in the command history</td>
</tr>
<tr>
<td><code>&lt;Ctrl + f&gt;</code> and <code>&lt;right arrow&gt;</code></td>
<td>Moves cursor forward by one character in command line</td>
</tr>
<tr>
<td><code>&lt;Ctrl + b&gt;</code> and <code>&lt;left arrow&gt;</code></td>
<td>Moves cursor backward by one character in command line</td>
</tr>
<tr>
<td><code>&lt;Esc&gt; + </code>&lt;f&gt;`</td>
<td>Moves cursor forward by one word in command line</td>
</tr>
<tr>
<td><code>&lt;Esc&gt; + </code>&lt;b&gt;`</td>
<td>Moves cursor backward by one word in command line</td>
</tr>
<tr>
<td><code>&lt;Ctrl&gt; + </code>&lt;a&gt;`</td>
<td>Moves cursor to the beginning of the command line</td>
</tr>
<tr>
<td><code>&lt;Ctrl&gt; + </code>&lt;e&gt;`</td>
<td>Moves cursor to the end of the command line</td>
</tr>
<tr>
<td><code>&lt;Ctrl&gt; + </code>&lt;k&gt;`</td>
<td>Deletes the current command line from the insertion point to the end of the line</td>
</tr>
<tr>
<td><code>&lt;Ctrl&gt; + </code>&lt;u&gt;`</td>
<td>Deletes the current command line from the insertion point to the beginning of the line</td>
</tr>
<tr>
<td><code>&lt;Ctrl&gt; + </code>&lt;d&gt;`</td>
<td>Deletes a single character in the current command line</td>
</tr>
<tr>
<td><code>&lt;Esc&gt; + </code>&lt;d&gt;`</td>
<td>Deletes a word in the current command line</td>
</tr>
<tr>
<td><code>&lt;Ctrl&gt; + </code>&lt;c&gt;`</td>
<td>Quits editing the current line</td>
</tr>
<tr>
<td><code>&lt;Ctrl&gt; + </code>&lt;l&gt;`</td>
<td>Refreshes the display</td>
</tr>
<tr>
<td><code>&lt;Ctrl&gt; + </code>&lt;t&gt;`</td>
<td>Transposes (or switches) the two characters surrounding the insertion point</td>
</tr>
</tbody>
</table>
Obtaining CLI Help

The CLI provides context-sensitive help for every command token and keyword available to you. To obtain, use one of these methods:

- **Command Help:** Command help provides assistance for a specific command. Type a question mark (?) at the end of the specific command to accesses help.

  ```
  [local]host_name# test?
  test - Performs test on followed mechanism
  ```

- **Keyword Help:** Keyword help provides assistance in determining the next keyword, argument, or option to use in the command syntax. Enter the command keyword, enter a space, and then type a question mark (?).

  ```
  [local]host_name# test alarm ?
  audible - Tests internal audible alarm buzzer on SPC
  central-office - Tests specified central office alarm relays
  <cr> - newline
  ```

- **Variable Help:** Variable help provides the correct format, value, or information type for each variable that is part of the command syntax. For commands with variables, enter the command keyword, enter a space, and then type a question mark (?).

  ```
  [local]host_name# show card info ?
  <Enter card number as an integer ranging 1 to n>
  | - Pipeline
  <cr> - Carriage Return or <Enter> key
  ```
Exiting the CLI and CLI Command Modes

A CLI session is defined as the successful login into the CLI. When you establish a CLI session, you are placed into the system’s Exec Mode. Depending upon your user privilege level, you can:

- Use the local context to perform system management functions.
- Move to an assigned context and work in Exec Mode.
- Move to an assigned context as an administrative user and work in Global Configuration Mode or other configuration sub-mode.

This section addresses how to properly exit the various modes and the CLI.

Exiting Configuration Sub-modes

To exit a configuration sub-mode and return to the next highest configuration sub-mode or Global Configuration Mode, type the exit command at the system prompt.

```
[context_name]host_name(config-ctx)# exit
[local]host_name(config)#
```

**Important:** The CLI supports implicit mode-exits when using configuration files. Therefore, configuration files do not have to contain all of the required exit commands for you to leave various sub-config modes.

To exit a sub-mode and return to the Exec Mode, enter the end command.

```
[local]host_name(config-ctx)# end
[local]host_name#
```

Exiting Global Configuration Mode

To exit Global Configuration Mode, and return to the Exec Mode prompt, type the exit command at the prompt.

Ending a CLI Session

To end a CLI session and exit the CLI, type the exit command at the Exec Mode prompt.
Accessing the CLI

Access the CLI through the following methods:

- Local login through an ASR 5x00 Console port via a serial connection with a management card
- Local login through a vConsole port via the hypervisor that initiated the StarOS virtual machine
- Remote login using Telnet and Secure Shell (SSH) access to the CLI through any IP interface on the system.

You can use remote login methods only after the system has been configured to support the various access methods.

**Important:** Even though you can access the CLI remotely through any available IP interface, management traffic should be isolated from network traffic by using one of the dedicated management interfaces supported on the ASR 5x00 platform or StarOS virtual machine.

Multiple CLI sessions are supported, but the number of sessions varies based on the amount of available memory. The Resource Manager reserves enough resources so that a minimum up to 15 CLI sessions are assured. One of the CLI sessions is always reserved for use exclusively by a CLI session on a Console or vConsole interface. Additional CLI sessions beyond the pre-reserved set are permitted if sufficient CPU or vCPU resources are available. If the Resource Manager is unable to reserve additional resources, you are prompted whether to allow the system to create the new CLI session, even without the reserved resources.

## Accessing the CLI Locally Using an ASR 5x00 Console Port

This section provides instructions for accessing the CLI locally through a Console port on the ASR 5x00 platform.

Establish a connection between the serial Console port on an ASR 5x00 and a workstation that has a communications application that accesses the workstation’s serial port, such as Minicom for Linux or HyperTerminal® for MicroSoft Windows®. Refer to the ASR 5x00 Installation Guide for detailed information on connecting to a serial Console port.

1. Configure the communications application to support the following:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Baud Rate</td>
<td>115,200 bps</td>
</tr>
<tr>
<td>Data Bits</td>
<td>8</td>
</tr>
<tr>
<td>Parity</td>
<td>None</td>
</tr>
<tr>
<td>Stop Bits</td>
<td>1</td>
</tr>
<tr>
<td>Flow Control</td>
<td>None</td>
</tr>
</tbody>
</table>

**Important:** To change the configuration defined in the table above, modify the `terminal` command located in the Global Configuration Mode.

2. At the terminal window, press **Enter**.
3. If no configuration file is present (that is, this is the first time the system is powered), the CLI prompts you as to whether or not you want to use the Quick Setup Wizard. If the system was configured previously, you are prompted to enter a username and password.

Accessing the CLI Locally Using a vConsole Port

You connect to a vConsole port via a hypervisor that initiates a virtual machine running StarOS. Refer to the hypervisor user documentation and the VPC Administration Guide for additional information.

Remotely Accessing the CLI

To remotely access the CLI through a defined management interface, you must first configure the remote access method (such as Telnet or SSH).

You can find examples of how to configure this in the Getting Started chapter in the System Administration Guide.
Platform Related CLI Issues

StarOS runs on ASR 5x00 and virtualized platforms. However, all CLI features and functions are not supported by all platforms.

This guide includes descriptions for all commands that have been qualified to run under StarOS. There may be specific instances where a command cannot be run and an error message is generated.

As features become fully qualified on specific or all platforms, this guide will be revised to reflect supported commands. For additional information, refer to the Release Notes provided with each StarOS version.
IP Address Notation

When configuring a port interface via the CLI you may be required to enter an IP address. The CLI always accepts an IPv4 address, and in some cases accepts an IPv6 address as an alternative.

For some configuration commands, the CLI also accepts CIDR notation when entering an IP address. Always view the online Help for the CLI command to verify acceptable forms of IP address notation.

IPv4 Dotted-Decimal Notation

An Internet Protocol Version 4 (IPv4) address consists of 32 bits divided into four octets. These four octets are written in decimal numbers, ranging from 0 to 255, and are concatenated as a character string with full stop delimiters (dots) between each number.

For example, the address of the loopback interface, usually assigned the host name localhost, is 127.0.0.1. It consists of the four binary octets 01111111, 00000000, 00000000, and 00000001, forming the full 32-bit address.
IPv4 allows 32 bits for an Internet Protocol address and can, therefore, support $2^{32}$ (4,294,967,296) addresses.

IPv6 Colon-Separated-Hexadecimal Notation

An Internet Protocol Version 6 (IPv6) address has two logical parts: a 64-bit network prefix, and a 64-bit host address part. An IPv6 address is represented by eight groups of 16-bit hexadecimal values separated by colons (:).

A typical example of a full IPv6 address is 2001:0db8:85a3:0000:0000:8a2e:0370:7334
The hexadecimal digits are case-insensitive.

The 128-bit IPv6 address can be abbreviated with the following rules:

- Leading zeroes within a 16-bit value may be omitted. For example, the address fe80:0000:0000:0000:0202:b3ff:fe1e:8329 may be written as fe80::202:b3ff:fe1e:8329
- One group of consecutive zeroes within an address may be replaced by a double colon. For example, fe80:0:0:0:202:b3ff:fe1e:8329 becomes fe80::202:b3ff:fe1e:8329

IPv6 allows 128 bits for an Internet Protocol address and can support $2^{128}$ (340,282,366,920,938,000,000,000,000,000,000,000) internet addresses.

CIDR Notation

Classless Inter-Domain Routing (CIDR) notation is a compact specification of an Internet Protocol address and its associated routing prefix. It is used for both IPv4 and IPv6 addressing in networking architectures.

CIDR is a bitwise, prefix-based standard for the interpretation of IP addresses. It facilitates routing by allowing blocks of addresses to be grouped into single routing table entries. These groups (CIDR blocks) share an initial sequence of bits in the binary representation of their IP addresses.

CIDR notation is constructed from the IP address and the prefix size, the latter being the number of leading 1 bits of the routing prefix. The IP address is expressed according to the standards of IPv4 or IPv6. It is followed by a separator character, the slash (/) character, and the prefix size expressed as a decimal number.
Important: On the ASR 5000, routes with IPv6 prefix lengths less than /12 and between the range of /64 and /128 are not supported.

The address may denote a single, distinct, interface address or the beginning address of an entire network. In the latter case the CIDR notation specifies the address block allocation of the network. The maximum size of the network is given by the number of addresses that are possible with the remaining, least-significant bits below the prefix. This is often called the host identifier.

For example:

- the address specification 192.168.100.1/24 represents the given IPv4 address and its associated routing prefix 192.168.100.0, or equivalently, its subnet mask 255.255.255.0.
- the IPv4 block 192.168.0.0/22 represents the 1024 IPv4 addresses from 192.168.0.0 to 192.168.3.255.
- the IPv6 block 2001:DB8::/48 represents the IPv6 addresses from 2001:DB8:0:0:0:0:0:0 to 2001:DB8:0:FFFF:FFFF:FFFF:FFFF.
- ::1/128 represents the IPv6 loopback address. Its prefix size is 128, the size of the address itself, indicating that this facility consists of only this one address.

The number of addresses of a subnet defined by the mask or prefix can be calculated as 2, in which the address size for IPv4 is 32 and for IPv6 is 128. For example, in IPv4, a mask of /29 gives 8 addresses.
Alphanumeric Strings

Some CLI commands require the entry of a string of characters that can contain a contiguous collection of alphabetic, numeric, or alphanumeric characters with a defined minimum and maximum length (number of characters).

Character Set

The alphanumeric character set is a combination of alphabetic characters (Latin letters) and numeric characters (Arabic numerals). The set consists of the letters A to Z (uppercase) and a to z (lowercase) and the numbers 0 to 9. The underscore character ( _ ) and dash/hyphen character ( - ) can also be used.

Blank spaces (whitespaces or SPACE characters) should mostly be avoided in alphabetic, numeric, and alphanumeric strings, except in certain ruledef formats, such as time/date stamps.

The following special characters can be used in ruledefs, APNs, license keys and other configuration/display parameters:

- < > (arrow brackets) [less than or greater than]
- * (asterisk) [wildcard]
- : (colon)
- $ (dollar sign) [wildcard]
- . (dot)
- = (equals sign)
- ! (exclamation point)
- % (percent)
- / (slash - forward)
- | (vertical bar)

The following special characters can be used to delimit the domain from the user name for global AAA functions:

- @ (at sign)
- - (dash or hyphen)
- # (hash or pound sign)
- % (percent)
- \ (slash - backward) [must be entered as double slash \ ]
- / (slash - forward)

Quoted Strings

If descriptive text requires the use of spaces between words, the string must be entered within double quotation marks (" ").

interface "Rack 3 Chassis 1 port 5/2"
Chapter 2
AAA Server Group Configuration Mode Commands

The AAA Server Group Configuration Mode is used to create and manage the Diameter/RADIUS server groups within the context or system. AAA server group facilitates management of group (list) of servers at per subscriber/APN/realm level for AAA functionality.

**Mode**

Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

```plaintext
configure > context context_name > aaa group group_name
```

Entering the above command sequence results in the following prompt:

```
/context_name/host_name(config-aaa-group)#
```

⚠️ **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
description

Sets the descriptive text for the object.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```
description text
```

```
no description
```

- **no**
  
  Clears the description for the object.

- **text**
  
  Specifies the descriptive text as an alphanumeric string of 1 to 79 characters. If you include spaces between words in the description, you must enclose the text within double quotation marks (" "), for example, “AAA BBBB”.

**Usage**

The description should provide useful information on the object’s primary function, services, endusers, etc.
**diameter accounting**

This command configures Diameter accounting parameters.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

```
configure > context context_name > aaa group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-aaa-group)#
```

**Syntax**

```
diameter accounting { dictionary { aaa-custom1 | aaa-custom10 | aaa-custom2 | aaa-custom3 | aaa-custom4 | aaa-custom5 | aaa-custom6 | aaa-custom7 | aaa-custom8 | aaa-custom9 | dynamic-load | nasreq | rf-plus } | endpoint endpoint_name | hd-mode fall-back-to-local | hd-storage-policy hd_policy | max-retries max_retries | max-transmissions max_transmissions | request-timeout request_timeout_duration | server host_name priority priority | upgrade-dict-avps { 3gpp-rel10 | 3gpp-rel9 } }

default diameter accounting { dictionary | hd-mode | max-retries | max-transmissions | request-timeout | upgrade-dict-avps }

no diameter accounting { endpoint | hd-mode | hd-storage-policy | max-retries | max-transmissions | server host_name | upgrade-dict-avps }
```

- **no diameter accounting**: Removes the configured accounting endpoint, and the default accounting server configured in the default AAA group will be used.
- **endpoint**: Sends records to the Diameter server, if all Diameter servers are down or unreachable, then copies records to the local hard disk drive (HDD) and periodically retries the Diameter server.
- **hd-mode**: Enables use of the specified HD storage policy.
- **max-retries**: Disables the configured retry attempts for Diameter accounting in the current AAA group.
- **max-transmissions**: Disables the configured maximum transmission attempts for Diameter accounting in the current AAA group.
- **server host_name**: Removes the configured Diameter host `host_name` from this AAA server group for Diameter accounting.
- **upgrade-dict-avps**: Sets the release version to 3GPP Rel. 8 for upgrading Diameter accounting dictionary in the current AAA group.

```
default diameter accounting { dictionary | hd-mode | max-retries | max-transmissions | request-timeout | upgrade-dict-avps }

dictionary: Sets the context’s dictionary as the system default.
**hd-mode**: Sends records to the Diameter server, if all Diameter servers are down or unreachable, then copies records to the local HDD and periodically retries the Diameter server.

**max-retries**: Sets the retry attempts for Diameter accounting in the current AAA group to default 0 (disable).

**max-transmissions**: Sets the configured maximum transmission attempts for Diameter accounting in the current AAA group to default 0 (disable).

**request-timeout**: Sets the timeout duration, in seconds, for Diameter accounting requests in the current AAA group to default 20.

**upgrade-dict-avps**: Sets the release version to 3GPP Rel. 8 for upgrading Diameter accounting dictionary in the current AAA group.

```bash
dictionary { aaa-custom1 | aaa-custom10 | aaa-custom2 | aaa-custom3 | aaa-custom4 
    | aaa-custom5 | aaa-custom6 | aaa-custom7 | aaa-custom8 | aaa-custom9 | dynamic-load | nasreq | rf-plus }
```

Specifies the Diameter accounting dictionary.

**aaa-custom1 ... aaa-custom10**: Configures the custom dictionaries. Even though the CLI syntax supports several custom dictionaries, not necessarily all of them have been defined. If a custom dictionary that has not been implemented is selected, the default dictionary will be used.

**dynamic-load**: Configures the dynamically loaded Diameter dictionary. The dictionary name must be an alphanumeric string of 1 through 15 characters. For more information on dynamic loading of Diameter dictionaries, see the `diameter dynamic-dictionary` in the `Global Configuration Mode Commands` chapter of this guide.

**nasreq**: nasreq dictionary— the dictionary as defined by RFC 3588.

**rf-plus**: RF Plus dictionary.

**endpoint endpoint_name**

Enables Diameter to be used for accounting, and specifies which Diameter endpoint to use. `endpoint_name` must be a string of 1 through 63 characters.

**hd-mode fall-back-to-local**

Specifies that records be copied to the local HDD if the Diameter server is down or unreachable. CDF/CGF will pull the records through SFTP.

**hd-storage-policy hd_policy**

Associates the specified HD Storage policy with the AAA group. `hd_policy` must be the name of a configured HD Storage policy, and must be an alphanumeric string of 1 through 63 characters.

HD Storage policies are configured through the Global Configuration Mode.

This and the **hd-mode** command are used to enable the storage of RF Diameter Messages to HDD in case all Diameter Servers are down or unreachable.

**max-retries max_retries**

Specifies how many times a Diameter request should be retried with the same server, if the server fails to respond to a request.

`max_retries` specifies the maximum number of retry attempts, and must be an integer from 1 through 1000.

Default: 0
max-transmissions max_transmissions

Specifies the maximum number of transmission attempts for a Diameter request. Use this in conjunction with the max-retries max_retries option to control how many servers will be attempted to communicate with.

max_transmissions must be an integer from 1 through 1000.
Default: 0

request-timeout request_timeout_duration

Specifies the number of seconds the system will wait for a response from a Diameter server before re-transmitting the request. request_timeout_duration specifies the number of seconds, and must be an integer from 1 through 3600.
Default: 20

server host_name priority priority

Specifies the current context Diameter accounting server’s host name and priority.
host_name specifies the Diameter host name, and must be an alphanumeric string of 1 through 63 characters.
priority specifies the relative priority of this Diameter host. The priority is used in server selection. The priority must be an integer from 1 through 1000.

upgrade-dict-avps { 3gpp-rel10 | 3gpp-rel9 }

Specifies to upgrade Diameter accounting dictionary to 3GPP Rel. 9 version or 3GPP Rel. 10 version.
3gpp-rel10: Upgrades the dictionary to 3GPP Rel. 10 version.
3gpp-rel9: Upgrades the dictionary to 3GPP Rel. 9 version.
Default: Sets the release version to 3GPP Rel. 8

Usage

Use this command to manage the Diameter accounting options according to the Diameter server used for the context.

Example

The following command configures the Diameter accounting dictionary, aaa-custom10:

```
diameter accounting dictionary aaa-custom10
```

The following command configures the Diameter endpoint, EAPI:

```
diameter accounting endpoint EAPI
```

The following commands configure Diameter accounting options:

```
diameter accounting max-retries 4
```
```
diameter accounting max-transmissions 2
```
```
diameter accounting request-timeout 10
```
```
diameter accounting server svc priority 1
```
diameter authentication

This command configures Diameter authentication parameters.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

```
configure > context context_name > aaa group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-aaa-group)#
```

**Syntax**

```
diameter authentication { dictionary { aaa-custom1 | aaa-custom10 | aaa-custom11 | aaa-custom12 | aaa-custom13 | aaa-custom14 | aaa-custom15 | aaa-custom16 | aaa-custom17 | aaa-custom18 | aaa-custom19 | aaa-custom2 | aaa-custom20 | aaa-custom3 | aaa-custom4 | aaa-custom5 | aaa-custom6 | aaa-custom7 | aaa-custom8 | aaa-custom9 | dynamic-load | nasreq } | endpoint endpoint_name | max-retries max_retries | max-transmissions max_transmissions | redirect-host-avp { just-primary | primary-then-secondary } | request-timeout request_timeout_duration | server host_name priority priority | upgrade-dict-avps { 3gpp-rel10 | 3gpp-rel19 } }

default diameter authentication { dictionary | max-retries | max-transmissions | redirect-host-avp | request-timeout | upgrade-dict-avps }

no diameter authentication { endpoint | max-retries | max-transmissions | server host_name | upgrade-dict-avps }
```

- **dictionary**: Sets the context’s dictionary as the system default.
- **endpoint**: Removes the configured authentication endpoint, and the default server configured in default AAA group will be used.
- **max-retries**: Disables the configured retry attempts for Diameter authentication in the currentAAA group.
- **max-transmissions**: Disables the configured maximum transmission attempts for Diameter authentication in the current AAA group.
- **server host_name**: Removes the configured Diameter host `host_name` from this AAA server group for Diameter authentication.
- **upgrade-dict-avps**: Sets the release version to 3GPP Rel. 8 for upgrading Diameter authentication dictionary in the current AAA group.

```
default diameter authentication { dictionary | max-retries | max-transmissions | redirect-host-avp | request-timeout | upgrade-dict-avps }
```

- **max-retries**: Sets the retry attempts for Diameter authentication requests in the current AAA group to default 0 (disable).
**max-transmissions**: Sets the configured maximum transmission attempts for Diameter authentication in the current AAA group to default 0 (disable).

**redirect-host-avp**: Sets the redirect choice to default (just-primary).

**request-timeout**: Sets the timeout duration, in seconds, for Diameter authentication requests in the current AAA group to default 20.

**upgrade-dict-avps**: Sets the release version to 3GPP Rel. 8 for upgrading Diameter authentication dictionary in the current AAA group.

```
dictionary { aaa-custom1 | aaa-custom10 | aaa-custom11 | aaa-custom12 | aaa-
 custom13 | aaa-custom14 | aaa-custom15 | aaa-custom16 | aaa-custom17 | aaa-
 custom18 | aaa-custom19 | aaa-custom2 | aaa-custom20 | aaa-custom3 | aaa-custom4
 | aaa-custom5 | aaa-custom6 | aaa-custom7 | aaa-custom8 | aaa-custom9 | dynamic-
 load | nasreq }
```

Specifies the Diameter authentication dictionary.

```
aaa-custom1 ... aaa-custom8, aaa-custom10 ... aaa-custom20: Configures the custom
dictionaries. Even though the CLI syntax supports several custom dictionaries, not necessarily all of them
have been defined. If a custom dictionary that has not been implemented is selected, the default dictionary
will be used.
```

**endpoint endpoint_name**

Enables Diameter to be used for authentication, and specifies which Diameter endpoint to use.

**max-retries max_retries**

Specifies how many times a Diameter authentication request should be retried with the same server, if the
server fails to respond to a request.

**max-transmissions max_transmissions**

Specifies the maximum number of transmission attempts for a Diameter authentication request. Use this in
conjunction with the "max-retries max_retries" option to control how many servers will be attempted
to communicate with.

```
diameter configuration
```

```
aaa-custom9: Configures the STa standard dictionary.

dynamic-load: Configures the dynamically loaded Diameter dictionary. The dictionary name must be an
alphanumeric string of 1 through 15 characters. For more information on dynamic loading of Diameter
dictionaries, see the diameter dynamic-dictionary in the Global Configuration Mode Commands
chapter of this guide.

**nasreq**: nasreq dictionary—the dictionary as defined by RFC 3588.

**endpoint endpoint_name**

Enables Diameter to be used for authentication, and specifies which Diameter endpoint to use.

**max-retries max_retries**

Specifies how many times a Diameter authentication request should be retried with the same server, if the
server fails to respond to a request.

**max-transmissions max_transmissions**

Specifies the maximum number of transmission attempts for a Diameter authentication request. Use this in
conjunction with the "max-retries max_retries" option to control how many servers will be attempted
to communicate with.

```
diameter configuration
```

```
aaa-custom9: Configures the STa standard dictionary.

dynamic-load: Configures the dynamically loaded Diameter dictionary. The dictionary name must be an
alphanumeric string of 1 through 15 characters. For more information on dynamic loading of Diameter
dictionaries, see the diameter dynamic-dictionary in the Global Configuration Mode Commands
chapter of this guide.

**nasreq**: nasreq dictionary—the dictionary as defined by RFC 3588.

**endpoint endpoint_name**

Enables Diameter to be used for authentication, and specifies which Diameter endpoint to use.

**max-retries max_retries**

Specifies how many times a Diameter authentication request should be retried with the same server, if the
server fails to respond to a request.

**max-transmissions max_transmissions**

Specifies the maximum number of transmission attempts for a Diameter authentication request. Use this in
conjunction with the "max-retries max_retries" option to control how many servers will be attempted
to communicate with.

```
diameter configuration
```

```
aaa-custom9: Configures the STa standard dictionary.

dynamic-load: Configures the dynamically loaded Diameter dictionary. The dictionary name must be an
alphanumeric string of 1 through 15 characters. For more information on dynamic loading of Diameter
dictionaries, see the diameter dynamic-dictionary in the Global Configuration Mode Commands
chapter of this guide.

**nasreq**: nasreq dictionary—the dictionary as defined by RFC 3588.

**endpoint endpoint_name**

Enables Diameter to be used for authentication, and specifies which Diameter endpoint to use.

**max-retries max_retries**

Specifies how many times a Diameter authentication request should be retried with the same server, if the
server fails to respond to a request.

**max-transmissions max_transmissions**

Specifies the maximum number of transmission attempts for a Diameter authentication request. Use this in
conjunction with the "max-retries max_retries" option to control how many servers will be attempted
to communicate with.
AAA Server Group Configuration Mode Commands

**redirect-host-avp { just-primary | primary-then-secondary }**

Specifies whether to use just one returned AVP, or use the first returned AVP as selecting the primary host and the second returned AVP as selecting the secondary host.

- **just-primary**: Redirect only to primary host.
- **primary-then-secondary**: Redirect to primary host, if fails then redirect to the secondary host.

Default: just-primary

**request-timeout request_timeout_duration**

Specifies how long the system will wait for a response from a Diameter server before re-transmitting the request.

**request_timeout_duration** specifies the number of seconds the system will wait for a response from a Diameter server before re-transmitting the request, and must be an integer from 1 through 3600.

Default: 20 seconds

**server host_name priority priority**

 Specifies the current context Diameter authentication server’s host name and priority.

- **host_name** specifies the Diameter authentication server’s host name, and must be an alphanumeric string of 1 through 63 characters.
- **priority** specifies the relative priority of this Diameter host. The priority is used in server selection. The priority must be an integer from 1 through 1000.

**upgrade-dict-avps { 3gpp-rel10 | 3gpp-rel9 }**

Specifies to upgrade Diameter authentication dictionary to 3GPP Rel. 9 version or 3GPP Rel. 10 version.

- **3gpp-rel10**: Upgrades the dictionary to 3GPP Rel. 10 version.
- **3gpp-rel9**: Upgrades the dictionary to 3GPP Rel. 9 version.

Default: Sets the release version to 3GPP Rel. 8

**Usage**

Use this command to manage the Diameter authentication options according to the Diameter server used for the context.

**Example**

The following command configures the Diameter authentication dictionary, *aaa-custom1*:

```
  diameter authentication dictionary aaa-custom1
```

The following command configures the Diameter endpoint, *EAPI*:

```
  diameter authentication endpoint EAPI
```

The following commands configure Diameter authentication options:

```
  diameter authentication max-retries 4
  diameter authentication max-transmissions 2
  diameter authentication redirect-host-avp primary-then-secondary
  diameter authentication server svc priority 1
  diameter authentication request-timeout 10
```
diameter authentication failure-handling

This command configures the failure handling for Diameter authentication requests and Diameter Extensible Authentication Protocol (EAP) requests.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

```bash
configure > context context_name > aaa group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-aaa-group)#
```

**Syntax**

```
diameter authentication failure-handling { authorization-request | eap-request | eap-termination-request } { request-timeout action { continue | retry-and-terminate | terminate } | result-code start_result_code { [ to end_result_code ] action { continue | retry-and-terminate | terminate } } }
```

```
o diameter authentication failure-handling { authorization-request | eap-request | eap-termination-request } result-code start_result_code { [ to end_result_code ]
```

```
default diameter authentication failure-handling { authorization-request | eap-request | eap-termination-request } request-timeout action
```

```bash
no
```

Disables Diameter authentication failure handling.

```bash
default
```

Configures the default Diameter authentication failure handling setting.

```bash
authorization-request
```

Specifies that failure handling must be performed on Diameter authorization request (AAR/AAA) messages.

```bash
eap-request
```

Specifies configuring failure handling for EAP requests.

```bash
eap-termination-request
```

Specifies configuring failure handling for EAP termination requests.

```bash
request-timeout action { continue | retry-and-terminate | terminate }
```

Specifies the action to be taken for failures:

- `continue`: Continues session
diameter authentication failure-handling

- **retry-and-terminate**: First retries, if it fails then terminates the session
- **terminate**: Terminates session

```sql
result-code start_result_code [ to end_result_code ] action { continue | retry-and-terminate | terminate }
```

- **start_result_code**: Specifies the result code number, must be an integer from 1 through 65535.
- **to end_result_code**: Specifies the upper limit of a range of result codes. **to end_result_code** must be greater than **start_result_code**.
- **action { continue | retry-and-terminate | terminate }**: Specifies the action to be taken for failures:
  - **continue**: Continues
  - **retry-and-terminate**: First retries, if it fails then terminates
  - **terminate**: Terminates

### Usage

Use this command to configure error handling for Diameter EAP, EAP-termination, and authorization requests. Specific actions (continue, retry-and-terminate, or terminate) can be associated with each possible result code. Ranges of result codes can be defined with the same action, or actions can be specific on a per-result code basis.

### Example

The following commands configure result codes 5001, 5002, 5004, and 5005 to use “action continue” and result code 5003 to use “action terminate”:

```sql
diameter authentication failure-handling eap-request result-code 5001 to 5005 action continue

diameter authentication failure-handling eap-request result-code 5003 action terminate
```
diameter dictionary

This command is deprecated and is replaced by the diameter accounting dictionary and diameter authentication dictionary commands. See the diameter accounting and diameter authentication commands respectively.
end

Exits the current configuration mode and returns to the Exec mode.

Product

exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
radius

This command configures basic RADIUS options.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

configure > context context_name > aaa group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-aaa-group)#

Syntax

radius { deadtime minutes | detect-dead-server { consecutive-failures consecutive_failures_count | response-timeout response_timeout_duration } | dictionary dictionary | max-outstanding max_messages | max-retries max_retries | max-transmissions max_transmissions | probe-message local-service-address ipv4/ipv6_address | strip-domain { authentication-only | accounting-only } | timeout idle_seconds }

default radius { deadtime | detect-dead-server | dictionary | max-outstanding | max-retries | max-transmissions | timeout }

no radius { detect-dead-server | max-transmissions | radius probe-message local-service-address | strip-domain }

no
Removes the specified configuration.

default
Configures default setting for the specified keyword.

dictionary dictionary
Specifies which dictionary to use. The following table describes the possible values for dictionary:

<table>
<thead>
<tr>
<th>Dictionary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>customXX</td>
<td>These are dictionaries that can be customized to fit your needs. Customization information can be attained by contacting your local service representative. XX is the integer value of the custom dictionary.</td>
</tr>
<tr>
<td>standard</td>
<td>This dictionary consists only of the attributes specified in RFC 2865, RFC 2866, and RFC 2869.</td>
</tr>
<tr>
<td>3gpp</td>
<td>This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in 3GPP 32.015.</td>
</tr>
</tbody>
</table>
Dictionary | Description
--- | ---
3gpp2 | This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835-A.
3gpp2-835 | This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835.
starent-vsa1 | This dictionary consists not only of the 3GPP2 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0 - 255). This is the default dictionary.

**Important:** In 12.0 and later releases, no new attributes can be added to the `starent-vsa1` dictionary. If there are any new attributes to be added, these can only be added to the `starent` dictionary. For more information, please contact your Cisco account representative.

<table>
<thead>
<tr>
<th>Dictionary</th>
<th>Description</th>
</tr>
</thead>
</table>
starent-vsa1-835 | This dictionary consists not only of the 3gpp2-835 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0 - 255). This is the default dictionary.|
starent | This dictionary consists of all of the attributes in the starent-vsa1 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the dictionaries supported by the system.|
starent-835 | This dictionary consists of all of the attributes in the starent-vsa1-835 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the -835 dictionaries supported by the system.

---

**deaddtime** *minutes*

Specifies the number of minutes to wait before changing the state of a RADIUS server from “Down” to “Active”. *minutes* must be an integer from 0 through 65535.
Default: 10

**Important:** This parameter should be set to allow enough time to remedy the issue that originally caused the server’s state to be changed to “Down”. After the deaddtime timer expires, the system returns the server’s state to “Active” regardless of whether or not the issue has been fixed.

**Important:** For a complete explanation of RADIUS server states, if you are using StarOS 12.3 or an earlier release, refer to the RADIUS Server State Behavior appendix in the AAA and GTTP Interface Administration and Reference. If you are using StarOS 14.0 or a later release, refer to the AAA Interface Administration and Reference.

**detect-dead-server**

```
detect-dead-server { consecutive-failures consecutive_failures_count | keepalive | response-timeout response_timeout_duration }
```

**consecutive-failures** *consecutive_failures_count:* Specifies the number of consecutive failures, for any AAA Manager, before a server’s state is changed from “Active” to “Down”.
`consecutive_failures_count` must be an integer from 1 through 1000. Default: 4.
**keepalive**: Enables the AAA server alive-dead detect mechanism based on sending keepalive authentication messages to all authentication servers. Default is disabled.

**response-timeout response_timeout_duration**: Specifies the number of seconds, for any AAA Manager, to wait for a response to any message before a server’s state is changed from “Active” to “Down”. `response_timeout_duration` must be an integer from 1 through 65535.

**Important**: If both `consecutive-failures` and `response-timeout` are configured, then both parameters must be met before a server’s state is changed to “Down”.

**Important**: The “Active” or “Down” state of a RADIUS server as defined by the system, is based on accessibility and connectivity. For example, if the server is functional but the system has placed it into a “Down” state, it could be the result of a connectivity problem. When a RADIUS server’s state is changed to “Down”, a trap is sent to the management station and the `deadtime` timer is started.

**max-outstanding max_messages**

Specifies the maximum number of outstanding messages a single AAA Manager instance will queue.

`max_messages` must be an integer from 1 through 4000.
Default: 256

**max-retries max_retries**

Specifies the maximum number of times communication with a AAA server will be attempted before it is marked as “Not Responding”, and the detect dead server’s consecutive failures count is incremented.

`max_retries` must be an integer from 0 through 65535.
Default: 5

**max-transmissions max_transmissions**

Sets the maximum number of re-transmissions for RADIUS authentication requests. This limit is used in conjunction with `max-retries` parameter for each server.

When failing to communicate with a RADIUS sever, the subscriber is failed once all of the configured RADIUS servers have been exhausted, or once the configured number of maximum transmissions is reached. For example, if three servers are configured and if the configured max-retries is 3 and max-transmissions is 12, then the primary server is tried four times (once plus three retries), the secondary server is tried four times, and then a third server is tried four times. If there is a fourth server, it is not tried because the maximum number of transmissions (12) has been reached.

`max_transmissions` must be an integer from 1 through 65535.
Default: Disabled

**probe-message local-service-address ipv4/ipv6_address**

**radius probe-message**: Configures AVPs to be sent in RADIUS authentication probe messages.
**local-service-address**: Configures the service ip-address to be sent as an AVP in RADIUS authentication probe messages.
**ipv4/ipv6_address**: Specifies the IP address of the server.

`ipv4/ipv6_address` must be specified in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation. A maximum of 128 RADIUS servers can be configured per context. This limit includes accounting and authentication servers.
strip-domain { authentication-only | accounting-only }

Specifies that the domain must be stripped from the user name prior to authentication or accounting. By default, strip-domain configuration will be applied to both authentication and accounting messages, if configured. When the argument authentication-only or accounting-only is present, strip-domain is applied only to the specified RADIUS message types.

timeout idle_seconds

Specifies the number of seconds to wait for a response from the RADIUS server before re-sending the messages. idle_seconds must be an integer from 1 through 65535. Default: 3

Usage

Use this command to configure the basic RADIUS parameters according to the RADIUS server used for the context.

Example

The following command configures the RADIUS timeout parameter to 300 seconds.

    radius timeout 300
radius accounting

This command configures the current context’s RADIUS accounting parameters.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

`configure > context context_name > aaa group group_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-aaa-group)#
```

**Syntax**

```
radius accounting { archive [ stop-only ] | deadtime minutes | detect-dead-server { consecutive-failures consecutive_failures_count | keepalive | response-timeout response_timeout_duration } | fire-and-forget | interim interval interim_interval | max-outstanding max_messages | max-pdu-size octets | max-retries max_retries | max-transmissions max_transmissions | timeout idle_seconds }

default radius accounting { deadtime | detect-dead-server | fire-and-forget | max-outstanding | max-pdu-size | max-retries | max-transmissions | timeout }

no radius accounting { archive | detect-dead-server | fire-and-forget | interim interval | max-transmissions }
```

**no**
Removes the specified configuration.

**default**
Configures the default setting for the specified keyword.

**archive [ stop-only ]**

Enables archiving of RADIUS accounting messages in the system after the accounting message has exhausted retries to all available RADIUS accounting servers. All RADIUS accounting messages generated by a session are serially delivered to the RADIUS accounting server. That is, previous RADIUS accounting messages from the same call must be delivered and acknowledged by the RADIUS accounting server before the next RADIUS accounting message is sent to the RADIUS accounting server.

`stop-only` specifies archiving of only STOP accounting messages.

Default: enabled

**deadtime minutes**

Specifies the number of minutes to wait before changing the state of a RADIUS server from “Down” to “Active”.

`minutes` must be an integer from 0 through 65535.
Default: 10 minutes

**Important:** This parameter should be set to allow enough time to remedy the issue that originally caused the server’s state to be changed to “Down”. After the deadtime timer expires, the system returns the server’s state to “Active” regardless of whether or not the issue has been fixed.

**Important:** For a complete explanation of RADIUS server states, if you are using StarOS 12.3 or an earlier release, refer to the RADIUS Server State Behavior appendix in the AAA and GTPP Interface Administration and Reference. If you are using StarOS 14.0 or a later release, refer to the AAA Interface Administration and Reference.

```
detect-dead-server { consecutive-failures consecutive_failures_count | keepalive | response-timeout response_timeout_duration }
```

- **consecutive-failures consecutive_failures_count:** Specifies the number of consecutive failures, for any AAA Manager, before a server’s state is changed from “Active” to “Down”.
- **keepalive:** Enables the AAA server alive-dead detect mechanism based on sending keepalive authentication messages to all authentication servers. Default: disabled
- **response-timeout response_timeout_duration:** Specifies the number of seconds, for any AAA Manager, to wait for a response to any message before a server’s state is changed from “Active” to “Down”.

**Important:** If both consecutive-failures and response-timeout are configured, then both parameters must be met before a server’s state is changed to “Down”.

**Important:** The “Active” or “Down” state of a RADIUS server as defined by the system, is based on accessibility and connectivity. For example, if the server is functional but the system has placed it into a “Down” state, it could be the result of a connectivity problem. When a RADIUS server’s state is changed to “Down”, a trap is sent to the management station and the deadtime timer is started.

**Important:** For a complete explanation of RADIUS server states, if you are using StarOS 12.3 or an earlier release, refer to the RADIUS Server State Behavior appendix in the AAA and GTPP Interface Administration and Reference. If you are using StarOS 14.0 or a later release, refer to the AAA Interface Administration and Reference.

**fire-and-forget**

Enables RADIUS Fire-and-Forget accounting for the AAA group.

Default: Disabled

The request sent to the RADIUS accounting server configured under the AAA group with this keyword configured will not expect a response from the server. If the request must be sent to more than one such type of server, the acct-algorithm first-n configuration in the AAA group can be used.

**Important:** The Fire-and-Forget feature is supported on GGSN, HA, PDSN and P-GW.

Keepalive feature for server state detection is supported in conjunction since there is no waiting for responses. Archiving in such a AAA group is not supported. If the server is down, the request is sent to the next server in the group. If all the servers in the group are down, the request is deleted.
This CLI is independent of the APN or subscriber profile configuration `aaa secondary-group aaa_group_name`.

```
interim interval interim_interval
```

Specifies the time interval, in seconds, for sending accounting INTERIM-UPDATE records. `interim_interval` must be an integer from 50 through 4000000.
Default: Disabled

**Important:** If RADIUS is used as the accounting protocol for the GGSN product, other commands are used to trigger periodic accounting updates. However, these commands would cause RADIUS STOP/START packets to be sent as opposed to INTERIM-UPDATE packets. Also, note that accounting interim interval settings received from a RADIUS server take precedence over those configured on the system.

```
max-outstanding max_messages
```

Specifies the maximum number of outstanding messages a single AAA Manager instance will queue. `max_messages` must be an integer from 1 through 4000.
Default: 256

```
max-pdu-size octets
```

Specifies the maximum sized packet data unit which can be accepted/generated, in bytes (octets). `octets` must be an integer from 512 through 2048.
Default: 2048

```
max-retries max_retries
```

Specifies the maximum number of times communication with a AAA server will be attempted before it is marked as “Not Responding” and the detect dead server consecutive failures count is incremented. `max_retries` must be an integer from 0 through 65535.
Default: 5
Once the maximum number of retries is reached this is considered a single failure for the consecutive failures count for detecting dead servers.

```
max-transmissions max_transmissions
```

Sets the maximum number of transmissions for a RADIUS accounting message before the message is declared as failed. `max_transmissions` must be an integer from 1 through 65535.
Default: Disabled

```
timeout timeout_duration
```

Specifies the duration to wait for a response from a RADIUS server before retransmitting a request. `timeout_duration` must be an integer from 1 through 65535.
Default: 3

**Usage**

Use this command to configure RADIUS accounting options according to the RADIUS server used for the context.

**Example**

The following command configures the accounting timeout parameter to 16 seconds.
radius accounting timeout 16
radius accounting apn-to-be-included

This command specifies the APN name inclusion for RADIUS accounting.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration
configure > context context_name > aaa group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-aaa-group)#

Syntax

radius accounting apn-to-be-included { gi | gn }
default radius accounting apn-to-be-included

default
Configures the default setting.

gi
Specifies the use of Gi APN name in RADIUS accounting request. Gi APN represents the APN received in the Create PDP context request message from SGSN.

gn
Specifies the use of Gn APN name in RADIUS accounting request. Gn APN represents the APN selected by the GGSN.

Usage

Use this command to specify the APN name to be included for RADIUS accounting.

Example

The following command configures the gn APN name to be included for RADIUS accounting:

radius accounting apn-to-be-included gn
radius accounting algorithm

This command specifies the fail-over/load-balancing algorithm to select the RADIUS accounting server(s) to which accounting data must be sent.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

```
configure > context context_name > aaa group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-aaa-group)#
```

**Syntax**

```
radius accounting algorithm { first-n n | first-server | round-robin }
```

**default radius accounting algorithm**

```
default
```

Configures the default setting.
Default: `first-server`

```
first-n n
```

Default: 1 (Disabled)
Specifies that the AGW must send accounting data to `n` (more than one) AAA accounting servers based on their priority. The full set of accounting data is sent to each of the `n` AAA servers. Response from any one of the servers would suffice to proceed with the call. On receiving an ACK from any one of the servers, all retries are stopped.

`n` is the number of AAA servers to which accounting data will be sent, and must be an integer from 2 through 128.

```
first-server
```

Specifies that the context must send accounting data to the RADIUS accounting server with the highest configured priority. In the event that this server becomes unreachable, accounting data is sent to the server with the next-highest configured priority. This is the default algorithm.

```
round-robin
```

Specifies that the context must load balance sending accounting data among all of the defined RADIUS accounting servers. Accounting data is sent in a circular queue fashion on a per Session Manager task basis, where data is sent to the next available server and restarts at the beginning of the list of configured servers. The order of the list is based upon the configured relative priority of the servers.

In releases to prior to 17, for subscribers with IMSI containing hexadecimal characters the round robin algorithm fails causing the messages to be forwarded to a single RADIUS server all the time. This algorithm works only for decimal based IMSI addresses.
radius accounting algorithm

Usage
Use this command to specify the algorithm to select the RADIUS accounting server(s) to which accounting data must be sent.

Example
The following command configures to use the round-robin algorithm for RADIUS accounting server selection:

    radius accounting algorithm round-robin
radius accounting billing-version

This command configures billing-system version of RADIUS accounting servers.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration
configure > context context_name > aaa group group_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-aaa-group)#
```

**Syntax**

```
radius accounting billing-version version
```

```
default radius accounting billing-version
```

- **default**
  Configures the default setting.
  Default: 0

- **version**
  Specifies the billing-system version, and must be an integer from 0 through 4294967295.

**Usage**

Use this command to configure the billing-system version of RADIUS accounting servers.

**Example**

The following command configures the billing-system version of RADIUS accounting servers as 10:

```
radius accounting billing-version 10
```
radius accounting gtp trigger-policy

This command configures the RADIUS accounting trigger policy for GTP messages.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

configure > context context_name > aaa group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-aaa-group)#

**Syntax**

```
radius accounting gtp trigger-policy [ standard | ggsn-preservation-mode ]
```

**default radius accounting gtp trigger-policy**

```
default
```

Resets the RADIUS accounting trigger policy to standard behavior for GTP session.

```
standard
```

This keyword sets the RADIUS accounting trigger policy to standard behavior which is configured for GTP session for GGSN service.

```
ggsn-preservation-mode
```

This keyword sends RADIUS Accounting Start when the GTP message with private extension of preservation mode is received from SGSN.

**Important:** This is a customer-specific keyword and needs customer-specific license to use this feature. For more information on GGSN preservation mode, refer to the *GGSN Service Configuration Mode Commands* chapter.

**Usage**

Use this command to set the trigger policy for the AAA accounting for a GTP session.

**Example**

The following command sets the RADIUS accounting trigger policy for GTP session to standard:

```
default radius accounting gtp trigger-policy
```
**radius accounting ha policy**

This command configures the RADIUS accounting policy for Home Agent (HA) sessions.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration
configure > context context_name > aaa group group_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-aaa-group)#
```

**Syntax**

```
radius accounting ha policy { custom1-aaa-res-mgmt | session-start-stop }
```

`default radius accounting ha policy`

```
default
Configures the default setting.
```

`session-start-stop`

Specifies sending Accounting Start when the Session is connected, and sending Accounting Stop when the session is disconnected. This is the default behavior.

`custom1-aaa-res-mgmt`

Accounting Start/Stop messages are generated to assist special resource management done by AAA servers. It is similar to the session-start-stop accounting policy, except for the following differences:

- Accounting Start is also generated during MIP session handoffs.
- No Accounting stop is generated when an existing session is overwritten and the new session continues to use the IP address assigned for the old session.
- Accounting Start is generated when a new call overwrites an existing session.

**Usage**

Use this command to configure the AAA accounting behavior for an HA session.

**Example**

The following command configures the HA accounting policy to `custom1-aaa-res-mgmt`:

```
radius accounting ha policy custom1-aaa-res-mgmt
```
radius accounting interim

This command configures the volume of uplink and downlink volume octet counts that trigger RADIUS interim accounting, and configures the time period between the sending of interim accounting records.

Product
- GGSN
- PDSN
- HA
- HSGW

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

configure > context context_name > aaa group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-aaa-group)#

Syntax

radius accounting interim { interval interim_interval | volume { downlink bytes uplink bytes | total bytes | uplink bytes downlink bytes } }

no radius accounting interim volume

- **no**
  Disables RADIUS interim accounting.

- **interval interim_interval**
  Specifies the time interval, in seconds, between sending interim accounting records. `interim_interval` must be an integer from 50 through 40000000.

- **volume { downlink bytes uplink bytes | total bytes | uplink bytes downlink bytes }**
  - **downlink bytes uplink bytes**: Specifies the downlink to uplink volume limit, in bytes, for RADIUS Interim accounting. `bytes` must be an integer from 100000 through 4000000000.
  - **total bytes**: Specifies the total volume limit, in bytes, for RADIUS interim accounting. `bytes` must be an integer from 100000 through 4000000000.
  - **uplink bytes downlink bytes**: Specifies the uplink to downlink volume limit, in bytes, for RADIUS interim accounting. `bytes` must be an integer from 100000 through 4000000000.

Usage

Use this command to trigger RADIUS interim accounting based on the volume of uplink and downlink bytes and/or to configure the time interval between the sending of interim accounting records.

Example
The following command triggers RADIUS interim accounting when the total volume of uplink and downlink bytes reaches 110000:

```
radius accounting interim volume total 110000
```

The following command sets the interval between sending interim accounting records to 3 minutes (180 seconds):

```
radius accounting interim interval 180
```
radius accounting ip remote-address

This command configures IP remote address-based RADIUS accounting parameters.

Product
PDSN
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration
configure > context context_name > aaa group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-aaa-group)#

Syntax

[ no ] radius accounting ip remote-address { collection | list list_id }

- **no**
  Removes the specified configuration.

- **collection**
  Enables collecting and reporting Remote-Address-Based accounting in RADIUS Accounting. This should be enabled in the AAA Context. It is disabled by default.

- **list list_id**
  Enters the Remote Address List Configuration mode. This mode configures a list of remote addresses that can be referenced by the subscriber's profile. list_id must be an integer from 1 through 65535.

Usage
This command is used as part of the Remote Address-based Accounting feature to both configure remote IP address lists and enable the collection of accounting data for the addresses in those lists on a per-subscriber basis.

Individual subscriber can be associated to remote IP address lists through the configuration/specification of an attribute in their local or RADIUS profile. (Refer to the radius accounting command in the Subscriber Configuration mode.) When configured/specified, accounting data is collected pertaining to the subscriber’s communication with any of the remote addresses specified in the list.

Once this functionality is configured on the system and in the subscriber profiles, it must be enabled by executing this command with the collection keyword.

Example
The following command enables collecting and reporting Remote-Address-Based accounting in RADIUS Accounting:

    radius accounting ip remote-address collection
radius accounting keepalive

This command configures the keepalive authentication parameters for the RADIUS accounting server.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

`configure > context context_name > aaa group group_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-aaa-group)#
```

**Syntax**

```
radius accounting keepalive { calling-station-id id | consecutive-response consecutive_responses | framed-ip-address ip_address | interval seconds | retries number | timeout seconds | username user_name }

default radius accounting keepalive { calling-station-id | consecutive-response | interval | retries | timeout | username }

no radius accounting keepalive framed-ip-address
```

---

**no**

Removes the specified configuration.

---

**default**

Configures the default setting for the specified keyword.

---

**calling-station-id id**

Configures the Calling-Station-Id to be used for the keepalive authentication.

*id* must be an alphanumeric string of size 1 to 15 characters.

Default: 000000000000000

---

**consecutive-response consecutive_responses**

Configures the number of consecutive authentication response after which the server is marked as reachable.

*consecutive_responses* must be an integer from 1 through 10.

Default: 1

---

**framed-ip-address ip_address**

Configures the framed-ip-address to be used for the keepalive accounting.

*ip_address* must be specified using IPv4 dotted-decimal notation.
AAA Server Group Configuration Mode Commands

radius accounting keepalive

- **interval seconds**
  - Configures the time interval between the two keepalive access requests.
  - Default: 30 seconds

- **retries number**
  - Configures the number of times the keepalive access request to be sent before marking the server as unreachable.
  - *number* must be an integer from 3 through 10.
  - Default: 3

- **timeout timeout_duration**
  - Configures the time interval between each keepalive access request retries.
  - *timeout_duration* must be an integer from 1 through 30.
  - Default: 3 seconds

- **username user_name**
  - Configures the user name to be used for authentication.
  - *user_name* must be an alphanumeric string of 1 through 127 characters.
  - Default: Test-Username

**Usage**

Use this command to configure the keepalive authentication parameters for the RADIUS accounting server.

**Example**

The following command sets the user name for RADIUS keepalive access requests to Test-Username2:

```
radius accounting keepalive username Test-Username2
```

The following command sets the number of RADIUS accounting keepalive retries to 4.

```
radius accounting keepalive retries 4
```
radius accounting pdif trigger-policy

This command configures the policy for generating START/STOP pairs in overflow condition.

### Product
PDIF

### Privilege
Administrator, Security Administrator

### Mode
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

```
configure > context context_name > aaa group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-aaa-group)#
```

### Syntax

```
radius accounting pdif trigger-policy { standard | counter-rollover }
default radius accounting pdif trigger-policy
```

- **default**
  The default option configures the “standard” policy.

- **standard**
  Applies a policy as defined by the standards.

- **counter-rollover**
  If the counter-rollover option is enabled, the system generates a STOP/START pair before input/output data octet counts (or input/output data packet counts) become larger than \(2^{32} - 1\) in value. This setting is used to guarantee that a 32-bit octet count in any STOP message has not wrapped to larger than \(2^{32}\) thus ensuring the accuracy of the count. The system may, at its discretion, send the STOP/START pair at any time, so long as it does so before the 32-bit counter has wrapped.

### Usage
Used to define the policy for dealing with overflow packet counts.

### Example
Use the following example to set the default policy to *standard*.

```
default radius accounting pdif trigger-policy
```
radius accounting rp

This command configures the RADIUS accounting R-P originated call options.

Product
PDSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration
configure > context context_name > aaa group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-aaa-group)#

Syntax

radius accounting rp { handoff-stop { immediate | wait-active-stop } | tod minute hour | trigger-event { active-handoff | active-start-param-change | active-stop } | trigger-policy { airlink-usage [ counter-rollover ] | custom { active-handoff | active-start-param-change | active-stop } | standard } | trigger-stop-start }

no radius accounting rp { tod minute hour | trigger-event { active-handoff | active-start-param-change | active-stop } | trigger-stop-start }

default radius accounting rp { handoff-stop | trigger-policy }

no
Removes the specified configuration.

default
Sets the default configuration for the specified keyword.

handoff-stop { immediate | wait-active-stop }
Specifies the behavior of generating accounting STOP when handoff occurs.

• immediate: Indicates that accounting STOP should be generated immediately on handoff, i.e. not to wait active-stop from the old PCF.

• wait-active-stop: Indicates that accounting STOP is generated only when active-stop received from the old PCF when handoff occurs.

Default: wait-active-stop

tod minute hour
Specifies the time of day a RADIUS event is to be generated for accounting. Up to four different times of the day may be specified through individual commands.

minute must be an integer from 0 through 59.
hour must be an integer from 0 through 23.
trigger-event { active-handoff | active-start-param-change | active-stop }

active-start-param-change: Enabled
active-stop: Disabled

Configures the events for which a RADIUS event is generated for accounting as one of the following:

- **active-handoff**: Disables a single R-P event (and therefore a RADIUS accounting event) when an Active PCF-to-PFC Handoff occurs. Instead, two R-P events occur (one for the Connection Setup, and the second for the Active-Start).

- **active-start-param-change**: Disables an R-P event (and therefore a RADIUS accounting event) when an Active-Start is received from the PCF and there has been a parameter change.

- **active-stop**: Disables an R-P event (and therefore a RADIUS accounting event) when an Active-Stop is received from the PCF.

Default: **active-handoff**: Disabled

**Important**: This keyword has been obsoleted by the `trigger-policy` keyword. Note that if this command is used, if the context configuration is displayed, radius accounting rp configuration is represented in terms of the trigger-policy.

trigger-policy { airlink-usage [ counter-rollover ] | custom [ active-handoff | active-start-param-change | active-stop ] | standard }

Default: **airlink-usage**: Disabled
Custom:
active-handoff = Disabled
active-start-param-change = Disabled
active-stop = Disabled
standard: Enabled

Configures the overall accounting policy for R-P sessions as one of the following:

- **airlink-usage [ counter-rollover ]**: Specifies the use of Airlink-Usage RADIUS accounting policy for R-P, which generates a start on Active-Starts, and a stop on Active-Stops.

- **If the counter-rollover option is enabled,** the system generates a STOP/START pair before input/output data octet counts (or input/output data packet counts) become larger than \(2^{32} - 1\) in value. This setting is used to guarantee that a 32-bit octet count in any STOP message has not wrapped to larger than \(2^{32}\) thus ensuring the accuracy of the count. The system, may, at its discretion, send the STOP/START pair at any time, so long as it does so before the 32-bit counter has wrapped. Note that a STOP/START pair is never generated unless the subscriber RP session is in the Active state, since octet/packet counts are not accumulated when in the Dormant state.

- **custom**: Specifies the use of custom RADIUS accounting policy for R-P. The custom policy can consist of the following:

  - **active-handoff**: Enables a single R-P event (and therefore a RADIUS accounting event) when an Active PCF-to-PFC Handoff occurs. Normally two R-P events will occur (one for the Connection Setup, and the second for the Active-Start)

  - **active-start-param-change**: Enables an R-P event (and therefore a RADIUS accounting event) when an Active-Start is received from the PCF and there has been a parameter change.

**Important**: Note that a custom trigger policy with only **active-start-param-change** enabled is identical to the **standard** trigger-policy.
**radius accounting rp**

- **active-stop**: Enables an R-P event (and therefore a RADIUS accounting event) when an Active-Stop is received from the PCF.

  **Important**: If the `radius accounting rp trigger-policy custom` command is executed without any of the optional keywords, all custom options are disabled.

- **standard**: Specifies the use of Standard RADIUS accounting policy for R-P in accordance with IS-835B.

  **trigger-stop-start**
  Specifies that a stop/start RADIUS accounting pair should be sent to the RADIUS server when an applicable R-P event occurs.

**Usage**

Use this command to configure the events for which a RADIUS event is sent to the server when the accounting procedures vary between servers.

**Example**

The following command enables an R-P event (and therefore a RADIUS accounting event) when an Active-Stop is received from the PCF:

```
radius accounting rp trigger-event active-stop
```

The following command generates the STOP only when active-stop received from the old PCF when handoff occurs:

```
default radius accounting rp handoff-stop
```
radius accounting server

For accounting, this command configures the RADIUS accounting server(s) in the current context.

Product

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

configure > context context_name > aaa group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-aaa-group)#

Syntax

radius [ mediation-device ] accounting server ip_address [ encrypted ] key value [ acct-on { disable | enable } ] [ acct-off { disable | enable } ] [ admin-status { disable | enable } ] [ max max_messages ] [ max-rate max_value ] [ oldports ] [ port port_number ] [ priority priority ] [ type { mediation-device | standard } ] [ -noconfirm ]

no radius [ mediation-device ] accounting server ip_address [ oldports | port port_number ]

no

Removes the server or server port(s) specified from the list of configured servers.

mediation-device

Enables mediation-device specific AAA transactions use to communicate with this RADIUS server.

Important: If this option is not used, by default the system enables standard AAA transactions.

ip_address [ port port_number ]

Specifies the IP address of the accounting server. \textit{ip_address} must be specified using IPv4 dotted-decimal notation. A maximum of 1600 RADIUS servers per context/system and 128 servers per server group can be configured. This limit includes accounting and authentication servers. \textit{port port_number} specifies the port number to use for communications. \textit{port_number} must be an integer from 0 through 65535. Default is 1813.

Important: The same RADIUS server IP address and port can be configured in multiple RADIUS server groups within a context.

[ encrypted ] key value

Specifies the shared secret key used to authenticate the client to the servers. The \textit{encrypted} keyword indicates the key specified is encrypted.
In 12.1 and earlier releases, the key value must be an alphanumeric string of 1 through 127 characters without encryption, and 1 through 256 characters with encryption. In StarOS 12.2 and later releases, the key value must be an alphanumeric string of 1 through 127 characters without encryption, and 1 through 236 characters with encryption enabled. The encrypted keyword is intended only for use by the chassis while saving configuration scripts. The system displays the encrypted keyword in the configuration file as a flag that the variable following the key keyword is the encrypted version of the plaintext key. Only the encrypted key is saved as part of the configuration file.

```
acct-on { disable | enable }
```

This keyword enables/disables sending of the Accounting-On message when a new RADIUS server is added to the configuration. By default, this keyword will be disabled. When enabled, the Accounting-On message is sent when a new RADIUS server is added in the configuration. However, if for some reason the Accounting-On message cannot be sent at the time of server configuration (for example, if the interface is down), then the message is sent as soon as possible. Once the Accounting-On message is sent, if it is not responded to after the configured RADIUS accounting timeout, the message is retried the configured number of RADIUS accounting retries. Once all retries have been exhausted, the system no longer attempts to send the Accounting-On message for this server.

```
acct-off { disable | enable }
```

Disables and enables the sending of the Accounting-Off message when a RADIUS server is removed from the configuration. The Accounting-Off message is sent when a RADIUS server is removed from the configuration, or when there is an orderly shutdown. However, if for some reason the Accounting-On message cannot be sent at this time, it is never sent. The Accounting-Off message is sent only once, regardless of how many accounting retries are enabled. Default: enable

```
max max_messages
```

Specifies the maximum number of outstanding messages that may be allowed to the server. *max_messages* must be an integer from 0 through 4000. Default: 0

```
max-rate max_value
```

Specifies the rate at which the accounting messages should be sent to the RADIUS server by a single AAA manager task. *max_value* must be an integer from 0 through 1000. Default: 0 (disabled)

```
oldports
```

Sets the UDP communication port to the out of date standardized default for RADIUS communications to 1646.

```
priority priority
```

Specifies the relative priority of this accounting server. The priority is used in server selection for determining which server to send accounting data to. *priority* must be an integer from 1 through 1000, where 1 is the highest priority. When configuring two or more servers with the same priority you will be asked to confirm that you want to do this. If you use the -
**noconfirm** option, you are not asked for confirmation and multiple servers could be assigned the same priority.
Default: 1000

```markdown
**type { mediation-device | standard }**
```
*mediation-device*: Obsolete keyword.
Specifies the type of AAA transactions to use to communicate with this RADIUS server.
*standard*: Use standard AAA transactions.
Default: *standard*

```markdown
**admin-status { disable | enable }**
```
Configures the admin-status for the RADIUS accounting server.
*enable*: Enables the RADIUS accounting server.
*disable*: Disables the RADIUS accounting server.

**-noconfirm**
Specifies that the command must execute without any prompts and confirmation from the user.

**Usage**
Use this command to configure the RADIUS accounting servers with which the system must communicate for accounting.
You can configure up to 1600 RADIUS servers per context/system and 128 servers per server group. The servers can be configured as Accounting, Authentication, Charging servers, or any combination thereof.

**Example**
The following command sets the accounting server with mediation device transaction for AAA server 10.2.3.4:

```
radius mediation-device accounting server 10.2.3.4 key sharedKey port 1024 max 127
```
radius algorithm

This command configures the RADIUS authentication server selection algorithm for the current context.

Product  All

Privilege  Security Administrator, Administrator

Mode  Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

configure > context context_name > aaa group group_name

Entering the above command sequence results in the following prompt:

[context_name] host_name(config-aaa-group)#

Syntax

radius algorithm { first-server | round-robin }

default radius algorithm

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configures the default setting.</td>
</tr>
<tr>
<td>Default: first-server</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>first-server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authentication data is sent to the first available authentication server based upon the relative priority of each configured server.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>round-robin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authentication data is sent in a circular queue fashion on a per Session Manager task basis where data is sent to the next available authentication server and restarts at the beginning of the list of configured servers. The order of the list is based upon the configured relative priority of the servers.</td>
</tr>
</tbody>
</table>

Usage

Use this command to configure the context’s RADIUS authentication server selection algorithm to ensure proper load distribution amongst the available authentication servers.

Example

The following command configures to use the round-robin algorithm for RADIUS authentication server selection:

radius algorithm round-robin
radius allow

This command configures the system behavior for allowing subscriber sessions when RADIUS accounting and/or authentication is unavailable.

**Product**

All products used in CDMA deployments

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

`configure > context context_name > aaa group group_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-aaa-group)#
```

**Syntax**

```
[ no ] radius allow { authentication-down | accounting-down }
```

- **no**
  
  Specifies that the specified option is to be disabled.

- **authentication-down**
  
  Allows sessions while authentication is not available (down).
  
  Default: Disabled

- **accounting-down**
  
  Allows sessions while accounting is unavailable (down).
  
  Default: Enabled

**Usage**

Allow sessions during system troubles when the risk of IP address and/or subscriber spoofing is minimal. The denial of sessions may cause dissatisfaction with subscribers at the cost/expense of verification and/or accounting data.

**Important:** Please note that this command is applicable ONLY to CDMA products. To configure this functionality in UMTS/LTE products (GGSN/P-GW/SAEGW), use the command `mediation-device delay-GTP-response` in APN Configuration mode.

**Example**

The following command configures the RADIUS server to allow the sessions while accounting is unavailable.

```
radius allow accounting-down
```
radius attribute

This command configures the system’s RADIUS identification parameters.

**Product**

```

**Syntax**

```
radius attribute { accounting accounting_attribute | authentication authentication_attribute | nas-identifier nas_id | nas-ip-address address primary_address [ backup secondary_address ] [ nexthop-forwarding-address nexthop_address ] [ mpls-label input in_label_value | output out_label_value1 [ out_label_value2 ] [ vlan vlan_id ] ] }
```

```
no radius attribute { accounting accounting_attribute | authentication authentication_attribute | nas-identifier | nas-ip-address }
```

```
default radius attribute { accounting | authentication | nas-identifier }
```

---

**no**

Removes or disables the specified configuration.

---

**default**

Configures the default setting(s).

---

**accounting accounting_attribute**

Enables RADIUS accounting attributes for the following options, provided they are supported in the configured RADIUS dictionary:

- 3gpp-cg-address
- 3gpp-charging-characteristics
- 3gpp-charging-id
- 3gpp-ggsn-address
- 3gpp-ggsn-mcc-mnc
- 3gpp-gprs-qos-negotiated-profile
- 3gpp-imeisv
- 3gpp-imsi-mcc-mnc
• 3gpp-ms-timezone
• 3gpp-nsapi
• 3gpp-pdp-type
• 3gpp-rat-type
• 3gpp-select-mode
• 3gpp-session-stopindicator
• 3gpp-sgsn-address
• 3gpp-sgsn-mcc-mnc
• 3gpp-user-location-info
• acct-authentic
• acct-delay-time
• acct-input-octets
• acct-input-packets
• acct-output-octets
• acct-output-packets
• acct-session-id
• acct-session-time
• acct-statustype
• called-station-id
• calling-station-id
• class
• event-timestamp
• framed-ip-address
• framed-ipv6-prefix
• imsi
• nas-identifier
• nas-ip-address
• nas-port-type
• service-type
• username

By default, all of the attributes are enabled.

authentication authentication_attribute

Enables RADIUS authentication attributes for the following options, provided they are supported in the configured RADIUS dictionary:

• 3gpp-cg-address
• 3gpp-charging-characteristics
• 3gpp-ggsn-address
• 3gpp-ggsn-mcc-mnc
• 3gpp-gprs-qos-negotiated-profile
• 3gpp-imeisv
• 3gpp-imsi-mcc-mnc
• 3gpp-ms-timezone
• 3gpp-nasapi
• 3gpp-pdp-type
• 3gpp-rat-type
• 3gpp-select-mode
• 3gpp-sgsn-address
• 3gpp-sgsn-mcc-mnc
• 3gpp-user-location-info
• called-station-id
• calling-station-id
• chap-challenge
• framed-ipaddress
• framed-ipv6-prefix
• imsi
• nas-identifier
• nas-ip-address
• nas-port-type
• service-type
• username

By default, all of the attributes are enabled.

---

**nas-identifier** *nas_id*

Specifies the attribute name by which the system will be identified in Access-Request messages. *nas_id* must be a case-sensitive alphanumeric string of 1 through 32 characters.

---

**nas-ip-address** *address* *primary_address*

Specifies the AAA interface IP address(es) used to identify the system. Up to two addresses can be configured.

*primary_address*: The IP address of the primary interface to use in the current context. This must be specified using the IPv4 dotted-decimal notation.

---

**Important**: In 12.0 and earlier releases, the configuration of NAS IP address with IPv6 prefix is currently not supported.
### backup secondary_address

**backup**: The IP address of the secondary interface to use in the current context. This must be specified using IPv4 dotted-decimal notation.

### nexthop-forwarding-address nexthop_address

Configures next hop IP address for this NAS IP address. It optionally sets the RADIUS client to provide VLAN ID and nexthop forwarding address to system when running in single nexthop gateway mode.  
*nexthop_address* must be specified using IPv4 dotted-decimal notation.

**Important**: To define more than one NAS IP address per context, in Global Configuration Mode use the `aaa large-configuration` command. If enabled, for a PDSN a maximum of 400 and for a GGSN a maximum of 800 NAS IP addresses/NAS identifiers (1 primary and 1 secondary per server group) can be configured per context.

### mpls-label input in_label_value | output out_label_value1 [ out_label_value2 ]

Configures the traffic from the specified RADIUS client NAS IP address to use the specified MPLS labels.

- **in_label_value** is the MPLS label that will identify inbound traffic destined for the configured NAS IP address.
- **out_label_value1** and **out_label_value2** identify the MPLS labels to be added to packets sent from the specified NAS IP address.
- **out_label_value1** is the inner output label.
- **out_label_value2** is the outer output label.

MPLS label values must be an integer from 16 to 1048575.

### vlan vlan_id

This optional keyword sets the RADIUS client to provide VLAN ID with nexthop forwarding address to system when running in single nexthop gateway mode.  
*vlan_id* must be a pre-configured VLAN ID, and must be an integer from 1 through 4096. It is the VLAN ID to be provided to the system in RADIUS attributes.

This option is available only when nexthop-forwarding gateway is also configured with nexthop-forwarding-address *nexthop_address* keyword and `aaa-large configuration` is enabled at Global Configuration level.

**Usage**

This is necessary for NetWare Access Server usage such as the system must be identified to the NAS. The system supports the concept of the active nas-ip-address. The active nas-ip-address is defined as the current source ip address for RADIUS messages being used by the system. This is the content of the nas-ip-address attribute in each RADIUS message.

The system will always have exactly one active nas-ip-address. The active nas-ip-address will start as the primary nas-ip-address. However, the active nas-ip-address may switch from the primary to the backup, or the backup to the primary. The following events will occur when the active nas-ip-address is switched:

- All current in-process RADIUS accounting messages from the entire system are cancelled. The accounting message is re-sent, with retries preserved, using the new active nas-ip-address. Acct-Delay-Time, however, is updated to reflect the time that has occurred since the accounting event. The value of Event-Timestamp is preserved.
• All current in-process RADIUS authentication messages from the entire system are cancelled. The authentication message is re-sent, with retries preserved, using the new active nas-ip-address. The value of Event-Timestamp is preserved.

• All subsequent in-process RADIUS requests uses the new active nas-ip-address.

The system uses a revertive algorithm when transitioning active NAS IP addresses as described below:

• If the configured primary nas-ip-address transitions from UP to DOWN, and the backup nas-ip-address is UP, then the active nas-ip-address switches from the primary to the backup nas-ip-address.

• If the backup nas-ip-address is active, and the primary nas-ip-address transitions from DOWN to UP, then the active nas-ip-address switches from the backup to the primary nas-ip-address.

Example

The following command configures the RADIUS identification parameter, NAS IP address to 10.2.3.4.

```
radius attribute nas-ip-address 10.2.3.4
```
radius authenticate

This command configures RADIUS authentication related parameters.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

```
configure > context context_name > aaa group group_name

```

**Syntax**

```
radius authenticate { apn-to-be-included { gi | gn } | null-username }  
default radius authenticate { apn-to-be-included | null-username }  
no radius authenticate null-username
```

---

**Default**

Configures the default setting.

**no radius authenticate null-username**

Disables sending an Access-Request message to the AAA server for user names (NAI) that are blank.

**apn-to-be-included**

Specifies the APN name to be included for RADIUS authentication.

- **gi**: Specifies the usage of Gi APN name in RADIUS authentication request. Gi APN represents the APN received in the Create PDP Context request message from SGSN.
- **gn**: Specifies the usage of Gn APN name in RADIUS authentication request. Gn APN represents the APN selected by the GGSN.

**null-username**

Specifies attempting RADIUS authentication even if the provided user name is NULL (empty). Default: Enables authenticating, sending Access-Request messages to the AAA server, all user names, including NULL user names.

**Usage**

Use this command to disable, or re-enable, sending Access-Request messages to the AAA server for user names (NAI) that are blank (NULL).

**Example**

The following command disables sending of Access-Request messages for user names (NAI) that are blank:
no radius authenticate null-username

The following command re-enables sending of Access-Request messages for user names (NAI) that are blank:

radius authenticate null-username
radius authenticator-validation

This command enables/disables the MD5 authentication of RADIUS user. MD5 authentication is enabled by default.

[context_name]host_name(config-aaa-group)#
```

**Syntax**

```
radius charging { deadtime dead_time | detect-dead-server { consecutive-failures consecutive_failures_count | response-timeout response_timeout_duration } | max-outstanding max_messages | max-retries max_retries | max-transmissions max_transmissions | timeout idle_seconds }

default radius charging { deadtime | detect-dead-server | max-outstanding | max-retries | max-transmissions | timeout }

no radius charging { detect-dead-server | max-transmissions | timeout }
```

**no**
Removes the specified configuration.

**default**
Configures the default setting for the specified keyword.

**deadtime dead_time**
Specifies the number of minutes to wait before attempting to communicate with a server that has been marked as unreachable.

`dead_time` must be an integer from 0 through 65535.
Default: 10

**detect-dead-server { consecutive-failures consecutive_failures_count | response-timeout response_timeout_duration }**

**consecutive-failures consecutive_failures_count:** Specifies the number of consecutive failures, for each AAA Manager, before a server is marked as unreachable.
`consecutive_failures_count` must be an integer from 1 through 1000.
Default: 4

**response-timeout response_timeout_duration:** Specifies the number of seconds for each AAA Manager to wait for a response to any message before a server is detected as failed, or in a down state.
`response_timeout_duration` must be an integer from 1 through 65535.
max-outstanding max-messages

Specifies the maximum number of outstanding messages a single AAA Manager instance will queue.

max-messages must be an integer from 1 through 4000.

Default: 256

max-retries max_retries

Specifies the maximum number of times communication with a AAA server will be attempted before it is marked as unreachable, and the detect dead servers consecutive failures count is incremented.

max_retries must be an integer from 0 through 65535.

Default: 5

max-transmissions max_transmissions

Sets the maximum number of re-transmissions for RADIUS authentication requests. This limit is used in conjunction with the max-retries parameter for each server.

When failing to communicate with a RADIUS server, the subscriber is failed once all of the configured RADIUS servers have been exhausted or once the configured number of maximum transmissions is reached.

For example, if three servers are configured and if the configured max-retries is 3 and max-transmissions is 12, then the primary server is tried four times (once plus three retries), the secondary server is tried four times, and then a third server is tried four times. If there is a fourth server, it is not tried because the maximum number of transmissions (12) has been reached.

max_transmissions must be an integer from 1 through 65535.

Default: Disabled

timeout idle_seconds

Specifies the number of seconds to wait for a response from the RADIUS server before re-sending the messages.

idle_seconds must be an integer from 1 through 65535.

Default: 3

Usage

Use this command to manage the basic Charging Service RADIUS options according to the RADIUS server used for the context.

Example

The following command configures the AAA server to be marked as unreachable when the consecutive failure count exceeds 6:

    radius charging detect-dead-server consecutive-failures 6

The following command sets the timeout value to 300 seconds to wait for a response from RADIUS server before resending the messages:

    radius charging timeout 300
radius charging accounting algorithm

This command specifies the fail-over/load-balancing algorithm to be used for selecting RADIUS servers for charging services.

**Product**

**Mode**

Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

configure > context context_name > aaa group group_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-aaa-group)#
```

**Syntax**

```
radius charging accounting algorithm { first-n n | first-server | round-robin }
```

**first-n n**

Specifies that the AGW must send accounting data to \(n\) (more than one) AAA servers based on their priority. Response from any one of the \(n\) AAA servers would suffice to proceed with the call. The full set of accounting data is sent to each of the \(n\) AAA servers.

\(n\) is the number of AAA servers to which accounting data will be sent, and must be an integer from 2 through 128.

Default: 1 (Disabled)

**first-server**

Specifies that the context must send accounting data to the RADIUS server with the highest configured priority. In the event that this server becomes unreachable, accounting data is sent to the server with the next-highest configured priority. This is the default algorithm.

**round-robin**

Specifies that the context must load balance sending accounting data among all of the defined RADIUS servers. Accounting data is sent in a circular queue fashion on a per Session Manager task basis, where data is sent to the next available server and restarts at the beginning of the list of configured servers. The order of the list is based upon the configured relative priority of the servers.

**Usage**

Use this command to specify the accounting algorithm to use to select RADIUS servers for charging services configured in the current context.

**Example**

The following command configures to use the round-robin algorithm for RADIUS server selection:

```
radius charging accounting algorithm round-robin
```
radius charging accounting server

This command configures RADIUS charging accounting servers in the current context for ACS Prepaid Accounting.

Security Administrator, Administrator
Mode
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

configure > context context_name > aaa group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-aaa-group)#

Syntax

radius charging accounting server ip_address [ encrypted ] key value [ max max_messages ] [ oldports ] [ port port_number ] [ priority priority ] [ admin-status { enable | disable } ] [ -noconfirm ]

no radius charging accounting server ip_address [ oldports | port port_number ]

no

Removes the server or server port(s) specified from the list of configured servers.

ip_address

Specifies the IP address of the accounting server. ip_address must be specified using IPv4 dotted-decimal notation. A maximum of 128 RADIUS servers can be configured per context. This limit includes accounting and authentication servers.

[ encrypted ] key value

Specifies the shared secret key used to authenticate the client to the servers. The encrypted keyword indicates the key specified is encrypted.
In 12.1 and earlier releases, the key value must be an alphanumeric string of 1 through 127 characters without encryption, and 1 through 256 characters with encryption.
In StarOS 12.2 and later releases, the key value must be an alphanumeric string of 1 through 127 characters without encryption, and 1 through 236 characters with encryption enabled.
The encrypted keyword is intended only for use by the system while saving configuration scripts. The system displays the encrypted keyword in the configuration file as a flag that the variable following the key keyword is the encrypted version of the plain text key. Only the encrypted key is saved as part of the configuration file.

max max_messages

Specifies the maximum number of outstanding messages that may be allowed to the server. max_messages must be an integer from 0 through 4000.
Default: 0
oldports
Sets the UDP communication port to the out of date standardized default for RADIUS communications to 1646.

port port_number
Specifies the port number to use for communication.
port_number must be an integer from 0 through 65535.
Default: 1813

priority priority
Specifies the relative priority of this accounting server. The priority is used in server selection for determining which server to send accounting data to. priority must be an integer from 1 through 1000, where 1 is the highest priority.
Default: 1000

admin-status { enable | disable }
Enables or disables the RADIUS authentication/accounting/charging server functionality and saves the status setting in the configuration file to re-establish the set status at reboot.

-noconfirm
Specifies that the command must execute without any prompts and confirmation from the user.

Usage
This command is used to configure the RADIUS charging accounting server(s) with which the system is to communicate for ACS Prepaid Accounting requests.
Up to 128 AAA servers can be configured per context when the system is functioning as a PDSN and/or HA.
Up to 16 servers are supported per context when the system is functioning as a GGSN.

Example
The following commands configure RADIUS charging accounting server with the IP address set to 10.1.2.3, port to 1024, priority to 10:

    radius charging accounting server 10.1.2.3 key sharedKey212 port 1024 max 127
    radius charging accounting server 10.1.2.3 encrypted key scrambledKey234 oldports priority 10
radius charging algorithm

This command specifies the RADIUS authentication server selection algorithm for ACS for the current context.

```
[context_name]host_name(config-aaa-group)##
```

**Syntax**

```
radius charging algorithm { first-server | round-robin }
```

```bash
default radius charging algorithm
```

- **default**
  Configures the default setting.
  Default: `first-server`

- **first-server**
  Accounting data is sent to the first available server based upon the relative priority of each configured server.

- **round-robin**
  Accounting data is sent in a circular queue fashion on a per Session Manager task basis where data is sent to the next available server and restarts at the beginning of the list of configured servers. The order of the list is based upon the configured relative priority of the servers.

**Usage**

Use this command to configure the context’s RADIUS server selection algorithm for ACS to ensure proper load distribution amongst the available servers.

**Example**

The following command configures to use the round-robin algorithm for RADIUS server selection:

```
radius algorithm round-robin
```
radius charging server

This command configures the RADIUS charging server(s) in the current context for ACS Prepaid Authentication.

max max_messages
Specifies the maximum number of outstanding messages that may be allowed to the server. max_messages must be an integer from 0 through 4000.
Default: 256
oldports
Sets the UDP communication port to the old default for RADIUS communications to 1645.

port port_number
Specifies the port number to use for communications.
port_number must be an integer from 1 through 65535.
Default: 1812

priority priority
Specifies the relative priority of this accounting server. The priority is used in server selection for
determining which server to send accounting data to.
priority must be an integer from 1 through 1000, where 1 is the highest priority.
Default: 1000

admin-status { enable | disable }
Enables or disables the RADIUS authentication, accounting, or charging server functionality and saves the
status setting in the configuration file to re-establish the set status at reboot.

-noconfirm
Specifies that the command must execute without any prompts and confirmation from the user.

Usage
This command is used to configure the RADIUS charging server(s) with which the system is to communicate
for ACS Prepaid Authentication requests. 
Up to 128 AAA servers can be configured per context when the system is functioning as a PDSN and/or HA.
Up to 16 servers are supported per context when the system is functioning as a GGSN.

Example
The following commands configure RADIUS charging server with the IP address set to 10.2.3.4, port to
1024, priority to 10:

```bash
radius charging server 10.2.3.4 key sharedKey212 port 1024 max 127
radius charging server 10.2.3.4 encrypted key scrambledKey234 oldports
priority 10
```
radius ip vrf

This command associates the specific AAA group (NAS-IP) with a Virtual Routing and Forwarding (VRF) Context instance for BGP/MPLS, GRE, and IPSec Tunnel functionality which needs VRF support for RADIUS communication. By default the VRF is NULL, which means that AAA group is associated with global routing table.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration
configure > context context_name > aaa group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-aaa-group)#

Syntax

radius ip vrf vrf_name

no radius ip vrf

Syntax

radius ip vrf vrf_name

Disables the configured IP Virtual Routing and Forwarding (VRF) context instance and removes the association between the VRF context instance and the AAA group instance (NAS-IP).
By default this command is disabled, which means the NAS-IP being used is assumed a non-VRF IP and specific AAA group does not have any VRF association.

vrf_name

Specifies the name of a pre-configured VRF context instance.
vrf_name is the name of a pre-configured virtual routing and forwarding (VRF) context configured in Context configuration mode through ip vrf command.

⚠️ Caution: Any incorrect configuration, such as associating AAA group with wrong VRF instance or removing a VRF instance, will fail the RADIUS communication.

Usage

Use this command to associate/disassociate a pre-configured VRF context for a feature such as BGP/MPLS VPN or GRE, and IPSec tunneling which needs VRF support for RADIUS communication.
By default the VRF is NULL, which means that AAA group (NAS-IP) is associated with global routing table and NAS-IP being used is assumed a non-VRF IP.
This IP VRF feature can be applied to RADIUS communication, which associates the VRF with the AAA group. This command must be configured whenever a VRF IP is used as a NAS-IP in the AAA group or at the Context level for the “default” AAA group.
This is a required configuration as VRF IPs may be overlapping hence AAA needs to know which VRF the configured NAS-IP belongs to. By this support different VRF-based subscribers can communicate with
different RADIUS servers using the same, overlapping NAS-IP address, if required across different AAA groups.

Example

The following command associates VRF context instance \textit{ip\_vrf1} with specific AAA group (NAS-IP):

\begin{verbatim}
radius ip vrf ip_vrf1
\end{verbatim}
radius keepalive

This command configures the RADIUS keepalive authentication parameters.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

configure > context context_name > aaa group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-aaa-group)#

Syntax

radius keepalive { calling-station-id id | consecutive-response number | encrypted | interval seconds | password | retries number | timeout seconds | username user_name | valid-response access-accept [ access-reject ] }

default radius keepalive { calling-station-id | consecutive-response | interval | password | retries | timeout | username | valid-response }

default

Configures the default setting for the specified keyword.

calling-station-id id

Specifies the Calling-Station-Id to be used for the keepalive authentication.

id must be an alphanumeric string of size 1 to 15 characters.

Default: 000000000000000

consecutive-response number

Specifies the number of consecutive authentication responses after which the server is marked as reachable.

number must be an integer from 1 through 10.

Default: 1

encrypted password

Specifies encrypting the password.

In 12.1 and earlier releases, the password must be an alphanumeric string of 1 through 63 characters.

In StarOS 12.2 and later releases, password must be an alphanumeric string of 1 through 132 characters.

Default password: Test-Password

interval seconds

Specifies the time interval, in seconds, between two keepalive access requests.

Default: 30 seconds
password

Specifies the password to be used for authentication.

_password must be an alphanumeric string of 1 through 63 characters.

Default password: Test-Password

retries number

Specifies the number of times the keepalive access request to be sent before marking the server as unreachable.

_number must be an integer from 3 through 10.

Default: 3

timeout timeout_duration

Specifies the time interval between keepalive access request retries.

_timeout_duration must be an integer from 1 through 30.

Default: 3 seconds

username user_name

Specifies the user name to be used for authentication.

_user_name must be an alphanumeric string of 1 through 127 characters.

Default: Test-Username

valid-response access-accept [ access-reject ]

Specifies the valid response for the authentication request.

If access-reject is configured, then both access-accept and access-reject are considered as success for the keepalive authentication request.

If access-reject is not configured, then only access-accept is considered as success for the keepalive access request.

Default: keepalive valid-response access-accept

Usage

Use this command to configure the keepalive authentication parameters for the RADIUS server.

Example

The following command configures the user name for RADIUS keepalive access requests to Test-Username2:

    radius keepalive username Test-Username2

The following command configures the number of RADIUS keepalive retries to 4:

    radius keepalive retries 4
radius mediation-device

See the radius accounting server command.
radius probe-interval

This command configures the time interval between two RADIUS authentication probes.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration
configure > context context_name > aaa group group_name

Entering the above command sequence results in the following prompt:

```

**Syntax**

```
radius probe-interval  seconds

default radius probe-interval
```

**default radius probe-interval**

```
default

Configures the default setting.
```

```
seconds

Specifies the number of seconds to wait before sending another probe authentication request to a RADIUS server.
seconds must be an integer from 1 through 65535.
Default: 60
```

**Usage**

Use this command for Interchassis Session Recovery (ICSR) support to set the duration between two authentication probes to the RADIUS server.

**Example**

The following command sets the RADIUS authentication probe interval to 30 seconds.

```
radius probe-interval 30
```
radius probe-max-retries

This command configures the number of retries for RADIUS authentication probe response.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

```

**Syntax**

```
radius probe-max-retries retries
default radius probe-max-retries
```

**Usage**
Use this command with Interchassis Session Recovery (ICSR) to set the number of attempts to send RADIUS authentication probe without a response before the authentication is declared as failed.

**Example**
The following command configures the maximum number of retries to 6 seconds.

```
radius probe-max-retries 6
```
radius probe-timeout

This command configures the timeout duration for Interchassis Session Recovery (ICSR) to wait for a response for RADIUS authentication probes.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > AAA Server Group Configuration

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-aaa-group)#
```

**Syntax**

```
radius server ip_address [ encrypted ] key value [ admin-status { disable | enable } ] [ max max_messages ] [ max-rate max_value ] [ oldports ] [ port port_number ] [ priority priority ] [ probe | no-probe ] [ probe-username user_name ] [ probe-password [ encrypted ] password password ] [ type { mediation-device | standard } ] [ -noconfirm ]
```

```
no radius server ip_address [ oldports | port port_number ]
```

**no**

Removes the server or server port(s) specified from the list of configured servers.

```
ip_address port port_number
```

Specifies the IP address and port number of the server.

- **ip_address**: Must be specified using IPv4 dotted-decimal notation. A maximum of 1600 RADIUS servers per context/system and 128 servers per Server group can be configured. This limit includes accounting and authentication servers.
- **port port_number**: Specifies the port number to use for communications. `port_number` must be an integer from 1 through 65535.
  Default: 1812.

**Important**: The same RADIUS server IP address and port can be configured in multiple RADIUS server groups within a context.

```
[ encrypted ] key value
```

Specifies the shared secret key used to authenticate the client to the servers. The `encrypted` keyword indicates the key specified is encrypted.

In 12.1 and earlier releases, the `key value` must be an alphanumeric string of 1 through 127 characters without encryption, and 1 through 256 characters with encryption.

In StarOS 12.2 and later releases, the `key value` must be an alphanumeric string of 1 through 127 characters without encryption, and 1 through 236 characters with encryption enabled.
The **encrypted** keyword is intended only for use by the chassis while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **key** keyword is the encrypted version of the plain text key. Only the encrypted key is saved as part of the configuration file.

```bash
admin-status { disable | enable }
```
Enables or disables the RADIUS authentication, accounting, or charging server functionality and saves the status setting in the configuration file to re-establish the set status at reboot.

```bash
max max_messages
```
Specifies the maximum number of outstanding messages that may be allowed to the server.

*max_messages* must be an integer from 0 through 4000.

Default: 256

```bash
max-rate max_value
```
Specifies the rate at which the authentication messages should be sent to the RADIUS server by a single AAA manager task.

*max_value* must be an integer from 0 through 1000.

Default: 0 (disabled)

```bash
oldports
```
Sets the UDP communication port to the old default for RADIUS communications to 1645.

```bash
priority priority
```
Specifies the relative priority of this accounting server. The priority is used in server selection for determining which server to send accounting data to.

*priority* must be an integer from 1 through 1000, where 1 is the highest priority. When configuring two or more servers with the same priority you will be asked to confirm that you want to do this. If you use the --noconfirm option, you are not asked for confirmation and multiple servers could be assigned the same priority.

Default: 1000

```bash
probe
```
Enable probe messages to be sent to the specified RADIUS server.

```bash
no-probe
```
Disable probe messages from being sent to the specified RADIUS server. This is the default behavior.

```bash
probe-username user_name
```
The user name sent to the RADIUS server to authenticate probe messages. *user_name* must be an alphanumeric string of 1 through 127 characters.

```bash
probe-password [ encrypted ] password password
```
The password sent to the RADIUS server to authenticate probe messages. **encrypted:** This keyword is intended only for use by the chassis while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the
password keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file.

**password** *password*: Specifies the probe-user password for authentication. *password* must be an alphanumeric string of 1 through 63 characters.

**type** { mediation-device | standard }

Specifies the type of transactions the RADIUS server accepts.

- **mediation-device**: Specifies mediation-device specific AAA transactions. This device is available if you purchased a transaction control services license. Contact your local Cisco representative for licensing information.
- **standard**: Specifies standard AAA transactions. (Default)

**-noconfirm**

Specifies that the command must execute without any prompts and confirmation from the user.

**Usage**

This command is used to configure the RADIUS authentication server(s) with which the system is to communicate for authentication.

You can configure up to 1600 RADIUS servers per context/system and 128 servers per Server group. The servers can be configured as accounting, authentication, charging servers, or any combination thereof.

**Example**

The following commands configure RADIUS server with the IP address set to 10.2.3.4, port to 1024, priority to 10:

```
radius server 10.2.3.4 key sharedKey212 port 1024 max 127
radius server 10.2.3.4 encrypted key scrambledKey234 oldports priority 10
```
radius trigger

This command enables specific RADIUS triggers.

radius trigger

ul-change
Specifies to enable RADIUS trigger for User Location Information change.

Usage
Use this command to enable RADIUS triggers.

Example
The following command enables RADIUS trigger for RAT change:

    radius trigger rat-change
Chapter 3
AAL2 Node Configuration Mode Commands

The AAL2 Node Configuration Mode is used to configure the ATM Adaptation Layer 2 nodes to manage the Access Link Control Application Part (ALCAP) on HNB-GW for IuCS-over-ATM support towards CS core network.

Exec > Global Configuration > Context Configuration > ALCAP Service Configuration > AAL2 Node Configuration
configure > context context_name > alcap-service service_name > aal2-node node_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-aal2-node-node_name)#

**Important**: The AAL2 Node configured here will be used to bind with ATM port in PVC configuration sub-mode of ATM configuration mode for IuCS-over-ATM functionality.

**Important**: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
aal2-path-id

This command sets the AAL2 path identifier with AAL2 node and also used to block a particular AAL2 path.

**Product**

HNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > ALCAP Service Configuration > AAL2 Node Configuration

`configure > context context_name > alcap-service service_name > aal2-node node_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-aal2-node-node_name)#
```

**Syntax**

```
[no] aal2-path-id aal2_path_id [block]
```

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>no</code></td>
<td>Removes the configured AAL2 path identifier from this AAL2 node configuration.</td>
</tr>
<tr>
<td><code>aal2_path_id</code></td>
<td>Specifies the AAL2 path identifier configured with adjacent AAL2 node(s). The AAL2 path id must be unique within an AAL2 node configuration. This value is used to identify a particular path towards an adjacent AAL2 node and is sent in ALCAP protocol messages to peer where path identification is required. The <code>aal2_path_id</code> must be an integer between 1 through 4294967295.</td>
</tr>
<tr>
<td><code>block</code></td>
<td>This keyword block the AAL2 path configured with specific path identifier. When this keyword is executed ALCAP-BLO-REQUEST shall be sent to the adjacent AAL2 node. To unblock an AAL2 path, the no keyword will be used for a locally blocked path by sending ALCAP-UNBLOCK-REQUEST to the adjacent AAL2 node.</td>
</tr>
</tbody>
</table>

**Important:** This AAL2 path id `aal2_path_id` will be used to bind with ATM port in PVC configuration mode of ATM configuration mode.

**Usage**

Use this command to configure an AAL2 path between a pair of adjacent nodes, which is identified by a unique number called AAL2 path identifier. An AAL2 path provides 248 AAL2 channels wherein each AAL2 channel is used for one circuit switched call. The AAL2 channel range defined is 8 to 255. This command can be used for blocking or unblocking an AAL2 path towards an adjacent AAL2 node.

**Important:** The AAL2 path id configured here will be used to bind with ATM port in PVC configuration sub-mode of ATM configuration mode for IuCS-over-ATM functionality.
Example

Following command sets the AAL2 path identifier 2 in an AAL2 node configuration.

```plaintext
al2-path-id 2
```

Following command unblocks the AAL2 path identifier 6 which was earlier blocked in an AAL2 node configuration.

```plaintext
no al2-path-id 6 block
```
end

Exits the current mode and returns to the Exec Mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Change the mode back to the Exec mode.
exit

Exits the current mode and returns to the previous mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

exit

Usage
Return to the previous mode.
point-code

This command configure the point code of adjacent AAL2 node in SS7 format address. This point code shall be filled in the destination point-code (dpc) field of MTP3 routing label. This is required if signaling transport network is based on MTP3-broadband (MTP3B).

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > ALCAP Service Configuration > AAL2 Node Configuration
configure > context context_name > alcap-service service_name > aal2-node node_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-aal2-node-node_name)#

Syntax

[no] point-code point_code

- no
  Removes the configured point code from this AAL2 node configuration.

  point_code
  Defines the point code to assign to adjacent AAL2 node in SS7 format.
  point_code: value entered must adhere to the point code variant selected when the AAL2 node was defined:
  - ITU Range 0.0.1 to 7.255.7
  - ANSI Range 0.0.1 to 255.255.255
  - TTC Range 0.0.1 to 15.31.255
  - a string of 1 to 11 combined digits ad period.

Usage

Use this command to configure configure the point code of adjacent AAL2 node in SS7 format address. This point code shall be filled in the destination point-code (dpc) field of MTP3 routing label. This is required if signaling transport network is based on MTP3-broadband (MTP3B).
A maximum of 16 point codes for adjacent AAL2 nodes can be configured in one ALCAP service.

Example

The following command configures the point code 4.121.5 for adjacent AAL2 node.

    point-code 4.121.5

The following command removes the point code 4.121.15 from AAL2 node configuration.

    no point-code 4.121.15
Chapter 4
Accounting Policy Configuration Mode Commands

The Accounting Policy Configuration Mode is used to define the accounting method, mode, and event trigger responses for the accounting policy supporting the Rf (off-line charging) interface.

**Mode**

Exec > Global Configuration > Context Configuration > Accounting Policy Configuration

```
configure > context context_name > policy accounting policy_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-accounting-policy)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
accounting-event-trigger

Configures the response to specific event triggers for this policy. Multiple event instances can be configured.

Product

HSGW
P-GW
S-GW
SAEGW

Privilege

Administrator

Mode

Exec > Global Configuration > Context Configuration > Accounting Policy Configuration
configure > context context_name > policy accounting policy_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-accounting-policy)#

Syntax

accounting-event-trigger { cgi-sai-change | ecgi-change | flow-information-change | interim-timeout | location-change | rai-change | tai-change } action { interim | stop-start }

[ default | no ] accounting-event-trigger { cgi-sai-change | ecgi-change | flow-information-change | interim-timeout | location-change | rai-change | tai-change }

default
Returns the command to its default setting of interim for the action keyword (for all events).

no
Removes the specified event trigger configuration from this policy.

cgi-sai-change
Specifies that the action is initiated upon indication of a Cell Global Identification-Service Area Identification (CGI-SAI) change.

cgi-change
Specifies that the action is initiated upon indication of an E-UTRAN Cell Global Identifier (ECGI) change.

flow-information-change
Specifies that the action is initiated upon indication of a change in the flow information.

interim-timeout
Specifies that the action is initiated upon expiration of the interim interval.
accounting-event-trigger

---

**location-change**
Specifies that the action is initiated upon indication of a location change.

---

**rai-change**
Specifies that the action is initiated upon indication of an Routing Area Identifier (RAI) change.

---

**tai-change**
Specifies that the action is initiated upon indication of a Tracking Area Identity (TAI) change.

---

**action { interim | stop-start }**
Default: interim
Specifies the action initiated upon the occurrence of an event.
**interim**: Specifies that an interim ACR (Accounting Request) is sent.
**stop-start**: Specifies that a Stop-Start ACR is sent.

---

**Usage**
Use the `is` command to configure that action taken upon the occurrence on an accounting event trigger.

---

**Example**
The following command configures the policy to send a Stop-Start ACR upon indication of an interim timeout:

```
accounting-event-trigger interim-timeout action stop-start
```
accounting-keys

Aggregates the accounting information, using the configurable keys (QCI) along with default keys.

Product
HSGW
P-GW
S-GW
SAEGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > Accounting Policy Configuration

configure > context context_name > policy accounting policy_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-accounting-policy)#

Syntax

accounting-keys qci
default accounting-keys

default
 Aggregate the accounting information, using QoS Class Identifier (QCI) as the additional key.

qci
Aggregate the accounting information, using QCI as the additional key.

Usage

Use this command to aggregate the accounting information, using the configurable keys (QCI) along with default keys.
In service data flow (SDF) level accounting, buckets are created and maintained using the Reporting-Level AVP value present in Gx message. The following are the accounting keys currently supported:
• Rating-group
• Rating-group and Service-Identifier
• Rating-group and QCI
• Rating-group, Service-Identifier, and QCI

Example

The following command aggregates the accounting information, using QCI as the additional key:

accounting-keys qci
accounting-level

Configures the type of accounting performed by this profile.

**Product**
- HSGW
- P-GW
- S-GW
- SAEGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Accounting Policy Configuration

```
configure > context context_name > policy accounting policy_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-accounting-policy)>
```

**Syntax**

```
accounting-level { flow | pdn | pdn-qci | qci | sdf | subscriber }
```

```default accounting-level```

**default**

Returns the command to the default setting of subscriber-based accounting.

**flow**

Specifies that flow-based accounting is to be used for this accounting profile. Accounting Request (ACR) Start messages include an AVP with the following Evolved Packet System (EPS) information:

- PDN identifier
- QCI for which accounting is done
- Charging rule name for which accounting is being done
- AF charging identifier (included if PCRF has provided a charging identifier to correlate AF generated information)
- Flow description for the flows
- User Equipment information if available (ESN/MEID)
- Address of HSGW/S-GW
- Address of the P-GW (if available), one or more instances

**pdn**

Specifies that PDN-based accounting is to be used for this accounting profile. ACR Start messages include an AVP with the following EPS information:

- Addresses allocated to the UE in this PDN
Accounting Policy Configuration Mode Commands

- PDN identifier
- User Equipment information if available (ESN/MEID)
- Address of HSGW/S-GW
- Address of the P-GW (if available), one or more instances

**pdn-qci**

Specifies that PDN-QCI accounting is to be used for this accounting profile. ACR Start messages include an AVP with the following EPS information:
- Addresses allocated to the UE in this PDN
- Address of HSGW/S-GW
- Address of the P-GW (if available), one or more instances

**qci**

Specifies that QCI-based accounting is to be used for this accounting profile. ACR Start messages include an AVP with the following EPS information:
- QCI for which accounting is done
- User Equipment information if available (ESN/MEID)
- Address of HSGW/S-GW
- Address of the P-GW (if available), one or more instances

**sdf**

Specifies that service data flow accounting is to be used for this accounting profile. ACR Start messages include an AVP with the following EPS information:

**subscriber**

Specifies that subscriber-based accounting is to be used for this accounting profile. ACR Start messages include an AVP with the following EPS information:
- User Equipment information if available (ESN/MEID)
- Address of HSGW/S-GW
- Address of the P-GW (if available), one or more instances

**Usage**

Use this command to specify the type of accounting performed by this profile.

**Example**

The following command sets the accounting type for this profile to flow-based:

```
accounting-level flow
```
accounting-mode

Configures the accounting mode for this profile.

Product
- HSGW
- P-GW
- S-GW
- SAEGW

Privilege
Administrator

Mode
- Exec > Global Configuration > Context Configuration > Accounting Policy Configuration
  - configure > context context_name > policy accounting policy_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-accounting-policy)#

Syntax

- accounting-mode normal
- default accounting-mode

Usage

Use this command to set the accounting mode for this profile.

- default
  Returns the accounting mode for this profile to its default setting of “normal”.

- normal
  Specifies that “normal” (start/interim/stop) accounting will be performed for this profile.
**apn-name-to-be-included**

This command configures whether the virtual or real Access Point Name (APN) is sent in Rf accounting message.

**Product**
- GGSN
- P-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Accounting Policy Configuration
```
configure > context context_name > policy accounting policy_name
```

Entering the above command sequence results in the following prompt:
```
[context_name]host_name(config-accounting-policy)#
```

**Syntax**
```
apn-name-to-be-included { gn | virtual }
default apn-name-to-be-included
```

- **default**
  Configures this command with the default setting.
  Default: **gn**

  - **gn**
    Sends the Gn APN name in the Rf accounting messages.

  - **virtual**
    Sends the virtual APN name, if configured in the APN Configuration Mode, in the Rf accounting messages.

**Usage**
Use this command to configure the APN name to be included in Rf accounting messages. Virtual APN name can be set to be sent in Rf accounting messages if it is configured in the APN Configuration Mode.

**Example**
The following command sets the virtual APN name to be sent in Rf accounting message:
```
apn-name-to-be-included virtual
```
attribute

This command configures the attributes to be reported in Rf accounting.

Product
P-GW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > Accounting Policy Configuration
configure > context context_name > policy accounting policy_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-accounting-policy)#

Syntax

[ default | no ] attribute csg

[ default | no ]
Specifies to disable reporting of attributes in Rf accounting.

csg
Specifies to enable reporting of Closed Subscriber Group (CSG) related IEs received during the initial attach (Create Session Request) for Rf accounting purpose.

Usage
Use this command to enable or disable the reporting of attributes received during the initial attach (Create Session Request) for Rf billing purpose.
**CC**

Configures a charging characteristics (CC) profile, within the accounting profile configuration, for CDR generation.

**Product**
- GGSN
- HSGW
- P-GW
- S-GW
- SAEGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Accounting Policy Configuration

```
configure > context context_name > policy accounting policy_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-accounting-policy)#
```

**Syntax**

```
cc profile index { buckets num | interval seconds | sdf-interval seconds | sdf-volume { downlink octets { uplink octets } | total octets | uplink octets { downlink octets } } | serving-nodes num | tariff time1 min hrs | time2 min hrs...time4 min hrs } | volume { downlink octets { uplink octets } | total octets | uplink octets { downlink octets } } }

default cc profile index

no cc profile index { buckets | interval | sdf-interval | sdf-volume | serving-nodes | tariff | volume }
```

**default**

Returns all profile features, for the specified profile index, to their default settings.

**no**

Returns the specified feature to its default setting.

**profile index**

Specifies a billing type to be applied to this profile. `index` must be one of the following:

1: Hot billing
2: Flat billing
4: Prepaid billing
8: Normal billing
## Accounting Policy Configuration Mode Commands

### buckets num

Default: 4

Specifies the number of container changes in the S-GW CDR due to QoS changes or tariff times. If an accounting policy is not configured, this value is 4. GTPP accounting will use the default value if the configured value is beyond 4.

In 12.1 and earlier releases, `num` must be an integer value from 1 through 4.
In release 12.2, `num` must be an integer value from 1 through 10.
In 12.3 and later releases, `num` must be an integer value from 1 through 20.

### interval seconds

Default: disabled

Specifies a time interval for closing the charging record if the minimum volume thresholds are satisfied. `seconds` must be an integer value from 60 through 40000000.

### sdf-interval seconds

Default: disabled

Specifies a time interval for closing the charging record for a specific flow if the minimum volume thresholds are satisfied. `seconds` must be an integer value from 60 through 40000000.

### sdf-volume { downlink octets { uplink octets } | total octets | uplink octets { downlink octets } }

Specifies octet volume thresholds for the generation of interim CDRs for a specific flow.

- **downlink octets**: Sets the threshold limit for the number of downlink octets that must be reached before the charging record for a specific flow is closed. `octets` must be an integer value from 100000 through 4000000000.
- **total octets**: Sets the threshold limit for the total number of octets that must be reached before the charging record for a specific flow is closed. `octets` must be an integer value from 100000 through 4000000000.
- **uplink octets**: Sets the threshold limit for the number of uplink octets that must be reached before the charging record for a specific flow is closed. `octets` must be an integer value from 100000 through 4000000000.

### serving-nodes num

Default: 4

Specifies the number of serving node changes (inter-serving node switchovers) after which the interim CDR is generated. In P-GW and S-GW, a partial record needs to be generated whenever there is a serving node address list overflow. Serving node is added to the CDR list during handover scenarios. `num` must be an integer value from 1 through 4. If an accounting policy is not configured, this value is 4.

### tariff time1 min hrs [ time2 min hrs...time4 min hrs ]

Specifies time-of-day values used to determine when a container is closed in the charging records.

- **time1 min hrs**: Specifies the first time-of-day value used to close the current container in the charging record. `min` must be an integer value from 0 through 59. `hrs` must be an integer value from 0 through 23.
time2 min hrs...time4 minutes hours: Specifies the second, third and fourth time-of-day values used to close containers in the charging record. min must be an integer value from 0 through 59. hrs must be an integer value from 0 through 23.

volume { downlink octets { uplink octets } | total octets | uplink octets { downlink octets } }

Specifies octet volume thresholds for the generation of interim CDRs.

downlink octets: Sets the threshold limit for the number of downlink octets that must be reached before the charging record is closed.
In 12.1 and earlier releases, the downlink octets must be an integer value from 100000 to 1345294336.
In 12.2 and later releases, the downlink octets must be an integer value from 100000 to 400000000.

total octets: Sets the threshold limit for the total number of octets that must be reached before the charging record is closed.
In 12.1 and earlier releases, the total octets must be an integer value from 100000 to 400000000.
In 12.2 and later releases, the total octets must be an integer value from 100000 to 4000000000.

uplink octets: Sets the threshold limit for the number of uplink octets that must be reached before the charging record is closed.
In 12.1 and earlier releases, the uplink octets must be an integer value from 100000 to 400000000.
In 12.2 and later releases, the uplink octets must be an integer value from 100000 to 4000000000.

Usage

Use this command to set charging characteristics that directly affect the CDR generation on the HSGW, P-GW, or S-GW.

Example

The following command creates a hot billing profile with a total octet volume threshold set to 500000:

    cc profile 1 volume total 500000
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```exit```

**Usage**

Use this command to return to the parent configuration mode.
**max-containers**

Control the number of containers in an ACR message.

**Product**
- GGSN
- HSGW
- P-GW
- S-GW
- SAEGW

**Privilege**
Administrator

**Mode**

Exec > Global Configuration > Context Configuration > Accounting Policy Configuration

`configure > context context_name > policy accounting policy_name`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-accounting-policy)#`

**Syntax**

```
max-containers { containers | fill-buffer }

default max-containers
```

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
</tr>
<tr>
<td>Cache containers until buffer is filled.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>containers</td>
</tr>
<tr>
<td>System can send any value equal or less than the maximum number of containers selected. The number of containers that can be sent can be dynamically selected by the system, but it should not cross the limit of containers in any message.</td>
</tr>
<tr>
<td>containers must be in integer from 1 to 30.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>fill-buffer</td>
</tr>
<tr>
<td>Cache containers until buffer is filled.</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to control the number of containers before an interim ACR message is triggered.

**Example**

The following command sets a maximum of 20 containers in an ACR message:

```
max-containers 20
```
**operator-string**

Configures a text string to be included with accounting messages sent by this policy.

**Product**
- HSGW
- P-GW
- S-GW
- SAEGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Accounting Policy Configuration

```
configure > context context_name > policy accounting policy_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-accounting-policy)#
```

**Syntax**

```
operator-string string

no operator-string
```

- **no**
  Removes the operator string from this policy.

- **string**
  Specifies a text string that is included with accounting messages originating from this policy. The string must be from 1 to 63 alphanumeric characters.

**Usage**

Use this command to create a text string to be included with accounting messages originating from this policy.

**Example**

The following command creates the text string `pgw_local` to be included with accounting messages originating from this policy:

```
operator-string pgw_local
```
service-context-id

Configures the value to be sent in the Service-Context-Id AVP, which defines the context in which Rf is used.

**Product**

GGSN  
HSGW  
P-GW  
S-GW  
SAEGW

**Privilege**

Administrator

**Mode**

Exec > Global Configuration > Context Configuration > Accounting Policy Configuration

configure > context context_name > policy accounting policy_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-accounting-policy)#
```

**Syntax**

```
service-context-id service_context_id

default service-context-id
```

**default service-context-id**

```
default

Configures this command with the default setting. Currently, the default value is encoded based on the dictionary wherever applicable; when not applicable, it is not encoded.
```

```
service_context_id

Specifies the service context as an alphanumeric string of 1 through 63 characters that can contain punctuation characters.
```

**Usage**

If Service-Context-Id is applicable and configured using this command, it will be sent in the AVP Service-Context-Id in the Rf ACR message.

**Example**

The following command specifies the value `version@customer.com` to be sent in the Service-Context-Id AVP in the Rf ACR message:

```
service-context-id version@customer.com
```
**session**

This command controls the behavior of whether to send or suppress the ACR-Interim records when the UE is idle.

**Product**

P-GW

**Privilege**

Administrator

**Mode**

Exec > Global Configuration > Context Configuration > Accounting Policy Configuration

`configure > context context_name > policy accounting policy_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-accounting-policy)#
```

**Syntax**

```
[ default | no ] session idle-mode suppress-interim
```

- **default | no**
  
  The default behavior is to send accounting interim records even when the UE is in idle state and when there is no data to report.

- **suppress-interim**

  Suppresses the ACR-I records when there is no data to report or the UE is in idle mode.

**Usage**

This CLI configuration is used to control sending of ACR-I records when the UE is in idle mode and when there is no data to report.

In a scenario where there is no data to report, upon configuring the CLI command “`session idle-mode suppress-interim`”, a call is established. AII timer (or any other event for which an Interim needs to be generated) happens, and ACR-I will be suppressed.

When there is data to report, on configuring the CLI command “`session idle-mode suppress-interim`”, a call is established, AII timer (or any other event for which an Interim needs to be generated) happens, and ACR-I will be sent out.

When there is data to report for the previous events, the following behavior is observed:

1. the CLI command “`session idle-mode suppress-interim`” is configured and a call is established.
2. QoS-Change happens (or any other event for which the container needs to be cached) happens, containers are cached.
3. AII timer (or any other event for which an Interim needs to be generated) happens, but there is no data to report with this event.
4. ACR-I will be sent with the previously cached containers (QoS-Change in this case).

**Example**

The following command suppresses sending of ACR-Interim message when the UE is idle or when there is no data to report:

```
session idle-mode suppress-interim
```
**trigger-type**

This command enables/disables the event triggers for Rf-Gy interaction.

**Product**
GGSN
HSGW
P-GW
S-GW
SAEGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Accounting Policy Configuration

configure > context context_name > policy accounting policy_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-accounting-policy)#

**Syntax**

```
trigger-type { gy-sdf-time-limit { cache | immediate } | gy-sdf-unit-limit { cache | immediate } | gy-sdf-volume-limit { cache | immediate } } +
```

{ default | no } trigger-type

---

**default | no**

The default behavior is to disable all the configured event triggers. The interims will be dropped if the event triggers are received from Gy.

---

**gy-sdf-time-limit { cache | immediate }**

Enables the SDF time-limit trigger for Rf-Gy interaction.

- **cache**: If this keyword option is configured then upon receipt of time-limit event trigger from Gy, the container record will be cached for reporting in a future transaction.
- **immediate**: If this keyword option is configured then upon receipt of time-limit event trigger from Gy, Rf will send out an interim record immediately.

---

**gy-sdf-unit-limit { cache | immediate }**

Enables the SDF unit-limit trigger for Rf-Gy interaction in Assume Positive scenario. Upon configuration of the CLI command `trigger-type gy-sdf-unit-limit { cache | immediate }`, when the session gets terminated during assume-positive case, ACR-Stop is sent with the container-level change-condition as SERVICE-SPECIFIC-UNIT-LIMIT.

---

**gy-sdf-volume-limit { cache | immediate }**

Enables the SDF volume-limit trigger for Rf-Gy interaction.
**cache**: If this keyword option is configured then upon receipt of volume-limit event trigger from Gy, the container record will be cached for reporting in a future transaction.

**immediate**: If this keyword option is configured then upon receipt of volume-limit event trigger from Gy, Rf will send out an interim record immediately.

---

**Usage**

In Release 15.0 when time/volume quota on the Gy interface gets exhausted, Gy will trigger SERVICE_DATA_VOLUME/TIME_LIMIT. Release 16.0 and beyond, this behavior is CLI controlled. This CLI configuration will either enable PCEF to send an ACR-Interim immediately or cache the container records for reporting in a future transaction. If there is no such configuration for that event-trigger, then the ACR-Interims will be dropped.

When the subscriber disconnects while in Assume Positive mode, then the CLI configuration enables the PCEF to send an ACR-Stop with PS-level change condition “Normal Release” and container level “Service Specific Unit Limit”. The presence of the “Service Specific Unit Limit” change condition at the container level indicates to the OFCS that data has gone unreported on Gy. The change-condition at container level is only present if the keyword option gy-sdf-unit-limit is configured.

The gateway provides a configuration option to enable/disable the functionality at the ACR level to control which of the triggers are enabled – Service Specific Unit Limit, Service Data Volume Limit and Service Data Time Limit. The gateway provides configuration options to control the various Rf messages triggered for sync on this feature.

**Gy Quota Update - Volume Limit** - CLI options are:

- Disabled
- Enabled, container with SDF Volume limit queued and sent at next ACR trigger.
- Enabled, container with SDF Volume limit created and ACR sent immediately with PS info level of Volume Limit

**Gy Quota Update – Validity Timer Expires** - CLI options are:

- Disabled
- Enabled, container with SDF Time limit queued and sent at next ACR trigger.
- Enabled, container with SDF Time limit created and ACR sent immediately with PS info level of Time Limit

---

**Example**

The following command specifies to send ACR-Interim message immediately when the time quota on the Gy interface expires:

```
trigger-type gy-sdf-time-limit immediate
```
Chapter 5
ACL Configuration Mode Commands

The Access Control List Configuration Mode is used to create and manage IP-based, user access privileges.

Mode

Exec > Global Configuration > Context Configuration > ACL Configuration

configure > context context_name > ip access-list acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-acl)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
deny/permit (by source IP address masking)

Filters subscriber sessions based on the IP address mask sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ACL Configuration

```
configure > context context_name > ip access-list acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-acl)#
```

**Syntax**

```
{ deny | permit } [ log ] source_address source_wildcard
after { deny | permit } [ log ] source_address source_wildcard
before { deny | permit } [ log ] source_address source_wildcard
no { deny | permit } [ log ] source_address source_wildcard
```

- **after**
  Indicates that all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

- **before**
  Indicates that all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

- **no**
  Removes the rule which exactly matches the options specified.

- **deny | permit**
  Specifies the rule is either block (deny) or an allow (permit) filter.
ACL Configuration Mode Commands

deny/permit (by source IP address masking)

- **deny**: Indicates the rule, when matched, drops the corresponding packets.
- **permit**: Indicates the rule, when matched, allows the corresponding packets.

**log**
Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

**Important**: The logging option is not supported for ACLs applied on SPIO or local contexts.

**source_address**
The IP address(es) from which the packet originated. IP addresses must be entered in IPv4 dotted-decimal format.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the **source_wildcard** parameter.

**source_wildcard**
This option is used in conjunction with the **source_address** option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the **source_address** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **source_address** parameter must be ignored.

**Important**: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**Usage**
Define a rule when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rules as it does not require a rule for each source and destination pair.

**Important**: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the **Engineering Rules** appendix in the **System Administration Guide**.

**Example**
The following command defines two rules with the second logging filtered packets:

```
permit 1.2.3.0 0.0.0.31
deny log 1.2.4.0 0.0.0.15
```

The following sets the insertion point before the first rule defined above:
deny/permit (by source IP address masking)

before permit 1.2.3.0 0.0.0.31

The following command sets the insertion point after the second rule defined above:

after deny log 1.2.4.0 0.0.0.15

The following deletes the first rule defined above:

no permit 1.2.3.0 0.0.0.31
deny/permit (any)

Filters subscriber sessions based on any packet received. This command is also sets the access control list insertion point.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > ACL Configuration

configure > context context_name > ip access-list acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-acl)#

Syntax

{ deny | permit } [ log ] any

after { deny | permit } [ log ] any

before { deny | permit } [ log ] any

no { deny | permit } [ log ] any

after
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no
Removes the rule which exactly matches the options specified.
deny/permit (any)

---

deny | permit

Specifies the rule is either block (deny) or an allow (permit) filter.

- **deny**: Indicates the rule, when matched, drops the corresponding packets.
- **permit**: Indicates the rule, when matched, allows the corresponding packets.

---

**log**

Default: Packets are not logged.
Indicates all packets which match the filter are to be logged.

---

**Important:** The logging option is not supported for ACLs applied on SPIO or local contexts.

---

**any**

Indicates all packets will match the filter regardless of source and/or destination.

---

**Usage**

Define a catch all rule to place at the end of the list of rules.

---

**Important:** It is suggested that any rule which is added to be a catch all should also have the log option specified. The logged packets may be used to determine if the current list of rules is adequate or needs modification to ensure proper security. The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

---

**Example**

The following commands define two rules with the second logging filtered packets:

```
permit any

deny log any
```

The following sets the insertion point before the first rule defined above:

```
before permit any
```

The following command sets the insertion point after the second rule defined above:

```
after deny log any
```

The following deletes the first rule defined above:

```
no permit any
```
deny/permit (by host IP address)

Filters subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > ACL Configuration

configure > context context_name > ip access-list acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-acl)#

Syntax

{ deny | permit } [ log ] host source_host_address
after { deny | permit } [ log ] host source_host_address
before { deny | permit } [ log ] host source_host_address
no { deny | permit } [ log ] host source_host_address

after
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no
Removes the rule which exactly matches the options specified.

deny | permit
Specifies the rule is either block (deny) or an allow (permit) filter.
**deny**/permit (by host IP address)

- **deny**: Indicates the rule, when matched, drops the corresponding packets.
- **permit**: Indicates the rule, when matched, allows the corresponding packets.

<table>
<thead>
<tr>
<th>Command</th>
<th>Line Interface Reference, StarOS Release 16</th>
</tr>
</thead>
<tbody>
<tr>
<td>log</td>
<td>Default: Packets are not logged. Indicates that all packets which match the filter are to be logged.</td>
</tr>
</tbody>
</table>

**Important**: The logging option is not supported for ACLs applied on SPIO or local contexts.

- **source_host_address**: The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

**Usage**

Define a rule when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rules to be very clear and concise.

**Important**: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Example**

The following commands define two rules with the second logging filtered packets:

```
permit host 10.2.3.4
deny log host 10.2.3.5
```

The following sets the insertion point before the first rule defined above:

```
before permit host 10.2.3.4
```

The following command sets the insertion point after the second rule defined above:

```
after deny log host 10.2.3.5
```

The following deletes the first rule defined above:

```
no permit host 10.2.3.4
```
**deny/permit (by source ICMP packets)**

Filters subscriber sessions based on the internet control message protocol (ICMP) packets sent by the source to the mobile node or the network.

**Product**
All

Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ACL Configuration

```
configure > context context_name > ip access-list acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ml)#
```

**Syntax**

```bash
{ deny | permit } [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

after { deny | permit } [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

before { deny | permit } [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

no { deny | permit } [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]
```

**after**

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
### Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.

**deny | permit**
Specifies the rule is either block (deny) or an allow (permit) filter.
- **deny**: Indicates the rule, when matched, drops the corresponding packets.
- **permit**: Indicates the rule, when matched, allows the corresponding packets.

**log**
Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

### Important: The logging option is not supported for ACLs applied on SPIO or local contexts.

**source_address**
The IP address(es) from which the packet originated. IP addresses must be entered in IPv4 dotted-decimal format.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- **Zero-bits** in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- **One-bits** in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

### Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**any**
Specifies that the rule applies to all packets.

**host**
Specifies that the rule applies to a specific host as determined by its IP address.
**source_host_address**
The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

**dest_host_address**
The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.

**dest_address**
The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **destWildcard** parameter.

**destWildcard**
This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.

**Important**: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.3, 0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**icmp_type**
Specifies that all ICMP packets of a particular type are to be filtered. The type can be an integer value between 0 and 255.

**icmp_code**
Specifies that all ICMP packets of a particular code are to be filtered. The type can be an integer value between 0 and 255.

**Usage**
Define a rule to block ICMP packets which can be used for address resolution and possible be a security risk. The IP filtering allows flexible controls for pairs of individual hosts or groups by IP masking which allows the filtering of entire subnets if necessary.

**Important**: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*.

**Example**
The following commands define two rules with the second logging filtered packets:

```
permit icmp host 10.2.3.4 any 168
```
deny log icmp 10.2.3.0 0.0.0.31 host 10.2.4.16 168 11

The following sets the insertion point before the first rule defined above:

before permit icmp host 10.2.3.4 any 168

The following command sets the insertion point after the second rule defined above:

after deny log icmp 10.2.3.0 0.0.0.31 host 10.2.4.16 168 11

The following deletes the first rule defined above:

no permit icmp host 10.2.3.4 any 168
deny/permit (by IP packets)

Filters subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

Product

{ deny | permit } [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]

after { deny | permit } [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]

before { deny | permit } [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]

no { deny | permit } [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

after
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

before
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
**deny/permit (by IP packets)**

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

---

**no**
Removes the rule which exactly matches the options specified.

---

**deny | permit**
Specifies the rule is either block (deny) or an allow (permit) filter.
- **deny:** Indicates the rule, when matched, drops the corresponding packets.
- **permit:** Indicates the rule, when matched, allows the corresponding packets.

---

**log**
Default: Packets are not logged.
Indicates all packets which match the filter are to be logged.

**Important:** The logging option is not supported for ACLs applied on SPIO or local contexts.

---

**source_address**
The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

---

**source_wildcard**
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

---

**any**
Specifies that the rule applies to all packets.

---

**host**
Specifies that the rule applies to a specific host as determined by its IP address.

**source_host_address**
The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.
ACL Configuration Mode Commands

deny/permit (by IP packets)

---

**dest_host_address**

The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.

**dest_address**

The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.

**dest_wildcard**

This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.

> **Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**fragment**

Indicates packet filtering is to be applied to IP packet fragments only.

**protocol num**

Indicates that the packet filtering is to be applied to a specific protocol number.
**num** can be an integer ranging from 0 to 255.

> **Important:** This keyword is not applicable to a SPIO interface. Instead, you must specify the type of protocol packets for which you want to deny/permit processing on a SPIO. For example, **deny icmp**, **deny tcp**, or **deny udp**.

---

**Usage**

Block IP packets when the source and destination are of interest.

> **Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the **Engineering Rules** appendix in the **System Administration Guide**.

**Example**

The following commands define two rules with the second logging filtered packets:

```
permit ip host 10.2.3.4 any fragment

deny log ip 10.2.3.0 0.0.0.31 host 10.2.4.16
```
The following sets the insertion point before the first rule defined above:

```plaintext
before permit ip host 10.2.3.4 any fragment
```

The following command sets the insertion point after the second rule defined above:

```plaintext
after deny log ip 10.2.3.0 0.0.0.31 host 10.2.4.16
```

The following deletes the first rule defined above:

```plaintext
no permit ip host 10.2.3.4 any fragment
```
deny/permit (by TCP/UDP packets)

Filters subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

```

| Important: If the options specified do not exactly match an existing rule, the insertion point does not change. |

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.
deny/permit (by TCP/UDP packets)

before
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

no
Removes the rule which exactly matches the options specified.

deny | permit
Specifies the rule is either block (deny) or an allow (permit) filter.

- **deny**: Indicates the rule, when matched, drops the corresponding packets.
- **permit**: Indicates the rule, when matched, allows the corresponding packets.

log
Default: Packets are not logged.
Indicates all packets which match the filter are to be logged.

**Important:** The logging option is not supported for ACLs applied on SPIO or local contexts.

tcp | udp
Specifies the filter is to be applied to IP based transmission control protocol or the user datagram protocol.

- **tcp**: Filter applies to TPC packets.
- **udp**: Filter applies to UDP packets.

source_address
The IP address(es) from which the packet originated. IP addresses must be entered in IPv4 dotted-decimal format. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the sourceWildcard parameter.

sourceWildcard
This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.
**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

---

**any**
Specifies that the rule applies to all packets.

**host**
Specifies that the rule applies to a specific host as determined by its IP address.

**source_host_address**
The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

**dest_host_address**
The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.

**eq source_port**
Specifies a single, specific source TCP port number to be filtered.

source_port must be an integer from 0 through 65535.

**gt source_port**
Specifies that all source TCP port numbers greater than the one specified are to be filtered.

source_port must be an integer from 0 through 65535.

**lt source_port**
Specifies that all source TCP port numbers less than the one specified are to be filtered.

source_port must be an integer from 0 through 65535.

**neq source_port**
Specifies that all source TCP port numbers not equal to the one specified are to be filtered.

source_port must be an integer from 0 through 65535.

**dest_address**
The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.

**dest_wildcard**
This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
One-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

`eq dest_port`

Specifies a single, specific destination TCP port number to be filtered.

`dest_port` must be an integer from 0 through 65535.

`gt dest_port`

Specifies that all destination TCP port numbers greater than the one specified are to be filtered.

`dest_port` must be an integer from 0 through 65535.

`lt dest_port`

Specifies that all destination TCP port numbers less than the one specified are to be filtered.

`dest_port` must be an integer from 0 through 65535.

`neq dest_port`

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered.

`dest_port` must be an integer from 0 through 65535.

`range start_port end_port`

Specifies a range of ports to be matched.

`start_port` must be an integer from 0 through 65535, and must be less than the `end_port` value.

`end_port` must be an integer from 0 through 65535, and must be greater than the `start_port` value.

**Important:** This option is supported in PDIF Release 8.3.

**Usage**

Block IP packets when the source and destination are of interest but for only a limited set of ports.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Example**

The following commands define four rules with the second and fourth rules logging filtered packets:

```plaintext
permit tcp host 10.2.3.4 any
deny log udp 10.2.3.0 0.0.0.31 host 10.2.4.16
permit tcp host 10.2.3.64 gt 1023 any
deny log udp 10.2.3.0 0.0.0.31 10.2.4.127 0.0.0.127
```
The following sets the insertion point before the first rule defined above:

```
before permit tcp host 10.2.3.4 any
```

The following command sets the insertion point after the second rule defined above:

```
after deny log udp 10.2.3.0 0.0.0.31 host 10.2.4.16
```

The following deletes the third rule defined above:

```
no permit tcp host 10.2.3.64 gt 1023 any
```
description

Sets the descriptive text for the object.

Product
All

Privilege
Security Administrator, Administrator

Syntax

description text

no description

  no
  Clears the description for the object.

  text
  Specifies the descriptive text as an alphanumeric string of 1 to 79 characters. If you include spaces between words in the description, you must enclose the text within double quotation marks (" "), for example, “AAA BBBB”.

Usage
The description should provide useful information on the object’s primary function, services, endusers, etc.
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
exit
```

**Usage**

Use this command to return to the parent configuration mode.
readdress server

Alters the destination address and port number in TCP or UDP packet headers to redirect packets to a different server.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > ACL Configuration

configure > context context_name > ip access-list acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-acl)#

Syntax

```
readdress server redirect_address [ port port_no ] { tcp | udp } { { source_address source wildcard | any | host source host address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest wildcard | any | host dest host address } [ eq ] dest_port | gt dest_port | lt dest_port | neq dest_port ] }

after readdress server redirect_address [ port port_no ] { tcp | udp } { { source_address source wildcard | any | host source host address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest wildcard | any | host dest host address } [ eq ] dest_port | gt dest_port | lt dest_port | neq dest_port ] }

before readdress server redirect_address [ port port_no ] { tcp | udp } { { source_address source wildcard | any | host source host address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest wildcard | any | host dest host address } [ eq ] dest_port | gt dest_port | lt dest_port | neq dest_port ] }

no readdress server redirect_address [ port port_no ] { tcp | udp } { { source_address source wildcard | any | host source host address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest wildcard | any | host dest host address } [ eq ] dest_port | gt dest_port | lt dest_port | neq dest_port ] }
```

after
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.
before
Indicates all rules defined subsequent to this command are to be inserted before the command identified by
the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified
such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

no
Removes the rule which exactly matches the options specified.

redirect_address
The IP address to which the IP packets are redirected. TCP or UDP packet headers are rewritten to contain
the new destination address. This must be an IPv4 address specified in dotted-decimal notation.

port port_no
The number of the port at the redirect address where the packets are sent. TCP or UDP packet headers are
rewritten to contain the new destination port number.

tcp | udp
Specifies the redirect is to be applied to the IP based transmission control protocol or the user datagram
protocol.
- **tcp**: Redirect applies to TCP packets.
- **udp**: Redirect applies to UDP packets.

source_address
The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then
be configured using the `source_wildcard` parameter.

source_wildcard
This option is used in conjunction with the `source_address` option to specify a group of addresses for
which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address`
  parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address`
  parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore,
allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and
0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.
any
Specifies that the rule applies to all packets.

host
Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address
The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.

eq source_port
Specifies a single, specific source TCP port number to be filtered. 
source_port must be an integer from 0 through 65535.

gt source_port
Specifies that all source TCP port numbers greater than the one specified are to be filtered. 
source_port must be an integer from 0 through 65535.

lt source_port
Specifies that all source TCP port numbers less than the one specified are to be filtered. 
source_port must be an integer from 0 through 65535.

neq source_port
Specifies that all source TCP port numbers not equal to the one specified are to be filtered. 
source_port must be an integer from 0 through 65535.

dest_address
The IP address(es) to which the packet is to be sent. 
This option is used to filter all packets to a specific IP address or a group of IP addresses. 
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

dest_wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered. 
The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.

- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.
**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

<table>

<td>Specifies that all destination TCP port numbers not equal to the one specified are to be filtered. dest_port must be an integer 0 through 65535.</td>
</tr>
</tbody>
</table>

**Usage**
Use this command to define a rule that redirects packets to a different destination address. The TCP and UDP packet headers are modified with the new destination address and destination port.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Important:** Prior to Release 8.3, for packets received from the packet data network destined for a subscriber's UE, the system applied logic to reset the source address of a packet to the original destination address of the input packet before applying the outbound access control list (ACL). In Release 8.3 and higher, the system reverses the order and applies the outbound ACL before resetting the source address. This change impacts all current readdress server rules in inbound IPv4 ACLs.

**Important:** After Release 8.3, for every readdress server rule in an inbound IPv4 ACL, you must add a permit rule to an outbound ACL that explicitly permits packets from the readdress rule's redirect address and port number. If the permit rule is omitted, the system will reject all packets destined for the subscriber's UE from the readdress rule's redirect address and port number.

**Example**
The following command defines a rule that redirects packets to the server at 192.168.10.4, UDP packets coming from any host with a destination of any host are matched:

```
readdress server 192.168.10.4 udp any any
```

The following sets the insertion point before the rule defined above:
before readdress server 192.168.10.4 udp any any

The following command sets the insertion point after the first rule defined above:

after readdress server 192.168.10.4 udp any any

The following deletes the rule defined above:

no readdress server 192.168.10.4 udp any any
redirect context (by IP address masking)

Redirects subscriber sessions based on the IP address mask sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > ACL Configuration

configure > context context_name > ip access-list acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-acl)#

Syntax

redirect context context_id [ log ] source_address source_wildcard

after redirect context context_id [ log ] source_address source_wildcard

before redirect context context_id [ log ] source_address source_wildcard

no redirect context context_id [ log ] source_address source_wildcard

after
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no
Removes the rule which exactly matches the options specified.
context context_id

The context identification number of the context to which packets are redirected. At the executive mode
prompt, use the show context all command to display context names and context IDs.

log

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then
be configured using the source_wildcard parameter.

source_wildcard

This option is used in conjunction with the source_address option to specify a group of addresses for
which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the source_address
  parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the source_address
  parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore,
allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and
0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

Usage

Define a rule when any packet from the IP addresses which fall into the group of addresses matching the IP
address masking. This allows the reduction of redirect rules as it does not require a rule for each source and
destination pair.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is
to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

Important: Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers
facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the context with the context ID of 23 and the
source IP and wildcard of 192.168.22.0 and 0.0.0.31:

```redirect context 23 198.162.22.0 0.0.0.31```

The following sets the insertion point before the rule defined above:
before redirect context 23 198.162.22.0 0.0.0.31

The following command sets the insertion point after the first rule defined above:

after redirect context 23 198.162.22.0 0.0.0.31

The following deletes the first rule defined above:

no redirect context 23 198.162.22.0 0.0.0.31
redirect context (any)

Rediects subscriber sessions based on any packet received. This command is also used to set the access control list insertion point.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ACL Configuration
configure > context context_name > ip access-list acl_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-acl)#
```

**Syntax**

```
redirect context context_id [ log ] any
after redirect context context_id [ log ] any
before redirect context context_id [ log ] any
no redirect context context_id [ log ] any
```

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.
**context context_id**

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

**log**

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**any**

Indicates all packets will match the redirect regardless of source and/or destination.

**Usage**

Define a catch all rule to place at the end of the list of rules to provide explicit handling of rules which do not fit any other criteria.

**Important:** Any rule which is added as a catch all should also have the log option specified. The logged packets may be used to determine if the current list of rules is adequate or needs modification to ensure proper security.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Important:** Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule that redirects packets to the context with the context ID of 23 and any source IP:

```
redirect context 23 any
```

The following sets the insertion point before the rule defined above:

```
beforeredirectcontext23any
```

The following command sets the insertion point after the first rule defined above:

```
after redirect context 23 any
```

The following deletes the first rule defined above:

```
no redirect context 23 any
```
redirect context (by host IP address)

Redirects subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ACL Configuration

`configure > context context_name > ip access-list acl_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-acl)#
```

**Syntax**

```
redirect context context_id [ log ] host source_ipv4_address

after redirect context context_id [ log ] host source_ipv4_address

before redirect context context_id [ log ] host source_ipv4_address

no redirect context context_id [ log ] host source_ipv4_address
```

**Important:**
If the options specified do not exactly match an existing rule, the insertion point does not change.

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:**
If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.
context context_id

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

log

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

host

Specifies that the rule applies to a specific host as determined by its IP address.

source_ipv4_address

The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

Usage

Define a rule when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rules to be very clear and concise.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

Important: Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the context with the context ID of 23 and a host IP address of 192.168.200.11:

```
redirect context 23 host 192.168.200.11
```

The following sets the insertion point before the rule defined above:

```
before redirect context 23 host 192.168.200.11
```

The following command sets the insertion point after first the rule defined above:

```
after redirect context 23 host 192.168.200.11
```

The following deletes the first rule defined above:

```
no redirect context 23 host 192.168.200.11
```
redirect context (by source ICMP packets)

Redirects subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

Product

Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > ACL Configuration
configure > context context_name > ip access-list acl_name

Entering the above command sequence results in the following prompt:
[context_name]host_name(config-acl)#

Syntax

```
redirect context context_id [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]
```

```
before redirect context context_id [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]
```

```
no redirect context context_id [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]
```

<table>
<thead>
<tr>
<th>Important:</th>
<th>If the options specified do not exactly match an existing rule, the insertion point does not change.</th>
</tr>
</thead>
</table>

| Important: | Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed. |
|------------| This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule. |

| Important: | Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed. |
|------------| This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule. |
**redirect context (by source ICMP packets)**

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.

**context context_id**
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

**log**
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**source_address**
The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**any**
Specifies that the rule applies to all packets.

**host**
Specifies that the rule applies to a specific host as determined by its IP address.

**source_host_address**
The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

**dest_host_address**
The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.
**dest_address**

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

**dest_wildcard**

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**icmp_type**

Specifies that all ICMP packets of a particular type are to be filtered. The type can be an integer value between 0 and 255.

**icmp_code**

Specifies that all ICMP packets of a particular code are to be filtered. The type can be an integer value between 0 and 255.

**Usage**

Define a rule to block ICMP packets which can be used for address resolution and possibly be a security risk. The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*.

**Important:** Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule that redirects packets to the context with the context ID of 23, and ICMP packets coming from the host with the IP address 198.162.100.25:

```
redirect context 23 icmp host 192.168.100.25
```

The following sets the insertion point before the rule defined above:
before redirect context 23 icmp host 192.168.100.25

The following command sets the insertion point after the first rule defined above:

after redirect context 23 icmp host 192.168.100.25

The following deletes the first rule defined above:

no redirect context 23 icmp host 192.168.100.25
redirect context (by IP packets)

Redirects subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ACL Configuration

```shell
configure > context context_name > ip access-list acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-acl)#
```

**Syntax**

```shell
redirect context context_id [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]
```

```shell
after redirect context context_id [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]
```

```shell
before redirect context context_id [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]
```

```shell
no redirect context context_id [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]
```

**Important**: If the options specified do not exactly match an existing rule, the insertion point does not change.

**after**

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**before**

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
redirect context (by IP packets)

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

- **no**
  Removes the rule which exactly matches the options specified.

- **context context_id**
  The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

- **log**
  Default: packets are not logged.
  Indicates all packets which match the redirect are to be logged.

- **source_address**
  The IP address(es) from which the packet originated.
  This option is used to filter all packets from a specific IP address or a group of IP addresses.
  When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `sourceWildcard` parameter.

- **sourceWildcard**
  This option is used in conjunction with the `sourceAddress` option to specify a group of addresses for which packets are to be filtered.
  The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the `sourceAddress` parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the `sourceAddress` parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

- **any**
  Specifies that the rule applies to all packets.

- **host**
  Specifies that the rule applies to a specific host as determined by its IP address.

- **source_host_address**
  The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

- **dest_host_address**
  The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.
ACL Configuration Mode Commands

redirect context (by IP packets)

Command

dest_address

The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

dest_wildcard

This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

fragment

Indicates packet redirection is to be applied to IP packet fragments only.

protocol num

Indicates that the packet filtering is to be applied to a specific protocol number. num can be an integer ranging from 0 to 255.

Usage

Block IP packets when the source and destination are of interest.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

Important: Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the context with the context ID of 23, and IP packets coming from the host with the IP address 198.162.100.25, and fragmented packets for any destination are matched:

```
redirect context 23 ip host 198.162.100.25 any fragment
```

The following sets the insertion point before the rule defined above:

```
before redirect context 23 ip host 198.162.100.25 any fragment
```
The following command sets the insertion point after the first rule defined above:

```
after redirect context 23 ip host 198.162.100.25 any fragment
```

The following deletes the first rule defined above:

```
no redirect context 23 ip host 198.162.100.25 any fragment
```
redirect context (by TCP/UDP packets)

Redirects subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ACL Configuration

```config
configure > context context_name > ip access-list acl_name
```

Entering the above command sequence results in the following prompt:

```
/context_name>host_name(config-acl)#
```

**Syntax**

```plaintext
redirect context context_id [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }

after redirect context context_id [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }

before redirect context context_id [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }

no redirect context context_id [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }
```

**after**

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.
**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.

**context context_id**
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

**log**
Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

**tcp | udp**
Specifies the redirect is to be applied to IP based transmission control protocol or the user datagram protocol.
- **tcp**: Redirect applies to TPC packets.
- **udp**: Redirect applies to UDP packets.

**source_address**
The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

**any**
Specifies that the rule applies to all packets.
**host**
Specifies that the rule applies to a specific host as determined by its IP address.

**source_host_address**
The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

**dest_host_address**
The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.

**eq source_port**
Specifies a single, specific source TCP port number to be filtered.
*source_port* must be configured to an integer value from 0 to 65535.

**gt source_port**
Specifies that all source TCP port numbers greater than the one specified are to be filtered.
*source_port* must be an integer from 0 through 65535.

**lt source_port**
Specifies that all source TCP port numbers less than the one specified are to be filtered.
*source_port* must be an integer from 0 through 65535.

**neq source_port**
Specifies that all source TCP port numbers not equal to the one specified are to be filtered.
*source_port* must be an integer from 0 through 65535.

**dest_address**
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.

**destWildcard**
This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.
### eq dest_port

Specifies a single, specific destination TCP port number to be filtered. `dest_port` must be an integer from 0 through 65535.

### gt dest_port

Specifies that all destination TCP port numbers greater than the one specified are to be filtered. `dest_port` must be an integer from 0 through 65535.

### lt dest_port

Specifies that all destination TCP port numbers less than the one specified are to be filtered. `dest_port` must be an integer from 0 through 65535.

### neq dest_port

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered. `dest_port` must be an integer from 0 through 65535.

### Usage

Block IP packets when the source and destination are of interest but for only a limited set of ports.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*.

**Important:** Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

### Example

The following command defines a rule that redirects packets to the context with the context ID of 23, and UDP packets coming from any host are matched:

```
redirect context 23 udp any
```

The following sets the insertion point before the rule defined above:

```
before redirect context 23 udp any
```

The following command sets the insertion point after the first rule defined above:

```
after redirect context 23 udp any
```

The following deletes the rule defined above:

```
o redirect context 23 udp any
```
redirect css delivery-sequence

This is a restricted command. In 9.0 and later releases, this command is obsoleted.
redirect css service (any)

Redirects subscriber sessions based on any packet received (Content Service Steering). This command is also used to set the access control list insertion point.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > ACL Configuration

```bash
configure > context context_name > ip access-list acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-acl)#
```

**Syntax**

```
redirect css service service_name [ log ] any
after redirect css service service_name [ log ] any
before redirect css service service_name [ log ] any
no redirect css service service_name [ log ] any
```

**after**
Indicates all rule definitions defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important**: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definitions which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important**: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**
Removes the rule definition which exactly matches the options specified.
ACL Configuration Mode Commands

**redirect css service (any)**

<table>
<thead>
<tr>
<th>Command Line Interface Reference, StarOS Release 16</th>
</tr>
</thead>
<tbody>
<tr>
<td>295</td>
</tr>
</tbody>
</table>

**css service service_name**

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging all` command to display the names of all configured charging services. `service_name` must be an alphanumeric string from 1 through 15 characters.

**log**

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**any**

Indicates all packets will match the redirect regardless of source and/or destination.

**Usage**

Define a catch all rule definitions to place at the end of the list of rule definitions to provide explicit handling of rule definitions which do not fit any other criteria.

**Important:** Any rule definition which is added to be a catch all should also have the `log` option specified. The logged packets may be used to determine if the current list of rule definitions is adequate or needs modification to ensure proper security.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the charging service with the name `chgsvc1` and any source IP:

```bash
redirect css service chgsvc1 any
```

The following sets the insertion point before the rule definition above:

```bash
before redirect service chgsvc1 any
```

The following command sets the insertion point after the first rule definitions above:

```bash
after redirect service chgsvc1 any
```

The following deletes the first rule definition above:

```bash
no redirect service chgsvc1 any
```
redirect css service (by host IP address)

Redirect subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network (Content Service Steering).

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ACL Configuration
configure > context context_name > ip access-list acl_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-acl)#
```

**Syntax**

```
redirect css service service_name [ log ] host source_host_address
```
```
after redirect css service service_name [ log ] host source_host_address
```
```
before redirect css service service_name [ log ] host source_host_address
```
```
no redirect css service service_name [ log ] host source_host_address
```

**after**
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**
Removes the rule definition which exactly matches the options specified.
**css service service_name**

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services.

*service_name* must be an alphanumeric string from 1 through 15 characters.

**log**

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**host**

Specifies that the rule definition applies to a specific host as determined by its IP address.

*source_host_address*

The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

### Usage

Define a rule definition when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rule definitions to be very clear and concise.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

### Example

The following command defines a rule definition that redirects packets to the charging service with the name *chgsvc1* and a host IP address of *192.168.200.11*:

```
redirect css service chgsvc1 host 192.168.200.11
```

The following sets the insertion point before the rule definition above:

```
before redirect css service chgsvc1 host 192.168.200.11
```

The following command sets the insertion point after the first rule definition above:

```
after redirect css service chgsvc1 host 192.168.200.11
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 host 192.168.200.11
```
redirect css service (by ICMP packets)

Redirects subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network (Content Service Steering).

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ACL Configuration

`configure > context context_name > ip access-list acl_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-acl)#
```

**Syntax**

```
redirect css service service_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ]

before redirect css service service_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ]

after redirect css service service_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ]

no redirect css service service_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ]
```

**after**

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.
ACL Configuration Mode Commands

redirect css service (by ICMP packets)

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

---

**no**

Removes the rule definition which exactly matches the options specified.

---

**css service service_name**

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services.

*service_name* must be an alphanumeric string from 1 through 15 characters.

---

**log**

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

---

**source_address**

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the **source_wildcard** parameter.

---

**source_wildcard**

This option is used in conjunction with the **source_address** option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the **source_address** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **source_address** parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

---

**any**

Specifies that the rule definition applies to all packets.

---

**host**

Specifies that the rule definition applies to a specific host as determined by its IP address.

---

**source_host_address**

The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.
**redirect css service (by ICMP packets)**

- **dest_host_address**
  The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.

- **dest_address**
  The IP address(es) to which the packet is to be sent.
  This option is used to filter all packets to a specific IP address or a group of IP addresses.
  When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.

- **dest_wildcard**
  This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered.
  The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.

  **Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

- **icmp_type**
  Specifies that all ICMP packets of a particular type are to be filtered. The type can be an integer value between 0 and 255.

- **icmp_code**
  Specifies that all ICMP packets of a particular code are to be filtered. The type can be an integer value between 0 and 255.

**Usage**

Define a rule definition to block ICMP packets which can be used for address resolution and possibly be a security risk.

The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the charging service named *chgsvcl*, and ICMP packets coming from the host with the IP address 198.162.100.25:
redirect css service chgsvcl icmp host 192.168.200.11

The following sets the insertion point before the rule definition above:

before redirect css service chgsvcl icmp host 192.168.200.11

The following command sets the insertion point after the first rule definition above:

after redirect css service chgsvcl icmp host 192.168.200.11

The following deletes the first rule definition above:

no redirect css service chgsvcl icmp host 192.168.200.11
redirect css service (by IP packets)

Redirects subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network (Content Service Steering).

before redirect css service service_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

no redirect css service service_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before
Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.
**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

---

**no**

Removes the rule definition that exactly matches the options specified.

---

**css service service_name**

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services.

*service_name* must be an alphanumeric string from 1 through 15 characters.

---

**log**

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

---

**source_address**

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

---

**source_wildcard**

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

---

**any**

Specifies that the rule definition applies to all packets.

---

**host**

Specifies that the rule definition applies to a specific host as determined by its IP address.

---

**source_host_address**

The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.
**dest_host_address**

The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.

**dest_address**

The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.

**dest_wildcard**

This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**fragment**

Indicates packet redirection is to be applied to IP packet fragments only.

**Usage**

Block IP packets when the source and destination are of interest.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the charging service named chgsvcl, and IP packets coming from the host with the IP address 198.162.100.25, and fragmented packets for any destination are matched:

```
redirect css service chgsvcl ip host 192.168.100.25 any fragment
```

The following sets the insertion point before the rule definition above:

```
before redirect css service chgsvcl ip host 192.168.100.25 any fragment
```

The following command sets the insertion point after the first rule definition above:
after redirect css service chgsvc1 ip host 192.168.100.25 any fragment

The following deletes the first rule definition above:

no redirect css service chgsvc1 ip host 192.168.100.25 any fragment
redirect css service (by source IP address masking)

Redirects subscriber sessions based on the IP address mask sent by the source to the mobile node or the network (Content Service Steering).

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > ACL Configuration

configure > context context_name > ip access-list acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-acl)#

Syntax

redirection css service service_name [ log ] source_address source_wildcard
after redirection css service service_name [ log ] source_address source_wildcard
before redirection css service service_name [ log ] source_address source_wildcard
no redirection css service service_name [ log ] source_address source_wildcard

after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no
Removes the rule definition which exactly matches the options specified.
**css service** service_name

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services.

*service_name* must be an alphanumeric string from 1 through 15 characters.

**log**

Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

**source_address**

The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**Usage**

Define a rule definition when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rule definitions as it does not require a rule definition for each source and destination pair.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Example**

The following command defines a rule definition to redirect packets to a charging service named *chgsvcl*:

```
redirect css service chgsvcl 10.2.3.0 0.0.0.31
```
redirect css service (by TCP/UDP packets)

Redirects subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network (Content Service Steering).

**Product**

```

**Syntax**

```
redirect css service service_name [ log ] [ tcp | udp ] { [ source_address source_wildcard | any | host source_host_address ] [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { [ dest_address dest_wildcard | any | host dest_host_address ] [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }
```

```
after redirect css service service_name [ log ] [ tcp | udp ] { [ source_address source_wildcard | any | host source_host_address ] [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { [ dest_address dest_wildcard | any | host dest_host_address ] [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }
```

```
before redirect css service service_name [ log ] [ tcp | udp ] { [ source_address source_wildcard | any | host source_host_address ] [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { [ dest_address dest_wildcard | any | host dest_host_address ] [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }
```

```
no redirect css service service_name [ log ] [ tcp | udp ] { [ source_address source_wildcard | any | host source_host_address ] [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { [ dest_address dest_wildcard | any | host dest_host_address ] [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }
```

**after**

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.
**Important**: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```
before
```

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important**: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```
no
```

Removes the rule definition which exactly matches the options specified.

```
css service service_name
```

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services. `service_name` must be an alphanumeric string from 1 through 15 characters.

```
log
```

Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

```
tcp | udp
```

Specifies the redirect is to be applied to IP-based transmission control protocol or the user datagram protocol.

- **tcp**: Redirect applies to TCP packets.
- **udp**: Redirect applies to UDP packets.

```
source_address
```

The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

```
source_wildcard
```

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.
**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**any**

Specifies that the rule definition applies to all packets.

**host**

Specifies that the rule definition applies to a specific host as determined by its IP address.

**source_host_address**

The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

**dest_host_address**

The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.

**eq source_port**

Specifies a single, specific source TCP port number to be filtered.

*source_port* must be configured to an integer value from 0 to 65535.

**gt source_port**

Specifies that all source TCP port numbers greater than the one specified are to be filtered.

*source_port* must be configured to an integer value from 0 to 65535.

**lt source_port**

Specifies that all source TCP port numbers less than the one specified are to be filtered.

*source_port* must be configured to an integer value from 0 to 65535.

**neq source_port**

Specifies that all source TCP port numbers not equal to the one specified are to be filtered.

*source_port* must be configured to an integer value from 0 to 65535.

**range start_source_port end_source_port**

Specifies that all source TCP ports within a specific range are to be filtered.

*start_source_port* is the initial port in the range and *end_source_port* is the final port in the range. Both *start_source_port* and *end_source_port* can be configured to an integer value from 0 to 65535.

**dest_address**

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.
dest_wildcard

This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

eq dest_port

Specifies a single, specific destination TCP port number to be filtered. dest_port must be configured to an integer value from 0 to 65535.

gt dest_port

Specifies that all destination TCP port numbers greater than the one specified are to be filtered. dest_port must be configured to an integer value from 0 to 65535.

lt dest_port

Specifies that all destination TCP port numbers less than the one specified are to be filtered. dest_port must be configured to an integer value from 0 to 65535.

neq dest_port

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered. dest_port must be configured to an integer value from 0 to 65535.

range start_dest_port end_dest_port

Specifies that all destination TCP ports within a specific range are to be filtered. start_dest_port is the initial port in the range and end_dest_port is the final port in the range. Both start_dest_port and end_dest_port can be configured to an integer value from 0 to 65535.

Usage

Block IP packets when the source and destination are of interest but for only a limited set of ports.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

Important: Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example
The following command defines a rule definition that redirects packets to the charging service named `chgsvc1`, and UDP packets coming from any host are matched:

```
redirect css service chgsvc1 udp any
```

The following sets the insertion point before the rule definition above:

```
before redirect css service chgsvc1 udp any
```

The following command sets the insertion point after the first rule definition above:

```
after redirect css service chgsvc1 udp any
```

The following command deletes the rule definition above:

```
no redirect css service chgsvc1 udp any
```
redirect css service (for downlink, any)

Redirects subscriber sessions based on any packet received in the downlink (from the Mobile Node) direction (Content Service Steering). This command is also used to set the access control list insertion point.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > ACL Configuration
configure > context context_name > ip access-list acl_name

Entering the above command sequence results in the following prompt:
[context_name]host_name(config-acl)#

Syntax

redirect css service service_name [ log ] downlink any
after redirect css service service_name [ log ] downlink any
before redirect css service service_name [ log ] downlink any
no redirect css service service_name [ log ] downlink any

**after**
Indicates all rule definitions defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**
Removes the rule definition which exactly matches the options specified.
css service service_name

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services. `service_name` must be an alphanumeric string from 1 through 15 characters.

downlink

Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

log

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

any

Indicates all packets will match the redirect regardless of source and/or destination.

Usage

Define a catch all rule definition to place at the end of the list of rule definitions to provide explicit handling of rule definitions which do not fit any other criteria.

Important: Any rule definition which is added to be a catch all should also have the `log` option specified. The logged packets may be used to determine if the current list of rule definitions is adequate or needs modification to ensure proper security.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

Important: Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule definition that redirects packets to the charging service with the name `chgsvc1` and any source IP:

```
redirect css service chgsvc1 downlink any
```

The following sets the insertion point before the rule definition above:

```
before redirect css service chgsvc1 downlink any
```

The following command sets the insertion point after the first rule definition above:

```
after redirect css service chgsvc1 downlink any
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 downlink any
```
redirect css service (for downlink, by host IP address)

Redirects subscriber sessions based on the targeted host IP address in the downlink (from the Mobile Node) direction (Content Service Steering).

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ACL Configuration

```
configure > context context_name > ip access-list acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-acl)#
```

**Syntax**

```
redirect css service service_name [ log ] downlink host source_host_address
before redirect css service service_name [ log ] downlink host source_host_address
after redirect css service service_name [ log ] downlink host source_host_address
no redirect css service service_name [ log ] downlink host source_host_address
```

**after**
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**
Removes the rule definition which exactly matches the options specified.
**redirect css service (for downlink, by host IP address)**

```markdown
css service service_name
```

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services. `service_name` must be an alphanumeric string from 1 through 15 characters.

```markdown
downlink
```

Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

```markdown
log
```

Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

```markdown
host
```

Specifies that the rule definition applies to a specific host as determined by its IP address.

```markdown
source_host_address
```

The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

**Usage**

Define a rule definition when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rule definitions to be very clear and concise.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the charging service with the name `chgsvcl` and a host IP address of `192.168.200.11`:

```
redirect css service chgsvcl downlink host 192.168.200.11
```

The following sets the insertion point before the rule definition above:

```
before redirect css service chgsvcl downlink host 192.168.200.11
```

The following command sets the insertion point after the first rule definition above:

```
after redirect css service chgsvcl downlink host 192.168.200.11
```

The following deletes the first rule definition above:

```
no redirect css service chgsvcl downlink host 192.168.200.11
```
redirect css service (for downlink, by ICMP packets)

Redirects subscriber sessions based on the internet control message protocol packets in the downlink (from the Mobile Node) direction (Content Service Steering).

Product

no redirect css service service_name [ log ] downlink icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ]

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.
**Important**: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```
no
```

Removes the rule definition which exactly matches the options specified.

```
css service service_name
```

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services.

*service_name* must be an alphanumeric string from 1 through 15 characters.

```
downlink
```

Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

```
log
```

Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

```
source_address
```

The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

```
source_wildcard
```

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important**: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

```
any
```

Specifies that the rule definition applies to all packets.

```
host
```

Specifies that the rule definition applies to a specific host as determined by its IP address.
**source_host_address**

The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

**dest_host_address**

The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.

**dest_address**

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.

**dest_wildcard**

This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.0.7 is **not** acceptable since the one-bits are not contiguous.

**icmp_type**

Specifies that all ICMP packets of a particular type are to be filtered. The type can be an integer value between 0 and 255.

**icmp_code**

Specifies that all ICMP packets of a particular code are to be filtered. The type can be an integer value between 0 and 255.

**Usage**

Define a rule definition to block ICMP packets which can be used for address resolution and possibly be a security risk.

The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.
Example

The following command defines a rule definition that redirects packets to the charging service named `chgsvc1`, and ICMP packets coming in the downlink (from the Mobile Node) direction from the host with the IP address 192.168.100.25:

```
redirect css service chgsvc1 downlink icmp host 192.168.100.25
```

The following sets the insertion point before the rule definition above:

```
before redirect css service chgsvc1 downlink icmp host 192.168.100.25
```

The following command sets the insertion point after the first rule definition above:

```
after redirect css service chgsvc1 downlink icmp host 192.168.100.25
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 downlink icmp host 192.168.100.25
```
redirect css service (for downlink, by IP packets)

Redirects subscriber sessions based on the internet protocol packets in the downlink (from the Mobile Node) direction (Content Service Steering).

redirect css service service_name [ log ] downlink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

after redirect css service service_name [ log ] downlink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

before redirect css service service_name [ log ] downlink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

no redirect css service service_name [ log ] downlink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

**after**

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**

Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.
**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>no</strong></td>
<td>Removes the rule definition which exactly matches the options specified.</td>
</tr>
<tr>
<td><strong>css service service_name</strong></td>
<td>The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the <code>show active-charging service all</code> command to display the names of all configured charging services. <code>service_name</code> must be an alphanumeric string from 1 through 15 characters.</td>
</tr>
<tr>
<td><strong>downlink</strong></td>
<td>Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.</td>
</tr>
<tr>
<td><strong>log</strong></td>
<td>Default: packets are not logged. Indicates all packets which match the redirect are to be logged.</td>
</tr>
<tr>
<td><strong>source_address</strong></td>
<td>The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the <code>sourceWildcard</code> parameter.</td>
</tr>
<tr>
<td><strong>source_wildcard</strong></td>
<td>This option is used in conjunction with the <code>source_address</code> option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement: • Zero-bits in this parameter mean that the corresponding bits configured for the <code>source_address</code> parameter must be identical. • One-bits in this parameter mean that the corresponding bits configured for the <code>source_address</code> parameter must be ignored. <strong>Important:</strong> The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.</td>
</tr>
<tr>
<td><strong>any</strong></td>
<td>Specifies that the rule definition applies to all packets.</td>
</tr>
<tr>
<td><strong>host</strong></td>
<td>Specifies that the rule definition applies to a specific host as determined by its IP address.</td>
</tr>
</tbody>
</table>
source_host_address
The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.

dest_address
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

dest_wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

fragment
Indicates packet redirection is to be applied to IP packet fragments only.

**Usage**
Block IP packets when the source and destination are of interest.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**
The following command defines a rule definition that redirects packets to the charging service named chgsvcl, and downlink IP packets coming from the host with the IP address 198.162.100.25, and fragmented packets for any destination are matched:

```bash
redirect css service chgsvcl downlink ip host 198.162.100.25 any fragment
```

The following sets the insertion point before the rule definition above:
before redirect css service chgsvcl downlink ip host 198.162.100.25 any fragment

The following command sets the insertion point after the first rule definition above:

after redirect css service chgsvcl downlink ip host 198.162.100.25 any fragment

The following deletes the first rule definition above:

no redirect css service chgsvcl downlink ip host 198.162.100.25 any fragment
redirect css service (for downlink, by source IP address masking)

Redirects subscriber sessions based on the IP address mask sent by the source in the downlink (from the Mobile Node) direction (Content Service Steering).

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > ACL Configuration

configure > context context_name > ip access-list acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-acl)#

Syntax

redirect css service service_name [ log ] downlink source_address source_wildcard
after redirect css service service_name [ log ] downlink source_address source_wildcard
before redirect css service service_name [ log ] downlink source_address source_wildcard
no redirect css service service_name [ log ] downlink source_address source_wildcard

after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before
Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.
redirect css service (for downlink, by source IP address masking)

no
Removes the rule definition which exactly matches the options specified.

css service service_name
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the show active-charging service all command to display the names of all configured charging services. service_name must be an alphanumeric string from 1 through 15 characters.

downlink
Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

log
Default: packets are not logged. Indicates all packets which match the filter are to be logged.

source_address
The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the source_wildcard parameter.

source_wildcard
This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

Usage
Define a rule definition when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rule definitions as it does not require a rule definition for each source and destination pair.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

Example
The following command defines a rule definition to redirect packets to a charging service named chgsvcl:
redirect css service chgsvcl downlink 10.2.3.0 0.0.0.31
redirect css service (for downlink, by TCP/UDP packets)

Redirects subscriber sessions to a charging service based on the transmission control protocol/user datagram protocol packets in the downlink (from the Mobile Node) direction (Content Service Steering).

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-acl)#

Syntax

redirect css service service_name [ log ] downlink { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

after redirect css service service_name [ log ] downlink { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

before redirect css service service_name [ log ] downlink { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

no redirect css service service_name [ log ] downlink { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.
**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```markdown
before
```
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```markdown
no
```
Removes the rule definition which exactly matches the options specified.

```markdown
css service service_name
```
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services. `service_name` must be an alphanumeric string from 1 through 15 characters.

```markdown
downlink
```
Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

```markdown
log
```
Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

```markdown
tcp | udp
```
Specifies the redirect is to be applied to IP based transmission control protocol or the user datagram protocol.
- **tcp**: Redirect applies to TPC packets.
- **udp**: Redirect applies to UDP packets.

```markdown
source_address
```
The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

```markdown
source_wildcard
```
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
 ACL Configuration Mode Commands

- One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

any
Specifies that the rule definition applies to all packets.

host
Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address
The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.

eq source_port
Specifies a single, specific source TCP port number to be filtered. source_port must be configured to an integer value from 0 to 65535.

gt source_port
Specifies that all source TCP port numbers greater than the one specified are to be filtered. source_port must be configured to an integer value from 0 to 65535.

lt source_port
Specifies that all source TCP port numbers less than the one specified are to be filtered. source_port must be configured to an integer value from 0 to 65535.

neq source_port
Specifies that all source TCP port numbers not equal to the one specified are to be filtered. source_port must be configured to an integer value from 0 to 65535.

range start_source_port end_source_port
Specifies that all source TCP ports within a specific range are to be filtered. start_source_port is the initial port in the range and end_source_port is the final port in the range. Both start_source_port and end_source_port can be configured to an integer value from 0 to 65535.

dest_address
The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.
**dest_wildcard**

This option is used in conjunction with the `dest_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**eq dest_port**

Specifies a single, specific destination TCP port number to be filtered. `dest_port` must be configured to an integer value from 0 to 65535.

**gt dest_port**

Specifies that all destination TCP port numbers greater than the one specified are to be filtered. `dest_port` must be configured to an integer value from 0 to 65535.

**lt dest_port**

Specifies that all destination TCP port numbers less than the one specified are to be filtered. `dest_port` must be configured to an integer value from 0 to 65535.

**neq dest_port**

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered. `dest_port` must be configured to an integer value from 0 to 65535.

**range start_dest_port end_dest_port**

Specifies that all destination TCP ports within a specific range are to be filtered. `start_dest_port` is the initial port in the range and `end_dest_port` is the final port in the range. Both `start_dest_port` and `end_dest_port` can be configured to an integer value from 0 to 65535.

**Usage**

Block IP packets when the source and destination are of interest but for only a limited set of ports.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**
The following command defines a rule definition that redirects packets to the charging service named `chgsvcl`, and UDP packets coming from any host are matched:

```
redirect css service chgsvcl downlink udp any
```

The following sets the insertion point before the rule definition above:

```
before redirect css service chgsvcl downlink udp any
```

The following command sets the insertion point after the first rule definition above:

```
after redirect css service chgsvcl downlink udp any
```

The following deletes the rule definition above:

```
no redirect css service chgsvcl downlink udp any
```
redirect css service (for uplink, any)

Redirects subscriber sessions based on any packet received in the uplink (to the Mobile Node) direction (Content Service Steering). This command is also used to set the access control list insertion point.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ACL Configuration

configure > context context_name > ip access-list acl_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-acl)#
```

**Syntax**

```
redirect css service service_name [ log ] uplink any
after redirect css service service_name [ log ] uplink any
before redirect css service service_name [ log ] uplink any
no redirect css service service_name [ log ] uplink any
```

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```
after
```

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

```
before
```

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```
no
```

Removes the rule definition which exactly matches the options specified.
`css service service_name`

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services. `service_name` must be an alphanumeric string from 1 through 15 characters.

`uplink`

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

`log`

Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

`any`

Indicates all packets will match the redirect regardless of source and/or destination.

**Usage**

Define a catch all rule definition to place at the end of the list of rule definitions to provide explicit handling of rule definitions which do not fit any other criteria.

**Important:** It is suggested that any rule definition which is added to be a catch all should also have the `log` option specified. The logged packets may be used to determine if the current list of rule definitions is adequate or needs modification to ensure proper security.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the charging service with the name `chgsvc1` and any source IP:

```
redirect css service chgsvc1 uplink any
```

The following sets the insertion point before the rule definition above:

```
before redirect css service chgsvc1 uplink any
```

The following command sets the insertion point after the first rule definition above:

```
after redirect css service chgsvc1 uplink any
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 uplink any
```
redirect css service (for uplink, by host IP address)

Redirects subscriber sessions based on the targeted host IP address in the uplink (to the Mobile Node) direction (Content Service Steering).

</tr>
</tbody>
</table>

**Usage**

Define a rule definition when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rule definitions to be very clear and concise.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the charging service with the name chgsvc1 and a host IP address of 192.168.200.11:

```
redirect css service chgsvc1 uplink host 192.168.200.11
```

The following sets the insertion point before the rule definition above:

```
before redirect css service chgsvc1 uplink host 192.168.200.11
```

The following command sets the insertion point after the first rule definition above:

```
after redirect css service chgsvc1 uplink host 192.168.200.11
```
The following deletes the first rule definition above:

\[\text{no redirect css service chgsvc1 uplink host 192.168.200.11}\]
redirect css service (for uplink, by ICMP packets)

Redirects subscriber sessions based on the internet control message protocol packets in the uplink (to the Mobile Node) direction (Content Service Steering).

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ACL Configuration
configure > context context_name > ip access-list acl_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-acl)#
```

**Syntax**

```plaintext
redirect css service service_name [ log ] uplink icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ]
before redirect css service service_name [ log ] uplink icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ]
no redirect css service service_name [ log ] uplink icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ]
```

**after**
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.
**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```no```
Removes the rule definition which exactly matches the options specified.

```css service service_name```
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services.
`service_name` must be an alphanumeric string from 1 through 15 characters.

```uplink```
Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

```log```
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

```source_address```
The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

```source_wildcard```
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

```any```
Specifies that the rule definition applies to all packets.

```host```
Specifies that the rule definition applies to a specific host as determined by its IP address.
source_host_address
The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.

dest_address
The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

dest_wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

icmp_type
Specifies that all ICMP packets of a particular type are to be filtered. The type can be an integer value between 0 and 255.

icmp_code
Specifies that all ICMP packets of a particular code are to be filtered. The type can be an integer value between 0 and 255.

**Usage**
Define a rule definition to block ICMP packets which can be used for address resolution and possibly be a security risk. The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.
Example

The following command defines a rule definition that redirects packets to the charging service named chgsvc1, and ICMP packets in the uplink (to the Mobile Node) direction from the host with the IP address 198.162.100.25:

```
redirect css service chgsvc1 uplink icmp host 192.168.100.25
```

The following sets the insertion point before the rule definition above:

```
before redirect css service chgsvc1 uplink icmp host 192.168.100.25
```

The following command sets the insertion point after the first rule definition above:

```
after redirect css service chgsvc1 uplink icmp host 192.168.100.25
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 uplink icmp host 192.168.100.25
```
redirect css service (for uplink, by IP packets)

Redirects subscriber sessions based on the internet protocol packets in the uplink (to the Mobile Node) direction (Content Service Steering).

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > ACL Configuration
configure > context context_name > ip access-list acl_name

Entering the above command sequence results in the following prompt:

[ccontext_name]host_name(config-acl)#

Syntax

redirect css service service_name [ log ] uplink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

after redirect css service service_name [ log ] uplink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

before redirect css service service_name [ log ] uplink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

no redirect css service service_name [ log ] uplink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.
**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```plaintext
no
```

Removes the rule definition which exactly matches the options specified.

```plaintext
css service service_name
```

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services.

*service_name* must be an alphanumeric string from 1 through 15 characters.

```plaintext
uplink
```

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

```plaintext
log
```

Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

```plaintext
source_address
```

The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

```plaintext
source_wildcard
```

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

```plaintext
any
```

Specifies that the rule definition applies to all packets.

```plaintext
host
```

Specifies that the rule definition applies to a specific host as determined by its IP address.
redirect css service (for uplink, by IP packets)

source_host_address
The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.

dest_address
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

dest_wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
• Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
• One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

fragments
Indicates packet redirection is to be applied to IP packet fragments only.

Usage
Block IP packets when the source and destination are of interest.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

Example
The following command defines a rule definition that redirects packets to the charging service named chgsvcl, and uplink IP packets going to the host with the IP address 198.162.100.25, and fragmented packets for any destination are matched:

    redirect css service chgsvcl uplink ip host 198.162.100.25 any fragment

The following sets the insertion point before the rule definition above:

    before redirect css service chgsvcl uplink ip host 198.162.100.25 any fragment

The following command sets the insertion point after the first rule definition above:

    after redirect css service chgsvcl uplink ip host 198.162.100.25 any fragment

The following command deletes the first rule definition above:
no redirect css service chgsvcl uplink ip host 198.162.100.25 any fragment
**redirect css service (for uplink, by source IP address masking)**

Redirects subscriber sessions based on the IP address mask sent by the source in the uplink (to the Mobile Node) direction (Content Service Steering).

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ACL Configuration
configure > context context_name > ip access-list acl_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-acl)#
```

**Syntax**

```plaintext
redirect css service service_name [ log ] uplink source_address source_wildcard
after redirect css service service_name [ log ] uplink source_address source_wildcard
before redirect css service service_name [ log ] uplink source_address source_wildcard
no redirect css service service_name [ log ] uplink source_address source_wildcard
```

- **after**
  Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
  This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

- **before**
  Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
  This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

- **no**
  Removes the rule definition which exactly matches the options specified.

- **css service service_name**
  The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services.
  `service_name` must be an alphanumeric string from 1 through 15 characters.
**uplink**

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

**log**

Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

**source_address**

The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Usage**

Define a rule definition when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rule definitions as it does not require a rule definition for each source and destination pair.

**Important**: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*.

**Example**

The following command defines a rule definition to redirect packets to a charging service named `chgsvcl`:

```
redirect css service chgsvcl uplink 10.2.3.0 0.0.0.31
```
redirect css service (for uplink, by TCP/UDP packets)

Redirects subscriber sessions to a charging service based on the transmission control protocol/user datagram protocol packets in the uplink (to the Mobile Node) direction (Content Service Steering).

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ACL Configuration

```
configure > context context_name > ip access-list acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-acl)#
```

**Syntax**

```
redirect css service service_name [ log ] uplink { tcp | udp } { { source_address source_wildcard | any | source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }
```

```
after redirect css service service_name [ log ] uplink { tcp | udp } { { source_address source_wildcard | any | source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }
```

```
before redirect css service service_name [ log ] uplink { tcp | udp } { { source_address source_wildcard | any | source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }
```

```
no redirect css service service_name [ log ] uplink { tcp | udp } { { source_address source_wildcard | any | source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }
```

**after**

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.
**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**no**
Removes the rule definition which exactly matches the options specified.

**css service service_name**
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.  
*service_name* must be an alphanumeric string from 1 through 15 characters.

**uplink**
Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

**log**
Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

**tcp | udp**
Specifies the redirect is to be applied to IP based transmission control protocol or the user datagram protocol.  
*tcp*: Redirect applies to TPC packets.  
*udp*: Redirect applies to UDP packets.

**source_address**
The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the **source_wildcard** parameter.

**source_wildcard**
This option is used in conjunction with the **source_address** option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:  
*Zero-bits in this parameter mean that the corresponding bits configured for the **source_address** parameter must be identical.*  
*One-bits in this parameter mean that the corresponding bits configured for the **source_address** parameter must be ignored.*

**any**
Specifies that the rule definition applies to all packets.
ACL Configuration Mode Commands

*redirect css service (for uplink, by TCP/UDP packets)*

**host**
Specifications that the rule definition applies to a specific host as determined by its IP address.

**source_host_address**
The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

**dest_host_address**
The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.

**eq source_port**
Specifications a single, specific source TCP port number to be filtered. 
source_port must be configured to an integer value from 0 to 65535.

**gt source_port**
Specifies that all source TCP port numbers greater than the one specified are to be filtered. 
source_port must be configured to an integer value from 0 to 65535.

**lt source_port**
Specifies that all source TCP port numbers less than the one specified are to be filtered. 
source_port must be configured to an integer value from 0 to 65535.

**neq source_port**
Specifies that all source TCP port numbers not equal to the one specified are to be filtered. 
source_port must be configured to an integer value from 0 to 65535.

**range start_source_port end_source_port**
Specifies that all source TCP ports within a specific range are to be filtered. 
start_source_port is the initial port in the range and end_source_port is the final port in the range.  
Both start_source_port and end_source_port can be configured to an integer value from 0 to 65535.

**dest_address**
The IP address(es) to which the packet is to be sent. 
This option is used to filter all packets to a specific IP address or a group of IP addresses.  
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the destWildcard parameter.

**destWildcard**
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.
eq dest_port
Specifies a single, specific destination TCP port number to be filtered.
dest_port must be configured to an integer value from 0 to 65535.

gt dest_port
Specifies that all destination TCP port numbers greater than the one specified are to be filtered.
dest_port must be configured to an integer value from 0 to 65535.

lt dest_port
Specifies that all destination TCP port numbers less than the one specified are to be filtered.
dest_port must be configured to an integer value from 0 to 65535.

neq dest_port
Specifies that all destination TCP port numbers not equal to the one specified are to be filtered.
dest_port must be configured to an integer value from 0 to 65535.

range start_dest_port end_dest_port
Specifies that all destination TCP ports within a specific range are to be filtered.
start_dest_port is the initial port in the range and end_dest_port is the final port in the range.
Both start_dest_port and end_dest_port can be configured to an integer value from 0 to 65535.

Usage
Block IP packets when the source and destination are of interest but for only a limited set of ports.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

Example
The following command defines a rule definition that redirects packets to the charging service named chgsvc1, and UDP packets coming from any host are matched:

    redirect css service chgsvc1 uplink udp any

The following sets the insertion point before the rule definition above:

    before redirect css service chgsvc1 uplink udp any

The following command sets the insertion point after the first rule definition above:

    after redirect css service chgsvc1 uplink udp any

The following deletes the rule definition above:

    no redirect css service chgsvc1 uplink udp any
redirect nexthop (by IP address masking)

Redirects subscriber sessions based on the IP address mask sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ACL Configuration

`configure > context context_name > ip access-list acl_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-acl)#
```

**Syntax**

```plaintext
redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
source_address source_wildcard

after redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
source_address source_wildcard

before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
source_address source_wildcard

no redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
source_address source_wildcard
```

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.
ACL Configuration Mode Commands

**redirect nexthop (by IP address masking)**

- **no**
  Removes the rule which exactly matches the options specified.

- **nexthop** *nexthop_addr*
  The directly connected IP address to which the IP packets are forwarded.

- **context** *context_id*
  The context identification number of the context to which packets are redirected. At the executive mode prompt, use the show context all command to display context names and context IDs.

- **interface** *interface_name*
  The name of the logical interface to which the packets should be redirected. *interface_name* must be an alphanumeric string from 1 to 79 characters.

- **log**
  Default: packets are not logged.
  Indicates all packets which match the redirect are to be logged.

- **source_address**
  The IP address(es) from which the packet originated.
  This option is used to filter all packets from a specific IP address or a group of IP addresses.
  When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

- **source_wildcard**
  This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.
  The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**Usage**

Define a rule when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of redirect rules as it does not require a rule for each source and destination pair.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.
Important: Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the next hop host at 192.168.10.4, the context with the context ID of 23 and the source IP and wildcard of 192.168.22.0 and 0.0.0.31:

```
redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31
```

The following sets the insertion point before the rule defined above:

```
before redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31
```

The following command sets the insertion point after the first rule defined above:

```
after redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31
```

The following deletes the first rule defined above:

```
no redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31
```
redirect nexthop (any)

Redirects subscriber sessions based on any packet received. This command is also used to set the access control list insertion point.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ACL Configuration

```
configure > context context_name > ip access-list acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-acl)#
```

**Syntax**

```
redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] any
```

```
after redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] any
```

```
before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] any
```

```
no redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] any
```

**Important:**
If the options specified do not exactly match an existing rule, the insertion point does not change.

```
after
```

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

```
before
```

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

```
Important: If the options specified do not exactly match an existing rule, the insertion point does not change.
```
**ACL Configuration Mode Commands**

- **redirect nexthop** (any)

  - **no**
    - Removes the rule which exactly matches the options specified.
  
  - **nexthop** *nexthop_addr*
    - The directly connected IP address to which the IP packets are forwarded.
  
  - **context** *context_id*
    - The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.
  
  - **interface** *interface_name*
    - The name of the logical interface to which the packets should be redirected. *interface_name* must be an alphanumeric string from 1 to 79 characters.
  
  - **log**
    - Default: packets are not logged.
    - Indicates all packets which match the redirect are to be logged.
  
  - **any**
    - Indicates all packets will match the redirect regardless of source and/or destination.

**Usage**

Define a catch all rule to place at the end of the list of rules to provide explicit handling of rules which do not fit any other criteria.

- **Important:** Any rule which is added to be a catch all should also have the log option specified. The logged packets may be used to determine if the current list of rules is adequate or needs modification to ensure proper security.

- **Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

- **Important:** Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule that redirects packets to the next hop host at 192.168.10.4, the context with the context ID of 23 and any source IP:

```
redirect nexthop 192.168.10.4 context 23 any
```

The following sets the insertion point before the rule defined above:

```
before redirect nexthop 192.168.10.4 context 23 any
```

The following command sets the insertion point after the first rule defined above:
after redirect nexthop 192.168.10.4 context 23 any

The following deletes the first rule defined above:

no redirect nexthop 192.168.10.4 context 23 any
redirect nexthop (by host IP address)

Redirects subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ACL Configuration

```
configure > context context_name > ip access-list acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-acl)#
```

**Syntax**

```
redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
host source_ipv4_address
```

```
before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] host source_ipv4_address
```

```
o redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] host source_ipv4_address
```

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

```
before
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.
**ACL Configuration Mode Commands**

**redirect nexthop (by host IP address)**

<td><code>source_ipv4_address</code></td>
<td>The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.</td>
</tr>
</tbody>
</table>

**Usage**

Define a rule when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rules to be very clear and concise.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*.

**Important:** Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule that redirects packets to the next hop host at 192.168.10.4, the context with the context ID of 23 and a host IP address of 192.168.200.11:

```
redirect nexthop 192.168.10.4 context 23 host 192.168.200.11
```

The following sets the insertion point before the rule defined above:

```
before redirect nexthop 192.168.10.4 context 23 host 192.168.200.11
```

The following command sets the insertion point after the first rule defined above:
after redirect nexthop 192.168.10.4 context 23 host 192.168.200.11

The following deletes the first rule defined above:

no redirect nexthop 192.168.10.4 context 23 host 192.168.200.11
redirect nexthop (by source ICMP packets)

Redirects subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > ACL Configuration
configure > context context_name > ip access-list acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-aecl)#

Syntax

redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
icmp { source_address source_wildcard | any | host source_host_address }{ dest_address
dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

after redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
icmp { source_address source_wildcard | any | host source_host_address }{
dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
icmp { source_address source_wildcard | any | host source_host_address }{
dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

no redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
icmp { source_address source_wildcard | any | host source_host_address }{ dest_address
dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

Important:
If the options specified do not exactly match an existing rule, the insertion point does not change.

before
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

---

**no**

Removes the rule which exactly matches the options specified.

---

**nexthop nexthop_addr**

The directly connected IP address to which the IP packets are forwarded.

---

**context context_id**

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

---

**interface interface_name**

The name of the logical interface to which the packets should be redirected. `interface_name` must be an alphanumeric string from 1 through 79 characters.

---

**log**

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

---

**source_address**

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

---

**source_wildcard**

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

---

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

---

**any**

Specifies that the rule applies to all packets.

---

**host**

Specifies that the rule applies to a specific host as determined by its IP address.
source_host_address

The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.

dest_address

The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

dest_wildcard

This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

icmp_type

Specifies that all ICMP packets of a particular type are to be filtered. The type can be an integer value between 0 and 255.

icmp_code

Specifies that all ICMP packets of a particular code are to be filtered. The type can be an integer value between 0 and 255.

Usage

Define a rule to block ICMP packets which can be used for address resolution and possible be a security risk. The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

Important: Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.
Example

The following command defines a rule that redirects packets to the next hop host at 192.168.10.4, the context with the context ID of 23, and ICMP packets coming from the host with the IP address 198.162.100.25:

```
redirect nexthop 192.168.10.4 context 23 icmp host 192.168.100.25
```

The following sets the insertion point before the rule defined above:

```
before redirect nexthop 192.168.10.4 context 23 icmp host 192.168.100.25
```

The following command sets the insertion point after the first rule defined above:

```
after redirect nexthop 192.168.10.4 context 23 icmp host 192.168.100.25
```

The following deletes the first rule defined above:

```
no redirect nexthop 192.168.10.4 context 23 icmp host 192.168.100.25
```
redirect nexthop (by IP packets)

Redirects subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

</thead>
</table>

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

---

**no**
Removes the rule which exactly matches the options specified.

**nexthop** *nexthop_addr*
The directly connected IP address to which the IP packets are forwarded.

**context** *context_id*
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

**interface** *interface_name*
The name of the logical interface to which the packets should be redirected. *interface_name* must be an alphanumeric string from 1 through 79 characters.

**log**
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**source_address**
The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

**source_wildcard**
This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**any**
Specifies that the rule applies to all packets.

**host**
Specifies that the rule applies to a specific host as determined by its IP address.
**source_host_address**
The IP address of the source host to filter against expressed in IPv4 dotted-decimal notation.

**dest_host_address**
The IP address of the destination host to filter against expressed in IPv4 dotted-decimal notation.

**dest_address**
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.

**dest_wildcard**
This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**fragment**
Indicates packet redirection is to be applied to IP packet fragments only.

**protocol** **num**
Indicates that the packet filtering is to be applied to a specific protocol number.
**num** can be an integer ranging from 0 to 255.

**Usage**
Block IP packets when the source and destination are of interest.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Important:** Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**
The following command defines a rule that redirects packets to the next hop host at 192.168.10.4, the context with the context ID of 23, and IP packets coming from the host with the IP address 198.162.100.25, and fragmented packets for any destination are matched:

```
redirect nexthop 192.168.10.4 context 23 ip host 192.168.100.25 any fragment
```

The following sets the insertion point before the rule defined above:

```
before redirect nexthop 192.168.10.4 context 23 ip host 192.168.100.25 any fragment
```

The following sets the insertion point after the first rule defined above:

```
after redirect nexthop 192.168.10.4 context 23 ip host 192.168.100.25 any fragment
```

The following deletes the first rule defined above:

```
no redirect nexthop 192.168.10.4 context 23 ip host 192.168.100.25 any fragment
```
redirect nexthop (by TCP/UDP packets)

Redirects subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

---

after

 Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

---

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.
**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.

**nexthop nexthop_addr**
The directly connected IP address to which the IP packets are forwarded.

**context context_id**
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

**interface interface_name**
The name of the logical interface to which the packets should be redirected. `interface_name` must be an alphanumeric string from 1 through 79 characters.

**log**
Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

**tcp | udp**
Specifies the redirect is to be applied to IP based transmission control protocol or the user datagram protocol.
- `tcp`: Redirect applies to TCP packets.
- `udp`: Redirect applies to UDP packets.

**source_address**
The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source wildcard` parameter.

**source wildcard**
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.
**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

```plaintext
any
Specifies that the rule applies to all packets.

host
Specifies that the rule applies to a specific host as determined by its IP address.

dest_wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
```
Redirect next hop (by TCP/UDP packets)

- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

- **eq dest_port**
  
  Specifies a single, specific destination TCP port number to be filtered. dest_port must be an integer from 0 through 65535.

- **gt dest_port**
  
  Specifies that all destination TCP port numbers greater than the one specified are to be filtered. dest_port must be an integer from 0 through 65535.

- **lt dest_port**
  
  Specifies that all destination TCP port numbers less than the one specified are to be filtered. dest_port must be an integer from 0 through 65535.

- **neq dest_port**
  
  Specifies that all destination TCP port numbers not equal to the one specified are to be filtered. dest_port must be an integer from 0 through 65535.

**Usage**

Block IP packets when the source and destination are of interest but for only a limited set of ports.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the **Engineering Rules** appendix in the **System Administration Guide**.

**Important:** Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule that redirects packets to the next hop host at 192.168.10.4, the context with the context ID of 23, and UDP packets coming from any host are matched:

```
redirect nexthop 192.168.10.4 context 23 udp any
```

The following sets the insertion point before the rule defined above:

```
before redirect nexthop 192.168.10.4 context 23 udp any
```

The following command sets the insertion point after the first rule defined above:

```
after redirect nexthop 192.168.10.4 context 23 udp any
```

The following deletes the first rule defined above:
no redirect nexthop 192.168.10.4 context 23 udp any
Chapter 6
ACS Bandwidth Policy Configuration Mode Commands

The ACS Bandwidth Policy Configuration Mode is used to create and manage Active Charging Service (ACS) Bandwidth Policies.

Mode

Exec > ACS Configuration > Bandwidth Policy Configuration

active-charging service service_name > bandwidth-policy policy_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-bandwidth-policy)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
**flow limit-for-bandwidth**

This command allows you to configure the flow limit-for-bandwidth parameter for the current bandwidth policy.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Bandwidth Policy Configuration

```
active-charging service service_name > bandwidth-policy policy_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-bandwidth-policy)#
```

**Syntax**

```
flow limit-for-bandwidth id bandwidth_id group-id group_id
```

```
no flow limit-for-bandwidth id bandwidth_id
```

- **id bandwidth_id**
  Specifies ID for the current bandwidth policy.
  `bandwidth_id` must be an integer from 1 through 65535.

- **group-id group_id**
  Specifies group ID for the current bandwidth policy.
  `group_id` must be an integer from 1 through 65535.

**Usage**

Use this command to configure the flow limit-for-bandwidth configuration for a bandwidth policy.

**Example**

The following command configures the Flow Limit-for-Bandwidth configuration with bandwidth policy ID `test123` and group ID `123`:

```
flow limit-for-bandwidth id test123 group-id 123
```
group-id

This command allows you to configure the group ID for the current bandwidth policy.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Bandwidth Policy Configuration

classify active-charging service service_name > bandwidth-policy policy_name

Entering the above command sequence results in the following prompt:

[local] host_name(config-bandwidth-policy)#

Syntax

```
group-id group_id direction { downlink | uplink } peak-data-rate peak_data_rate peak-burst-size peak_burst_size violate-action { discard | lower-ip-precedence } [ committed-data-rate committed_data_rate committed-burst-size committed_burst_size [ exceed-action { discard | lower-ip-precedence } ] ]

{ default | no } group-id group_id direction { downlink | uplink }
```

```
default

Configures this command with default settings for the specified group ID.
```

```
no

If previously configured, removes the specified group ID configuration from the current bandwidth policy.
```

```
group_id

Specifies the group ID.
group_id must be an integer from 1 through 65535.
```

```
direction { downlink | uplink }

Specifies the direction for which bandwidth will be controlled.
```

```
peak-data-rate peak_data_rate

Specifies the peak data rate, in bits per second.
peak_data_rate must be an integer from 1 through 4294967295.
Default: 0
```

```
peak-burst-size peak_burst_size

Specifies the peak burst size, in bytes.
peak_burst_size must be an integer from 1 through 4294967295.
Default: 0
```
violate-action { discard | lower-ip-precedence }
Specifies the action to be taken if Peak Data Rate is surpassed.
  • discard: Specifies to discard the packet
  • lower-ip-precedence: Specifies to lower IP precedence of the packet

committed-data-rate  committed_data_rate
Specifies the committed Data Rate, in bits per second. This can also be used to specify the Guaranteed Bit Rate (GBR) for Network Controlled QoS (NCQoS) without exceed-action.
committed_data_rate must be an integer from 1 through 4294967295.
Default: 0

committed-burst-size  committed_burst_size
Specifies the committed burst size, in bytes.
committed_burst_size must be an integer from 1 through 4294967295.
Default: 0

exceed-action { discard | lower-ip-precedence }
Specifies the action to be taken if Committed Data Rate is surpassed.
  • discard: Specifies to discard the packet.
  • lower-ip-precedence: Specifies to lower IP precedence of the packet.

Usage
Use this command to configure the Group ID for an bandwidth policy.

Example
The following command configures the group ID 111 to control bandwidth in the downlink direction specifying peak data rate of 10000 bits per second and peak burst size of 10000 bytes while specifying the action to be taken on violation as discard:

group-id 111 direction downlink peak-data-rate 10000 peak-burst-size 10000 violate-action discard
Chapter 7
ACS Charging Action Configuration Mode Commands

The ACS Charging Action Configuration Mode is used to configure Active Charging Service (ACS) charging actions.

**Mode**

Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
allocation-retention-priority

This command allows you to configure the Allocation Retention Priority (ARP).

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Syntax**

```
allocation-retention-priority priority [ pci pci_value | pvi pvi_value ]
```

```
no allocation-retention-priority
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>If previously configured, disables ARP configuration in the current charging action.</td>
</tr>
<tr>
<td>priority</td>
<td>priority must be an integer from 1 through 15.</td>
</tr>
<tr>
<td>pci pci_value</td>
<td>Specifies the Pre-emption Capability Indicator (PCI). pci_value must be integer 0 or 1.</td>
</tr>
<tr>
<td>pvi pvi_value</td>
<td>Specifies the Pre-emption Vulnerability Indicator (PVI). pvi_value must be integer 0 or 1.</td>
</tr>
</tbody>
</table>

**Important:** If not explicitly enabled, then the default value of 1 will hold true.

```
pvi pvi_value
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pvi pvi_value</td>
<td>Specifies the Pre-emption Vulnerability Indicator (PVI). pvi_value must be integer 0 or 1.</td>
</tr>
</tbody>
</table>

**Important:** If not explicitly enabled, then the default value of 0 will hold true.

**Usage**

This command configures the ARP, which indicates the priority of allocation and retention of the service data flow. The ARP resolves conflicts in demand for network resources. At the time of resource crunch, this parameter prioritizes allocation of resources during bearer establishment and modification. In a congestion...
situation, a lower ARP flow may be dropped to free up capacity. Once a service flow is successfully established, this parameter plays no role in quality of service (QoS) experienced by the flow.

**Example**

The following command sets the ARP to 10:

```plaintext
allocation-retention-priority 10
```
**billing-action**

This command allows you to configure the billing action for packets that match specific rule definitions (ruledefs).

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Syntax**

In StarOS 12.2 and later releases:

```
billing-action { create-edrs { charging-edr charging_edr_format_name | reporting-edr reporting_edr_format_name } + [ wait-until-flow-ends ] | egcdr | exclude-from-udrs | radius | rf } +

no billing-action [ create-edrs | egcdr | exclude-from-udrs | radius | rf ] +
```

In StarOS 12.1 and earlier releases:

```
billing-action { edr edr_format_name [ wait-until-flow-ends ] | egcdr | exclude-from-udrs | radius | rf } +

no billing-action [ edr | egcdr | exclude-from-udrs | radius | rf ] +
```

**Important:**
If previously configured, disables the specified configuration in the current charging action.

```
edr edr_format_name [ wait-until-flow-ends ]
```

**Important:**
This option is available only in 12.1 and earlier releases. In 12.2 and later releases, it is deprecated and is replaced by the `create-edrs charging-edr` option.

Enables EDR billing for packets matching this charging action.

`edr_format_name` must be the name of an existing EDR format, and must be an alphanumeric string of 1 through 63 characters.

**Important:**
If the EDR format name specified here is not configured in the EDR Format Configuration Mode, or has been deleted, the system accepts it without applying any EDR format for the billing action in this ACS service.
If this option is configured, the system generates an EDR immediately when a packet is received and it matches a ruledef that is associated with this charging action. Other events configured for flow end-condition, flow action, termination, and/or session control also create the triggers for EDR generation.

**wait-until-flow-ends**: By default, the EDR is generated immediately after a ruledef hit results in this charging action. When this keyword is specified, no EDR is generated on a ruledef hit. When the flow ends, an attempt is made to generate an EDR with the format specified.

```
create-edrs { charging-edr charging_edr_format_name | reporting-edr reporting_edr_format_name } + [ wait-until-flow-ends ]
```

**Important**: This option is available only in 12.2 and later releases.

Enables EDR billing for packets matching this charging action.

- **charging-edr charging_edr_format_name**: Specifies to generate charging EDR. `charging_edr_format_name` must be the name of a charging EDR format, and must be an alphanumeric string of 1 through 63 characters.

- **reporting-edr reporting_edr_format_name**: Specifies to generate reporting EDR. `reporting_edr_format_name` must be the name of a reporting EDR format, and must be an alphanumeric string of 1 through 63 characters.

If the above options are configured, the system generates an EDR immediately when a packet is received and it matches a ruledef that is associated with this charging action. Other events configured for flow end-condition, flow action, termination, and/or session control also creates the triggers for EDR generation.

- **wait-until-flow-ends**: By default, the EDR is generated immediately after a ruledef hit results in this charging action. When this keyword is specified, no EDR is generated on a ruledef hit. When the flow ends, an attempt is made to generate an EDR with the format specified.

**egcdr**

Enables eG-CDR billing for packets matching this charging action.

If this option is configured, the system generates an eG-CDR when the subscriber session ends or an interim trigger condition occurs. The interim triggers are configurable in the ACS Rulebase Configuration Mode. In addition, whenever there is an SGSN-to-SGSN handoff the system treats that as a trigger.

To generate an eG-CDR the `accounting-mode` command in the APN Configuration Mode must be configured with the “none” option.

The format of enhanced G-CDRs is controlled by the `inspector` CLI command in the Context Configuration Mode.

**exclude-from-udrs**

By default, statistics are accumulated on a per content ID basis for possible inclusion in UDRs. The `exclude-from-udrs` keyword causes the system to not include the packet’s statistics in UDRs.

When this option is disabled, (the default setting) UDRs will be generated based on the UDR format specified in the rulebase.

Default: Disabled.

**radius**

Enables billing action as RADIUS Charging Data Records (CDRs) for packets matching this charging action, and the data packet statistics will be included in the postpaid RADIUS accounting.

Default: Disabled.
rf

Enables Rf accounting. Rf accounting is applicable only for dynamic and predefined rules that are marked for it. Dynamic rules have a field offline-enabled to indicate this. To mark a predefined rule as offline-enabled, use this keyword and the `billing-records` CLI in the ACS Rulebase Configuration Mode.

Usage

Use this command to enable an EDR, eG-CDR and/or RADIUS CDR type of billing for content matching this charging action.

Example

In 12.1 and earlier releases, the following command enables the EDR billing type with EDR format `chargel_format`:

```
billing-action edr chargel_format
```

In 12.2 and later releases, the following command is applied to both charging and reporting EDRs since the trigger for both the EDRs is the same:

```
billing-action create-edrs charging-edr charging_edrformat1 reporting-edr reporting_edrformat1 wait-until-flow-ends
```
**cca charging credit**

This command allows you to enable/disable Credit Control Application (CCA) and configure the RADIUS/Diameter prepaid charging behavior.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action) #
```

**Syntax**

```
cca charging credit [ rating-group coupon_id ] [ preemptively-request ]

{ default | no } cca charging
```

- **no**
  
  If previously configured, disables RADIUS/Diameter Prepaid Credit Control Charging in the current charging action.

- **default**
  
  Disables RADIUS/Diameter Prepaid Credit Control Charging.

- **credit**
  
  Specifies RADIUS/Diameter Prepaid Credit Control Charging Credit behavior.

- **preemptively-request**
  
  Specifies RADIUS/Diameter prepaid credit preemptively requested charging credit behavior. If this option is used, a quota is requested for the specific type of content during session initialization.

- **rating-group coupon_id**
  
  Specifies the coupon ID used in prepaid charging as rating-group which maps to the coupon ID for prepaid customer.

  `coupon_id` must be an integer from 0 through 65535.

  This option also assigns different content-types for the same charging action depending upon whether or not prepaid is enabled.

**Important:** This rating-group overrides the content ID, if present in the same charging-action for the prepaid customer in Diameter Credit Control Application (DCCA). But only the content IDs will be used in eG-CDRs irrespective of the presence of rating-group in that charging action.
Usage

Use this command to configure RADIUS/Diameter Prepaid Credit Control Charging behavior. This command selects reservation based credit control. A CCR-Initial is used to reserve quota upon the first traffic, then a series of CCR-updates are issued as the traffic proceeds and quota dwindles. A CCR-Terminate is issued at the end of the session or at the end of the quota-hold-time.

Example

The following is an example of this command:

    cca charging credit
charge-units

This command allows you to configure the charge units for RADIUS/DCCA charging calculation.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Charging Action Configuration

active-charging service service_name > charging-action charging_action_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-charging-action)#

Syntax

charge-units units

{ default | no } charge-units

---

default

Configures this command with its default setting.
Default: 0; disables the counter, same as no charge-units

---

no

If previously configured, disables the charge-units configuration in the current charging action.

---

units

Specifies the service-specific fixed unit counter per content ID for RADIUS/DCCA charging.
units is the value set for charging unit, and must be an integer from 1 through 65535.

Usage

This command configures the unit amount counters for charging calculation on per content ID basis for different protocols and packets regardless of packet direction (uplink or downlink).

Important: For more information on content ID, refer to the if-protocol command in the ACS Ruledef Configuration Mode Commands chapter.

Example

The following command sets the charging unit to 1024:

charge-units 1024
charge-volume

This command allows you to configure how the volume amount counter for eG-CDRs, UDRs, and DCCA charging are calculated.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Charging Action Configuration

active-charging service service_name > charging-action charging_action_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-charging-action)#

Syntax

charge-volume { { dns | ftp-control | ftp-data | http | icmp | imap | ip | mms | pop3 | pptp | rtcp | rtp | rtsp | sdp | secure-http | sip | smtp | tcp | tftp | udp | wsp | wtp } { bytes | packet-length | packets } [ downlink | uplink ] | constant fixed_value }

{ default | no } charge-volume

default

Configures this command with its default setting.
Default: charge-volume ip bytes

no

If previously configured, deletes the charge-volume configuration in the current charging action.

{ dns | ftp-control | ftp-data | http | icmp | imap | ip | mms | pop3 | pptp | rtcp | rtp | rtsp | sdp | secure-http | sip | smtp | tcp | tftp | udp | wsp | wtp }

Specifies the charge volume method for the specific rule definition.

- dns: Charge volume for DNS
- ftp-control: Charge volume for FTP-Control
- ftp-data: Charge volume for FTP-Data
- http: Charge volume for HTTP
- icmp: Charge volume for ICMP
- imap: Charge volume for Internet Message Access Protocol (IMAP)
- ip: Charge volume for IP
- mms: Charge volume for MMS
- pop3: Charge volume for POP3
- pptp: Charge volume for PPTP
• rtcp: Charge volume for RTCP
• rtp: Charge volume for RTP
• rtsp: Charge volume for RTSP
• sdp: Charge volume for SDP
• secure-http: Charge volume for secure-https
• sip: Charge volume for SIP
• smtp: Charge volume for SMTP
• tcp: Charge volume for TCP
• tftp: Charge volume for TFTP
• udp: Charge volume for UDP
• wsp: Charge volume for WSP
• wtp: Charge volume for WTP

bytes
Sets charge volume for bytes.

packet-length
Sets charge volume for packet length.

packets
Sets charge volume for packets.

constant fixed_value
This sets the fixed increment value for charging.
fixed_value is the value set for charging, and must be an integer from 0 through 65535.
If constant 3 is configured for every invocation of this Charging Action, the system adds 3 to the
downlink/uplink volume counter, depending on the direction of packet.

Usage
This command provides the method for charging volume calculation for different protocols and packets.
For information on supported protocols see the ACS Ruledef Configuration Mode Commands chapter.
If charge-volume rtp packets is configured, system computes volume amounts for different options for
RTP as follows:

<table>
<thead>
<tr>
<th>Volume</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Volume amount</td>
<td>Total (downlink and uplink) RTP packets</td>
</tr>
<tr>
<td>Volume amount uplink</td>
<td>Uplink RTP packets</td>
</tr>
<tr>
<td>Volume amount downlink</td>
<td>Downlink RTP packets</td>
</tr>
<tr>
<td>Volume amount uplink packets</td>
<td>Uplink RTP packets</td>
</tr>
<tr>
<td>Volume amount downlink packets</td>
<td>Downlink RTP packets</td>
</tr>
<tr>
<td>Volume amount uplink bytes</td>
<td>Uplink RTP bytes</td>
</tr>
</tbody>
</table>
 ACS Charging Action Configuration Mode Commands

<table>
<thead>
<tr>
<th>Volume</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Volume amount downlink bytes</td>
<td>Downlink RTP bytes</td>
</tr>
</tbody>
</table>

**Important:** Whenever service counts volume, it counts all packets that the relevant analyzers accepted.

**Important:** If a TCP packet is routed to the HTTP analyzer but there is no HTTP payload, then the TCP statistics will be updated but the HTTP statistics will not be updated (except for the “packets ignored by the HTTP analyzer” statistic).

**Example**

Following command sets the charging volume of downlink packets for RTP:

```
charge-volume rtp packets downlink
```
content-filtering processing server-group

This command allows you to enable/disable Category-based Content Filtering.

Product
CF

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Charging Action Configuration

active-charging service service_name > charging-action charging_action_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-charging-action)#

Syntax

content-filtering processing server-group

{ default | no } content-filtering processing

default
Configures this command with its default setting.
Default: Content filtering configured for the rulebase is attempted

no
Specifies to bypass content filtering.
This configuration should only be specified for charging actions that are performed when known safe sites are being accessed.

Usage
Use this command to enable or disable Category-based Content Filtering in the charging action.
This command works as second-level filter to process the HTTP/WAP GET request with Internet Content Adaptation Protocol (ICAP) after ruledef matching. The first-level filtering is in the rulebase configuration.
This CLI command is only effective when the content-filtering mode server-group command is configured in the rulebase.

Example
The following command enables content filtering in the current charging action:

content-filtering processing server-group
**content-id**

This command allows you to specify the content ID to use in the generated billing records, as well as the AVP used by the Credit Control Application, such as the “Rating-Group” AVP for use by the Diameter Credit Control Application (DCCA).

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Syntax**

```
content-id content_id
no content-id
```

**Usage**

This command specifies an optional content ID to use in the generated billing records. This identifier assists the carrier’s billing post processing and also used by credit-control system to use independent quotas for different value of `content-id`.

If the specified ruledef uses the `if-protocol` command to select a value for content ID, then the `content_id` specified through this command is not used for billing record generation.

**Important:** For more information on `content-id`, refer to the `if-protocol` command in the *ACS Ruledef Configuration Mode Commands* chapter.

**Example**

The following command sets the content ID in the current charging action to 23:

```
content-id 23
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

end

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
flow action

This command allows you to specify the action to take on packets that match rule definitions.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Charging Action Configuration

active-charging service service_name > charging-action charging_action_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-charging-action)#

Syntax

In StarOS 12.2 and later releases:

flow action { conditional user-agent end-token end_token_name | discard [ downlink | uplink ] | random-drop interval interval_start to interval_end pkts-to-drop packet_min to packet_max | readdress [ [ server ipv4_address/ipv6_address [ discard-on-failure ] [ dns-proxy-bypass ] ] [ port port_number [ discard-on-failure ] [ dns-proxy-bypass ] ] [ discarding on-failure ] ] | redirect-ocs-url | redirect-url redirect_url [ [ encryption { blowfish128 | blowfish64 }] | { { aes128 | aes256 } [salt] } ] [ encrypted ] key key ] [ clear-quota-retry-timer ] [ first-request-only [ post-redirect { allow | discard | terminate } ] ] | rulebase-change rulebase_name | terminate-flow | terminate-session }

no flow action

In StarOS 12.1 and earlier releases:

flow action { conditional user-agent end-token end_token_name | discard [ downlink | uplink ] | random-drop interval interval_start to interval_end pkts-to-drop packet_min to packet_max | readdress [ server ipv4_address/ipv6_address ] [ port port_number ] | terminate-flow | terminate-session }

no flow action

no

If previously configured, deletes the flow action configuration in the current charging action.

conditional user-agent end-token end_token_name

Specifies to conditionally redirect the HTTP packets matched to a configured user-agent to a specified URL. The user agent is configured using the redirect user-agent command in the ACS Configuration Mode. end_token_name must be an alphanumeric string of 1 through 32 characters, and is configured with this command to end the redirection condition.
discard [ downlink | uplink ]
Specifications to discard the specified packets.

- **downlink**: Downlink packets
- **uplink**: Uplink packets

If **downlink** or **uplink** keyword is not specified, both downlink and uplink packets will be discarded.

random-drop interval interval_start to interval_end pkts-to-drop packet_min to packet_max
Specifications to drop a group of consecutive packets (**pkts-to-drop**) to be dropped in the specified time interval (**random-drop interval**). This will cause degradation in user experience. P2P VoIP would need more than one packet to be dropped, since that type of protocol is geared to handle occasional single packet drops.

- **random-drop interval interval_start to interval_end**: Specifies the random drop interval, in seconds, at which the voice packets will be dropped.
  - **interval_start** and **interval_end** must be integers from 1 through 999.

- **pkts-to-drop packet_min to packet_max**: Specifies the number of voice packets to be dropped at a time in a flow when the packets have to be dropped.
  - **packet_min** and **packet_max** must be integers from 1 through 100.

readdress [ [ server ipv4_address/ipv6_address [ discard-on-failure ] [ dns-proxy-bypass ] ] [ port port_number [ discard-on-failure ] [ dns-proxy-bypass ] ] | server-list server_list_name [ hierarchy ] [ round-robin ] [ discard-on-failure ] [ dns-proxy-bypass ] ]
Specifications to readdress the location of the uplink packets for charging action.

- **server ipv4_address/Ipv6**: Specifies the re-address server’s IPv4/IPv6 address.
- **port port_number**: Specifies the re-address server’s port number.
  - **port_number** must be an integer from 1 through 65535.

  **Important**: You can optionally keep the original destination address and just change the destination TCP/UDP port number.

- **server-list server_list_name**

  **Important**: This option is available only in StarOS 14.1 and later releases. This keyword is license dependent. For more information please contact your Cisco account representative.

  Specifies to readdress the packet flow to the DNS servers configured under the server list.

  For more information about configuring the server list, see the **ACS Readdress Server List Configuration Mode** chapter.

- **discard-on-failure**

  **Important**: This option is available only in StarOS 14.0 and later releases.
Specifies to discard the packets if readdressing fails due to duplicate key. If this keyword is not configured, no action is taken and the packets are allowed to pass.

If already configured, to revert the behavior, configure the `flow action readdress` command again without the `discard-on-failure` keyword.

**dns-proxy-bypass**

---

**Important:** This option is available only in StarOS 12.3 and later releases.

Specifies the DNS packets to bypass interception at the session manager when readdressing for flow occurs, and go through ECS-based DNS redirection. If this keyword is not configured, DNS redirection from ECS is disabled.

**redirect-ocs-url**

---

**Important:** This option is available only in StarOS 12.3 and later releases.

Specifies to redirect to the URL provided by OCS only for post-processing dynamic rules.

```
redirect-url redirect_url [ { encryption { blowfish128 | blowfish64 } | { aes128 | aes256 } [salt] } } [ encrypted ] key key ] [ clear-quota-retry-timer ] [ first-request-only { post-redirect { allow | discard | terminate } } ] ] ]
```

Specifies to return a redirect response to the subscriber, and terminate the TCP connections (to the subscriber and server). The subscriber's Web browser should automatically send the original HTTP packet to the specified URL. Redirection is only possible for certain types of HTTP packets (for example, GET requests), which typically are only sent in the uplink direction. If the flow is not HTTP, the `redirect-url` option is ignored, that is the packet is forwarded normally, except for SIP. For SIP, a Contact header with the redirect information is inserted.

The redirect-url consists of the redirect url and may additionally include one or more dynamic fields. Earlier, the dynamic fields could be encrypted using 128 and 256 bit blowfish encryption. The new functionality provides the additional AES-CBC encryption of the dynamic fields as well.

**redirect-url** specifies the redirect URL. `redirect-url` must be an alphanumeric string of 1 through 511 characters. It may include one or more dynamic fields (up to 16 may be specified). For example, `http://search.com/subtarg=#HTTP.URL#`.

Dynamic fields must be enclosed in “#” (hash).

Up to 16 dynamic fields out of the following 23 are allowed:

- `#BEARER.CALLED-STATION-ID#`
- `#BEARER.CALLING-STATION-ID#`
- `#BEARER.NAS-IP-ADDRESS#`
- `#BEARER.USER-NAME#`
- `#BEARER.ACCT-SESSION-ID#`
- `#BEARER.CORRELATION-ID#`
- `#BEARER.RULEBASE#`
- `#BEARER.SERVED-BSA-ADDR#`
- `#BEARERSERVICE-NAME#`
- #BEARER.SUBSCRIBER-ID#
- #BEARER.MSISDN#
- #HTTP.URL#
- #HTTP.URI#
- #HTTP.HOST#
- #RTSP.URI#
- #WSP.URL#
- #CONTENT-ID-LABEL#
- #CONTENT-ID-LABEL-CAUSING-REDIRECTION#
- #BEARER.HWID#
- #BEARER.IMSI#
- #BEARER.IMEI#
- #BEARER.ESN#
- #BEARER.MEID#

Concatenated fields separated by ; (semi colon) can also be inserted. For example, #BEARER.IMSI;BEARER.IMEI#

```plaintext
*encryption { blowfish128 | blowfish64 } | { aes128 | aes256 } [salt] |
```

```
encrypted ] key key
```

**Important:** This option is available only in StarOS 12.2 and later releases.

- **encryption**: Specifies to enable encryption for dynamic fields of the redirect URL.
  - **blowfish128**: Specifies to use Blowfish encryption with 128 bit key for encrypting the dynamic fields.
  - **blowfish64**: Specifies to use Blowfish encryption with 64 bit key for encrypting the dynamic fields.
  - **aes128**: Specifies to use AES-CBC encryption with 128 bit key for encrypting the dynamic fields.
  - **aes256**: Specifies to use AES-CBC encryption with 256 bit key for encrypting the dynamic fields.
  - **salt**: Specifies to use salt with AES-CBC encryptions of the dynamic fields.
- **encrypted**: Specifies to encrypt the key.
- **key key**: Specifies the key to use for encryption of dynamic fields.
  - ```plaintext
  key must be an alphanumeric string of 1 through 523 characters.
  ```

Note that encryption is supported only for the following fields:
- #BEARER.CALLING-STATIO-N-ID#
- #BEARER.MSISDN#
- #BEARER.IMEI#
- #BEARER.MEID#
Also, concatenated fields having any of the above will be encrypted. %3furl= can be used as a delimiter between URL. As in http://search.com/subtarg/%3furl=#HTTP.URL# format.

- **clear-quota-retry-timer**: Specifies to reset Credit Control Application (CCA) Quota Retry Timer upon redirection.

- **first-request-only [ post-redirect { allow | discard | terminate } ]**

  **Important**: This option is available only in StarOS 12.3 and later releases.

- **first-request-only**: Specifies the url-redirection to be performed only once per session after the first web traffic has been detected.

- **post-redirect**: Specifies the action to be taken on subsequent flow packets that invoke this charging action after the first url-redirection has been performed for that session.

  The following are the different actions allowed on the flow packets:
  - **allow**: allows the packets subsequent to the first url-redirection to flow
  - **discard**: discards the packets subsequent to the first url-redirection
  - **terminate**: terminates the flow of packets on receiving packets subsequent to the first url-redirection

To disable this option if configured earlier, reuse the same flow action redirect-url redirect_url command without the first-request-only keyword.

  **Important**: Disabling the first-request-only keyword will not affect the existing subscriber calls.

- **rulebase-change rulebase_name**

  Specifies the rulebase to change to when the charging action is applied. The new rulebase will be applied to the next packet on the call, and applied only to the current PDN.

- **terminate-flow**

  Specifies to terminate the flow.
  Terminates the TCP connection gracefully between the subscriber and external server and sends a TCP FIN to the subscriber and a TCP RST to the server. If the flow does not use TCP, this option simply discard the packets. This option is applicable only for flows that use TCP.

- **terminate-session**

  Specifies to terminate the session.
  When a rule pointing to a charging action configured with the terminate-session keyword is hit, then the corresponding session will be terminated.
**Usage**

Use this command to specify the action to take on packets, for example to discard, terminate, or redirect. When a readdress server is configured for a charging action, the `show configuration` command will display the readdress related configuration only if server address is configured. The `show configuration verbose` command will display the readdress sever if configured, else will display “no flow action”.

The redirect-url option can be used to redirect SIP requests as well. The following is a sample configuration:

```plaintext
configure

active-charging service s1

charging-action ca_sip_redir

content-id 10

flow action redirect-url sip:test@sip.org

exit

ruledef sip_req

sip request packet = TRUE

exit

rulebase plan1

action priority 08 ruledef sip_req charging-action ca_sip_redir

/* other rules, routing rules for sip, etc */

derulebase
```

This would mean any SIP request that hits the `sip_req` ruledef, would get redirected to the url given in `ca_sip_redir`. This involves creating a redirection packet with the following response line and “Contact” header in the response.

```
SIP/2.0 302 Moved Temporarily
302 Moved Temporarily
```

Most of the header fields are copied directly from the request, so that the mandatory SIP headers are present. If content-length header was seen in the original message, it is replaced in the reply with “Content-Length: 0”.

**Example**

The following command sets the flow action to terminate:

```plaintext
flow-action terminate-flow
```

The following command resets quota retry timer upon redirection of flow to HTTP URL `http://search.com/?url=#http://msn.com#`:

```plaintext
flow action redirect-url http://search.com/?url=#http://msn.com# clear-quota-retry-timer
```
**flow idle-timeout**

This command allows you to configure the maximum duration a flow can remain idle after which the system automatically terminates the flow.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Syntax**

```
flow idle-timeout { idle_timeout | flow-mapping flow_timeout }

{ default | no } flow idle-timeout [ flow-mapping ]
```

- **no**
  Disables the idle-timeout configuration; sets the idle-timeout to 0 seconds.

- **default**
  Configures this command with its default setting.
  Default: 300 seconds

- **idle-timeout idle_timeout**
  Specifies the maximum duration, in seconds, a flow can remain idle.
  `idle_timeout` must be an integer from 0 through 86400.

- **flow-mapping flow_timeout**
  Specifies the maximum duration of flow-mapping timeout, in seconds.
  `flow_timeout` must be an integer from 0 through 86400.

**Usage**

Use this command to configure the maximum duration a flow can remain idle after which the system automatically terminates the flow.

**Example**

The following command configures the idle-timeout setting to 400 seconds:

```
flow idle-timeout 400
```
flow limit-for-bandwidth

For Session Control functionality this command allows you to enable/disable bandwidth limiting and configure the uplink and downlink bandwidth limits for subscriber.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Syntax**

```
flow limit-for-bandwidth { { direction { downlink | uplink } peak-data-rate bps peak-
burst-size bytes violate-action { discard | lower-ip-precedence } [ committed-data-rate
bps committed-burst-size bytes [ exceed-action { discard | lower-ip-precedence } ] ] } } |
{ default | no } flow limit-for-bandwidth { direction { downlink | uplink } | id }
```

### no

If previously configured, disables bandwidth control traffic policing for the specified direction for the current subscriber.

### default

Configures this command with its default setting.

### direction { downlink | uplink }

Specifies the direction of flow to apply bandwidth limit:
- **downlink**: Flow of data towards subscriber.
- **uplink**: Flow of data from subscriber.

### peak-data-rate bps

Specifies the peak data-rate for the subscriber, in bps (bits per second).
- `bps` must be an integer from 1 through 4294967295.
- Default: 256000

### peak burst-size bytes

The peak burst size allowed, in bytes.
- `bytes` must be an integer from 1 through 4294967295.
- Default: 3000
Important: It is recommended that this parameter be configured to at least the greater of the following two values: 1) three times greater than packet MTU for the subscriber connection, OR 2) three seconds worth of token accumulation within the “bucket” for the configured peak-data-rate.

```
violate-action { discard | lower-ip-precedence }
```

Specifies the action to take on packets that exceed both the committed-data-rate and the peak-data-rate. The following actions are supported:

- **discard**: Discard the packet
- **lower-ip-precedence**: Transmit the packet after lowering the IP precedence

Default: discard

```
committed-data-rate bps
```

The committed data rate (guaranteed-data-rate) in bits per second (bps). In releases prior to 15.0, the committed-data-rate based policing was not effected for non-GBR bearers even if it is configured in Charging Action configuration mode. In 15.0 and later releases, the committed-data-rate policing can be implemented for both GBR bearers and non-GBR bearers. If the customer does not want to implement the committed-data-rate policing for non-GBR bearers, then the committed-data-rate keyword should not configured with the flow limit-for-bandwidth command in Charging Action configuration mode.

Default: 144000

```
committed-burst-size bytes
```

The committed burst size allowed, in bytes.

Default: 3000

```
exceed-action { discard | lower-ip-precedence }
```

The action to take on the packets that exceed the committed-data-rate but do not violate the peak-data-rate. The following actions are supported:

- **discard**: Discard the packet
- **lower-ip-precedence**: Transmit the packet after lowering the ip-precedence

If exceed-action is not configured, the packets are forwarded.

Default: lower-ip-precedence

```
id id
```

Important: This option is available only in StarOS 8.1 and later releases.

Specifies the bandwidth limiting identifier.

Default: lower-ip-precedence

```

id must be an integer from 1 through 65535.
```

This identifier enables traffic policing based on a separate identifier other than content ID. This identifier will always take priority over content ID. If this identifier is not configured, traffic policing will be based on the content ID.
Usage

Use this command to limit the bandwidth a subscriber uses in the uplink and downlink directions under Session Control.

Important: If the exceed/violate action is set to “lower-ip-precedence”, the TOS value for the outer packet becomes “best effort” for packets that exceed/violate the traffic limits regardless of what the `ip user-datagram-tos copy` command is configured to. In addition, the `lower-ip-precedence` option may also override the `ip qos-dscp` command configuration. Therefore, it is recommended that command not be used when specifying this option.

More information on the QoS feature is available in the QoS Management appendix of the System Administration Guide.

Example

The following command sets an uplink peak data rate of 128000 bps and lowers the IP precedence when the committed-data-rate and the peak-data-rate are exceeded:

```
flow limit-for-bandwidth uplink peak-data-rate 128000 violate-action lower-ip-precedence
```

The following command sets a downlink peak data rate of 256000 bps and discards the packets when the committed-data-rate and the peak-data-rate are exceeded:

```
flow limit-for-bandwidth downlink peak-data-rate 256000 violate-action discard
```
**flow limit-for-flow-type**

This command allows you to specify the maximum number of simultaneous flows (of this type) that a subscriber may have, and the action to take if the limit is reached.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Syntax**

```
flow limit-for-flow-type limit over-limit-action { discard | redirect-url url | terminate-flow | terminate-session }

no flow limit-for-flow-type
```

**no**
If previously configured, deletes the flow limit-for-flow-type configuration in the current charging action.

**limit**
Specifies the maximum number of flows of a type exceeding which the specified over-limit-action triggers. `limit` must be an integer from 1 through 4000000000.

**over-limit-action { discard | redirect-url url | terminate-flow | terminate-session }**
Specifies the action to take on exceeding `limit` for a flow type:

- **discard**: Discards the packets
- **redirect-url url**: Redirects the flow to the specified URL. `url` must be an alphanumeric string of 1 through 511 characters. For example, http://search.com.
- **terminate-flow**: Terminates the flow to which this packet belongs
- **terminate-session**: Terminates the session to which this packet belongs

**Usage**
Use this command to specify the number of simultaneous flows (of a type) that a subscriber may have, and the action to take if the limit is reached.

All flows with the same content-id are considered to be the same type. This limit applies to the total of all flows for a subscriber connection (that is, an individual PDP context or individual A10 tunnel).

If the flow is not HTTP, the `redirect-url` option is ignored, that is the packet is forwarded normally. Refer to the `flow action` CLI command.
If the limit specified by the `flow limit-across-applications` command in the Rulebase Configuration Mode is also exceeded, action is taken for that over-limit condition rather than the action configured here.

Example

The following command terminates the flow if total number of flows of a type exceeds 1024:

```
flow limit-for-flow-type 1024 over-limit-action terminate-flow
```
**ip tos**

This command allows you to configure the IP Type of Service (ToS) octets.

**Product**

ACS

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Charging Action Configuration

`active-charging service service_name > charging-action charging_action_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Syntax**

```
ip tos { af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | ef | lower-bits tos_value } [ uplink | downlink ]
{ default | no } ip tos [ uplink | downlink ]
```

- **default**
  Configures this command with its default setting. Default: IP ToS is not modified.

- **no**
  If previously configured, deletes the IP ToS configuration in the current charging action.

- **af xx**
  Specifies the use of an assured forwarding `xx` per hop behavior (PHB).

- **be**
  Specifies the use of best effort forwarding PHB.

- **ef**
  Specifies the use of expedited forwarding PHB.

- **lower-bits tos_value**

**Important:** In StarOS 8.1 and later releases, this option is “lower-bits tos_value”. In StarOS 8.0, it is `tos_value`.

specifies the least-significant 6 bits in the TOS byte with the specified numeric value. `tos_value` must be an integer from 0 through 63.
**ip tos**

- **downlink**
  Specifies the ToS only for downlink packets.

- **uplink**
  Specifies the ToS only for uplink packets.

**Usage**

Use this command to specify the IP Type of Service (ToS) octets to use in the charging action. If one of the enumerated values is set, the DSCP bits which are the six most-significant bits in the TOS byte are marked. If the integer value is set, it will be written into the six least-significant bits of the TOS byte. If **downlink** or **uplink** keywords are not specified, the command applies to both directions. This command may be used multiple times. For example, the following sequence of commands will cause to set the ToS to af11 in the uplink direction, but not modify the ToS in the downlink direction:

```
ip tos af11
no ip tos downlink
```

**Example**

The following command sets the IP ToS to be with **downlink**:

```
  ip tos be downlink
```
ip vlan

This command allows you to configure the VLAN identifier to be associated with the subscriber traffic in the destination context.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Charging Action Configuration

Syntax

```
ip vlan vlan_id

{ default | no } ip vlan
```

- **default**
  Configures this command with its default setting.
  Default: Disable this IP VLAN configuration. Same as `no ip vlan` command.

- **no**
  If previously configured, deletes the IP VLAN configuration in the current charging action. Whatever value is configured for the VLAN tag in the subscriber configuration or IP pool configuration (or no VLAN tag if there is no configuration elsewhere) is used.

- **vlan_id**
  Specifies the VLAN ID.
  `vlan_id` must be an integer from 1 through 4094.

Usage
This command configures the subscriber VLAN ID which is used with the assigned address for the subscriber session to receive packets. If the IP pool from which the address is assigned is configured with a VLAN ID, then this subscriber configured VLAN ID overrides it.

Subscriber traffic can be routed to specific VLANs based on the configuration of their user profile. Using this functionality provides a mechanism for routing all traffic from a subscriber over the specified VLAN. All packets destined for the subscriber must also be sent using only IP addresses valid on the VLAN or they will be dropped.

Example
The following command sets the IP VLAN range to go up to 500:

```
ip vlan 500
```
The following command sets the IP VLAN range back to default.

```plaintext
default ip vlan
```
nexthop-forwarding-address

This command allows you to configure the nexthop forwarding address.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Charging Action Configuration

active-charging service service_name > charging-action charging_action_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-charging-action)#

Syntax

nexthop-forwarding-address ipv4_address

no nexthop-forwarding-address

no
If previously configured, deletes the nexthop-forwarding-address configuration in the current charging action.

ipv4_address
Specifies the nexthop-forwarding-address for the current charging action.
ipv4_address must be the nexthop forwarding address, and must be an IPv4 address.

Usage

Use this command to configure the nexthop-forwarding-address for a charging action. When an uplink packet matches a rule and a charging action is applied to it this nexthop forwarding address is used. There are different methods to configure a nexthop forwarding address, they are prioritized as follows:

• The nexthop forwarding address, if configured, in a redirect ACL is used
• Else, the nexthop address configured in the charging action is used
• Else, the nexthop address, if configured, in the IP pool is used

Example

The following command sets the nexthop forwarding address for the current charging action to 10.1.1.1:

nexthop-forwarding-address 10.1.1.1
pco-custom1

This command configures the Protocol Configuration Options (PCO) value that will be sent to all UEs, and relates to the PCO for UE Notification feature.

Product
P-GW

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Charging Action Configuration

active-charging service service_name > charging-action charging_action_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-charging-action)#

Syntax

pco-custom1 custom1_value

{ no | default } pco-custom1

---

**Syntax**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Configures custom1 with the default setting. Default: 0</td>
</tr>
<tr>
<td>no</td>
<td>If previously configured, resets the pco-custom1 value to the default setting.</td>
</tr>
<tr>
<td>custom1_value</td>
<td>Specifies the PCO custom1 value. custom1_value must be an integer from 0 through 255.</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to configure the PCO custom1 value to be sent to the MS GTP messages. To enable or disable sending customized PCO options, use the **pco-options** command in the APN Configuration Mode.

**Example**

The following command configures PCO custom1 value to 5:

```
pco-custom1 5
```
product-offer-id-avp

This command enables sending the “Product-Offer-ID” AVP with traffic identifier for Home Agent (HA)/Content Charging Gateway (CCG) instead of the “Rating-Group” AVP. This allows to identify and report application service traffic interval or volume.

**Important:** This command is customer-specific. For more information please contact your Cisco account representative.

**Product**
- HA
- PDSN

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Syntax**

```
product-offer-id-avp
```

**Usage**

Use this command to send the “Product-Offer-ID” AVP in Diameter message instead of the “Rating-Group” AVP for HA/CCG implementation. This implementation means that HA/CCG is deployed to work with both AAA server and OCS via Diameter Gy Online Charging Protocol for content based billing on both offline and online charging.

**Important:** If there is no mapping label configured for a content-id with the `label content-id` command in Active Charging Service Configuration Mode, the rating group will be sent in Product-Offer-ID AVP as Label.
**qos-class-identifier**

This command allows you to configure the QoS Class Identifier (QCI).

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-charging-action)#
```

**Syntax**

```
qos-class-identifier qos_class_identifier

no qos-class-identifier
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>no</strong></td>
<td>If previously configured, deletes the QCI configuration in the current charging action.</td>
</tr>
</tbody>
</table>
| **qos_class_identifier** | Specifies the QCI.  
*qos_class_identifier* must be an integer from 1 through 9 or from 128 through 254 (Operator specific). |

**Usage**
Use this command to configure the QCI for a charging action.

**Example**
The following command configures the QCI as 3:

```
qos-class-identifier 3
```
qos-renegotiate

This command allows you to configure the QoS traffic class for the Layer 7 QoS Renegotiation feature, enabling the triggering of QoS renegotiation from a rule.

Important: This command is license dependent. For more information please contact your Cisco account representative.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Charging Action Configuration

Syntax

qos-renegotiate traffic-class { background | conversational | interactive priority | streaming }

no qos-renegotiate

no
If previously configured, deletes the qos-renegotiate traffic-class configuration in the current charging action.

background
Specifies the traffic class as Background, for traffic patterns in which the data transfer is not time-critical (for example e-mail exchange).

conversational
Specifies the traffic class as Conversational, for traffic patterns in which there is a constant flow of packets.

interactive priority
Specifies the traffic class as Interactive, for traffic patterns in which there is an intermittent flow of packets. priority specifies the traffic handling priority, and must be an integer from 1 through 3.

streaming
Specifies the traffic class as Streaming, for traffic patterns in which there is a constant flow of data in one direction, either upstream or downstream.
Usage

Use this command to configure the QoS traffic class for a charging action for the Layer 7 QoS Renegotiation feature, enabling triggering QoS renegotiation from an active-charging rule.
Layer 7 QoS Renegotiation is an extension of the Dynamic QoS Renegotiation feature. Upon matching a particular layer 7 rule, for example the access of a particular URL, the GGSN triggers the renegotiation of the PDP context.

Example

The following command sets the QoS traffic class in the charging action to streaming:

```
qos-renegotiate traffic-class streaming
```
retransmissions-counted

This command allows you to specify whether to count (for billing purposes) the number of packet retransmissions.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Syntax**

```
[ default | no ] retransmissions-counted
```

- **default**
  Configures this command with its default setting.
  Default: Disabled; same as **no retransmissions-counted**

- **no**
  If previously enabled, disables the retransmissions-counted configuration in the current charging action.

**Usage**
Use this command to enable counting of the number of retransmissions.
If not enabled, retransmissions are automatically detected but discounted. The retransmissions will still be analyzed by the TCP analyzer (and higher layer analyzers), but the statistics (except for the count of retransmissions) will not be updated. Also, some higher layer analyzers (MMS, SIP, WSP, and WTP) can detect retransmissions when UDP is the transport layer.

**Example**
The following is an example of this command:

```
retransmissions-counted
```
service-detection

The `service-detection session-update` command enables the support for users’ QoS updation by PDSN/PCEF based on service start or stop.

**Important:** This command is customer specific. For more information contact your Cisco account representative.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Syntax**

```
cfg

active-charging service service-name

  charging-action action-name

  [no] service-detection session-update qos

  end

  no
```

If previously configured, deletes the service-detection configuration in the current charging action.

**Usage**

Use this command to configure the service detection to enable the support for users’ QoS updation by PDSN/PCEF based on service start or stop.
Example

The following command configures service detection for a subscriber session and sets the QoS updation.

```
service-detection session-update qos
```
service-identifier

This command allows you to configure the service identifier to use in the generated billing records, as well as the AVP used by the Credit Control Application, such as the “Service-Identifier” AVP for use by DCCA. This is a more general classifier than content-id.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Charging Action Configuration

active-charging service service_name > charging-action charging_action_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-charging-action)#

Syntax

service-identifier service_id

no service-identifier

no

If previously configured, deletes the service ID configuration in the current charging action.

service_id

Specifies the service identifier.
In 12.1 and earlier releases service_id must be an integer from 1 through 65535.
In 12.2 and later releases, service_id must be an integer from 1 through 2147483647.

Usage

Use this command to configure the service identifier to use in generated billing records, as well as the AVP used by the Credit Control Application, such as the “Service-Identifier” AVP for use by DCCA. This is a more general classifier than content-id.

Example

The following command configures the service identifier in the current charging action to 99:

service-identifier 99
tft packet-filter

This command allows you to specify the packet filter to use in TFTs sent to the MS.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Syntax**

```
[ no ] tft packet-filter packet_filter_name
```

- **no**
  If previously configured, removes the specified packet filter from the current charging action.

- **packet_filter_name**
  Specifies the packet filter to add/remove from the current charging action.
  `packet_filter_name` must be the name of a packet filter, and must be an alphanumeric string of 1 through 63 characters.

**Usage**
Use this command to configure the packet filter to be sent to the MS. Up to eight packet filters can be specified in a charging action.

**Example**
The following command configures the packet filter `filter23` to be sent to the MS:

```
tft packet-filter filter23
```
**tft-notify-ue**

This command allows you to control whether TFT updates are sent to UE or not.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-charging-action) #
```

**Syntax**

```
[ no ] tft-notify-ue
```

- **no**
  
  If this option is configured, TFTs for that charging action are not sent to UE if certain trigger conditions are met.

**Usage**

Use this command to suppress the selected TFT updates from being sent to the UE. This helps to identify if the appropriate TFT defined in the charging action needs to be sent to the UE or not. This CLI command is supported for both default and dedicated bearers.

The ability to include TFTs in the initial session creation are also controlled through this command. This way, the operator can suppress any unwanted TFTs to the UE.

Releases prior to 15.0, all predefined rules charging actions are associated with TFTs and the system includes TFTs towards the UE for all scenarios. In some scenarios it results in creating duplicate TFTs. This CLI-based approach is developed to overcome this situation.

NOTE: The TFT updates are not sent to UE based on certain trigger conditions.
**tos**

This command allows you to configure the Type of Service (ToS) octets.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Syntax**

```
tos { af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af41 | af42 | af43 | be | ef | lower-bits tos_value } [ downlink | uplink ]
```

**no tos [ downlink | uplink ]**

- **no**
  Disables the ToS being used in the charging action.

- **af xx**
  Specifies the use of an assured forwarding xx Per Hop Behavior (PHB).

- **be**
  Specifies use of Best Effort forwarding PHB.

- **ef**
  Specifies use of Expedited Forwarding PHB.

- **lower-bits tos_value**
  Sets the least-significant 6 bits in the ToS byte with the specified numeric value.
  
  **Important:** In StarOS 8.1 and later releases, this option is “lower-bits tos_value”. In StarOS 8.0 release, it is tos_value.

- **downlink**
  Specifies the ToS only for downlink packets.
**tos**

---

**uplink**

Specifies the ToS only for uplink packets.

---

**Usage**

Use this command to set the ToS octets used in the charging action. If one of the enumerated values is set, the Differentiated Services Code Point (DSCP) bits (the six most-significant bits (MSBs) in the ToS byte) are marked. If the integer value is set, it will be written into the six least-significant bits (LSBs) of the ToS byte.

**Example**

The following command sets the ToS to be for downlink packets:

```
tos be downlink
```
tpo profile

The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
**video bitrate**

This command allows you to specify the default target bit rate to use for the video pacing feature on the Mobile Video Gateway. This value is also used as the suggested maximum bit rate for the video optimization policy control feature.

**Product**

MVG

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Syntax**

```
[ default | no ] video bitrate bit_rate [ -noconfirm ]
```

- **default**
  Sets video bitrate to its default value.

- **no**
  Deletes the video bit rate if previously configured.

- **video bitrate bit_rate**
  Specifies the bit rate, in bits per second, at which the TCP video flow should be paced during video pacing. This value is also used as the suggested maximum bit rate for the video optimization policy control feature. For video pacing, this default bit rate is used on each video flow until the rate determination function calculates the optimal bit rate for pacing.
  - `bit_rate` must be an integer from 0 to 25600000.
  - Default: 0

- **-noconfirm**
  Specifies that the command must execute without prompting for confirmation.

**Usage**

Use this command to specify the default bit rate to use for the video pacing feature, and the suggested maximum bit rate for the video optimization policy control feature.

**Example**

The following command sets the bit rate for the video flow at 300000 (300kbps):

```
video bitrate 300000
```
video cae-readdressing

This command allows you to enable CAE (Content Adaptation Engine) re-addressing, allowing video traffic to be fetched from the CAEs in the CAE group. The CAE is an optional component of the Mobile Videoscape.

Product
MVG

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Charging Action Configuration

active-charging service service_name > charging-action charging_action_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-charging-action)#

Syntax

[ no ] video cae-readdressing [ xheader-format xheader_format_name ]

- no
  Disables CAE re-addressing if previously configured.

video cae-readdressing
  Enables CAE re-addressing, allowing video traffic to be fetched from the CAEs in the CAE group.

xheader-format xheader_format_name
  Specifies an HTTP x-header (Extension header) format for readdressing. When specified, the MVG inserts a destination IP address and TCP port number in a proprietary HTTP x-header in the HTTP request to the CAE. The CAE uses this information to connect to the OS (Origin Server) to retrieve selected video clips for adaptation.
  xheader_format_name must be an alphanumeric string of 1 through 63 characters.

Usage
Use this command to enable CAE re-addressing on the Mobile Video Gateway.

Example

The following command enables CAE re-addressing:

    video cae-readdressing xheader-format format_1
video detailed-statistics

This command allows you to enable the collection of detailed video statistics.

**Product**

MVG

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Syntax**

```
[ default | no ] video detailed-statistics [ -noconfirm ]
```

- **default**
  
  Sets video detailed-statistics to its default value, which is the same as **[ no ]**.

- **no**

  Disables the video statistics feature if previously enabled.

- **video detailed-statistics**

  Enables the video statistics feature. When a flow matches a rule definition for video during DPI (Deep Packet Inspection), the video statistics feature begins collecting detailed statistics for the video flow.

- **-noconfirm**

  Specifies that the command must execute without prompting for confirmation.

**Usage**

Use this command to enable the video statistics feature.

**Example**

The following command enables the video statistics feature:

```
video detailed-statistics
```
video optimization-preprocessing all

This command allows you to enable CAE re-addressing by enabling the Active Charging Service (ACS) to re-address video requests to the CAEs in the CAE group.

**Product**
MVG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Charging Action Configuration

```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Syntax**

```
[ no ] video optimization-preprocessing all
```

- **no**
  Disables CAE re-addressing if currently enabled.

```
video optimization-preprocessing cae-readdressing
```

Enables CAE re-addressing by enabling the ACS to re-address video requests to the CAEs in the CAE group.

**Usage**
Use this command to enable CAE re-addressing by enabling the ACS to re-address video requests to the CAEs in the CAE group.

**Example**
The following command enables CAE re-addressing:

```
video optimization-preprocessing all
```
video optimization-preprocessing cae-readdressing

This command allows you to enable CAE re-addressing by enabling the Active Charging Service (ACS) to re-address video requests to the CAEs in the CAE group.

**Product**
MVG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Charging Action Configuration
```
active-charging service service_name > charging-action charging_action_name
```

Entering the above command sequence results in the following prompt:
```
[local]host_name(config-charging-action)#
```

**Syntax**
```
[ no ] video optimization-preprocessing cae-readdressing
```

- **no**
  Disables CAE re-addressing if currently enabled.

- **video optimization-preprocessing cae-readdressing**
  Enables CAE re-addressing by enabling the ACS to re-address video requests to the CAEs in the CAE group.

**Usage**
Use this command to enable CAE re-addressing by enabling the ACS to re-address video requests to the CAEs in the CAE group.

**Example**
The following command enables CAE re-addressing:
```
video optimization-preprocessing cae-readdressing
```
**video pacing by-policing**

This command allows you to enable the video pacing feature.

**Product**
MVG

**Privilege**
Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Charging Action Configuration

*active-charging service service_name > charging-action charging_action_name*

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Syntax**

```
[ default | no ] video pacing by-policing [ initial-burst-duration value | normal-burst-duration value ][ -noconfirm ]
```

- **default**
  
  Sets video pacing by-policing to its default value, which is the same as **no**.

- **no**
  
  Deletes the video pacing by-policing settings and disables video pacing if previously configured.

- **video pacing by-policing**
  
  Enables the video pacing feature. When enabled, video pacing is applied per TCP video flow. The command syntax **by-policing** enables pacing enforcement by the policing method, which is the available method for this software release.

- **initial-burst-duration value**
  
  Specifies the duration, in seconds, for the allowed initial burst of video content. Note that the initial burst is configured in terms of time, so that for video files with different encoding bit rates, the amount of bytes allowed without enforcing pacing gets adjusted accordingly. The amount of bytes allowed is calculated by (video encoding rate * initial-burst-duration). **value** must be an integer between 1 and 30. Default: 10 seconds

- **normal-burst-duration value**
  
  Specifies the duration, in seconds, for the allowed normal burst of video content after the initial burst is completed. Like the initial burst, the normal burst is also configured in terms of time, so that for video files with different encoding bit rates, the amount of bytes allowed without enforcing pacing gets adjusted accordingly. The amount of bytes allowed is calculated by (video encoding rate * normal-burst-duration). **value** must be an integer between 1 and 30. Default: 3 seconds
-noconfirm

Specifies that the command must execute without prompting for confirmation.

Usage

Use this command to enable video pacing by policing.

Example

The following command enables video pacing by policing with an initial burst duration of 15 seconds and a normal burst duration of 3 seconds:

```plaintext
video pacing by-policing initial-burst-duration 15 normal-burst-duration 3
```
xheader-insert

This command allows you to specify the extension-header (x-header) format whose fields have to be inserted in HTTP GET and POST request packets.

**Important:** This command is license dependent. For more information please contact your Cisco account representative.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Charging Action Configuration

`active-charging service service_name > charging-action charging_action_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-charging-action)#
```

**Syntax**

```
xheader-insert xheader-format xheader_format_name [ encryption rc4md5 [ encrypted ] key key ] [ first-request-only ] [ -noconfirm ]
```

```
o xheader-insert
```

no

Removes previously configured x-header format name.

---

```
xheader-format xheader_format_name
```

Enables x-header mode configuration, and specifies the x-header format whose fields are to be inserted in the packets.

`xheader_format_name` must be the name of an x-header format, and must be an alphanumeric string of 1 through 63 characters.

```
encryption rc4md5 [ encrypted ] key key
```

If the x-header format has any encrypted fields defined, specifies to use RC4MD5 encryption.

After configuring this option, the fields in xheader format having “encrypt” enabled will be encrypted as follows:

1. The MD5 hash of the configure key will be calculated.
2. This MD5 hash will be used as a key for RC4 encryption.
3. This encrypted value will be base64 encoded to get the final X-header value. The final inserted X-header will be X-alias: base64(RC4(MD5(key),MSISDN)).

In the default case, if encryption is not enabled as above, the plain text value of the xheader field will be inserted.
Note that if the value of the key is changed on the fly, it will take effect only in case of new calls. Also, if the per rulebase RSA encryption is also enabled in the same config, per charging-action RC4MD5 encryption will take precedence over it.

`key` specifies the key as an alphanumeric string of 8 through 15 characters.

`encryption` specifies use of encryption.

The `key` can be configured either as plain text or encrypted. However, in the output of the `show configuration` command it will always be displayed as encrypted. And, in the output of the `show configuration showsecrets` command it will be displayed as plain text.

first-request-only

Specifies x-header insertion only for the first HTTP request in the IP flow. If not configured, the default behavior is insertion for all requests.

-noconfirm

Specifies that the command must execute without any prompts and confirmation from the user.

Usage

Use this command to enable x-header mode, and specify the x-header format name whose fields are to be inserted in HTTP GET and POST request packets.

Also, see the `xheader-format` command in the ACS Configuration Mode Commands and ACS X-header Format Configuration Mode Commands chapters.

Example

The following command enables x-header mode, and specifies the x-header format name as `test12`:

```
xheader-insert xheader-format test12
```
Chapter 8
ACS Configuration Mode Commands

The ACS Configuration Mode is used to manage active charging service (ACS)/enhanced charging service (ECS) configurations. ACS provides flexible, differentiated, and detailed billing to subscribers through Layer 3 through Layer 7 packet inspection and the ability to integrate with back-end billing mediation systems.

**Important:** In this release only one active charging service can be configured per system.

Mode

Exec > ACS Configuration

**active-charging service** *service_name*

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
access-ruledef

This command allows you to create/configure/delete access rule definitions (ruledefs).

**Important:** This command is available only in StarOS 8.1 and in StarOS 9.0 and later releases, and must be used to configure the Policy-based Stateful Firewall and NAT features.

**Product**
- NAT
- PSF

**Privilege**
- Security Administrator, Administrator

**Mode**
- `Exec > ACS Configuration`

```
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
access-ruledef access_ruledef_name [ -noconfirm ]
no access-ruledef access_ruledef_name
```

- **no**
  - If previously configured, deletes the specified access ruledef.

```
  access_ruledef_name
```

- Specifies the access ruledef to add/configure/delete.

```
  access_ruledef_name
```

- Must be the name of an access ruledef, and must be an alphanumeric string of 1 through 63 characters, and can contain punctuation characters. Each access ruledef must have a unique name. If the named access ruledef does not exist, it is created, and the CLI mode changes to the Firewall-and-NAT Access Ruledef Configuration Mode wherein the ruledef can be configured.

- If the named access ruledef already exists, the CLI mode changes to the Firewall-and-NAT Access Ruledef Configuration Mode for that access ruledef.

- **-noconfirm**
  - Specifies that the command must execute without prompting for confirmation.

**Usage**

Use this command to create/configure/delete an access ruledef. A ruledef contains different conditions/criteria to permit, drop, or reject a packet/connection/traffic based on one or more parameters. The ruledef name must be unique within the service. Host pool, port map, IMSI pool, and access/firewall, routing, and charging ruledefs configured in the active charging service must all have unique names.
**Important:** An access ruledef can be referenced by multiple Stateful Firewall rulebases.

**Important:** Access ruledefs are different from ACS ruledefs.

On entering this command, the CLI prompt changes to:

```
[context_name]hostname(config-acs-fw-ruledef)#
```

Also see the *Firewall-and-NAT Access Ruledef Configuration Mode Commands* chapter.

**Example**

The following command creates an access ruledef named `ruledef1`, and enters the Firewall-and-NAT Access Ruledef Configuration Mode:

```
access-ruledef ruledef1
```
bandwidth-policy

This command allows you to create/configure/delete bandwidth policies.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-ac)

Syntax

bandwidth-policy bandwidth_policy_name [ -noconfirm ]

no bandwidth-policy bandwidth_policy_name

- no
If previously configured, deletes the specified bandwidth policy from the active charging service.

bandwidth_policy_name
Specifies the bandwidth policy to add/configure/delete. 
bandwidth_policy_name must be the name of a bandwidth policy, and must be an alphanumeric string of 
1 through 63 characters. Each bandwidth policy must have a unique name.

If the named bandwidth policy does not exist, it is created, and the CLI mode changes to the ACS Bandwidth 
Policy Configuration Mode wherein the bandwidth policy can be configured.
If the named bandwidth policy already exists, the CLI mode changes to the ACS Bandwidth Policy 
Configuration Mode for that bandwidth policy.

-noconfirm
Specifies that the command must execute without prompting for confirmation.

Usage
Use this command to create/configure/delete a bandwidth policy.
In 12.3 and earlier releases, a maximum of 64 bandwidth policies can be configured.
In 14.0 and later releases, a maximum of 256 bandwidth policies can be configured.

On entering this command, the CLI prompt changes to:

[context_name]hostname(config-bandwidth-policy) #

Also see the ACS Bandwidth Policy Configuration Mode Commands chapter.

Example
The following command creates a bandwidth policy named test73, and enters the ACS Bandwidth Policy 
Configuration Mode:
bandwidth-policy test73
buffering-limit

This command allows you to configure packet buffering limits.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

`active-charging service service_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
buffering-limit { flow-max-packets flow_max_packets | subscriber-max-packets subscriber_max_packets }

{ default | no } buffering-limit { flow-max-packets | subscriber-max-packets }
```

- **default**
  - Configures this command with its default setting.
  - Default: In 14.0 and earlier releases, no limit, other than the maximum amount of available memory.
  - Default: In 14.1 and later releases, 255

- **no**
  - Disables the buffering limit configuration.

- **flow-max-packets flow_max_packets**
  - Specifies the maximum number of packets that can be buffered per flow.
  - `flow_max_packets` must be an integer from 1 through 255.

- **subscriber-max-packets subscriber_max_packets**
  - Specifies the maximum number of packets that can be buffered per subscriber.
  - `subscriber_max_packets` must be an integer from 1 through 255.

**Usage**

Use this command to configure the limits for buffering packets sent by a subscriber, while waiting for a response from the Diameter server. Packets need to be buffered for various reasons, such as, waiting for Credit Control Authorization or waiting for the result of a content filtering rating request.

**Example**

The following command sets the buffering limit per flow to 55:

```
buffering-limit flow-max-packets 55
```
charging-action

This command allows you to create/configure/delete ACS charging actions.

**Important:** A maximum of 2048 charging actions can be configured in the active charging service.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

```
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
[ no ] charging-action charging_action_name [ -noconfirm ]
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>If previously configured, deletes the specified charging action from the active charging service.</td>
</tr>
<tr>
<td>charging_action_name</td>
<td>Specifies the charging action to add/configure/delete. charging_action_name must be the name of a charging action, and must be an alphanumeric string of 1 through 63 characters and can contain punctuation characters. Each charging action must have a unique name. If the named charging action does not exist, it is created, and the CLI mode changes to the ACS Charging Action Configuration Mode wherein the charging action can be configured. If the named charging action already exists, the CLI mode changes to the ACS Charging Action Configuration Mode for that charging action.</td>
</tr>
<tr>
<td>-noconfirm</td>
<td>Specifies that the command must execute without prompting for confirmation.</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to create/configure/delete an ACS charging action. A charging action represents actions to be taken when a configured rule is matched. Actions could range from generating an accounting record (for example, an EDR) to dropping the IP packet, etc. The charging action will also determine the metering principle—whether to count retransmitted packets and which protocol field to use for billing (L3/L4/L7 etc). On entering this command, the CLI prompt changes to:

```
[context_name]hostname(config-charging-action)#
```
Also see the *ACS Charging Action Configuration Mode Commands* chapter.

**Example**

The following command creates a charging action named `action123` and changes to the ACS Charging Action Configuration Mode:

```
charging-action action123
```
content-filtering category match-method

This command allows you to specify the match method to look up URLs in the Category-based Content Filtering database.

Product
CF

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs)#

Syntax

content-filtering category match-method { exact | generic }

default content-filtering category match-method

default

Configures this command with its default setting.
Default: generic

generic

Specifies the generic match method, wherein normalization, multi-lookups, and rollback algorithms are applied to URLs during look up. URLs are rated on generic match with URLs present in the Category-based Content Filtering database.

Example

The following command sets the exact-match method to look up URLs in the Category-based Content Filtering database:

content-filtering category match-method exact
content-filtering category policy-id

This command allows you to create/configure/delete Content Filtering Category Policies for Category-based Content Filtering support.

**Important:** A maximum of 64 Content Filtering Category Policies can be configured in the active charging service.

**Product**
CF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

```
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-acs)#
```

**Syntax**

```
content-filtering category policy-id cf_policy_id [ description [ description_string ] ]
[ -noconfirm ]

no content-filtering category policy-id cf_policy_id
```

**no**

If previously configured, deletes the specified Content Filtering Category Policy from the active charging service.

**cf_policy_id**

Specifies the Content Filtering Category Policy ID to add/configure/delete.

- `cf_policy_id` must be an integer from 1 through 4294967295.
- If the specified policy ID does not exist, it is created and the CLI mode changes to the Content Filtering Policy Configuration Mode, wherein the policy can be configured.
- If the specified policy ID already exists, the CLI mode changes to the Content Filtering Policy Configuration Mode for that policy.

**description [ description_string ]**

Specifies a description for the Content Filtering Category Policy.

- `description_string` must be an alphanumeric string of 1 through 31 characters.
- Note that both `description` and `description_string` are optional.
- “`description description_string`” saves `description_string` as the new description.
- “`description`” removes the previously specified description.

This description is displayed in the output of the "`show content-filtering category policy-id id`" and "`show active-charging service name service_name`" commands.
-noconfirm

Specifies that the command must execute without prompting for confirmation.

Usage

Use this command to create/configure/delete a Content Filtering Category Policy. On entering this command, the CLI prompt changes to:

```
[context_name]hostname(config-acs-content-filtering-policy)#
```

Also see the Content Filtering Policy Configuration Mode Commands chapter.

Example

The following command creates a Content Filtering Policy with the ID 101, and enters the Content Filtering Policy Configuration Mode:

```
content-filtering category policy-id 101
```
credit-control

This command allows you to enable/disable Prepaid Credit Control Configuration Mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

```bash
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```bash
[ no ] credit-control [ group cc_group_name ]
```

- **no**
  Disables the specified Prepaid Credit Control Application configuration.

- **group cc_group_name**
  Specifies the credit control group to add/configure/delete.
  `cc_group_name` must be the name of a credit control group, and must be an alphanumeric string of 1 through 63 characters. Each credit control group must have a unique name.
  If the named credit control group does not exist, it is created, and the CLI mode changes to the Credit Control Configuration Mode, wherein the credit control group can be configured.
  If the named credit control group already exists, the CLI mode changes to the Credit Control Configuration Mode for that credit control group.
  Creating different credit control groups enables applying different credit control configurations (DCCA dictionary, failure-handling, session-failover, Diameter endpoint selection, etc.) to different subscribers on the same system.
  Without credit control groups, only one credit control configuration is possible on a system. All the subscribers in the system will have to use the same configuration.

**Important:** This option is only available in StarOS 8.1 and later releases.

**Usage**

Use this command to enable/disable Prepaid Credit Control Configuration for RADIUS/Diameter charging mode.

On entering this command, the CLI prompt changes to:

```
[context_name]hostname(config-dcca)#
```

**Example**

Also see the `Credit Control Configuration Mode Commands` chapter.
The following command enables prepaid credit control accounting to use RADIUS and/or Diameter interface mode.

```
credit-control
```
diameter credit-control

*Description* This command has been deprecated, and is replaced by the `credit-control` command.
edr-format

This command allows you to create/configure/delete ACS Event Data Record (EDR) formats.

Important: A maximum of 256 EDR plus UDR formats can be configured in the active charging service.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs)#

Syntax

edr-format edr_format_name [ -noconfirm ]

no edr-format edr_format_name

no

If previously configured, deletes the specified EDR format from the active charging service.

edr_format_name

Specifies the EDR format to add/configure/delete. edr_format_name must be an alphanumeric string of 1 through 63 characters. Each EDR format must have a unique name.

If the named EDR format does not exist, it is created, and the CLI mode changes to the EDR Format Configuration Mode wherein the EDR format can be configured.

If the named EDR format already exists, the CLI mode changes to the EDR Format Configuration Mode for that EDR format.

-noconfirm

Specifies that the command must execute without prompting for confirmation.

Usage

Use this command to create/configure/delete an EDR format.

On entering this command, the CLI prompt changes to:

[context_name]host_name(config-acs-edr)#

Also see the EDR Format Configuration Mode Commands chapter.

Example
The following command creates an EDR format named `edr_format1`, and enters the EDR Format Configuration Mode:

```
  edr-format edr_format1
```
edr-ipproto-port-map

This command enables IP protocol and server port mapping for Event Data Records (EDR).

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

```plaintext
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```plaintext
[local]host_name(config-ac)#
```

**Syntax**

```
[ default | no ] edr-ipproto-port-map
```

---

**default**

Configures this command with its default setting.
Default: Disabled

---

**no**

If previously enabled, disables the IP protocol and server port mapping for EDR.

**Usage**

Use this command to enable IP protocol and server port mapping for EDR. As part of EDR generation, packets can be mapped based on IP header protocol and Transport Header Port. Generating statistics based on IP Protocol and Transport Port number is an added advantage for offline packet analysis.
edr-udr-flow-control

This command allows you to enable/disable flow control between Session Managers (SessMgrs) and the CDRMOD process.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local] host_name(config-acsc)#

Syntax

edr-udr-flow-control [ unsent-queue-size unsent_queue_size ]

{ default | no } edr-udr-flow-control

no

If previously enabled, disables the flow control configuration.

default

Configures this command with its default setting.
Default: Flow control is enabled; unsent-queue-size: 375

unsent-queue-size unsent_queue_size

Specifies the flow control unsent queue size at Session Manager (SessMgr) level.
unsent_queue_size must be an integer from 1 through 2500.

Usage
Use this command to enable Flow Control between SessMgr and the CDRMOD process, and configure the unsent queue size.

Example
The following command enable Flow Control between SessMgrs and the CDRMOD process, and configure the unsent queue size to 1000:

edr-udr-flow-control unsent-queue-size 1000
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Use this command to return to the parent configuration mode.
**fair-usage deact-margin**

This command allows you to configure the deactivate margin for the Fair Usage feature.

**Product**

ACS
ADC
CF
PSF
NAT

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration

*active-charging service service_name*

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
fair-usage deact-margin deactivate_margin

default fair-usage deact-margin
```

**default**

Configures this command with its default setting.
Default: 5 percent

**deactivate_margin**

Specifies that Fair Usage monitoring must be disabled when the instance-level credit usage goes *deactivate_margin* percentage below *usage_threshold*.

*deactivate_margin* is a percentage value, and must be an integer from 1 through 100.

**Usage**

Use this command to configure when to disable the Fair Usage feature, which enables SessMgr instance-level load balancing for in-line service features, and resource usage control for subscribers. For additional information, refer to the feature description in the *Enhanced Charging Service Administration Guide*.

**Example**

The following command configures the deactivate margin to disable Fair Usage monitoring to 10% below the session resource usage threshold (65%):

```
fair-usage deact-margin 10
```
**fair-usage tcp-proxy**

This command allows you to configure the maximum number of flows for which TCP Proxy can be used per subscriber, and what portion of ECS memory should be reserved for TCP Proxy flows.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

```shell
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```shell
fair-usage tcp-proxy { max-flows-per-subscriber max_flows_subscriber | memory-share memory_share }
```

**default**

```shell
default fair-usage [ max-flows-per-subscriber | memory-share ]
```

**default**

Configures this command with its default setting.

**max-flows-per-subscriber max_flows_subscriber**

Specifies the maximum number of flows for which TCP Proxy can be used per subscriber. This limit is per Session Manager.

```shell
max_flows_subscriber must be an integer from 1 through 1000.
Default: 5
```

**memory-share memory_share**

Specifies what portion of ECS memory should be reserved for TCP Proxy flows.

```shell
memory_share is a percentage value, and must be an integer from 1 through 100.
Default: 10%
```

**Usage**

Use this command to configure the maximum number of flows for which TCP Proxy can be used for a subscriber, and what portion of ECS memory should be reserved for TCP Proxy flows.

**Example**

The following command configures 100 as the maximum number of flows for which TCP Proxy can be enabled for the subscriber:

```shell
fair-usage tcp-proxy max-flows-per-subscriber 100
```
fair-usage threshold-percent

This command allows you to configure the usage threshold to start Fair Usage monitoring.

Product

ACS
ADC
CF
PSF
NAT

Privilege

Security Administrator, Administrator

Mode

Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs)#

Syntax

fair-usage threshold-percent usage_threshold

default fair-usage threshold-percent

default

Configures this command with its default setting.
Default: 50 percent

usage_threshold

Specifies the threshold to start Fair Usage monitoring. Until the credit usage hits this threshold, all session resource allocation is allowed. On crossing this threshold, any new resource allocation request is evaluated before being allowed or denied.
usage_threshold is a percentage value, and must be an integer from 1 through 100.

Usage

Use this command to configure the threshold to enable the Fair Usage feature, which enables SessMgr instance-level load balancing for in-line service features, and resource usage control for subscribers. For additional information, refer to the feature description in the Enhanced Charging Service Administration Guide.

Example

The following command enables the Fair Usage feature, and configures the session resource usage threshold to start Fair Usage monitoring to 75%:

fair-usage threshold-percent 75
firewall dos-protection flooding

This command is configured to protect servers from mobile subscribers in the uplink direction.

**Product**
PSF
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

```
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acss)#
```

**Syntax**

```
firewall dos-protection flooding { { icmp | tcp-syn | udp } protect-servers { all | host-pool hostpool_name } packet_limit packet_limit | inactivity-timeout timeout | uplink-sample-interval interval }

default firewall dos-protection flooding { icmp | tcp-syn | udp | inactivity-timeout | uplink-sample-interval }

no firewall dos-protection flooding { icmp | tcp-syn | udp }
```

- `no`
  Disables Stateful Firewall protection for subscribers against the specified Denial of Service (DoS) attack(s).

- `default`
  Disables Stateful Firewall protection for subscribers against all DoS attacks.

```
firewall dos-protection flooding { icmp | tcp-syn | udp } protect-servers { all | host-pool hostpool_name }
```

Enables protection against the specified flooding attack:

- `icmp`
  Enables ICMP uplink flooding protection.
- `tcp-syn`
  Enables TCP Syn uplink flooding protection.
- `udp`
  Enables UDP uplink flooding protection.

- `all`
  Enables protection for all the servers.

- `host-pool hostpool_name`
  Specifies the name of the host pool. `hostpool_name` must be an alphanumeric string of 1 through 63 characters.

```
packet_limit packet_limit
```

Specifies the maximum number of packets allowed during a sampling interval. `packet_limit` must be an integer from 1 through 4294967295. Default: 1000 packets per sampling interval for all protocols.
**inactivity-timeout inactivity_timeout**

Specifies the inactivity timeout period, in seconds. This allows flooding traffic if the destination is inactive for more than the configured period.

- `inactivity_timeout` must be an integer from 1 through 4294967295.
- Default: 300 seconds

**uplink-sample-interval interval**

Specifies the uplink sampling interval, in seconds. The maximum sampling-interval configurable is 60 seconds.

- `interval` must be an integer from 1 through 60.
- Default: 1 second

**Usage**

Use this command to enable Stateful Firewall protection from different types of DoS attacks for all servers or for those servers mentioned in the host pool. This allows users to safeguard their own servers and other hosts. DoS attacks are also detected in the downlink direction. The `firewall dos-protection` command must be configured in the FW-and-NAT Policy Configuration mode.

**Example**

The following command enables ICMP uplink protection for all servers with packet limit set to 10:

```
firewall dos-protection flooding icmp protect-servers all packet limit 10
```
**firewall dos-protection ip-sweep**

This command is configured to detect Source IP-based flooding attacks in the uplink direction.

**Product**

PSF

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration

`active-charging service service_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
faultfirewall dos-protection ip-sweep { icmp | tcp | udp } protect-servers { all | host-pool hostpool_name } packet limit packet limit | downlink-server-limit server_limit | inactivity-timeout timeout | sample-interval interval }

default firewall dos-protection ip-sweep { downlink-server-limit | icmp | inactivity-timeout | sample-interval | tcp-syn | udp }

no firewall dos-protection ip-sweep { icmp | tcp-syn | udp }
```

**default**

Disables Stateful Firewall protection for subscribers against all DoS attacks.

**no**

Disables Stateful Firewall protection for subscribers against the specified Denial of Service (DoS) attack(s).

**ip-sweep { icmp | tcp-syn | udp } protect-servers { all | host-pool hostpool_name**

Enables protection against the specified flooding attack:

- **icmp**: Enables source IP-based flood attack detection for ICMP.
- **tcp-syn**: Enables source IP-based flood attack detection for TCP-SYN.
- **udp**: Enables source IP-based flood attack detection for UDP.

**all**

Enables protection for all the servers.

**host-pool hostpool_name**: Specifies the name of the host pool. `hostpool_name` must be an alphanumeric string of 1 through 63 characters.

**packet limit packet_limit**

Specifies the maximum number of packets allowed during a sampling interval for uplink and downlink.

`packet_limit` must be an integer from 1 through 4294967295.

Default: 1000 packets per sampling interval for all protocols.
**Usage**

Use this command to enable or disable IP Sweep Protection in the uplink direction for mobile subscribers and internet hosts on a per protocol basis. The purpose of the Uplink IP Sweep protection is to check whether a particular source IP address is generating more flows per sample interval than is permitted. If so, the first packets that come after the maximum packet limit during the particular time interval will be dropped.

IP Sweep attacks are also detected in the downlink direction. The `firewall dos-protection ip-sweep` command must be configured in the FW-and-NAT Policy Configuration mode. The configuration values for packet limit and sampling interval are common for both uplink and downlink.

**Example**

The following command enables ICMP uplink protection for all servers with packet limit set to 30:

```
firewall dos-protection ip-sweep icmp protect-servers all packet limit 30
```
firewall flow-recovery

This command allows you to configure the Stateful Firewall’s Flow Recovery feature.

Product
PSF

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs)#

Syntax

firewall flow-recovery { { downlink [ [ timeout timeout ] [ no-flow-creation ] + ] } | { uplink [ timeout timeout ] } } { default | no } firewall flow-recovery { downlink | uplink }

default
Configures this command with its default setting.
Default: Downlink and uplink flow recovery enabled, 300 seconds

no
Disables the flow recovery configuration.

downlink | uplink
Specifies the packets:
• downlink: Enables flow recovery for packets from the downlink direction.
• uplink: Enables flow recovery for packets from the uplink direction.

timeout timeout
Specifies the Stateful Firewall Flow Recovery Timeout setting, in seconds.
timeout must be an integer from 1 through 86400.
Default: 300 seconds

no-flow-creation
Specifies not to create data session/flow-related information for downlink-initiated packets (from the Internet to the subscriber) while the firewall downlink flow-recovery timer is running, but send to subscriber.

Usage
Use this command to configure Stateful Firewall Flow Recovery feature.
**Important:** NAT flows will not be recovered.

**Example**

The following command configures Stateful Firewall Flow Recovery for packets in downlink direction with a timeout setting of 600 seconds:

```
firewall flow-recovery downlink timeout 600
```
firewall max-ip-packet-size

**Description** In StarOS 8.1 and later releases, for Rulebase-based Stateful Firewall this command is available in the ACS Rulebase Configuration Mode, and for Policy-based Stateful Firewall in the Firewall-and-NAT Policy Configuration Mode. In StarOS 8.3, this command is available in the ACS Rulebase Configuration Mode.
firewall mime-flood

**Description** In StarOS 8.1 and later releases, for Rulebase-based Stateful Firewall this command is available in the ACS Rulebase Configuration Mode, and for Policy-based Stateful Firewall in the Firewall-and-NAT Policy Configuration Mode. In StarOS 8.3, this command is available in the ACS Rulebase Configuration Mode.
**firewall nat-alg**

This command enables/disables Network Address Translation (NAT) Application Level Gateways (ALGs).

**Product**
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

`active-charging service service_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acsc)#
```

**Syntax**

```
[ default | no ] firewall nat-alg { all | ftp | h323 | pptp | rtsp | sip } [ ipv4-and-ipv6 | ipv4-only | ipv6-only ]
```

### default

Configures this command with the default setting for the specified parameter.

Default:
- **ftp**: Enabled
- **h323**: Enabled
- **pptp**: Disabled
- **rtsp**: Disabled
- **sip**: Disabled

### no

Disables all/ or the specified NAT ALG configuration. When disabled, the ALG(s) will not do any payload translation for NATd calls.

### all | ftp | h323 | pptp | rtsp | sip

Specifies the NAT ALG to enable/disable.

- **all**: Enables/disables all of the following NAT ALGs.
- **ftp**: Enables/disables File Transfer Protocol (FTP) NAT ALG.
- **h323**: Enables/disables H323 NAT ALG.
- **pptp**: Enables/disables Point-to-Point Tunneling Protocol (PPTP) NAT ALG.
- **rtsp**: Enables/disables Real Time Streaming Protocol (RTSP) ALG.
- **sip**: Enables/disables Session Initiation Protocol (SIP) NAT ALG.
firewall nat-alg

Specifies to enable/disable NAT44/NAT64 ALG.

- **ipv4-and-ipv6**: Enables both NAT44 and NAT64 ALGs.
- **ipv4-only**: Enables only NAT44 ALG.
- **ipv6-only**: Enables only NAT64 ALG.

Usage

Use this command to enable/disable NAT ALGs.
To enable NAT ALG processing, in addition to this configuration, ensure that the routing rule for that particular protocol is added in the rulebase.

Example

The following command enables FTP NAT ALG:

```
firewall nat-alg ftp
```

The following command disables FTP NAT ALG:

```
no firewall nat-alg ftp
```

The following command enables FTP NAT ALG, and disables H.323, PPTP, RTSP, and SIP NAT ALGs:

```
default firewall nat-alg all
```
firewall no-ruledef-matches

**Description** In StarOS 8.1 and later releases, this command is available in the ACS Rulebase Configuration Mode.
**firewall port-scan**

This command allows you to configure Stateful Firewall’s Port Scan Detection algorithm.

**Product**
PSF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

```sh
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```sh
firewall port-scan { connection-attempt-success-percentage { non-scanner | scanner } percentage | inactivity-timeout inactivity_timeout | protocol { tcp | udp } response-timeout response_timeout | scanner-policy { block inactivity-timeout inactivity_timeout | log-only } }

default firewall port-scan { connection-attempt-success- percentage { non-scanner | scanner } | inactivity-timeout | protocol { tcp | udp } response-timeout | scanner-policy }
```

---

**default**

Configures this command with its default setting.

**connection-attempt-success-percentage { non-scanner | scanner } percentage**

Specifies the connection attempt success percentage.

- **non-scanner**: Specifies the connection attempt success percentage for a non-scanner.
  
  ```sh
  percentage
  ```

  `percentage` must be an integer from 60 through 99.

  Default: 70%

- **scanner**: Specifies the connection attempt success percentage for a scanner.

  ```sh
  percentage
  ```

  `percentage` must be an integer from 1 through 40.

  Default: 30%

**inactivity-timeout inactivity_timeout**

Specifies the port scan inactivity timeout period, in seconds.

`inactivity_timeout` must be an integer from 60 through 1800.

Default: 300 seconds

**protocol { tcp | udp } response-timeout response_timeout**

Specifies transport protocol and response-timeout period.
• **tcp**: Specifies response timeout for TCP.
  
  `response_timeout` must be an integer from 1 through 30.

• **udp**: Specifies response timeout for UDP.
  
  `response_timeout` must be an integer from 1 through 60.

Default: 3 seconds

```
scanner-policy { block inactivity-timeout inactivity_timeout | log-only }
```

Specifies how to treat packets from a source address that has been detected as a scanner.

• **block inactivity-timeout inactivity_timeout**: Specifies blocking any subsequent traffic from the scanner. If the scanner is found to be inactive for the inactivity-timeout period, then the scanner is no longer blocked, and traffic is allowed.

  `inactivity_timeout` specifies the scanner inactivity timeout period, in seconds, and must be an integer from 1 through 4294967295.

• **log-only**: Specifies logging scanner information without blocking scanner traffic.

Default: `log-only`

**Usage**

Use this command to configure the Stateful Firewall Port Scan Detection algorithm enabled by the `firewall dos-protection port-scan` CLI command.

This protection tracks all uplink source addresses, and the packets they initiate towards all subscribers that have this protection enabled.

**Example**

The following command configures the Stateful Firewall Port Scan inactivity timeout setting to 900 seconds:

```
firewall port-scan inactivity-timeout 900
```
### firewall protect-servers

This command is configured to protect ISP servers from mobile space devices.

#### Product
PSF

#### Privilege
Security Administrator, Administrator

#### Mode
Exec > ACS Configuration

```bash
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ac)#
```

#### Syntax

```bash
firewall protect-servers { all | host-pool hostpool_name } policy policy_name
```

```bash
{ default | no } firewall protect-servers
```

- **default**
  - Configures this command with its default setting.

- **no**
  - Disables protection of the servers.

- **all**
  - Configured to protect all servers from attacking mobile nodes.

- **host-pool hostpool_name**
  - Specifies the name of the host pool where all servers in that host pool need to protected.
  - `hostpool_name` must be an alphanumeric string of 1 through 63 characters.

- **policy policy_name**
  - Specifies the Firewall-and-NAT policy to be applied to packets that are destined to the IPs mentioned in the host pool.
  - `policy_name` must be the name of a Firewall-and-NAT policy, and must be an alphanumeric string of 1 through 63 characters.

#### Usage

Use this command to protect all ISP servers or specific ISP servers from mobile space devices. All the uplink packets will be inspected, and the action will be taken based on the configuration in Firewall-and-NAT policy. Uplink protection can be enabled or disabled based on the server IP of the packet.

#### Example
The following command is configured to protect all servers within a Firewall-and-NAT policy named test123:

```
firewall protect-servers all policy test123
```
**firewall ruledef**

This command allows you to create/configure/delete Stateful Firewall ruledefs.

**Important:** This command is available only in StarOS 8.1. This command must be used to configure the Rulebase-based Stateful Firewall and NAT features.

**Product**

PSF

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration

`active-charging service service_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
firewall ruledef firewall_ruledef_name [ -noconfirm ]

no firewall ruledef firewall_ruledef_name
```

- **firewall_ruledef_name**

  Specifies the Stateful Firewall ruledef to add/configure/delete. 
  *firewall_ruledef_name* must be the name of a Stateful Firewall ruledef, and must be an alphanumeric string of 1 through 63 characters and can contain punctuation characters. Each ruledef must have a unique name. 
  If the named ruledef does not exist, it is created, and the CLI mode changes to the Firewall Ruledef Configuration Mode wherein the ruledef can be configured. 
  If the named Stateful Firewall ruledef already exists, the CLI mode changes to the Firewall Ruledef Configuration Mode for that ruledef.

- **-noconfirm**

  Specifies that the command must execute without prompting for confirmation.

**Usage**

Use this command to create/configure/delete a Stateful Firewall ruledef. A Stateful Firewall ruledef contains different conditions to permit, drop, or reject a packet/connection/traffic based on one or more parameters. The ruledef name must be unique within the active charging service. Host pool, port map, IMSI pool, and Stateful Firewall, routing, and charging ruledefs must have unique names. 
A Stateful Firewall ruledef can be referenced by multiple Stateful Firewall rulebases.
**Important:** The Stateful Firewall ruledefs are different from the ACS ruledefs.

Also see the *Firewall-and-NAT Access Ruledef Configuration Mode Commands* chapter.

**Example**

The following command creates a Stateful Firewall ruledef named `fw_ruledef1`, and enters the Firewall Ruledef Configuration Mode:

```
fqwall ruledef fw_ruledef1
```
**firewall tcp-syn-flood-intercept**

**Description** In StarOS 8.1 and later releases, for Rulebase-based Stateful Firewall this command is available in the ACS Rulebase Configuration Mode, and for Policy-based Stateful Firewall in the Firewall-and-NAT Policy Configuration Mode. In StarOS 8.3, this command is available in the ACS Rulebase Configuration Mode.
**firewall track-list**

This command allows you to configure the maximum number of server IP addresses to be tracked that are involved in any kind of denial-of-service (DoS) attacks.

**Product**
PSF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration
`active-charging service service_name`

Entering the above command sequence results in the following prompt:
`[local]host_name(config-acs)#`

**Syntax**

```
firewall track-list attacking-servers no_of_servers
{ default | no } firewall track-list attacking-servers
```

**Important:** This command variant is available only in StarOS 8.3 and later releases.

If previously configured, deletes the configuration from the active charging service.

```
attacking-servers no_of_servers
```

Specifies the maximum number of servers to track.
`no_of_servers` must be an integer from 1 through 100.

**Usage**
Use this command to configure the maximum number of server IP addresses to be tracked that are involved in any kind of DoS attacks.

**Example**
The following command configures the maximum number of server IP addresses to be tracked that are involved in any kind of DoS attacks to 20:
```
firewall track-list attacking-servers 20
```
fw-and-nat action

This command allows you to create/configure/delete Firewall-and-NAT actions.

**Important:** This command is available only in 11.0 and later releases. This command must be used to configure the Stateful Firewall and NAT Action.

### Syntax

```
fw-and-nat action action_name [ -noconfirm ]
no fw-and-nat action action_name
```

If previously configured, deletes the specified Firewall-and-NAT action from the active charging service.

**action_name**
Specifies the Firewall-and-NAT action to add/configure/delete.  
**action_name** must be the name of a Firewall-and-NAT action, and must be an alphanumeric string of 1 through 63 characters. Each Firewall-and-NAT action must have a unique name.

**-noconfirm**
Specifies that the command must execute without prompting for confirmation.

### Usage

Use this command to create/configure/delete a Firewall-and-NAT action.  
On entering this command, the CLI prompt changes to:  
```
[context_name]hostname(config-fw-and-nat-action)#
```
Also see the Firewall-and-NAT Action Configuration Mode Commands chapter.

### Example

The following command creates a Firewall-and-NAT action named **test1**, and changes to the Firewall-and-NAT Action Configuration Mode:
fw-and-nat action test1
fw-and-nat policy

This command allows you to create/configure/delete Firewall-and-NAT policies.

**Important:** This command is available only in StarOS 8.1 and in StarOS 9.0 and later releases. This command must be used to configure the Policy-based Stateful Firewall and NAT features.

Product
- PSF
- NAT

Privilege
- Security Administrator,
- Administrator

Mode
- Exec > ACS Configuration
- `active-charging service service_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

Syntax

```
fw-and-nat policy policy_name [ -noconfirm ]

no fw-and-nat policy fw_nat_policy_name
```

- `no`
  - If previously configured, deletes the specified Firewall-and-NAT policy from the active charging service.

**Important:** When a Firewall-and-NAT policy is deleted, for all subscribers using the policy, Stateful Firewall and NAT processing is disabled, also ACS sessions for the subscribers are dropped. In case of session recovery, the calls are recovered but with Stateful Firewall and NAT disabled.

```
fw_nat_policy_name
```

- Specifies the Firewall-and-NAT policy to add/configure/delete.
- `fw_nat_policy_name` must be the name of a Firewall-and-NAT policy, and must be an alphanumeric string of 1 through 63 characters. Each Firewall-and-NAT policy must have a unique name.

```
-noconfirm
```

- Specifies that the command must execute without prompting for confirmation.

Usage

Use this command to create/configure/delete a Firewall-and-NAT policy.

On entering this command, the CLI prompt changes to:

```
[context_name]hostname(config-fw-and-nat-policy)#
```
Also see the *Firewall-and-NAT Policy Configuration Mode Commands* chapter.

**Example**

The following command creates a Firewall-and-NAT policy named *test321*, and changes to the Firewall-and-NAT Policy Configuration Mode:

```
fw-and-nat policy test321
```
group-of-objects

This command allows you to create/configure/delete an ACS group-of-objects.

Important: This command is available only in StarOS 10.2 and later releases.

Important: A maximum of 16 object groups can be configured in the active charging service. And a maximum of 128 objects can be configured within each object group.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

Syntax

```
no group-of-objects objects_group_name
```

```
no

If previously configured, deletes the specified group-of-objects from the active charging service.

objects_group_name

Specifies the group-of-objects to add/configure/delete.

objects_group_name must be the name of a group-of-objects, and must be an alphanumeric string of 1 through 63 characters. Each group-of-objects must have a unique name.

If the named group-of-objects does not exist, it is created, and the CLI mode changes to the ACS Group-of-Objects Configuration Mode wherein the group can be configured.

If the named group-of-objects already exists, the CLI mode changes to the ACS Group-of-Objects Configuration Mode for that group.

```
type
```

Specifies the data type for the group-of-objects.

Important: “string” is the only data type supported in this release.
**string**

Specifies the data type as string.
When creating a group, specifying the data type is mandatory.
When modifying an existing group, specifying the data type is optional.

---

**-noconfirm**

Specifies that the command must execute without prompting for confirmation.

---

**Usage**

Use this command to create/configure/delete a group-of-objects.
On entering this command, the CLI prompt changes to:
```
[context_name]hostname(config-acs-group-of-objects)#
```
Also see the *ACS Group-of-Objects Configuration Mode Commands* chapter.

---

**Example**

The following command creates a group-of-objects named `test4` with the data type string, and enters the ACS Group-of-Objects Configuration Mode:

```
grroup-of-objects test4 type string
```
group-of-prefixed-urls

This command allows you to create/configure/delete an ACS group-of-prefixed-URLs.

Important: This command is customer specific. For more information contact your Cisco account representative.

Important: A maximum of 64 group-of-prefixed-URL groups can be configured in the active charging service.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration
active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]hostname(config-acs)#

Syntax

group-of-prefixed-urls prefixed_urls_group_name [ -noconfirm ]

no group-of-prefixed-urls prefixed_urls_group_name

no
If previously configured, deletes the specified group-of-prefixed-urls from the active charging service.

prefixed_urls_group_name
Specifies the group-of-prefixed-urls to add/configure/delete.
prefixed_urls_group_name must be the name of a group-of-prefixed-urls, and must be an alphanumeric string of 1 through 63 characters. Each group-of-prefixed-urls must have a unique name.
If the named group-of-prefixed-urls does not exist, it is created, and the CLI mode changes to the ACS Group-of-Prefixed-URLs Configuration Mode wherein the group can be configured.
If the named group-of-prefixed-urls already exists, the CLI mode changes to the ACS Group-of-Prefixed-URLs Configuration Mode for that group.

-noconfirm
Specifies that the command must execute without prompting for confirmation.

Usage
Use this command to create/configure/delete a group-of-prefixed-URLs.
On entering this command, the CLI prompt changes to:

[context_name]hostname(config-acs-grp-of-prefixed-urls)#

Also see the ACS Group-of-Prefixed-URLs Configuration Mode Commands chapter.
Example

The following command creates group-of-prefixed-urls named test5, and enters the ACS Group-of-Prefixed-URLs Configuration Mode:

```
  group-of-prefixed-urls test5
```
group-of-ruledefs

This command allows you to create/configure/delete an ACS group-of-ruledefs.

Important: In 14.1 and earlier releases, a maximum of 64 group-of-ruledefs can be configured in the active charging service. In 15.0 and later releases, a maximum of 128 group-of-ruledefs can be configured.

Product
ACS
Privilege
Security Administrator, Administrator
Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]hostname(config-acs)#

Syntax

```
group-of-ruledefs ruledefs_group_name [ -noconfirm ]

no group-of-ruledefs ruledefs_group_name
```

- no
  If previously configured, deletes the specified group-of-ruledefs from the active charging service.

  `ruledefs_group_name`
  Specifies the group-of-ruledefs to add/configure/delete.
  `ruledefs_group_name` must be unique within the active charging service, and must be an alphanumeric string of 1 through 63 characters. Each group-of-ruledefs must have a unique name.
  If the named group-of-ruledefs does not exist, it is created, and the CLI mode changes to the ACS Group-of-Ruledefs Configuration Mode wherein the group can be configured.
  If the named group-of-ruledefs already exists, the CLI mode changes to the ACS Group-of-Ruledefs Configuration Mode for that group.

- -noconfirm
  Specifies that the command must execute without prompting for confirmation.

Usage

Use this command to create/configure/delete a group-of-ruledefs.
A group-of-ruledefs is a collection of rule definitions to use in access policy creation.
On entering this command, the CLI prompt changes to:

```
[context_name]hostname(config-group-of-ruledefs)#
```

Also see the ACS Group-of-Ruledefs Configuration Mode Commands chapter.
The following command creates a group-of-ruledefs named `group1`, and enters the ACS Group-of-Ruledefs Configuration Mode:

```
 group-of-ruledefs group1
```
**h323 time-to-live**

This command allows you to configure the time period for which an endpoint’s registration to an H.323 gatekeeper is valid.

**Product**

NAT

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration

`active-charging service service_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
h323 time-to-live timeout
default h323 time-to-live
```

**default h323 time-to-live**

- **default**
  
  Configures this command with its default setting.
  Default: 3600 seconds

- **timeout**
  
  Specifies the timeout setting, in seconds.
  `timeout` must be an integer from 1 through 2147483647.

**Usage**

Use this command to configure the time period for which an endpoint’s registration to a gatekeeper is valid.

**Example**

The following command configures the time for an endpoint registration with a timeout setting of 5 seconds:

```
h323 time-to-live 5
```
**h323 timeout**

This command allows you to configure the timeout intervals for various H.323 requests.

**Product**
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

*active-charging service service_name*

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
h323 timeout { admission admission_timeout | discovery discovery_timeout | location location_timeout | registration registration_timeout | unregistration unregistration_timeout }
default h323 timeout { admission | discovery | location | registration | unregistration }
```

**default**

Configures this command with the default setting for the specified parameters.

**admission admission_timeout**

Configures the timeout value for the admission request sent to the gatekeeper.

*admission_timeout* must be an integer from 1 through 20.

Default: 10 seconds

**discovery discovery_timeout**

Configures the timeout value for the gatekeeper request message sent to the Gatekeeper.

*discovery_timeout* must be an integer from 1 through 20.

Default: 10 seconds

**location location_timeout**

Configures the timeout value for the location request message sent to the Gatekeeper.

*location_timeout* must be an integer from 1 through 20.

Default: 10 seconds

**registration registration_timeout**

Configures the timeout value for the registration request message sent to the Gatekeeper.

*registration_timeout* must be an integer from 1 through 20.

Default: 6 seconds
ACS Configuration Mode Commands

h323 timeout

unregistration unregistration_timeout

Configures the timeout value for the unregistration request message sent to the Gatekeeper. unregistration_timeout must be an integer from 1 through 20.
Default: 3 seconds

Usage
Use this command to configure the timeout interval for the various H.323 requests.

Example
The following command configures the admission request message with a timeout value of 15 seconds:

h323 timeout admission 15
h323 tpkt

This command allows you to configure the maximum size of Transport Protocol Data Unit Packets (TPKT) that the H.323 Application Layer Gateway (ALG) can handle.

**Product**
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

```plaintext
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```plaintext
h323 tpkt max_tpkt_size
default h323 tpkt
```

- `default`
  Configures this command with its default setting.
  Default: 2048 bytes

- `max_tpkt_size`
  Specifies the maximum TPKT size, in bytes.
  `max_tpkt_size` must be an integer from 4 through 4096.

**Usage**

Use this command to configure the maximum packet size for the H.323 ALG.

**Example**

The following command configures a maximum TPKT packet size of 100 bytes:

```
h323 tpkt 100
```
h323 version

This command allows you to configure the H.323 version number supported by an H.323 Application Layer Gateway (ALG).

Product

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs)#

Syntax

h323 version h323_version_number

default h323 version

default

Configures this command with its default setting.
Default: 5

h323_version_number

Specifies the H.323 version number.

h323_version_number must be an integer from 1 through 7.

Usage

Use this command to configure the H.323 version number supported by the H.323 ALG.

Example

The following command configures the H.323 version as 1:

h323 version 1
host-pool

This command allows you to create/configure/delete host pools.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acos)#

Syntax

host-pool host_pool_name [ -noconfirm ]

no host-pool host_pool_name

no

If previously configured, deletes the specified host pool from the active charging service.

host_pool_name

Specifies the host pool to add/configure/delete.

host_pool_name must be the name of a host pool, and must be an alphanumeric string of 1 through 63 characters and can contain punctuation characters. Each host pool must have a unique name.

If the named host pool does not exist, it is created, and the CLI mode changes to the ACS Host Pool Configuration Mode wherein the host pool can be configured.

If the named host pool already exists, the CLI mode changes to the ACS Host Pool Configuration Mode for that host pool.

-noconfirm

Specifies that the command must execute without prompting for confirmation.

Usage

Use this command to create/configure/delete ACS host pools.

A host pool is a collection of hosts and IP addresses to use in access policy creation. The host pool name must be unique within the service. Host pool, port map, IMSI pool, and firewall, routing, and charging ruledefs must have unique names. A maximum of the 256 host pools can be created.

Important: Host pools configured in other ruledefs cannot be deleted.

On entering this command, the CLI prompt changes to:

[context_name]hostname(config-acos-host-pool)#
Also see the *ACS Host Pool Configuration Mode Commands* chapter.

Example

The following command creates a host pool named `hostpool1`, and enters the ACS Host Pool Configuration Mode:

```
host-pool hostpool1
```
idle-timeout

This command allows you to configure the maximum duration a flow can remain idle for, after which the system automatically terminates the flow.

Product
ACS
NAT
PSF

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:
[l]ocal[host_name(config-ac)s]#

Syntax

idle-timeout { alg-media | flow-mapping { tcp | udp } | icmp | tcp [ half-open ] | udp } idle_timeout

{ default | no } idle-timeout { alg-media | flow-mapping { tcp | udp } | icmp | tcp [ half-open ] | udp }

---
default

Configures this command with the default setting for the specified parameter.
Default:
  • alg-media: 120 seconds
  • flow-mapping { tcp | udp }: 300 seconds for TCP and 0 seconds for UDP
  • icmp, tcp, udp: 300 seconds
  • tcp half-open: 200 seconds

---
no

Disables the idle-timeout configuration for the specified flow.

---
alg-media

Configures the ALG media for the specified flow.

---
flow-mapping { tcp | udp }

The Flow Mapping timer is an extension to the existing flow idle-timeout in ACS. This flow mapping timeout applies only for NAT enabled calls and is supported only for TCP and UDP flows. The purpose of this timer is to hold the resources (NAT IP, NAT port, Private IP NPU flow) associated with a 5-tuple flow until Mapping timeout expiry.
If the Flow Mapping timer is disabled, then the Mapping timeout will not get triggered for UDP/TCP idle timed out flows. The resources such as NAT mapping will be released along with the 5-tuple flow.

---

**icmp**

Configures the ICMP protocol for the specified flow.

**tcp** [ half-open ]

Configures the TCP protocol for the specified flow. Use the *half-open* keyword to configure timeout interval for half-open TCP flows.

**udp**

Configures the UDP protocol for the specified flow.

---

**idle_timeout**

Specifies the timeout duration, in seconds, and must be an integer from 0 through 86400. For *alg-media* specifies the media inactivity timeout. The *idle_timeout* value gets applied on RTP and RTCP media flows that are created for SIP/H.323 calls. The timeout is applied only on those flows that actually match the RTP and RTCP media pinholes that are created by the SIP/H.323 ALG. A value of 0 disables the idle-timeout setting.

---

**Usage**

Use this command to configure the maximum duration a flow can remain idle, in seconds, after which the system automatically terminates the flow. Setting the value to 0 will cause the idle-timeout setting to be disabled. For flows other than TCP, UDP and ICMP, timeout value will always be 300 seconds (unless configured in the charging-action). Charging action’s flow idle-timeout will have precedence over ACS idle-timeout. If charging action’s flow idle-timeout is default, then flows will have the value configured in the active charging service.

---

**Example**

The following command configures the maximum duration a TCP flow can remain idle to 3000 seconds, after which the system automatically terminates the flow:

```
idle-timeout tcp 3000
```
**imsi-pool**

This command allows you to create/configure/delete International Mobile Subscriber Identity (IMSI) pools.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

```
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
imsi-pool imsi_pool_name [ -noconfirm ]
```

```
no imsi-pool imsi_pool_name
```

- **no**
  If previously configured, deletes the specified IMSI pool from the active charging service.

```
imsi_pool_name
```

- Specifies the IMSI pool to add/configure/delete.

```
imsi_pool_name
```

- must be the name of an IMSI pool, and must be an alphanumeric string of 1 through 63 characters, and can contain punctuation characters. Each IMSI pool must have a unique name.

- If the named IMSI pool does not exist, it is created, and the CLI mode changes to the ACS IMSI Pool Configuration Mode wherein the IMSI pool can be configured.

- If the named IMSI pool already exists, the CLI mode changes to the ACS IMSI Pool Configuration Mode for that IMSI pool.

```
-noconfirm
```

- Specifies that the command must execute without prompting for confirmation.

**Usage**

Use this command to create/configure/delete pools of International Mobile Subscriber Identifier (IMSI) numbers having group of single or range of IMSI numbers to use in access policy creation. The IMSI pool name must be unique with in the service. Host pool, port map, IMSI pool, and firewall, routing, and charging ruledefs must have unique names. A maximum of 256 IMSI pools can be created.

**Important:** IMSI pools configured in other ruledefs cannot be deleted.

On entering this command, the CLI prompt changes to:

```
[context_name]host_name(config-acs-imsi-pool)#
```
Also see the *ACS IMSI Pool Configuration Mode Commands* chapter.

**Example**

The following command creates an IMSI pool named *imsipool1*, and enters the ACS IMSI Pool Configuration Mode:

```
imsi-pool imsipool1
```
**ip dns-learnt-entries**

This command allows you to configure how long to keep the snooped IPv4 addresses that were extracted from DNS responses.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

```text
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acsc)#
```

**Syntax**

```
ip dns-learnt-entries timeout timeout_period

{ default | no } ip dns-learnt-entries timeout
```

- **default**
  Configures this command with the default DNS-learnt-entries timeout setting.
  Default: 300 seconds

- **no**
  Specifies to always use the TTL value in the DNS response, and not the timeout configured with this command.

- **timeout_period**
  Specifies the DNS-learnt-entries timeout period, in seconds.
  `timeout_period` must be an integer from 1 through 2147483647.

**Usage**

Use this command to configure how long to keep the snooped IPv4 addresses that were extracted from DNS responses—for the TTL specified in the DNS response, or for the time period configured with this command, if greater.

The configurable timer will be at global ECS level and shared across all IP addresses. Internally, a five-minute (300 seconds, non configurable) timer will be started whenever DNS analyzer is enabled. On timeout of this timer, all the learnt IP addresses will be checked for TTL expiry and the expired entries will be flushed.

**Example**

The following command specifies to keep the snooped IPv4 addresses that were extracted from DNS responses for a time period of **900 seconds**, or for the TTL value specified in the DNS response, whichever is greater:

```
ip dns-learnt-entries timeout 900
```
ip dns-learnt-entries timeout 900
**ip max-fragments**

This command allows you to limit the maximum number of IPv4/IPv6 fragments per fragment chain.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

**Syntax**

```
ip max-fragments max_fragments
default ip max-fragments
```

**Usage**
Use this command to limit the maximum number of IPv4/IPv6 fragments.

**Example**
The following command limits the maximum number of IPv4/IPv6 fragments to 100:

```
ip max-fragments 100
```
**label content-id**

This command allows you to specify a label (text string) to associate with a content ID for UDRs/EDRs/eG-CDRs.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
`Exec > ACS Configuration`

```
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acst)#
```

**Syntax**

```
label content-id content_id text label_text

no label content-id content_id
```

If previously configured, deletes the specified label.

```
content-id content_id
```

Specifies the content ID to associate with the label.

*content_id* must be an integer from 1 through 65535.

```
text label_text
```

Specifies the label to associate with the specified content ID.

*label_text* must be an alphanumeric string of 1 through 64 characters.

**Usage**

Use this command to create a text label to associate with a content ID.

A maximum of 2048 labels can be configured in the active charging service.

**Example**

The following command creates the label `test_charge1` to be associated with the content ID 1378:

```
label content-id 1378 text test_charge1
```
nat allocation-failure

This command allows you to configure the action to take when NAT IP/Port allocation fails.

Important: This command is available only in StarOS 8.3 and later releases.

Product
NAT

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs)#

Syntax

nat allocation-failure send-icmp-dest-unreachable

{ default | no } nat allocation-failure

default
Configures this command with its default setting.
Default: Packets are dropped silently

no
If previously enabled, disables the NAT Allocation Failure configuration. Packets are dropped silently.

nat allocation-failure send-icmp-dest-unreachable

Specifies to send ICMP Destination Unreachable message when NAT IP/Port allocation fails.

Usage
Use this command to configure the action to take when NAT IP/port allocation fails—to send or not to send an “ICMP destination unreachable message” when a NAT IP/port cannot be assigned to a flow in data path.

Example
The following command configures sending ICMP Destination Unreachable message when NAT IP/Port allocation fails:

nat allocation-failure send-icmp-dest-unreachable
nat allocation-in-progress

This command allows you to configure the action to take on packets when NAT IP/NPU allocation is in progress.

**Important:** This command is available only in StarOS 8.3 and later releases.

**Product**
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

```
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ac)#
```

**Syntax**

```
nat allocation-in-progress { buffer | drop }
```

```
default nat allocation-in-progress
```

```
default

    Configures this command with its default setting.
    Default: buffer
```

```
buffer | drop
```

Specifies the action to take on packets when NAT IP/NPU allocation is in progress:

- **buffer:** Buffers the packets.
- **drop:** Drops the packets.

**Usage**

In On-demand NAT IP allocation (wherein NAT IP address is allocated to the subscriber when a packet is being sent), if no free NAT IP address is available, a NAT-IP Alloc Request is sent to the VPNMgr to get NAT-IP. During that time packets are dropped. This command enables buffering the packets received when IP Alloc Request is sent to VPNMgr.

**Example**

The following command specifies to buffer packets when NAT IP/NPU allocation is in progress:

```
nat allocation-in-progress buffer
```
**nat ip downlink reassembly-timeout**

This command configures the downlink IP reassembly timer.

**Product**
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local] host_name(config-acs) #

**Syntax**

```
[ default ] nat ip downlink reassembly-timeout timeout
```

- **default**
  Configures this command with its default setting.
  Default: 2000 milliseconds

- **timeout**
  The maximum duration for which IP packet fragments can be retained, in milliseconds.
  `timeout` must be an integer from 1 through 3000.

**Usage**

Use this command to configure the downlink IP reassembly timer by setting the duration for which IP packet fragments can be retained.

**Example**

The following command configures the duration for IP packet fragments with a timeout setting of 3000 seconds:

```
nat ip downlink reassembly-timeout 3000
```
**nat tcp-2msl-timeout**

This command allows you to configure the TCP 2MSL (Maximum Segment Lifetime) timeout value for NAT.

---

**Important:** This command is available only in StarOS 8.3 and later releases.

**Product**

NAT

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration

```
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
nat tcp-2msl-timeout timeout

default nat tcp-2msl-timeout
```

---

**default**

Configures this command with its default setting.
Default: 60 seconds

**timeout**

Specifies the TCP 2MSL timeout period, in seconds.
**timeout** must be an integer from 30 through 240.

**Usage**

Use this command to configure the TCP 2MSL timeout value for NAT.

**Example**

The following command configures the TCP 2MSL timeout for NAT to 120 seconds:

```
nat tcp-2msl-timeout 120
```
nat unsolicited-pkts

This command allows you to configure unsolicited packets.

Product
ACS
NAT

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration
active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs)#

Syntax

nat unsolicited-pkts { icmp-host-unreachable { max-rate packets_num } | server-list { max-limit servers_num } }

[ default | no ] nat unsolicited-pkts { icmp-host-unreachable | server-list }

default
Configures this command with its default setting.
Default: Disabled

no
Configures this command with its default setting.

icmp-host-unreachable max-rate packets_max
Configures the maximum number of allowed ICMP response packets, in seconds.
packets_max must be an integer from 1 through 100.

server-list max-limit servers_num
Configures the maximum number of servers to be stored per Session Manager instance.
servers_num must be an integer from 2 through 50.

Usage
Use the following command to configure the number of allowed ICMP responses and the number of servers where most number of unsolicited packets are received.

Example
The following command configures the number of allowed ICMP responses per second to 10:
nat unsolicited-pkts host-unreachable max-rate 10
The following command configures the number of servers to be stored as 20:
nat unsolicited-pkts server-list max-limit 20
p2p-detection attribute

This command enables or disables the detection of SSL renegotiation flows.

**Product**
ADC

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

`active-charging service service_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
[ no ] p2p-detection attribute { attribute_list [ sub_attribute_name sub_attribute_value ] }
```

- **no**
  If previously enabled, disables detection of SSL renegotiation flows.

- **attribute_list**
  List of configurable P2P detection attributes populated from the currently loaded P2P plugin.
  Supported attribute: `ssl-renegotiation`

- **sub_attribute_name**
  List of configurable P2P detection sub-attributes related to the attribute selected from the attribute list. This list is populated from the currently loaded P2P plugin.
  Supported sub-attributes if selected attribute is `ssl-renegotiation`:
  - `max-entry-per-sessmgr`: Specifies maximum SSL Session IDs tracked per session manager.
  - `id-reduce-factor`: Specifies by how much factor the SSL ID is stored in the SSL Session ID tracker table. Possible values are 1, 2, 4.

- **sub_attribute_value**
  Value of the selected sub-attribute. If sub-attribute is not specified, the default value set in the P2P plugin will be used.
  The value for `max-entry-per-sessmgr` must be an integer from 1 through 65535. Default: 20000
  Possible values for `id-reduce-factor` are 1,2,4. Default: 4

**Usage**

Use this command to enable or disable the detection of SSL renegotiation flows.

**Example**

The following command enables SSL renegotiation with SSL session IDs as 40000 and factor as 4:
p2p-detection attribute ssl-renegotiation max-entry-per-sessmgr 40000 id-reduce-factor 4
p2p-detection behavioral

This command enables or disables behavioral detection for unidentified traffic.

Product
ADC

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acsc)#

Syntax

[ no ] p2p-detection behavioral { behavioral_list | all }

no
If previously configured, disables the behavioral configuration.

behavioral_list
Specifies the behavior to match. The behavioral list is the list of supported behavioral detection logic populated from the currently loaded ADC plugin.

behavioral_list must be one of the following:

- **all**: Enables all behavioral detection types supported by the ADC plugin
- **download**: Detects unknown flows which are data download using behavioral analysis
- **p2p**: Detects P2P and file sharing protocols using behavioral analysis
- **upload**: Detects unknown flows which are data upload using behavioral analysis
- **video**: Detects video flows using behavioral analysis
- **voip**: Detects VoIP (voice and video) protocols using behavioral analysis

Usage
Use this command to enable or disable behavioral detection for unidentified traffic. Behavioral VoIP is meant for zero day detection of VoIP traffic. Behavioral upload/download is similar to client-server upload/download using HTTP, FTP, SFTP, etc. It must also detect flows of non-standard ports which ECS cannot detect and falls under the client-server model. The behavioral feature is disabled by default.

Example

The following command specifies to configure behavioral VoIP:

```plaintext
p2p-detection behavioral voip
```
p2p-detection ecs-analysis

This command enables or disables ECS analysis for analyzers — FTP, HTTP, RTSP and SIP.

**Product**
ADC

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

**Syntax**

```
[ no ] p2p-detection ecs-analysis { all | ftp | http | rtsp | sip }
```

- **no**
  If previously enabled, disables the configured analyzers.

- **all**
  ECS analysis for all analyzers — FTP, HTTP, RTSP and SIP.

- **ftp**
  ECS analysis for FTP analyzer.

- **http**
  ECS analysis for HTTP analyzer.

- **rtsp**
  ECS analysis for RTSP analyzer.

- **sip**
  ECS analysis for SIP analyzer.

**Usage**
Use this command to enable or disable the interworking of analyzers — FTP, HTTP, RTSP and SIP. This feature is enabled by default if P2P protocols are enabled.

**Example**
The following command enables ECS analysis for the **ftp** analyzer:

```
p2p-detection ecs-analysis ftp
```
p2p-detection protocol

This command enables/disables the detection of all or specified peer-to-peer (P2P) protocols.

**Product**
ADC

**Privilege**
Security Administrator, Administrator

**Mode**

```
no
If previously enabled, disables the detection of the specific peer-to-peer protocol.

all
Specifies to detect all supported P2P protocols.
In 12.2 and earlier releases: Specifying all is the same as configuring each of the following protocols individually.
In 14.0 and later releases: Specifying all means all of the protocols supported by the currently loaded plugin.

actionvoip
Specifies to detect ActionVoip protocol.

actsync
Specifies to detect ActiveSync protocol.

adobeconnect
Specifies to detect Adobe Connect protocol.

aimini
Specifies to detect Aimini protocol.

amazoncloud
Specifies to detect AmazonCloud protocol.

antsp2p
Specifies to detect ANts P2P protocol.

apple-push
Specifies to detect Apple Push Notification protocol.

apple-store
Specifies to detect iPhone Appstore protocol.

applejuice
Specifies to detect Applejuice protocol.

applemaps
Specifies to detect Apple Maps protocol.

ares
Specifies to detect Ares Galaxy protocol.

armagettron
Specifies to detect Armagetron protocol.
avi
Specifies to detect AVI protocol.

badoo
Specifies to detect Badoo protocol.

battlefld
Specifies to detect Battlefield protocol.

bbm
Specifies to detect BBM protocol.

bitcasa
Specifies to detect Bitcasa protocol.

bittorrent
Specifies to detect BitTorrent protocol.

bittorrent-sync
Specifies to detect BitTorrent Sync protocol.

blackberry-store
Specifies to detect Blackberry World protocol.

blackberry
Specifies to detect BlackBerry protocol.

blackdialer
Specifies to detect Blackdialer protocol.

box
Specifies to detect BOX protocol.

callofduty
Specifies to detect Call of Duty protocol.

chikka
Specifies to detect Chikka protocol.

cisco-jabber
Specifies to detect Cisco Jabber protocol.

citrix
Specifies to detect Citrix Independent Computing Architecture (ICA) protocol.

+ More than one of the above keywords can be entered within a single command.
Usage
Use this command to configure the detection of all or specific P2P protocol(s). Multiple keywords can be specified in a single command.

Example
The following command enables detection of all P2P protocols:

```
p2p-detection protocol all
```
packet-filter

This command allows you to create/configure/delete ACS packet filters.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs)#

Syntax

packet-filter packet_filter_name [ -noconfirm ]

no packet-filter packet_filter_name

no

If previously configured, deletes the specified packet filter from the active charging service.

packet_filter_name

Specifies the packet filter to add/configure/delete. packet_filter_name must be the name of a packet filter, and must be an alphanumeric string of 1 through 63 characters. Each packet filter must have a unique name.

If the named packet filter does not exist, it is created, and the CLI mode changes to the ACS Packet Filter Configuration Mode wherein the packet filter can be configured.

If the named packet filter already exists, the CLI mode changes to the ACS Packet Filter Configuration Mode for that packet filter.

-noconfirm

Specifies that the command must execute without prompting for confirmation.

Usage

Use this command to create/configure/delete an ACS packet filter.

On entering this command, the CLI prompt changes to:

[context_name]hostname(config-packet-filter)#

Also see the ACS Packet Filter Configuration Mode Commands chapter.

Example

The following command creates a packet filter named filter3, and enters the ACS Packet Filter Configuration Mode:

    packet-filter filter3
passive-mode

This command allows you to configure the Active Charging Service to operate in passive mode, wherein ACS passively monitors copies of packets.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

**active-charging service** service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs)#

Syntax

```
[ default | no ] passive-mode
```

**no**

If previously enabled, disables the passive mode configuration.

**default**

Configures this command with its default setting.
Default: Disabled

Usage

Use this command to put the active charging service in/out of passive mode operation, wherein ACS passively monitors copies of packets.

Example

The following command puts the active charging service into passive mode operation:

```
passive-mode
```
pcp-service

Creates or deletes a Port Control Protocol (PCP) service.

---

**Important:** This command is customer specific. Contact your Cisco account representative for more information.

---

**Product**
- ACS
- NAT
- PSF

**Privilege**
- Security Administrator
- Administrator

**Mode**
- Exec > ACS Configuration
- active-charging service service_name

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
[ no ] pcp-service pcp_service_name [ -noconfirm ]
```

- **no**
  - If previously configured, deletes the specified PCP service.

- **pcp_service_name**
  - Specifies the name of a PCP service.
  - `pcp_service_name` must be the name of a PCP service, and must be an alphanumeric string of 1 through 63 characters. A maximum of 5 PCP services can be configured in the active charging service.
  - If the named PCP service does not exist, it is created, and the CLI mode changes to the PCP Configuration Mode wherein the service can be configured. If the named PCP service already exists, the CLI mode changes to the PCP Configuration Mode.

- **-noconfirm**
  - Specifies that the command must execute without any additional prompt and confirmation from the user.

**Usage**

Use this command to create or delete a PCP service.
On entering this command, the CLI prompt changes to:

```
[context_name]host_name(config-pcp-service)#
```

Also see the *PCP Configuration Mode Commands* chapter.

**Example**

The following command creates a PCP service named `pcp1`, and changes to the PCP Configuration mode:
pcp-service pcpl
policy-control bearer-bw-limit

This command allows you to enable/disable per-bearer MBR policing—bandwidth limiting.

Product
ACD

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs)#

Syntax

{ default | no } policy-control bearer-bw-limit

---

default
Configures this command with its default setting.
Default: Enable; by default, per-bearer MBR policing is enabled.

---

no
Disables per-bearer MBR policing.

Usage

This command allows you to enable/disable per-bearer bandwidth limiting based on bitrates received over Gx. Note that there are only two variants of this command, the default and no variants.
policy-control bind-default-bearer

For PCEF Bearer Binding in 3G and when BCM mode is UE only, this command allows you to enable/disable binding rules having QoS of default bearer to the default bearer and to not ignore/ignore other rules.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs)#

Syntax

[ default | no ] policy-control bind-default-bearer

---
default

Configures this command with its default setting.
Default: Disables only binding those rules having QoS of default bearer to the default bearer and specifies to not ignore other rules. Rules having respective QoS will get attached to the relevant bearers. Also TFT updates towards the UE (access side) will not be suppressed.

---
no

The no keyword functionality is same as the default setting.

Usage

This CLI command is used to bind all the PCC dynamic or predef rules received from PCRF (Bearer Control Mode (BCM) is UE_only) without QoS and ARP or with the same QoS and ARP as that of the default bearer, to the default bearer. This CLI is used for UE_Only mode.
In case no QoS is specified the rule gets attached to the default bearer. Also no TFT updates will be sent towards UE (access side). So only one default bearer will ever be created.
On receiving a PCC dynamic rule or predef rule from PCRF, having QoS/ARP other than the default bearer, then those rules are ignored and a response indicating that the rule could not be installed, is sent.
This CLI command will not work currently for dedicated bearers (secondary PDP contexts). Secondary bearers initiated by UE are not supported.
Releases prior to 12.2, when UE_Only BCM is received from PCRF, IMSA terminates the call for P-GW (GnGp setup). Release 12.2 onwards, the P-GW call is not terminated so as to be in compliance with 3GPP standard specification TS 29.212, but Traffic Flow Template (TFT) updates towards UE (access side) will be supported.
**Important:** This CLI is applicable to all the rulebases in the chassis configuration. If the rulebase is changed to some other rulebase in the interim period or anytime later, this CLI will continue to apply to the current new rulebase too.
policy-control burst-size

This command allows you to configure the burst size for bandwidth limiting per dynamic-rule or per bearer.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

```
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
policy-control burst-size { auto-readjust [ duration duration ] | bytes bytes } | default | no } policy-control burst-size
```

- **default | no**
  Configures this command with its default setting.
  Default: 65535 bytes

- **duration duration**
  Configures the burst size equal to <seconds> of traffic.
  `duration` must be an integer from 1 through 20.
  Default: In 12.1 and earlier releases, 10 seconds. In 12.2 and later releases, 5 seconds.

- **bytes bytes**
  Specifies the burst size, in bytes.
  `bytes` must be an integer from 1 through 4000000000.

**Usage**

Use this command to configure the burst size for bandwidth limiting per dynamic-rule or per bearer.

**Example**

The following command configures the burst size for bandwidth limiting per dynamic-rule or per bearer equal to 10 seconds of traffic:

```
policy-control burst-size auto-readjust
```
policy-control charging-action-override

This command has been removed from the ACS Configuration Mode, and replaced by the charging-action-override command in the ACS Rulebase Configuration Mode.
policy-control charging-rule-base-name

This command allows you to configure how the Charging-Rule-Base-Name AVP from PCRF is interpreted, either as ACS rulebase or ACS group-of-ruledefs.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-ac)#

Syntax

policy-control charging-rule-base-name { active-charging-group-of-ruledefs | active-charging-rulebase [ ignore-when-removed ] [ use-first ]}

default policy-control charging-rule-base-name

no policy-control charging-rule-base-name active-charging-rulebase use-first

default

Configures this command with its default setting(s).

Default:

  • charging-rule-base-name: active-charging-group-of-ruledefs
  • use-first: Disabled

no

If multiple Charging-Rule-Base-Name are received from the PCRF, specifies to select the last rulebase. This is the default behavior.

active-charging-group-of-ruledefs

Specifies interpreting Charging-Rule-Base-Name as ACS group-of-ruledefs.

active-charging-rulebase [ ignore-when-removed ][ use-first ]

Specifies interpreting Charging-Rule-Base-Name as ACS rulebase.

When Charging-Rule-Base-Name AVP is interpreted as ACS rulebase, if PCRF requests the removal of a Charging-Rule-Base-Name, which is the same as the rulebase used for that PDP context, the PDP context is terminated. This is because after removal of the rulebase, the PDP context will have no rulebase. This is the default behavior.

ignore-when-removed: Specifies to ignore PCRF request for removal of Charging-Rule-Base-Name, and take no action. If this keyword is not configured, the PDP context from which the rulebase is removed gets terminated.
use-first: If multiple Charging-Rule-Base-Name are received from the PCRF, since a call can only have one ACS rulebase applied, specifies to select the first rulebase. If previously enabled, to disable this configuration, use the no policy-control charging-rule-base-name active-charging-rulebase use-first command. If this keyword is not configured, by default, the last rulebase is selected. For each call, this interpretation is decided at call setup, and will not be changed during the life of that call. Change will only apply to new calls coming up after the change.

Usage
Use this command to configure interpretation of Charging-Rule-Base-Name AVP from PCRF either as ACS group-of-ruledefs or as ACS rulebase.

Example
The following command configures interpreting of Charging-Rule-Base-Name AVP as ACS rulebase:

```
policy-control charging-rule-base-name active-charging-rulebase
```
policy-control dynamic-rule-limit

This command allows you to enable/disable per-dynamic-rule MBR policing—bandwidth limiting.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

```
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ac)#
```

**Syntax**

```
{ default | no } policy-control dynamic-rule-limit
```

- **default**
  Configures this command with its default setting.
  Default: Enable; by default, per-dynamic-rule MBR policing is enabled.

- **no**
  Disables per-dynamic-rule MBR policing.

**Usage**

This command allows you to enable/disable per-dynamic-rule bandwidth limiting based on bitrates received over Gx. Note that there are only two variants of this command, the default and no variants.
policy-control retransmissions-counted

This command allows you to enable/disable charging of retransmitted packets when they hit a dynamic rule.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local] host_name(config-acsc)#

Syntax

[ default | no ] policy-control retransmissions-counted

default | no

Disables charging of retransmitted packets when they hit a dynamic rule.
Default: Disabled; no retransmissions counted.

Usage

Use this command to enable/disable charging of retransmitted packets when they hit a dynamic rule.

Example

The following command enables retransmissions to be charged when they hit a dynamic rule:

    policy-control retransmissions-counted
policy-control update-default-bearer

For PCEF Bearer Binding in 4G, this command allows you to enable/disable binding rules having QoS of default bearer to the default bearer and to not ignore/ignore other rules.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs)#

Syntax

[ default | no ] policy-control update-default-bearer

default
Configures this command with its default setting. Disables only binding those rules having QoS of default bearer to the default bearer and specifies to not ignore other rules. Rules having respective QoS will get attached to the relevant bearers. Also TFT updates towards UE (access side) will not be suppressed.

no
Enables binding rules having QoS of default bearer to the default bearer and specifies to ignore other rules. In case no QoS is specified the rule gets attached to default bearer. Also TFT updates towards UE (access side) will be suppressed for default bearer. So only one default-bearer will ever be created.

⚠️ Caution: Upon executing this CLI command “no policy-control update-default-bearer”, system crash is likely to occur if the TFT information is not added to the charging-action.

Usage
This CLI command is used to bind all the PCC dynamic or predef rules received from PCRF without QoS and ARP or with the same QoS and ARP as that of the default bearer, to the default bearer. On receiving a PCC dynamic rule or predef rule from PCRF, having QoS/ARP other than the default bearer, then those rules are ignored and a response indicating that the rule could not be installed, is sent. This CLI command will not work currently for dedicated bearers (secondary PDP contexts). Secondary bearers initiated by UE are not supported. Releases prior to 12.2 TFT updates were sent towards the UE (access side) on all bearers. Release 12.2 onwards, TFT updates will be suppressed towards the UE (access side) for default bearer, if the CLI is enabled.
**Important:** This CLI is applicable to all the rulebases in the chassis configuration. If the rulebase is changed to some other rulebase in the interim period or anytime later, this CLI will continue to apply to the current new rulebase too.
**port-map**

This command allows you to create/configure/delete port maps.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration

```
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
port-map port_map_name [ -noconfirm ]

no port-map port_map_name
```

- **no**
  - If previously configured, deletes the specified port map from the active charging service.

- **port_map_name**
  - Specifies the port map to add/configure/delete.
  - **port_map_name** must be the name of a port map, and must be an alphanumeric string of 1 through 63 characters, and can contain punctuation characters. Each port map must have a unique name.
  - If the named port map does not exist, it is created, and the CLI mode changes to the ACS Port Map Configuration Mode wherein the port map can be configured.
  - If the named port map already exists, the CLI mode changes to the ACS Port Map Configuration Mode for that port map.

- **-noconfirm**
  - Specifies that the command must execute without prompting for confirmation.

**Usage**

Use this command to create/configure/delete an ACS port map.

The port map name must be unique with in the service. Host pool, port map, IMSI pool, and firewall, routing, and charging ruledefs must have unique names. A maximum of the 256 port maps can be created.

---

**Important:** Port maps in use in other ruledefs cannot be deleted.

---

**Example**

Also see the *ACS Port Map Configuration Mode Commands* chapter.
The following command creates a port map named \textit{portmap1}, and enters the ACS Port Map Configuration Mode:

\texttt{port-map portmap1}
qos-group-of-ruledefs

This command allows you to create/configure/delete a qos-group-of-ruledefs.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

```
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
qos-group-of-ruledefs qos_group_of_ruledefs_name [ -noconfirm ] [ description description ]

no qos-group-of-ruledefs qos_group_of_ruledefs_name
```

---

**no**
If previously configured, deletes the specified qos-group-of-ruledefs from the active charging service.

```
qos_group_of_ruledefs_name
```

Specifies the qos-group-of-ruledefs to add/configure/delete.

- `qos_group_of_ruledefs_name` must be the name of a qos-group-of-ruledefs, and must be an alphanumeric string of 1 through 63 characters. Each qos-group-of-ruledefs must have a unique name.

- If the named qos-group-of-ruledefs does not exist, it is created, and the CLI mode changes to the ACS QoS-Group-of-Ruledefs Configuration Mode wherein the group can be configured.

- If the named qos-group-of-ruledefs already exists, the CLI mode changes to the ACS QoS-Group-of-Ruledefs Configuration Mode for that group.

---

**-noconfirm**
Specifies that the command must execute without prompting for confirmation.

```
description description
```

Specifies an optional description of the group, such as purpose of setting up the group, to be included in the configuration.

**Usage**

Use this command to create/configure/delete a qos-group-of-ruledefs.

On entering this command, the CLI prompt changes to:

```
[context_name]hostname(config-qos-group-of-ruledefs)#
```

Also see the *ACS QoS-Group-of-Ruledefs Configuration Mode Commands* chapter.

**Example**
The following command creates a qos-group-of-ruledefs named `group1`, and enters the ACS QoS-Group-of-Ruledefs Configuration Mode:

```
qos-group-of-ruledefs group1
```
readdress-server-list

This command allows you to create/delete server list for DNS redirection.

Important: This command is license dependent. For more information please contact your Cisco account representative.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration
active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-ac)#

Syntax

[ no ] readdress-server-list server_list_name [ -noconfirm ]

no
If previously configured, deletes the specified readdress server list from the active charging service.

server_list_name
Specifies the server list to add/configure/delete for DNS redirection.
server_list_name must be an alphanumeric string of 1 through 63 characters and can contain punctuation characters. Each server list must have a unique name.
If the named server list does not exist, it is created, and the CLI mode changes to the ACS Readdress Server List Configuration Mode wherein the servers can be configured.
If the named server list already exists, the CLI mode changes to the ACS Readdress Server List Configuration Mode for that server list.

-noconfirm
Specifies that the command must execute without prompting for confirmation.

Usage
Use this command to create/delete server list for DNS redirection.
To add the servers to the server list, see the server command in the ACS Readdress Server List Configuration Mode chapter.
On entering this command, the CLI prompt changes to:
[context_name]hostname(config-readdress-server-list)#
Also see the ACS Readdress Server List Configuration Mode chapter.
The following command creates a charging action named \texttt{homeDNSserver} and changes to the ACS Readdress Server List Configuration Mode:

\texttt{readdress-server-list homeDNSserver}
redirect user-agent

This command allows you to specify the user agent for conditional redirection of traffic flows.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

```
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
[ no ] redirect user-agent user_agent_name
```

- **no**
  If previously configured, deletes the specified user agent from the active charging service.

- **user_agent_name**
  Specifies the user agent to be used for redirecting traffic flow.
  *user_agent_name* must be the name of a user agent, and must be an alphanumeric string of 1 through 32 characters.
  A maximum of 16 user-agents can be configured in the active charging service.

**Usage**

Use this command to redirect the traffic flow with conditions based on configured user-agent name. This user agent is used with *flow action* command in the ACS Charging Action Configuration Mode.

**Example**

The following command specifies the redirect user agent *user_rule1* for conditional redirection of traffic flow:

```
redirect user-agent user_rule1
```
rulebase

This command allows you to create/configure/delete ACS rulebases.

**Important:** A maximum of 512 rulebases can be configured in the active charging service.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-ac)#

**Syntax**

rulebase rulebase_name [ -noconfirm ]

no rulebase rulebase_name

- **no**  
  If previously configured, deletes the specified rulebase from the active charging service.

  rulebase_name  

  Specifies the rulebase to add/configure/delete.  
  rulebase_name must be the name of an ACS rulebase, and must be an alphanumeric string of 1 through 63 characters, and can contain punctuation characters. Each rulebase must have a unique name. 
  If the named rulebase does not exist, it is created, and the CLI mode changes to the ACS Rulebase Configuration Mode wherein the rulebase can be configured. 
  If the named rulebase already exists, the CLI mode changes to the ACS Rulebase Configuration Mode for that rulebase.

  -noconfirm  

  Specifies that the command must execute without prompting for confirmation.

**Usage**

Use this command to create/configure/delete an ACS rulebase. A rulebase is a collection of protocol rules to match a flow and associated actions to be taken for matching flow.

The default rulebase is used when a subscriber/APN is not configured with a specific rulebase to use.

On entering this command, the CLI prompt changes to:

[context_name]hostname(config-rule-base)#

Also see the *ACS Rulebase Configuration Mode Commands* chapter.

**Example**

Command Line Interface Reference, StarOS Release 16
The following command creates a rulebase named $test1$, and enters the ACS Rulebase Configuration Mode:

```
rulebase test1
```
rulebase-list

This command allows you to create and delete ACS rulebase lists.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-ac)#

Syntax

rulebase-list rulebase_list_name rulebase_name [ rulebase_name + ]

no rulebase-list rulebase_list_name

no

If previously configured, deletes the specified rulebase list from the active charging service.

rulebase_list_name

Specifies the rulebase list to add/modify/delete.
rulebase_list_name must be the name of an ACS rulebase list, and must be an alphanumeric string of 1 through 63 characters.

rulebase_name

Specifies the rulebase name(s) to add to the rulebase list.
Each rulebase list must contain a minimum of one rulebase name, and the cumulative length of all rulebase names must not exceed 256 bytes.
rulebase_name must be the name of an ACS rulebase, and each rulebase name must be an alphanumeric string of 1 through 63 characters.

Usage

Use this command to create or delete an ACS rulebase list. A rulebase list is a space-separated string of rulebase names supplied to the OCS, from which the OCS chooses the rulebase to use for the subscriber. The rulebase list to use for a subscriber is specified in the APN for the subscriber.

In 12.3 and earlier releases, a maximum of 20 rulebase lists can be configured.
In 14.0 and later releases, a maximum of 128 rulebase lists can be configured.

See the active-charging rulebase-list command in the APN Configuration Mode Commands chapter.

Example

The following command creates a rulebase list named rblist, and adds the rulebases named rulebase1, rulebase3, and rulebase5 to it:
The following command deletes the rulebase list named rblist:

```text
no rulebase-list rblist
```
ruledef

This command allows you to create/configure/delete ACS rule definitions.

**Important:** A maximum of 2048 ruledefs can be configured in the active charging service.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

`active-charging service service_name`

Entering the above command sequence results in the following prompt:

`[local] host_name(config-acs)#`

**Syntax**

```
ruledef ruledef_name [ -noconfirm ]
```

```
no ruledef ruledef_name
```

**ruledef**

Specifies the ruledef to add/configure/delete.

`ruledef_name` must be the name of an ACS ruledef, and must be an alphanumeric string of 1 through 63 characters, and can contain punctuation characters. Each ruledef must have a unique name. Host pool, port map, IMSI pool, and firewall, routing, and charging ruledefs must have unique names.

If the named ruledef does not exist, it is created, and the CLI mode changes to the ACS Ruledef Configuration Mode wherein the ruledef can be configured.

If the named ruledef already exists, the CLI mode changes to the ACS Ruledef Configuration Mode for that ruledef.

**Important:** If there are any changes to ruledef and the Override Control/Inheritance feature is enabled, then execute the CLI command “update active-charging override-control rulebase-config”. For more information on this command, see the Command Line Interface Reference.

```
-noconfirm
```

Specifies that the command must execute without prompting for confirmation.

**Usage**

Use this command to create/configure/delete an ACS ruledef.
A ruledef represents a set of matching conditions across multiple L3 – L7 protocol based on protocol fields and state information. Each ruledef can be used across multiple rulebases within the active charging service. On entering this command, the CLI prompt changes to:

```
[context_name]hostname(config-acs-ruledef)#
```

Also see the "ACS Ruledef Configuration Mode Commands" chapter.

**Example**

The following command creates an ACS ruledef named `test1`, and enters the ACS Ruledef Configuration Mode:

```
ruledef test1
```
**sip advanced**

This command enables SIP ALG to maintain the same tag parameters (from and to tag) for Authorization or Proxy Authentication requests.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

```
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
[ default | no ] sip advanced out-of-dialog-request retain-tag
```

- **default**
  Configures this command with its default setting.
  Default: Disabled

- **no**
  If previously enabled, disables the SIP ALG configuration.

**Usage**

Use this command to enable SIP ALG to maintain the same tag parameters (from and to tag) while processing 4xx responses for Authorization or Proxy Authentication requests as described in section 8.1.3.5 of RFC 3261 (SIP: Session Initiation Protocol).
system-limit l4-flows

This command allows you to configure the system-wide Layer 4 flow limit.

**Important:** This command is customer specific. For more information contact your Cisco account representative.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

*active-charging service service_name*

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
system-limit l4-flows limit
{ default | no } system-limit l4-flows
```

- **default**
  Configures this command with its default setting.
  Default: Disabled; same as **no system-limit l4-flows**

- **no**
  Disables the limit checking configuration.

- **limit**
  Specifies the Layer 4 flows limit.
  *limit* must be an integer from 1 through 2147483647.

**Usage**

Use this command to configure the system-wide limit for Layer 4 flows.

The System-wide L4 Flow Limiting feature provides the capability to limit the number of TCP and UDP flow over the system. This limiting can be applied to all subscribers attaching to the system and to all APNs. This feature is compatible with the existing per-subscriber limiting (configured using the flow limit-for-flow-type charging action). Both limiting can be active in the same time.

System-wide flow limiting is implemented by comparing the “Effective Flows” periodically (~ every 10 seconds) against the configurable “System-wide Flow Limit”. Where “Effective Flows” is the number of active data sessions, each identified by the 5-tuple key. If the “Effective Flows” exceeds the “System-wide Flow Limit”, the Resource Manager indicates it to the active charging service. When ACS is aware of the “System-wide Flow Limit” being reached, no more data sessions are setup. The packets are discarded. While
processing a successive flow-usage update from active charging service a change in behavior is indicated to active charging service to start accepting data sessions. As this relies on periodic reporting there is an inherent delay in the detection of “exceeding/returning once exceeded” to the flow limit.

**Example**

The following command sets the system limit for L4 flows to 100:

```
  system-limit l4-flows 100
```
tethering-database

This command allows you to enable/disable the Tethering Detection feature, and load the databases from the specified files into the service.

**Important:** This command is available only if the Smartphone Tethering Detection license is enabled. For more information please contact your Cisco account representative.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs)#

**Syntax**

tethering-database [ os-signature os_signature_db_file_name | tac tac_db_file_name | ua-signature ua_signature_db_file_name ] +

{ default | no } tethering-database

default

Configures this command with its default setting. Default: Tethering Detection feature is disabled, and the database file names are reset to their default values.

no

Disables Tethering Detection.

tethering-database os-signature os_signature_db_file_name

Specifies the OS Signature database file to load. os_signature_db_file_name must be the name of the OS Signature database file, and must be an alphanumeric string of 1 through 255 characters.

tethering-database tac tac_db_file_name

Specifies the TAC database file to load. tac_db_file_name must be the name of a TAC database file, and must be an alphanumeric string of 1 through 255 characters.

tethering-database ua-signature ua_signature_db_file_name

Specifies the User Agent (UA) Signature database file to load.
**tethering-database**

*ua_signature_db_file_name* must be the name of a UA Signature database file, and must be an alphanumeric string of 1 through 255 characters.

+ Indicates that more than one of the preceding option can be entered in a single command.

---

**Usage**

Use this command to enable the Tethering Detection feature, and load the OS, TAC, and UA databases from the specified files into the service.

Tethering refers to the use of a smartphone as a USB dongle/modem to provide Internet connectivity to laptops/PDAs/tablets like iPad, using the smartphone's data plan. Typically many operators have in place an eat-all-you-can-get data plan for smartphones, the usage of which is intended to be from the smartphone as a mobile device. However, some users use the low rate/unlimited usage of data plan to provide Internet connectivity to their laptops in places where normal Internet connection via broadband/WiFi might be more costly/not available/insecure.

Operators are interested in detecting such usage of a smartphone as a modem to better understand the usage across their networks and offer plans inline to that usage to their customers. They may also charge the tethered and non-tethered traffic separately.

After Tethering Detection has been enabled here (regardless, it must also be enabled within the rulebase), this CLI command may be used to change the databases with the specified databases.

The files are picked from the disk file system within the /databases directory. If a file name value is not configured, the default file names, *os-db*, *tac-db*, and *ua-db*, are used.

For more information on the Tethering Detection feature, refer to the *Enhanced Charging Services Administration Guide*.

---

**Example**

The following command enables Tethering Detection and selects the UA Signature database file named *test*:

```
tethering-database ua-signature test
```
timedef

This command allows you to create/configure/delete ACS Time Definitions (timedefs).

**Important:** This command is available only in StarOS 8.1 and in StarOS 9.0 and later releases.

**Important:** A maximum of 10 timedefs can be configured in the active charging service.

---

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

`active-charging service service_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```
timedef timedef_name [ -noconfirm ]

no timedef timedef_name
```

- **no**
  If previously configured, deletes the specified timedef from the active charging service.

  **timedef_name**
  Specifies the timedef to add/configure/delete.
  `timedef_name` must be the name of a timedef, and must be an alphanumeric string of 1 through 63 characters. Each timedef must have a unique name.
  If the named timedef does not exist, it is created, and the CLI mode changes to the ACS Timedef Configuration Mode wherein timeslots for the timedef can be configured.
  If the named timedef already exists, the CLI mode changes to the ACS Timedef Configuration Mode for that timedef.

  **-noconfirm**
  Specifies that the command must execute without prompting for confirmation.

---

**Usage**

Use this command to create/configure/delete ACS timedefs for the Time-of-Day Activation/Deactivation of Rules feature. Timedefs enable activation/deactivation of ruledefs/groups-of-ruledefs such that they are available for rule matching only when they are active.

On entering this command, the CLI prompt changes to:
Also see the ACS Timedef Configuration Mode Commands chapter.

Example

The following command creates a timedef named `test1`, and enters the ACS Timedef Configuration Mode:

```plaintext
timedef test1
```
tpo policy

The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
tpo profile

The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
udr-format

This command allows you to create/configure/delete a User Data Record (UDR) format.

**Important:** A maximum of 256 UDR plus EDR formats can be configured in the active charging service.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

```
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acsc)#
```

Syntax

```
udr-format udr_format_name [ -noconfirm ]

no udr-format udr_format_name
```

- **no**
  If previously configured, deletes the specified UDR format from the active charging service.

- **udr_format_name**
  Specifies the UDR format to add/configure/delete.
  *udr_format_name* must be the name of a UDR format, and must be an alphanumeric string of 1 through 63 characters. Each UDR format must have a unique name.
  If the named UDR format does not exist, it is created, and the CLI mode changes to the UDR Format Configuration Mode wherein the UDR format can be configured.
  If the named UDR format already exists, the CLI mode changes to the UDR Format Configuration Mode for that UDR format.

- **-noconfirm**
  Specifies that the command must execute without prompting for confirmation.

Usage

Use this command to create/configure/delete a UDR format in the active charging service.

On entering this command, the CLI prompt changes to:

```
[context_name]hostname(config-acsc-udr)#
```

Also see the *UDR Format Configuration Mode Commands* chapter.

Example
The following command creates an UDR format named \textit{udr\_format1} and changes to the UDR Format Configuration Mode:

\texttt{udr-format udr\_format1}
url-blacklisting match-method

This command allows you to specify the match method to look up URLs in the URL Blacklisting database.

**Product**
CF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration

```plaintext
active-charging service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs)#
```

**Syntax**

```plaintext
url-blacklisting match-method { exact | generic }
```

**Default**

```plaintext
default url-blacklisting match-method
```

- **default**
  Configures this command with its default setting.
  Default: **exact**

**Important:** In 14.0 and later releases, it is recommended to use the generic match method for URL Blacklisting.

- **exact**
  Specifies the exact-match method, wherein URL Blacklisting is performed only on exact match with a URL present in the URL Blacklisting database.

- **generic**
  Specifies the generic-match method, wherein URL Blacklisting is performed on a generic match with URLs present in the URL Blacklisting database.

**Usage**

Use this command to set the match method to look up URLs in the URL Blacklisting database.

**Example**

The following command sets the exact-match method to look up URLs in the URL Blacklisting database:

```
url-blacklisting match-method exact
```
xheader-format

This command allows you to create/configure/delete ACS extension-header (x-header) format specifications.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration

active-charging service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs)#

Syntax

xheader-format xheader_format_name [ -noconfirm ]

no xheader-format xheader_format_name

Syntax:

xheader-format xheader_format_name [ -noconfirm ]

- no

If previously configured, deletes the specified x-header format from the active charging service.

xheader_format_name

Specifies the x-header format to add/configure/delete. xheader_format_name must be the name of an xheader format, and must be an alphanumeric string of 1 through 63 characters. Each x-header format must have a unique name.
If the named x-header format does not exist, it is created, and the CLI mode changes to the ACS X-header Format Configuration Mode wherein the x-header format can be configured.
If the named x-header format already exists, the CLI mode changes to the ACS X-header Format Configuration Mode for that x-header format.

- noconfirm

Specifies that the command must execute without prompting for confirmation.

Usage

Use this command to create/configure/delete an x-header format specification in the active charging service. On entering this command, the CLI prompt changes to:
[context_name]host_name(config-acs-xheader)#

An x-header may be specified in a charging action to be inserted into HTTP GET and POST request packets. See xheader-insert CLI command in the ACS Charging Action Configuration Mode Commands chapter. Also see the ACS X-header Format Configuration Mode Commands chapter.

Example

The following command creates an x-header format named test, and enters the ACS X-header Format Configuration Mode:
xheader-format test
Chapter 9
ACS Group-of-Objects Configuration Mode Commands

The ACS Group-of-Objects Configuration Mode is used to configure groups of Active Charging Service (ACS) objects.

**Important:** This configuration mode is available only in 10.2 and later releases.

Mode

Exec > ACS Configuration > ACS Group-of-Objects Configuration

```
active-charging service service_name > group-of-objects object_name [ type string ]
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-group-of-objects)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**

```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-acs-group-of-objects)#
```

**Syntax**

```
[ no ] member-object object
```

- **no**
  If previously added, removes the specified member object from the current group-of-objects.

- **object**
  Specifies the member object to add to or remove from the current group-of-objects. 
  `object` must be an alpha and/or numeric string of 1 through 63 characters.

**Usage**
Use this command to add or remove member objects from a group-of-objects.

**Example**
The following command adds the object `test` to the current group-of-objects:

```
member-object test
```
Chapter 10
ACS Group-of-Prefixed-URLs Configuration Mode Commands

The ACS Group-of-Prefixed-URLs Configuration Mode is used to create and configure groups of prefixed URLs.

Important: This configuration mode is customer specific. For more information, contact your Cisco account representative.

Mode

Exec > ACS Configuration > ACS Group-of-Prefixed-URLs Configuration

active-charging service service_name > group-of-prefixed-urls group_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-grp-of-prefixed-urls)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

Product

Use this command to return to the parent configuration mode.
**prefixed-url**

This command allows you to add or remove URLs from the current group of prefixed URLs.

---

**Important:** A maximum of 10 URLs can be added per group.

---

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > ACS Group-of-Prefixed-URLs Configuration

```
active-charging service service_name > group-of-prefixed-urls group_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-grp-of-prefixed-urls)#
```

**Syntax**

```
[ no ] prefixed-url url
```

- **no**
  
  If added previously, removes the specified URL from the current group of prefixed URLs.

- **url**
  
  Specifies the URL to add/remove.

  *url* must be an alphanumeric string of 1 through 63 characters.

---

**Usage**

Use this command to add or remove URLs to be filtered from the group of prefixed URLs.

**Example**

The following command adds the URL `http://abc.net` to the current group of prefixed URLs:

```
prefixed-url http://abc.net
```
Chapter 11
ACS Group-of-Ruledefs Configuration Mode Commands

The ACS Group-of-Ruledefs Configuration Mode is used to configure groups of rule definitions (ruledefs).

**Important:** In 14.1 and earlier releases, a maximum of 64 group-of-ruledefs can be configured. In 15.0 and later releases, a maximum of 128 group-of-ruledefs can be configured.

Mode

Exec > ACS Configuration > ACS Group-of-Ruledefs Configuration

```
active-charging service service_name > group-of-ruledefs group_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-group-of-ruledefs)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**add-ruledef**

This command allows you to add or remove ruledefs from a group-of-ruledefs.

> **Important:** A maximum of 128 ruledefs can be added to a group-of-ruledefs.

**Product**  
ACS

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > ACS Configuration > ACS Group-of-Ruledefs Configuration

```bash
active-charging service service_name > group-of-ruledefs group_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-group-of-ruledefs)#
```

**Syntax**

```
add-ruledef priority ruledef_priority ruledef ruledef_name

no add-ruledef priority ruledef_priority
```

*no*  
If previously configured, specifies that the ruledef associated with the specified priority number be removed from the current group-of-ruledefs.

*priority ruledef_priority*  
Specifies priority of the ruledef in the current group-of-ruledefs.  
*ruledef_priority* must be unique in the group-of-ruledefs, and must be an integer from 1 through 10000.

*ruledef ruledef_name*  
Specifies name of the ruledef to add to the current group-of-ruledefs.  
*ruledef_name* must be the name of an ACS ruledef, and must be an alpha and/or numeric string of 1 through 63 characters.

**Usage**

Use this command to add/remove ruledefs from a group-of-ruledefs.  
A group-of-ruledefs can contain optimizable ruledefs. Whether a group is optimized or not is decided on whether all the ruledefs in the group-of-ruledefs can be optimized, and if the group is included in a rulebase that has optimization turned on, then the group will be optimized.  
When a new ruledef is added, it is checked if it is included in any group-of-ruledefs, and whether it needs to be optimized, etc.

**Example**

The following command adds the ruledef *ruledef23* to the current group-of-ruledefs, and assigns it a priority of 3:

```
add-ruledef priority 3 ruledef23
```
add-ruledef priority 3 ruledef ruledef23
dynamic-command

This command allows you to add or remove dynamic commands from a group-of-ruledefs.

Product
ACS
CF

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > ACS Group-of-Ruledefs Configuration

active-charging service service_name > group-of-ruledefs group_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acg-group-of-ruledefs)#

Syntax

dynamic-command content-filtering category policy-id policy_id

no dynamic-command content-filtering category policy-id

no

Specifies to remove dynamic command configuration from the current group-of-ruledefs.

content-filtering category policy-id policy_id

Specifies the dynamic command for Content Filtering Category Policy ID configuration.

policy_id must be a Content Filtering Category Policy ID, and must be an integer from 1 through 4294967295.

Usage
Use this command to add a dynamic command to a group-of-ruledefs, which will be executed when a dynamic protocol specifies that group-of-ruledefs (via the Rulebase-Name AVP).

Important: This release supports only one command option, which is dynamic-command content-filtering category policy-id policy_id

Example

The following command configures a dynamic command for Content Filtering Category Policy ID configuration using the policy ID 100:

    dynamic-command content-filtering category policy-id 100
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
group-of-ruledefs-application

This command allows you to specify the purpose of setting up a group-of-ruledefs as either charging, post-processing, or for other purposes.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > ACS Group-of-Ruledefs Configuration

Syntax

```plaintext
active-charging service service_name > group-of-ruledefs group_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-group-of-ruledefs)#
```

Group-of-Ruledefs Application Command

```plaintext
group-of-ruledefs-application { charging | content-filtering | gx-alias | post-processing | tpo }
```

```plaintext
no group-of-ruledefs-application
```

**no**
If previously configured, deletes the group-of-ruledefs-application configuration from the current group-of-ruledefs.

**charging**
Specifies that the current group-of-ruledefs is for charging purposes.

**content-filtering**
Specifies that the current group-of-ruledefs is for content-filtering purposes.

**gx-alias**
Specifies that the current group-of-ruledefs is for Gx-alias purposes.

**post-processing**
Specifies that the current group-of-ruledefs is for post-processing purposes, that is, for use by the post-processing CLI command or automatic name-matching to the Diameter Filter-Id AVPs.

**tpo**

**Important:** The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
Usage

Use this command to specify the purpose of setting up a group-of-ruledefs. If not specified, by default the rule-application type will be charging. If the group-of-ruledefs-application is configured for content-filtering, no ruledef can be added to it. Similarly, if configured explicitly for charging or post-processing, a content-filtering policy cannot be configured in it.

The group-of-ruledefs may be dynamically selected by Diameter, as described by the policy-control charging-rulebase-name command in the Active Charging Service Configuration Mode. If so selected, the priority field of the add-ruledef instances within the group-of-ruledefs are ignored, and all of the rules named by the ruledef keyword that are also configured with the same name in the action command are selected.

Example

The following command configures the current group-of-ruledefs as for post-processing purposes:

```
group-of-ruledefs-application post-processing
```
Chapter 12
ACS Host Pool Configuration Mode Commands

The ACS Host Pool Configuration Mode is used to define a pool of host addresses within the ACS Configuration Mode. The host pool facilitates to create rules to handle the packets coming from or going to a group of hosts within an access policy.

**Mode**

Exec > ACS Configuration > ACS Host Pool Configuration

```
active-charging service service_name > host-pool host_pool_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-host-pool)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**

Security Administrator, Administrator

Syntax

```
exit
```

Usage
Use this command to return to the parent configuration mode.
ip

This command allows you to add/remove an individual or a range of host IPv4/IPv6 address(es) from the current host pool.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > ACS Host Pool Configuration

```bash
active-charging service service_name > host-pool host_pool_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-host-pool)#
```

**Syntax**

```
[ no ] ip { ipv4/ipv6_address | ipv4/ipv6_address/maskbit | range start_ipv4/ipv6_address to end_ipv4/ipv6_address }
```

<table>
<thead>
<tr>
<th><strong>no</strong></th>
<th>If added previously, removes the specified IPv4/IPv6 address(es) from the current host pool.</th>
</tr>
</thead>
</table>
| **ipv4/ipv6_address** | Specifies an IPv4/IPv6 address to add to the current host pool.  
`ipv4/ipv6_address` must be an IPv4/IPv6 address. |
| **ipv4/ipv6_address/maskbit** | Specifies an IPv4/IPv6 address/mask bits combination to add to the current host pool.  
`ipv4/ipv6_address` must be an IPv4/IPv6 address.  
`maskbit` must be the number of bits in the subnet mask, and must be a numeric value. |
| **range start_ipv4/ipv6_address to end_ipv4/ipv6_address** | Specifies a range of IPv4/IPv6 addresses to add to the current host pool.  
`start_ipv4/ipv6_address` specifies the starting IPv4/IPv6 address of the range, and must be less than `end_ipv4/ipv6_address`.  
`end_ipv4/ipv6_address` specifies the ending IPv4/IPv6 address of the range, and must be greater than `start_ipv4/ipv6_address`. |

**Usage**

Use this command to add an individual or a range of IPv4/IPv6 addresses to a host pool. Up to 10 sets of IPv4/IPv6 addresses can be configured in each host pool.

**Example**

The following command adds all IPv4 addresses from 10.2.3.4 through 10.4.5.6 to the current host pool:
ip range 10.2.3.4 to 10.4.5.6
Chapter 13
ACS IMSI Pool Configuration Mode Commands

The ACS IMSI Pool Configuration Mode is used to define a pool of subscriber International Mobile Station Identifier (IMSI) numbers within the ACS Configuration Mode. IMSI pool configuration facilitates creation of rules to handle the packets coming from or going to a group of subscriber of IMSI numbers within an access policy.

Mode

Exec > ACS Configuration > ACS IMSI Pool Configuration

active-charging service service_name > imsi-pool imsi_pool_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-imsi-pool)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

exit

Usage
Use this command to return to the parent configuration mode.
imsi

This command allows you to add/remove an individual or a range of subscriber IMSI numbers from the current IMSI pool.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > ACS IMSI Pool Configuration

```
active-charging service service_name > imsi-pool imsi_pool_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-imsi-pool)#
```

**Syntax**

```
[ no ] imsi { imsi_number | range start_imsi to end_imsi }
```

- **no**
  If added previously, removes the specified subscriber IMSI number(s) from the current IMSI pool.

- **imsi_number**
  Specifies an IMSI number to add to the current IMSI pool. 
  `imsi_number` must be an IMSI number, and must be a sequence of hexadecimal digits between 1 and 15.

- **start_imsi to end_imsi**
  Specifies a range of IMSI numbers to add to the current IMSI pool.
  `start_imsi` specifies the starting IMSI number of the range and must be less than `end_imsi`. 
  `end_imsi` specifies the ending IMSI number of the range and must be greater than `start_imsi`.

**Usage**

Use this command to add an individual or range of subscriber IMSI numbers to an IMSI pool. Up to 10 sets of IMSI numbers can be configured in each IMSI pool.

**Example**

The following command adds IMSI numbers from `310150987654321` to `310150987656879` to the current IMSI pool:

```
imsi range 310150987654321 to 310150987656879
```
Chapter 14
ACS Packet Filter Configuration Mode Commands

The ACS Packet Filter Configuration Mode is used to create and configure Active Charging Service (ACS) packet filters.

Mode

Exec > ACS Configuration > Packet Filter Configuration

```
active-charging service service_name > packet-filter packet_filter_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-packet-filter)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**direction**

This command allows you to specify the direction in which the current packet filter will be applied.

**Product**  
ACS

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > ACS Configuration > Packet Filter Configuration

```
active-charging service service_name > packet-filter packet_filter_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-packet-filter)#
```

**Syntax**

```
direction { bi-directional | downlink | uplink }  
default direction
```

---

**default**

Configures this command with its default setting.

Default: **bi-directional**

---

**bi-directional**

Specifies that the packet filter has to be applied in both uplink and downlink directions.

---

**downlink**

Specifies that the packet filter has to be applied only in the downlink direction.

---

**uplink**

Specifies that the packet filter has to be applied only in the uplink direction.

---

**Usage**

Use this command to specify the direction in which the packet filter has to be applied.

---

**Example**

The following command specifies that the packet filter must be applied in the downlink direction:

```
direction downlink
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
ip local-port

This command allows you to configure the IP 5-tuple local port(s) for the current packet filter.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Packet Filter Configuration

active-charging service service_name > packet-filter packet_filter_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-packet-filter)#

Syntax

ip local-port { = port_number | range start_port_number to end_port_number }

no ip local-port

no
If previously configured, deletes the ip local-port configuration from the current packet filter.

port_number
Specifies the port number of the transport protocol.
port_number must be the port number, and must be an integer from 1 through 65535.

range start_port_number to end_port_number
Specifies a range of port numbers.
start_port_number and end_port_number must be integers from 1 through 65535.
end_port_number must be greater than start_port_number.

Usage
Use this command to configure the IP local port(s) for a packet filter.

Example
The following command configures the IP local port as 456:

    ip local-port 456
**ip protocol**

This command allows you to configure the IP protocol(s) for the current packet filter.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Packet Filter Configuration

```plaintext
active-charging service service_name > packet-filter packet_filter_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-packet-filter)#
```

**Syntax**

In StarOS 9.0 and later releases:

```
ip protocol = protocol_number
no ip protocol
```

In StarOS 8.2 and earlier releases:

```
ip protocol { = protocol_number | range start_protocol_number to end_protocol_number }
no ip protocol
```

---

**protocol_number**

Specifies the transport protocol field in the IP header.
```
protocol_number
```

Specifies the numerical value of the protocol, and must be an integer from 1 through 255.

**range start_protocol_number to end_protocol_number**

```
range start_protocol_number to end_protocol_number
```

---

**Important:** In StarOS 9.0 and later releases this option is deprecated.

Specifies a range of protocol assignment numbers.
```
start_protocol_number and end_protocol_number must be integers from 1 through 255.
end_protocol_number must be greater than start_protocol_number.
```

**Usage**

Use this command to configure the protocol(s) for a packet filter.

**Example**

The following command configures the protocol assignment number 300:
ip protocol = 300
ip remote-address

This command allows you to configure the IP remote address(es) for the current packet filter.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Packet Filter Configuration

active-charging service service_name > packet-filter packet_filter_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-packet-filter)#

Syntax
In StarOS 9.0 and later releases:

ip remote-address = { ipv4/ipv6_address | ipv4/ipv6_address/mask }

no ip remote-address

In StarOS 8.2 and earlier releases:

ip remote-address { = { ipv4/ipv6_address | ipv4/ipv6_address/mask } | range { start_ipv4/ipv6_address | start_ipv4/ipv6_address/mask } to { end_ipv4/ipv6_address | end_ipv4/ipv6_address/mask } }

no ip remote-address

no

If previously configured, deletes the IP remote-address configuration from the current packet filter.

ipv4/ipv6_address specifies the IPv4/IPv6 address.
ipv4/ipv6_address/mask specifies the IPv4/IPv6 address and the number of subnet bits representing the subnet mask in shorthand.

ip remote-address range { start_ipv4/ipv6_address | start_ipv4/ipv6_address/mask } to { end_ipv4/ipv6_address | end_ipv4/ipv6_address/mask }

Important: In StarOS 9.0 and later releases this keyword has been deprecated.

range specifies a range of IPv4/IPv6 addresses.
start_ipv4/ipv6_address and end_ipv4/ipv6_address specify, for the range, the starting and ending IPv4/IPv6 addresses.end_ipv4/ipv6_address must be greater than start_ipv4/ipv6_address.
 ACS Packet Filter Configuration Mode Commands

ip remote-address

start_ipv4/ipv6_address/mask and end_ipv4/ipv6_address/mask specify, for the range, the starting and ending IPv4/IPv6 address, and the number of subnet bits representing the subnet mask in shorthand. end_ipv4/ipv6_address/mask must be greater than start_ipv4/ipv6_address/mask.

Usage

Use this command to configure the remote address(es) for a packet filter.

Example

The following command configures the IP remote address as 10.2.3.4/24:

   ip remote-address = 10.2.3.4/24
ip remote-port

This command allows you to configure the IP remote port(s) for the current packet filter.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Packet Filter Configuration

active-charging service service_name > packet-filter packet_filter_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-packet-filter)#

Syntax

ip remote-port { = port_number | range start_port_number to end_port_number }

no ip remote-port

no

If previously configured, deletes the ip remote-port configuration from the current packet filter.

port_number

Specifies the port number of the transport protocol.

port_number must be the port number, and must be an integer from 1 through 65535.

range start_port_number to end_port_number

Specifies a range of port numbers.

start_port_number and end_port_number must be integers from 1 through 65535.

end_port_number must be greater than start_port_number.

Usage

Use this command to configure the IP remote port(s) for a packet filter.

Example

The following command configures the IP remote port as 789:

    ip remote-port = 789
priority

This command allows you to configure the current packet filter’s priority.

Important: This command is deprecated in certain 9.0 releases and in 10.0 and later releases. The precedence values of packet filters (those from both dynamic and predefined rules) are assigned by the PCEF based on an internal process.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Packet Filter Configuration

active-charging service service_name > packet-filter packet_filter_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-packet-filter)#

Syntax

priority priority

no priority

Usage

Use this command to configure the packet filter’s priority. The priority must be configured for the packet filter to be used in a TFT. Packets are compared against packet filters in a prioritized fashion, with 0 being the highest priority. Without this setting, this filter will not be used.

Example

The following command configures the packet filter’s priority as 3:

priority 3
Chapter 15
ACS Port Map Configuration Mode Commands

The ACS Port Map Configuration Mode is used to define an application-port mapping in the ACS Configuration Mode. The application-port map associates a range of TCP/UDP ports to a specific application/protocol within a rule definition (ruledef).

Mode

Exec > ACS Configuration > ACS Port Map Configuration

`active-charging service service_name > port-map port_map_name`

Entering the above command sequence results in the following prompt:

`[local]host_name(config-acs-port-map)#`

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
port

Add or removes an individual or a range of TCP/UDP port numbers associated with an application or protocol from the current port map.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > ACS Port Map Configuration

active-charging service service_name > port-map port_map_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-port-map)#

Syntax

[ no ] port { port_number | range start_port_number to end_port_number }

no
If added previously, removes the specified TCP/UDP port numbers from the current port map.

port_number
Specifies a TCP/UDP port number to add to the current port map.

port_number is expressed an integer from 1 through 65535.

range start_port_number to end_port_number
Specifies a range of port numbers to add to the current port map.

start_port_number specifies the starting port number of the range, it must be an integer from 1 through 65535, and must be less than end_port_number.

end_port_number specifies the ending port number of the range, it must be an integer from 1 through 65535, and must be greater than start_port_number.

Usage
Use this command to add an individual or a range of TCP/UDP port numbers to a port map. Up to 10 sets of ports can be configured in each port map.

Example
The following command adds all TCP/UDP port numbers from 3112 through 5000 to the port map:

port range 3112 to 5000
Chapter 16
ACS QoS-Group-of-Ruledefs Configuration Mode
Commands

The ACS QoS-Group-of-Ruledefs Configuration Mode is used to configure groups of rule definitions (ruledefs).

Mode

Exec > ACS Configuration > QoS-Group-of-Ruledefs Configuration

active-charging service service_name > qos-group-of-ruledefs group_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-qos-group-of-ruledefs)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**add-group-of-ruledef**

This command allows you to add or remove groups-of-ruledefs from a qos-group-of-ruledefs.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > QoS-Group-of-Ruledefs Configuration

```
active-charging service service_name > qos-group-of-ruledefs group_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-qos-group-of-ruledefs)#
```

**Syntax**

```
[ no ] add-group-of-ruledef group_of_ruledef_name
```

- **no**
  If added previously, removes the specified group-of-ruledef from the current qos-group-of-ruledefs.

- **group_of_ruledef_name**
  Specifies name of the group-of-ruledef to add/remove from the current qos-group-of-ruledefs.
  `group_of_ruledef_name` must be the name of an ACS group-of-ruledef, and must be an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to add/remove a group-of-ruledefs from a qos-group-of-ruledefs.

**Example**

The following command adds the group-of-ruledef named `grpruledef1` to the current qos-group-of-ruledefs:

```
add-group-of-ruledef grpruledef1
```
add-ruledef

This command allows you to add or remove ruledefs from a qos-group-of-ruledefs.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > QoS-Group-of-Ruledefs Configuration

```
active-charging service service_name > qos-group-of-ruledefs group_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-qos-group-of-ruledefs)#
```

**Syntax**

```
[ no ] add-ruledef ruledef_name
```

- **no**
  If added previously, removes the specified ruledef from the current qos-group-of-ruledefs.

- **ruledef_name**
  Specifies name of the ruledef to add/remove from the current qos-group-of-ruledefs.
  `ruledef_name` must be the name of an ACS ruledef, and must be an alpha and/or numeric string of 1 through 63 characters.

**Usage**

Use this command to add/remove ruledefs from a qos-group-of-ruledefs.

**Example**

The following command adds the ruledef `ruledef23` to the current qos-group-of-ruledefs:

```
add-ruledef ruledef23
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

exit

Usage
Use this command to return to the parent configuration mode.
Chapter 17
ACS Readdress Server List Configuration Mode

The ACS Readdress Server List Configuration Mode is used to add, configure, and delete servers to the server list for DNS redirection.

```
Mode
Exec > ACS Configuration > Readdress Server List Configuration
active-charging service service_name > readdress-server-list server_list_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-readdress-server-list)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**consecutive-failures**

This command allows you to configure the consecutive number of times a server can be unreachable after which the system marks the server as inactive.

**Important:** This command is license dependent. For more information contact your Cisco account representative.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Readdress Server List Configuration

```
active-charging service service_name > readdress-server-list server_list_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-readdress-server-list)#
```

**Syntax**

```
consecutive-failures consecutive_failures
default consecutive-failures
```

**default consecutive-failures**

```
default
Configures this command with its default setting.
Default: 5
```

```
consecutive_failures
Specifies the consecutive number of times a server can be unreachable after which the system marks the server as inactive.
consecutive_failures must be an integer from 1 through 10.
```

**Important:** If not explicitly configured, the default value of 5 will be used.

**Usage**
Use this command to configure the consecutive number of response failures, after which a server is marked as inactive.

**Example**
The following command configures the number of consecutive server response failures to 4:

```
consecutive-failures 4
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

exit

**Usage**

Use this command to return to the parent configuration mode.
reactivation-time

This command allows you to configure the time duration (in seconds) after which the status of a previously inactive server is rechecked.

**Important:** This command is license dependent. For more information contact your Cisco account representative.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Readdress Server List Configuration

```
active-charging service service_name > readdress-server-list server_list_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-readdress-server-list)#
```

**Syntax**

```
reactivation-time reactivation_time
default reactivation-time
```

- **default**
  
  Configures this command with its default setting.
  Default: 300 seconds

- **reactivation_time**
  
  Specifies the time duration after which the status of the inactive server is rechecked.
  *reactivation_time* must be an integer from 1 through 1800.

**Important:** If not explicitly configured, the default value of 300 seconds will be used.

**Usage**

Use this command to configure the time duration (in seconds) after which the status of a previously inactive server is rechecked.

**Example**

The following command configures the reactivation time to 180 seconds:

```
reactivation-time 180
```
**response-timeout**

This command allows you to configure the time duration for which the system will wait for a response from the server before marking it unreachable.

**Important:** This command is license dependent. For more information contact your Cisco account representative.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Readdress Server List Configuration

```
active-charging service service_name > readdress-server-list server_list_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-readdress-server-list)#
```

**Syntax**

```
response-timeout response_timeout
default response-timeout
```

**default**

Configures this command with its default setting.
Default: 1000 milliseconds

```
response_timeout
```

Specifies the time duration (in milliseconds) for which the system will wait for a response from the server before marking it unreachable.

`response_timeout` must be an integer from 1 through 10000.

**Important:** If not explicitly configured, the default value of 1000 milliseconds will be used.

**Usage**

Use this command to configure the time duration (in milliseconds) for which the system will wait for a response from the server before marking it unreachable.

**Example**

The following command sets the server response timeout to 4500 milliseconds:

```
response-timeout 4500
```
server

This command allows you to configure the DNS server(s) to which flow will be readdressed.

Important: This command is license dependent. For more information contact your Cisco account representative.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Readdress Server List Configuration

active-charging service service_name > readdress-server-list server_list_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-readdress-server-list)#

Syntax

server [ipv4_address | ipv6_address] [ port port_number ]

no server [ ipv4_address|ipv6_address ]

no

If previously configured, disables the specified server configuration.

ipv4_address

Specifies the IP address of the DNS server.
ipv4_address must be expressed in IPv4 dotted-decimal notation format.

ipv6_address must be expressed in IPv6 colon-separated-hexadecimal notation.

port port_number

Specifies the TCP port of the DNS server.
port_number must be an integer from 1 through 65535.

Usage

Use this command to configure the DNS server(s) to which the flow will be readdressed based on the contents of the Fully Qualified Domain Name (FQDN).

Example

The following commands configure the DNS servers for packet flow to 192.168.12.101, 192.168.12.102, and 2607:f0d0:1002:51::4/64:

server 192.168.12.101
server 192.168.12.102
server 2607:f0d0:1002:51::4/64

The following command removes the DNS server configuration for 192.168.12.101 that was configured above:

no server 192.168.12.101
Chapter 18
ACS Rulebase Configuration Mode Commands

The ACS Rulebase Configuration Mode is used to configure Active Charging Service (ACS) rulebases.

**Mode**

Exec > ACS Configuration > Rulebase Configuration

*active-charging service service_name > rulebase rulebase_name*

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**action priority**

This command allows you to configure the action priority for a ruledef / group-of-ruledefs in the current rulebase.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
action priority action_priority { [ dynamic-only | static-and-dynamic | timedef timedef_name ] { group-of-ruledefs ruledefs_group_name | ruledef ruledef_name } charging-action charging_action_name [ monitoring-key monitoring_key ] [ description description ] }
```

- **no action priority action_priority**

  If previously configured, deletes the specified action priority configuration from the current rulebase.

- **priority action_priority**

  Specifies a priority for the specified ruledef / group-of-ruledefs in the current rulebase. The priority controls the order in which this instance of the CLI command will be examined. Lower numbered priorities are examined first. Up to 2048 instances may be configured, totaled among all rulebases.

**Important**: If there are any changes to action priority and the Override Control/Inheritance feature is enabled, then execute the CLI command “update active-charging override-control rulebase-config”. For more information on this command, see the Command Line Interface Reference.

- **dynamic-only**

  Enables matching of dynamic rules with static rules for this action priority on a flow. Configuring the `dynamic-only` keyword causes the configuration to be defined, but not enabled. If enabled, the action associated with this option will not be matched against a flow until it is enabled from a dynamic charging interface like Gx. Gx can disable or enable this action entry in the rulebase using Gx messages. Default: Disabled

- **static-and-dynamic**

  The static-and-dynamic option causes the configuration to be defined and enabled, and allows a dynamic protocol (such as the Gx interface) to disable or re-enable the configuration.
**Important:** When R7 Gx is enabled, “static-and-dynamic” rules behave exactly like “dynamic-only” rules. That is, they must be activated explicitly by the Policy and Charging Rules Function (PCRF). When Gx is not enabled, “static-and-dynamic” rules behave exactly like static rules.

```
timedef timedef_name
```

**Important:** This keyword is only available in StarOS 8.1 and StarOS 9.0 and later releases.

Associates the specified time definition with the ruledef / group-of-ruledefs. Timedefs activate or deactivate ruledefs / groups-of-ruledefs, making them available for rule matching only when they are active. `timedef_name` must be the name of a timedef, and must be an alphanumeric string of 1 through 63 characters. A timedef can be used with several ruledefs / group-of-ruledefs. When a packet is received, and a ruledef / group-of-ruledefs is eligible for rule matching, if a timedef is associated with the ruledef / group-of-ruledefs, before rule matching the packet-arrival time is compared with the timeslots configured in the timedef. If the packet arrived in any of the timeslots configured in the associated timedef, rule matching is undertaken, else the next ruledef / group-of-ruledefs is considered.

**Important:** The time considered for timedef matching is the system’s local time.

```
ruledef ruledef_name
```

Adds the specified ruledef to the current rulebase. `ruledef_name` must be the name of a ruledef, and must be an alphanumeric string of 1 through 63 characters. If the specified ruledef does not exist, there will be no ruledef triggers for this action priority within the current rulebase.

**Important:** If the ruledef specified here is deleted or is not configured, the system accepts it without applying any ruledef under current rulebase for this action priority.

```
group-of-ruledefs ruledefs_group_name
```

Adds the specified group-of-ruledefs to the current rulebase. `ruledefs_group_name` must be the name of a group-of-ruledefs, and must be an alphanumeric string of 1 through 63 characters. When a group-of-ruledefs is specified, if any of the ruledefs within the group matches, the specified charging-action is applied, any more of the action instances are not processed.

**Important:** If the group-of-ruledefs specified here is deleted or is not configured, the system accepts it without applying any ruledefs under current rulebase for this action priority.

```
charging-action charging_action_name
```

Specifies the charging action.
**charging_action_name** must be the name of a charging action, and must be an alphanumeric string of 1 through 63 characters.

If the specified charging action does not exist, there will be no charging action triggers for this action priority within the current rulebase.

**Important:** If the charging action specified here is not configured or is later deleted, the system will not apply any charging action under current rulebase for this action priority.

**monitoring_key monitoring_key**

Associates the specified monitoring-key with ruledefs for usage monitoring.

*monitoring_key* must be an integer from 1 through 4000000000.

**description description**

Adds specified text to the rule and action.

*description* must be an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to configure action priorities for ruledefs / group-of-ruledefs in a rulebase. This CLI command can be entered multiple times to specify multiple ruledefs and charging actions. The ruledefs are examined in priority order, until a match is found and the corresponding charging action is applied.

**Example**

The following command assigns a rule and action with the action priority of 23, a ruledef named *test*, and a charging action named *test1* to the current rulebase:

```
action priority 23 ruledef test charging-action test1
```
active-charging rf

This command allows you to enforce default rating group / service identifier on all PCC rules, predefined ACS rules, and static ACS rules for Rf-based accounting.

⚠️ Important: This command is customer specific. For more information contact your Cisco account representative.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

active-charging rf { rating-group-overide rating_group | service-id-overide service_id }

{ default | no } active-charging rf { rating-group-overide | service-id-overide }

default

Configures this command with its default setting.
Default: Override configuration is disabled; same as no.

no

Disables the override configuration.

no active-charging rf rating-group-overide: Rating group override will not be enforced on the PCC rules, predefined ACS rules, and static ACS rules. If any of these rules have their own rating group, it will continue to use that.

no active-charging rf service-id-overide: Service ID override will not be enforced on the PCC rules, predefined ACS rules, and static ACS rules. If any of these rules have their own service ID, it will continue to use that.

rating-group-overide rating_group

Enforces the specified rating group on all PCC rules, predefined ACS rules, and static ACS rules. If any of these rules have their own rating group, it will be overridden by the specified rating group.

rating_group must be an integer from 1 through 65535.

service-id-overide service_id

Enforces the specified service ID on all PCC rules, predefined ACS rules, and static ACS rules. If any of these rules have their own service ID, it will be overridden by the specified service ID.
**active-charging rf**

- **service_id** must be an integer from 1 through 65535.

**Usage**

Use this command to enforce a specific rating group / service identifier on all PCC rules, predefined ACS rules, and static ACS rules for RF-based accounting. As this CLI configuration is applied at the rulebase level, all the APNs that have the current rulebase defined will inherit the configuration.

**Example**

The following command configures the service ID 100:

```
active-charging rf service-id-override 100
```
bandwidth default-policy

This command allows you to configure the default bandwidth policy for the current rulebase.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]\host_name(config-rule-base)#

Syntax

bandwidth default-policy bandwidth_policy_name [ fallback-enabled ]

no bandwidth default-policy

no

If previously configured, deletes the bandwidth default-policy configuration from the current rulebase.

bandwidth_policy_name

Specifies the default bandwidth policy for the current rulebase.

bandwidth_policy_name must be the name of a bandwidth policy, and must be an alphanumeric string of 1 through 63 characters.

fallback-enabled

Determines whether policy under rulebase can be applied as a fallback value. Fallback is disabled by default.

Usage

Use this command to configure the default bandwidth policy for a rulebase.
For subscribers using the current rulebase, the default bandwidth policy will be used if in the APN/subscriber profile the default active-charging bandwidth-policy fallback-enabled command is configured, or no bandwidth policy is configured.

Example

The following command configures a bandwidth policy named standard for the rulebase:

    bandwidth default-policy standard fallback-enabled
billing-records

This command allows you to configure the type of billing to be performed for subscriber sessions.

Product

GGSN
P-GW
SAEGW

Privilege

Security Administrator, Administrator

Mode

Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local] host_name(config-rule-base)#

Syntax

billing-records { egcdr | radius | rf | udr udr-format udr_format_name [ failure-handling-udr-format udr_format_name ] } +

no billing-records

no

If previously configured, deletes the billing-records configuration from the current rulebase.

egcdr

Generates an enhanced G-CDR (eG-CDR) for GGSN / P-GW-CDR for P-GW, and/or UDR with specified format on the occurrence of an interim trigger condition at the end of a subscriber session, or an SGSN-to-SGSN handoff.

radius

Generates postpaid RADIUS accounting records at the start and end of a subscriber session, and on the occurrence of an interim trigger condition. RADIUS accounting records are generated for each content ID.

Important: In the GGSN, if in the APN configuration the “accounting-mode” is set to “none”, the system continues to send ACS-generated RADIUS accounting messages. In the PDSN, if in the subscriber default configuration the “accounting-mode” is set to “none”, the system does not send any RADIUS accounting messages (including ACS accounting messages).

rf

Enables Rf accounting.
Rf accounting is applicable only for dynamic and predefined rules that are marked for it. Dynamic rules have a field offline-enabled to indicate this. To mark a predefined rule as offline-enabled, use this keyword and the billing-action command in the ACS Charging Action Configuration Mode.
**Usage**

Use this command to generate enhanced G-CDRs (eG-CDRs), P-GW-CDR for P-GW, RADIUS CDRs and/or UDRs for billing records. The format of eG-CDRs for the default GTPP group is controlled by the `inspector` command in the Context Configuration Mode.

If, in the APN configuration, the “accounting-mode” is set as default (GTPP), and in the rulebase configuration “billing-records eegcdr” is configured, both G-CDRs and eG-CDRs are generated if configured. If, in the APN, the accounting-mode is set to “none” G-CDRs will not be generated.

**Example**

The following command sets the billing record to UDR with UDR format named `udr_format1`:

```
billing-records udr udr-format udr_format1
```
cca diameter requested-service-unit

This command allows you to specify the Diameter sub-AVPs to be included in the Diameter group AVP “Requested-Service-Unit” sent with DCCA Credit Control Requests (CCRs).

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
cca diameter requested-service-unit sub-avp { time cc-time duration | units cc-service-specific-units charging_unit | volume { cc-input-octets bytes | cc-output-octets bytes | cc-total-octets bytes } + }
```

```
no cca diameter requested-service-unit sub-avp
```

No sub-AVPs are included in the Requested-Service-Unit grouped AVP.

```
time cc-time duration
```

Specifies requested service unit for charging time duration in seconds in included sub-AVP.

*duration* specifies charging time in seconds, and must be an integer from 1 through 4000000000.

```
units cc-service-specific-units charging_unit
```

Specifies requested service unit by service specific units in bytes/packets in included sub-AVP.

*charging_unit* specifies service-specific charging unit and must be an integer from 1 through 4000000000.

```
volume { cc-input-octets bytes | cc-output-octets bytes | cc-total-octets bytes } +
```

Specifies requested service unit for charging octets by input, output, and total volume in included sub AVP.

*cc-input-octets*: Specifies input charging octets.

*cc-output-octets*: Specifies output charging octets.

*cc-total-octets*: Specifies total charging octets.

*bytes*: Specifies volume in bytes and must be an integer from 1 through 4000000000.

+: Indicates that more than one of the previous keywords can be entered within a single command.
Usage

Use this command to include sub-AVPs based on time, volume, and service specific unit in the “Requested-Service-Unit” grouped AVP with CCRs through Gy interface.

Example

The following command sets the time based sub-AVP with charging duration of 45 seconds in “Requested-Service-Unit” group AVP on DCCA CCRs:

```
  cca diameter requested-service-unit sub-avp time cc-time 45
```
**cca quota**

This command allows you to configure various time- and threshold-based quotas in the Prepaid Credit Control Service (Credit Control Application).

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
cca quota { holding-time holding_time content-id content_id | retry-time retry_time [ max-retries retries ] }
{ default | no } cca quota { holding-time content-id content_id | retry-time }
```

<table>
<thead>
<tr>
<th>holding-time holding_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the value for the Quota Holding Time (QHT). QHT is used with both time-based and volume-based quotas. After <code>holding_time</code> seconds has passed without user traffic, the quota is reported back and the charging stops until new traffic starts. <code>holding_time</code> must be an integer from 1 through 4000000000.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>content-id content_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the content ID (Rating group AVP) to use for the Quota holding time for the current rulebase. <code>content_id</code> is the content ID specified for credit control service in ACS. In 12.1 and earlier releases, <code>content_id</code> must be an integer from 1 through 65535. In 12.2 and later releases, <code>content_id</code> must be an integer from 1 through 2147483647.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>retry-time retry_time [ max-retries retries ]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the retry time for the quota request, in seconds. <code>retry_time</code> must be an integer from 0 through 86400. To disable this assign 0. Default: 60</td>
</tr>
</tbody>
</table>

This parameter defines the maximum frequency at which the Credit-Control Application (CCA) tries to obtain quota for a subscriber passing traffic for a category with no/exhausted quota. For a subscriber not passing traffic, the CCA will not try to obtain quota (except once at session start time, if so configured). The quota request from the no quota state is sent in response to user packets only (never based on a timer). When subscriber hits a charging action that is a flow redirect, the operator can optionally specify that this redirection shall clear the retry-time timer.
This allows the immediately following chargeable user traffic to trip a quota request, even if it would otherwise have been subject to the retry time limit. Such configuration allows quite a large value for retry-time in quota charging or a top-up scenario.

`max-retries retries` configures the maximum number of retries allowed for blacklisted categories. This option has a default value of 65535 retries (the maximum value).

`retries` must be an integer from 1 through 65535. To disable this assign 0.

**Usage**

Use this command to set the prepaid credit control quotas.

`cca quota retry time` allows an operator to set the amount of time that the ACS waits before it retries the prepaid server for a content ID for which quota was exhausted earlier.

When the server sends the quota holding time (QHT) it has highest priority to use that QHT regardless of the value configured in the rulebase or Credit Control Application Configuration Mode. QHT configured here has the second priority for the content ID (rating group) configured here.

If the QHT is not available from the server or rulebase configuration mode, the QHT values configured via the Credit Control Application Configuration Mode are used.

**Example**

The following command configures the prepaid credit control request retry time to 30 seconds:

```
cca quota retry-time 30
```

The following command specifies the system to use the QHT value configured in the Credit Control Application Mode:

```
no cca quota holding-time content-id 1
```

The following command specifies the system to ignore the QHT value configured in the Credit Control Application Mode:

```
default cca quota holding-time content-id 1
```

The following command configures the prepaid credit control request retry time to 60 seconds and the maximum number of retries to 65535:

```
default cca quota retry-time max-retries
```
cca quota time-duration algorithm

This command allows you to specify the algorithm to compute time duration for Prepaid Credit Control Application quotas in the current rulebase.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
cca quota time-duration algorithm { consumed-time seconds [ plus-idle ] | continuous-time-periods seconds | parking-meter seconds } [ content-id content_id ]
```

```
default cca quota time-duration algorithm
```

```
no cca quota time-duration algorithm { consumed-time | continuous-time-periods | parking-meter } [ content-id content_id ]
```

```
no
```

If previously configured, deletes the quota time-duration algorithm configuration from the current rulebase.

```
default
```

Configures this command with its default setting.

```
consumed-time seconds
```

Specifies the Quota Consumption Time (QCT) in seconds. QCT is used with active time-based quotas and to determine chargeable time envelopes for consuming time quota. 

```
seconds must be an integer from 1 through 4294967295.
```

Default: 0 (disabled)

A time envelope is the basis for reporting active usage. For each time envelope, the quota consumption includes the last QCT (duration between first packet and last packet + QCT).

```
plus-idle
```

Specifies the idle time for QCT.

When used along with `consumed-time` it indicates the active usage + idle time, when no traffic flow occurs.

```
continuous-time-periods seconds
```

Specifies the charging quota continuous period, in seconds.

```
seconds must be an integer from 1 through 4294967295.
```
Default: 0 (disabled)
The Continuous Time Periods (CTP) mechanism constructs time-envelopes from consecutive base time intervals in which traffic has occurred up to and including a base time interval which contains no traffic. As with Quota-Consumption-Time envelopes, the end of an envelope can only be determined “retrospectively”. Again, as with Quota-Consumption-Time, the envelope for CTP includes the last base time interval (the one which contained no traffic).

\[ \text{parking-meter } \text{seconds} \]

Specifies the Parking Meter (PM) period, in seconds, for a particular rating group.
\text{seconds} must be an integer from 1 through 4294967295.
Default: 0 (disabled)
This mechanism utilizes time quota, but instead of consuming linearly—once a decision to consume has been taken—the granted quota is consumed discretely in “chunks” of the base time interval at the start of each base time interval. Traffic is then allowed to flow for the period of the consumed quota.
The time interval \text{seconds} defines the length of the Parking Meter. A time-envelope corresponds to exactly one PM (and thus to one base time interval).

\[ \text{content-id } \text{content_id} \]

Specifies the content ID (Rating group AVP) to use for the CCA Quota time duration algorithm selection in the current rulebase.
\text{content_id} is the content ID specified for credit control service in ACS.
In 12.1 and earlier releases, \text{content_id} must be an integer from 1 through 65535.
In 12.2 and later releases, \text{content_id} must be an integer from 1 through 2147483647.

**Usage**

Use this command to set the various time charging algorithms/schemes for prepaid credit control charging.
If operator chooses \text{parking-meter} \text{seconds} style charging, then time is billed in \text{seconds} chunks.

**Example**

The following command configures the QCT to consumed-time duration of 400 seconds:

\[ \text{cca quota time-duration algorithm consumed-time 400} \]
cca radius accounting interval

This command allows you to configure how often interim updates are generated by the RADIUS Credit Control Application to be sent to the prepaid server.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration
active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

cca radius accounting interval interval

{ default | no } cca radius accounting interval

default
Configures the command with its default setting.
Default: Disabled; same as no cca radius accounting interval

no
Disables interim updates.

interval
Specifies the time interval, in seconds, between interim updates generated by the RADIUS Credit Control Application.
interval must be an integer from 1 through 3600.
Default: 1 (Disabled)

Usage
Use this command to specify the RADIUS accounting interval between accounting of a prepaid subscriber. The same parameters are applicable for RADIUS server group.

Example
The following command defines RADIUS accounting interval of 20 seconds for RADIUS prepaid service in the rulebase:

cca radius accounting interval 20
**cca radius charging context**

This command allows you to specify the RADIUS servers used for the current rulebase when RADIUS credit control is enabled.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
cca radius charging context vpn_context [ group server_group_name ]

no cca radius charging context
```

**no**
RADIUS credit control will not be performed.

**vpn_context**
Specifies the charging context where RADIUS prepaid charging parameters are configured. `vpn_context` must be an alphanumeric string of 1 through 79 characters.

**group server_group_name**
Specifies the RADIUS server group. `server_group_name` must be the name of a RADIUS server group, and must be an alphanumeric string of 1 through 63 characters.

**Usage**
Use this command to specify the RADIUS charging context where RADIUS prepaid charging parameters are configured. The same parameters are applicable for RADIUS server group.

**Example**
The following command defines RADIUS charging context `prepaid仁` for RADIUS prepaid charging in the rulebase:

```
cca radius charging context prepaid_rad1
```
**cca radius user-password**

This command allows you to configure the value to use for the “User-Password” attribute in RADIUS messages sent to the prepaid server.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
cca radius user-password [ encrypted ] password password
```

**no cca radius user-password**

- **no**
  
  If previously configured, deletes the RADIUS prepaid service user password configured in the current rulebase.

```
[ encrypted ] password password
```

Specifies the password for prepaid services within the current rulebase.

- In 12.1 and earlier releases, `password` must be an alphanumeric string of 1 through 63 characters with or without encryption.
- In 12.2 and later releases, `password` must be an alphanumeric string of 1 through 63 characters without encryption, and 1 through 132 characters with encryption enabled.

The `encrypted` keyword is intended only for use by the system while saving configuration scripts. The system displays the `encrypted` keyword in the configuration file as a flag that the variable following the `password` keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file.

**Usage**

Use this command to specify the RADIUS user password for prepaid services within the current rulebase.

**Example**

The following command configures the user password as `user_123` without encryption in the current rulebase:

```
cca radius user-password password user_123
```
charging-action-override

This command allows you to enable/disable overriding charging parameters of static rule with those of an ip-any rule or a specified dynamic rule.

Product
GGSN
P-GW

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration
active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

charging-action-override custom1 [ use-rule dynamic_rule_name ]

{ default | no } charging-action-override

default
Configures this command with its default setting. Default: Disables overriding charging parameters of static rule with those of an ip-any or a specified dynamic rule.

no
Disables overriding charging parameters of static rule with those of an ip-any or a specified dynamic rule.

custom1
Specifies overriding Online/Offline, Service ID, Content ID, Flow Control, ARP, and QCI.

use-rule dynamic_rule_name
Optional: Specifies the dynamic rule to inherit charging parameters from. If a dynamic rule name is not specified, the charging properties will be inherited from any dynamic rule. dynamic_rule_name specifies name of the dynamic rule, and must be an alpha and/or numeric string of 1 through 63 characters in length.

Usage

Use this command to enable/disable overriding charging parameters of static rule with those of a dynamic ip-any rule or a specified dynamic rule.

Example

The following command specifies to enable overriding charging parameters of static rule with those of a dynamic rule named test:
charging-action-override custom1 use-rule test
charging-rule-optimization

This command allows you to configure the internal optimization level to use, for improved performance, when evaluating each instance of the action priority command.

**Important:** In StarOS 14.0 and later releases, this command is deprecated. In StarOS 14.0 and later releases, rule optimization is always enabled with the optimization level set to high.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
charging-rule-optimization \{ high | low | medium \}

default charging-rule-optimization
```

**default charging-rule-optimization**

- **default**
  
  Configures this command with its default setting.
  
  Default: In 11.0 and later releases: **high** In 10.0 and earlier releases: **low**

- **high**
  
  Enables the highest level of optimization with high memory utilization.

- **low**
  
  Enables minimal level of optimization with minimal memory utilization.

- **medium**

**Important:** In 11.0 and later releases, the **medium** keyword is deprecated.

- Enables medium level of optimization with moderate memory utilization.

**Usage**

Use this command to specify the level of internal optimization for improved performance when evaluating each instance of the action priority command.
Both the high and medium options cause re-organization of the entire memory structure whenever any change is made, such as on the addition of an `action priority` command.

**Example**

The following command specifies the highest optimization level for rule search and matching in the rulebase:

```
charging-rule-optimization high
```
constituent-policies

This command allows you to configure the Bandwidth, Content Based Billing (CBB), and Firewall/Firewall-and-NAT constituent policies. The combination of the values of all three policies will uniquely identify the associated rulebase.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

constituent-policies { bandwidth-policy bandwidth_policy_name | cbb-policy cbb_policy_name | firewall-policy fw_policy_name | fw-and-nat-policy fw_nat_policy_name } +

no constituent-policies

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
</table>
| If previously configured, deletes the constituent-policies configuration from the current rulebase.

<table>
<thead>
<tr>
<th>bandwidth-policy bandwidth_policy_name</th>
</tr>
</thead>
</table>
| Specifies the Bandwidth policy.  
bandwidth_policy_name must be the name of a bandwidth policy, and must be an alphanumeric string of 1 through 63 characters.

<table>
<thead>
<tr>
<th>cbb-policy cbb_policy_name</th>
</tr>
</thead>
</table>
| Specifies the Content Based Billing (CBB) policy.  
cbb_policy_name must be the name of a CBB policy, and must be an alphanumeric string of 1 through 63 characters.

<table>
<thead>
<tr>
<th>firewall-policy fw_policy_name</th>
</tr>
</thead>
</table>
| Specifies the Stateful Firewall policy.  
fw_policy_name must be the name of a Stateful Firewall policy, and must be an alphanumeric string of 1 through 63 characters.

---

**Important:** This keyword is customer specific. For more information, please contact your Cisco account representative.
fw-and-nat-policy fw_nat_policy_name

**Important:** This keyword is customer specific, and is only available in StarOS 8.1 and in StarOS 9.0 and later releases.

Specifies the Firewall-and-NAT policy.

fw_nat_policy_name must be the name of a Firewall-and-NAT policy, and must be an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to configure the bandwidth, CBB, and Firewall/Firewall-and-NAT constituent policies that will identify the rulebase. The combination of the values of all three policies will uniquely identify the rulebase associated.

**Example**

The following command configures the constituent bandwidth policy named test123:

```
constituent-policies bandwidth-policy test123
```
content-filtering category policy-id

This command allows you to configure the Content Filtering Category Policy Identifier for Policy-based Content Filtering support in the current rulebase.

**Product**

CF

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
content-filtering category policy-id cf_policy_id

no content-filtering category policy-id [ cf_policy_id ]
```

- **no**
  
  If previously configured, deletes the configuration from the current rulebase.
  
  In StarOS 8.1 and later releases, optionally the policy ID can be specified. If the specified policy ID is invalid, or is not configured in the rulebase, an error message is displayed. If no policy ID is specified, whatever policy is configured, if any, is removed from the rulebase.

```
content-filtering category policy-id cf_policy_id
```

Confirms the specified Content Filtering Category Policy in the current rulebase.

* cf_policy_id must be the ID of an existing Content Filtering Category Policy, and must be an integer from 1 through 4294967295.

**Important:** If the specified Content Filtering Category Policy does not exist, all packets will be passed regardless of the categories/actions determined for such packets.

**Important:** The category policy ID that is configured using the `category policy-id cf_policy_id` command in the APN/Subscriber Configuration Mode prevails over this configuration.

**Usage**

Use this command to configure the Content Filtering Category Policy ID for Policy-based Content Filtering support in the rulebase.

The Content Filtering Category Policy is created/deleted in the ACS Configuration Mode, and is configured in the Content Filtering Policy Configuration Mode.

**Example**

The following command configures the Content Filtering Category Policy ID 101 in the rulebase:
content-filtering category policy-id 101
content-filtering flow-any-error

This command allows you to specify action to take on Content Filtering packets in the case of ACS error scenarios.

**Product**
CF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
content-filtering flow-any-error { deny | permit }
```

**default content-filtering flow-any-error**

`default`

Configures this command with its default setting.
Default: `permit`

`deny`

Configures flow-any-error configuration as deny.
All the denied packets will be accounted for by the `discarded-flow-content-id` configuration in the Content Filtering Policy Configuration Mode. This content ID will be used to generate UDRs for packets denied via content filtering.

`permit`

Configures flow-any-error configuration as permit.

**Usage**
Use this command to allow/discard content filtering packets in case of ACS error scenarios.

**Example**
The following command allows content filtering packets in case of an ACS error:

```
content-filtering flow-any-error permit
```
content-filtering mode

This command allows you to enable/disable the specified Category-based Content Filtering mode in the current rulebase.

Product
CF

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

content-filtering mode { category { static-and-dynamic | static-only } | server-group cf_server_group }

no content-filtering mode

no

If previously configured, deletes the content-filtering mode configuration from the current rulebase. Content filtering will not to be performed for the current rulebase. This is the default setting.

category { static-and-dynamic | static-only }

Specifies the Category-based Content Filtering mode.

• static-only: Configures Category-based Content Filtering in static only mode, wherein all URLs are compared against an internal database to categorize the requested content.

Using Category-based Content Filtering support requires configuration of the require active-charging content-filtering category command in the Global Configuration Mode.

• static-and-dynamic: Configures Category-based Content Filtering in Static-and-Dynamic mode, wherein a static rating of the URL is first performed, and only if the static rating fails to find a match, dynamic rating of the content that the server returns is then performed.

Important: Before enabling static-and-dynamic rating in the rulebase, it must be enabled at the global level as the resources required for dynamic rating are allocated at the global level. To enable static-and-dynamic rating at the global level, in the Global Configuration Mode use the require active-charging content-filtering category static-and-dynamic command.

server-group cf_server_group

Enables and configures the Content Filtering Server Group (CFSG) mode within the rulebase to manage an external content filtering server with an Internet Content Adaptation Protocol (ICAP) client system.
**Usage**

Use this command to enable and apply the content filtering mode in the rulebase to manage a content filtering server with an ICAP client system.

**Example**

The following command enables the content filtering mode for external content filtering server group `CF_Server1` in the rulebase:

```
content-filtering mode server-group CF_Server1
```

The following command enables the category based static and dynamic content filtering mode for in the rulebase:

```
content-filtering mode category static-and-dynamic
```
description

Sets the descriptive text for the object.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

description text

no
description

no
description text

Clears the description for the object.

description text

Specifies the descriptive text as an alphanumeric string of 1 to 79 characters. If you include spaces between words in the description, you must enclose the text within double quotation marks (" "), for example, “AAA BBBB”.

**Usage**
The description should provide useful information on the object’s primary function, services, endusers, etc.
**dynamic-rule order**

This command allows you to specify whether dynamic rules are matched before statically configured rules.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
dynamic-rule order { always-first | first-if-tied }
```

```
no dynamic-rule order
```

- **no**
  If previously configured, deletes the dynamic-rule order configuration from the current rulebase. By default, dynamic rules are matched against the flow prior to static rules.

- **always-first**
  Specifies to match all the dynamic rules against the flow prior to any static rule.

- **first-if-tied**
  Specifies to match rules against the flow based on their priority with the condition that dynamic rules match before a static rule of the same priority.

A rule is a combination of a ruledef, charging action, and precedence. Static rules are defined by the action CLI command in the ACS Rulebase Configuration Mode, and are applicable to all subscribers that are associated with the rulebase. Dynamic rules are obtained via a dynamic protocol, such as, the Gx-interface for a particular subscriber session.

**Usage**

Use this command to configure the order in which rules are selected for matching in between dynamic rules (per subscriber) and static rules (from rulebase).

**Example**

The following command matches all dynamic rules against the flow prior to any static rule:

```
dynamic-rule order always-first
```
edr edr-dcca-fh

This command configures generation of EDRs when the OCS is in unreachable state.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
advisor service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
edr edr-dcca-fh [ charging-edr charging_edr_format_name | edr-format edr_format_name | reporting-edr reporting_edr_format_name ] +

{ default | no } edr edr-dcca-fh
```

---

**default**

Configures this command with its default setting.
Default: Disabled

---

**no**

If previously configured, deletes the configuration from the current rulebase.

---

**charging-edr charging_edr_format_name**

Specifies to generate charging EDR during OCS unreachable period.  
**charging_edr_format_name** must be the name of a charging EDR format, and must be an alphanumeric string of 1 through 63 characters.

---

**edr-format edr_format_name**

Specifies to generate EDR during OCS unreachable period.  
**edr_format_name** must be the name of an EDR format, and must be an alphanumeric string of 1 through 63 characters.

---

**reporting-edr reporting_edr_format_name**

Specifies to generate reporting EDR during OCS unreachable period.  
**reporting_edr_format_name** must be the name of a reporting EDR format, and must be an alphanumeric string of 1 through 63 characters.
Usage

Use this command to configure the trigger to generate EDRs when the OCS is in unreachable state. This configuration provides the facility to track and report the actual quota usage through EDRs during Assume Positive scenarios for HA. This feature has been enhanced to support reporting / recording the appropriate usage in volume and time during regular OCS sessions and during assume positive scenarios separately. In this release, EDRs will be generated with new closure reasons when OCS goes down for HA.

Example

The following command configures the generation of charging EDRs when OCS is unreachable:

```
edr edr-dcca-fh charging-edr edrl
```
edr p2p

This command configures generation of Event Detail Records (EDR) for P2P events. This command is associated with the Dynamic Software Upgrade process.

Product
ACS
ADC

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

Example: 
active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

```
edr p2p p2p_event_list [ charging-edr charging_edr_format_name | edr-format edr_format_name | reporting-edr reporting_edr_format_name ] +
{ default | no } edr p2p p2p_event_list
```

---

default
Configures this command with its default setting.
Default: Disabled

---

no
If previously configured, deletes the configuration from the current rulebase.

---

p2p_event_list
Specifies the name of the P2P EDR Event. The plugin supports only the “audio-end” and “video-end” events. This P2P event list can be any P2P event that is supported by the plugin.
p2p_event_list must be an alphanumeric string of 1 through 128 characters.

---

charging-edr charging_edr_format_name
Specifies to generate charging EDR for P2P events.
charging_edr_format_name must be the name of a charging EDR format, and must be an alphanumeric string of 1 through 63 characters.

---

edr-format edr_format_name
Specifies to generate EDR for P2P events.
edr_format_name must be the name of an EDR format, and must be an alphanumeric string of 1 through 63 characters.
**reporting-edr** *reporting_edr_format_name*

Specifies to generate reporting EDR for P2P events.

*reporting_edr_format_name* must be the name of a reporting EDR format, and must be an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to configure the P2P events to generate EDRs. The list of P2P events will be populated from the currently loaded plugin.

A plugin is a functional software entity that provides incremental updates to a pre-existing StarOS software component. Plugins can be dynamically loaded at runtime and do not require a system restart. For more information on the Dynamic Software Upgrade feature, refer to *Application Detection and Control Administration Guide*.

**Example**

The following command configures the generation of EDRs for P2P *audio-end* event specifying to use the EDR format named *edr1*:

```
  edr p2p audio-end edr-format edr1
```
**edr sn-charge-volume**

This command allows you to exclude/include packets/bytes that are dropped/retransmitted by the ACS in the total charge volume — “sn-charge-volume” EDR attribute.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
[ default | no ] edr sn-charge-volume { count-dropped-units | count-retransmitted-units }
```

- **default**
  Configures this command with its default setting.
  Default: Exclude, in the total charge volume, packets/bytes dropped/retransmitted by ACS.

- **no**
  Exclude, in the total charge volume, packets/bytes dropped/retransmitted by ACS.

- **count-dropped-units**
  Specifies to include dropped units in the total charge volume.

- **count-retransmitted-units**
  Specifies to include retransmitted units in the total charge volume.

**Usage**

Use this command to exclude/include packets/bytes that are dropped/retransmitted by ACS in the total charge volume — “sn-charge-volume” EDR attribute.

This command applies only to the “sn-charge-volume” attribute and does not affect the “sn-volume-amt” counts in any way.

**Example**

The following specifies to include units retransmitted by ACS in the sn-charge-volume EDR attribute:

```
edr sn-charge-volume count-retransmitted-units
```
**edr suppress-zero-byte-records**

This command disables/enables the creation of EDRs when there is no data for the flows.

**Product**  
ACS

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > ACS Configuration > Rulebase Configuration

```bash
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
[ default | no ] edr suppress-zero-byte-records
```

- **default**  
  Configures this command with its default setting.  
  Default: Disabled; same as `no edr suppress-zero-byte-records`

- **no**  
  Disables the suppression of zero-byte EDRs.

- **edr suppress-zero-byte-records**  
  Suppresses zero-byte EDRs.

**Usage**

Use this command to disable/enable the creation of EDRs that are empty. The situation where there is a zero-byte EDR would typically be possible when two successive EDRs are generated for a flow. This CLI command suppresses the second such EDR for the flow.
edr transaction-complete

This command enables/disables the generation of an EDR on the completion of a transaction.

**Important:** This command is available only in StarOS 8.1 and in StarOS 9.0 and later releases.

**Product:** ACS

**Privilege:** Security Administrator, Administrator

**Mode:**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

In StarOS 12.2 and later releases:

```
edr transaction-complete http [ charging-edr charging_edr_format_name | edr-format edr_format_name | reporting-edr reporting_edr_format_name ]

{ default | no } edr transaction-complete
```

In StarOS 12.1 and earlier releases:

```
edr transaction-complete http edr-format edr_format_name

{ default | no } edr transaction-complete
```

```
default
```

Configures this command with its default setting.
Default: Disabled; same as no edr transaction-complete

```
no
```

If previously configured, deletes the configuration from the current rulebase.

```
edr-format edr_format_name
```

**Important:** This option is available only in 12.1 and earlier releases. In 12.2 and later releases, this option is deprecated and is replaced by the charging-edr option.

Specifies to generate EDR on transaction completion, for HTTP protocol.
`edr_format_name` must be the name of an EDR format, and must be an alphanumeric string of 1 through 63 characters.
```
cmd edr transaction-complete http http edr-format test123
```

## Important

This option is available only in 12.2 and later releases.

Specifies to generate charging EDR on transaction completion.

`charging_edr_format_name` must be the name of a charging EDR format, and must be an alphanumeric string of 1 through 63 characters.

```
cmd charging-edr charging_edr_format_name
```

## Important

This option is available only in 12.2 and later releases.

Specifies to generate reporting EDR on transaction completion.

`reporting_edr_format_name` must be the name of a reporting EDR, and must be an alphanumeric string of 1 through 63 characters.

```
cmd reporting-edr reporting_edr_format_name
```

## Usage

Use this command to configure the generation of an EDR when certain application transactions (for example, request/response pairs) complete. In this release EDR generation is supported only for HTTP protocol. Note that these EDRs are in addition to those that might be generated due to other conditions, for example, EDR configurations in a Charging Action.

## Example

In 12.1 and earlier releases, the following command configures the generation of EDRs on the completion of transactions for HTTP protocol specifying the EDR format as `test123`:

```
edr transaction-complete http edr-format test123
```

In 12.2 and later releases, the following command configures the generation of charging EDRs on the completion of transactions for HTTP protocol specifying the EDR format as `test123`:

```
edr transaction-complete http charging-edr test123
```
edr voip-call-end

This command enables/disables generation of EDRs on the completion of Voice over IP (VoIP) calls. This command is no longer supported for ADC in 14.0 and later releases.

Product
ACS
ADC

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax
In StarOS 12.2 and later releases:

edr voip-call-end { charging-edr charging_edr_format_name | edr-format edr_format_name | reporting-edr reporting_edr_format_name } +

{ default | no } edr voip-call-end

In StarOS 12.1 and earlier releases:

edr voip-call-end edr-format edr_format_name

{ default | no } edr voip-call-end

default

Configures this command with its default setting.
Default: Disabled; same as no edr voip-call-end

no

If previously configured, deletes the edr voip-call-end configuration from the current rulebase.

edr-format edr_format_name

Important: This option is available only in 12.1 and earlier releases. In 12.2 and later releases, it has been deprecated and is replaced by the charging-edr option.

Specifies to generate an EDR when a VoIP call ends.
edr_format_name must be the name of an EDR format, and must be an alphanumeric string of 1 through 63 characters.
### charging-edr charging_edr_format_name

*Important:* This option is available only in 12.2 and later releases.

Specifies to generate a charging EDR when a VoIP call ends. `charging_edr_format_name` must be the name of a charging EDR format, and must be an alphanumeric string of 1 through 63 characters.

### reporting-edr reporting_edr_format_name

*Important:* This option is available only in 12.2 and later releases.

Specifies to generate a reporting EDR when a VoIP call ends. `reporting_edr_format_name` must be the name of a reporting EDR format, and must be an alphanumeric string of 1 through 63 characters.

### Usage

Use this command to generate an EDR on the completion of voice calls. Note that these EDRs are in addition to those that might be generated due to other conditions, for example EDR configurations in a Charging Action. This command facilitates P2P voice duration reporting.

### Example

In 12.1 and earlier releases, the following command specifies generating EDRs on completion of VoIP calls using the EDR format `test13`:

```bash
edr voip-call-end edr-format test13
```

In 12.2 and later releases, the following command specifies generating charging EDRs on completion of VoIP calls using the EDR format named `test23`:

```bash
edr voip-call-end charging-edr test23
```
egcdr inactivity-meter

**Description** This command has been deprecated. It is included in the CLI for backward compatibility with older configuration files. When executed performs no function. Use the `egcdr threshold interval interval [regardless-of-other-triggers]` command for this functionality.
egcdr cdr-encoding

This command allows you to configure the eG-CDR encoding type.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

egcdr cdr-encoding { ascii [ delimiter { colon | comma | pipe } ] | asn.1 }

default egcdr cdr-encoding

default

Configures the default eG-CDR CDR-encoding format.
Default: asn.1

ascii [ delimiter { colon | comma | pipe } ]

Specifies to use ASCII encoding type to generate eG-CDR in ASCII format.

delimiter { colon | comma | pipe }: Specifies the delimiter character to use in eG-CDRs in ASCII format.

• colon: Specifies to use “:” (colon) as a delimiter in eG-CDR.
• comma: Specifies to use “,” (comma), as a delimiter in eG-CDR.
• pipe: Specifies to use “|” (pipe) as a delimiter in eG-CDR.

Default: pipe

asn.1

Specifies to use ASN.1 encoding type to generate eG-CDR in ASN.1 format.
This is the default setting.

Usage

Use this command to configure the eG-CDR encoding type.
For more information on using eG-CDR ASCII encoding type in your deployment, contact your Cisco account representative.

Example

The following command specifies to use ASCII encoding type to generate eG-CDR in ASCII format while specifying the delimiter character as comma:
egcdr cdr-encoding ascii delimiter comma
egcdr tariff

This command allows you to configure the eG-CDR tariff time to generate new eG-CDRs for GGSN and P-GW-CDRs for P-GW.

Product
  GGSN
  P-GW
  SAEGW

Privilege
  Security Administrator, Administrator

Mode
  Exec > ACS Configuration > Rulebase Configuration
  active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

[ no ] egcdr tariff minute minute hour hour

- **no**
  If previously configured, deletes the configuration from the current rulebase.

- **minute minute**
  Specifies the minute for the time-of-day configuration.
  *minute* must be an integer from 0 through 59.

- **hour hour**
  Specifies the hour for the time-of-day configuration.
  *hour* must be an integer from 0 through 23.

Usage

Use this command to configure the eG-CDR tariff time to generate new eG-CDRs for GGSN and P-GW-CDRs for P-GW. Up to four different time-of-day settings may be configured. When any configured tariff time is reached, the current eG-CDR/P-GW-CDR will be closed and a new eG-CDR/P-GW-CDR is opened.

Example

The following command defines an eG-CDR tariff for the 23rd minute of the 22nd hour of the day (10:23 PM):

```
egocdr tariff minute 23 hour 22
```
egcdr threshold

This command allows you to configure the thresholds for generating eG-CDRs for GGSN and P-GW-CDRs for P-GW.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

egcdr threshold { interval interval [ regardless-of-other-triggers ] | volume { downlink | total | uplink } bytes }
{ default | no } egcdr threshold { interval | volume }

no

If previously configured, deletes the eG-CDR threshold configuration from the current rulebase.

default

Configures this command with the default settings.
Default: Disabled; same as no egcdr threshold interval and no egcdr threshold interval volume commands.

interval interval [ regardless-of-other-triggers ]

Specifies the time interval, in seconds, for closing the eG-CDR/P-GW-CDR if the minimum time duration thresholds are satisfied.
interval must be an integer from 60 through 40000000.
regardless-of-other-triggers: This option enables eG-CDR/P-GW-CDR generation at the fixed time interval irrespective of any other eG-CDR/P-GW-CDR triggers that may have happened in between.
Default: Disabled.

volume { downlink | total | uplink } bytes

Specifies the uplink/downlink volume octet counts for the generation of the interim eG-CDRs/P-GW-CDRs.

• downlink bytes: Specifies the limit for the number of downlink (from network to subscriber) octets after which the eG-CDR/P-GW-CDR is closed.
bytes must be an integer from 100000 through 4000000000.
Default: 4000000000
• **total bytes**: Specifies the limit for the total number of octets (uplink+downlink) after which the eG-CDR/P-GW-CDR is closed.
  
  *bytes* must be an integer from 100000 through 4000000000.

  Default: Disabled

• **uplink bytes**: Specifies the limit for the number of uplink (from subscriber to network) octets after which the eG-CDR/P-GW-CDR is closed.
  
  *bytes* must be an integer from 100000 through 4000000000.

  Default: 4000000000

### Usage

Use this command to configure thresholds to generate eG-CDRs/P-GW-CDRs. Thresholds can be specified for both time interval and for data volume, by entering the command twice (once with interval and once with volume). When either configured threshold is reached, the eG-CDR/P-GW-CDRs will be closed. The volume trigger can be specified for uplink or downlink or combined total (uplink + downlink) byte thresholds. The exact keyword forces the configured volume to exactly match the volume in the eG-CDR/P-GW-CDRs, so the triggering packet might have to be divided across two eG-CDRs/P-GW-CDRs.

When both interval and volume triggers are configured, we'll reset the interval time and accumulated volume amount whenever the eG-CDR/P-GW-CDRs is closed regardless of whether it was due to the interval time expiration or reaching the volume limit. Use the regardless-of-other-triggers optional keyword, if you want the eG-CDRs/P-GW-CDRs closed at the configured regular intervals, regardless of whether eG-CDRs/P-GW-CDRs are being closed due to reaching a volume limit.

When the PDP context is terminated, the eG-CDR/P-GW-CDRs will be closed regardless of whether the thresholds have been reached.

### Example

The following command defines an eG-CDR threshold interval of 600 seconds:

```
  egcdr threshold interval 600
```
egcdr time-duration algorithm

This command allows you to specify the algorithm to compute the duration of time utilization in an eG-CDR for the current rulebase.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)>

Syntax

egcdr time-duration algorithm { consumed-time consumed_time [ plus-idle ] | continuous-time-periods ctp_time | parking-meter seconds }

{ default | no } egcdr time-duration algorithm

no

If previously configured, deletes the eG-CDR time-duration algorithm configuration from the current rulebase.

default

Configures this command with its default setting.
Default: Algorithm configured for CCA, or the CCA default if none is configured.

consumed-time consumed_time [ plus-idle ]

Specifies the actual consumption time in seconds. This is used to determine the actual used chargeable time envelopes for the purpose of consuming time quota.
consumed_time must be an integer from 1 through 4294967295.
Default: 0 (disabled)
Time envelope is the basis for reporting active usage. For each time envelope, the time consumption includes the time duration between arrival of last packet and first packet only.
plus-idle: Specifies the idle time between arrival of two packets to include in time usage record in eG-CDR.
When used along with consumed-time it indicates the active usage + idle time, when no traffic flow occurs.

continuous-time-periods ctp_time

Specifies the continuous time period to compute the usage record in eG-CDR.
ctp_time sets the audition, in seconds, to start a counter on arrival of the first packet and thereafter include only that period in charging in which one or more packets arrived. For the period where no packets arrived or no traffic was detected, usage will not be computed.
ctp_time must be an integer from 1 through 4294967295.
**parking-meter seconds**

Specifies the Parking Meter (PM) period, in seconds.  
*seconds* must be an integer from 1 through 4294967295.  
Parking meter is the method with which the usage time is set in the content-id containers in eG-CDRs. When a parking meter value is set, the user is charged for time in increments of the value set. For example, if the parking meter is set to 300 seconds (5 minutes) and the subscriber only uses one minute, the charge is for 5 minutes.

**Usage**

Use this command to set the various time charging algorithms/schemes for time usage in eG-CDR.  
For example, packets arrive at times T1, T2, T3 and T4. Then the typical time usage might be computed to be T4 – T1. However, if say there is an idle period between times T2 and T3, then system will compute the time usage to be (T2 – T1) + (T4 – T3).  
*consumed-time* in above scenario calculates the time duration as (T2 – T1) + (T4 – T3) where *consumed-time* with *plus-idle* calculates the time duration as (T2-T1)+I + (T4 – T3)+I or (T4-T1).

**Example**

The following command sets consumed time duration to 400 seconds:

```
egcdr time-duration algorithm consumed-time 400
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
end

**Usage**
Use this command to return to the Exec mode.
**exit**

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
extract-host-from-uri

This command allows you to configure whether to use the host name embedded in the URI as the host field, when the host field option in the HTTP or Wireless Session Protocol (WSP) header is absent.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-rule-base) #
```

**Syntax**

```
extract-host-from-uri { http | wsp } +
{ default | no } extract-host-from-uri
```

- **default**
  Configures this command with its default setting.
  Default: Disabled; same as no extract-host-from-uri

- **no**
  If previously configured, disables the extract-host-from-uri configuration, for both HTTP and WSP, from the current rulebase.

- **http | wsp**
  Specifies the protocol(s).

  +
  Indicates that more than one of the previous keywords can be entered within a single command.

**Usage**

If the host field is not present in HTTP/WSP header, this command will extract host from the URI, and store it in the host field to enable “http host” and “wsp host” rule matches using the stored value.

**Important:** Applying the extract-host-from-uri command a second time will overwrite the previous configuration. For example, if you apply the command extract-host-from-uri http wsp http, and then apply the command extract-host-from-uri http wsp, extraction of host from URI will happen only for WSP analyzer.

**Example**

Command Line Interface Reference, StarOS Release 16
The following command configures extraction of host from URI for both HTTP and WSP protocols:

```
extract-host-from-uri http wsp
```
**firewall dos-protection**

This command allows you to configure Stateful Firewall protection for subscribers from Denial-of-Service (DoS) attacks.

⚠️ **Important:** In StarOS 8.0, this command is available in the ACS Configuration Mode. In StarOS 8.1 and StarOS 8.3, use this command for Rulebase-based Firewall-and-NAT configuration. In StarOS 8.1 and StarOS 9.0 and later releases, for Policy-based Firewall-and-NAT configuration, this command is available in the Firewall-and-NAT Policy Configuration Mode.

**Product**
PSF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
[ no ] firewall dos-protection { all | flooding { icmp | tcp-syn | udp } | ftp-bounce | ip-unaligned-timestamp | mime-flood | port-scan | tcp-window-containment | source-router | teardrop | winnuke }
```

**default firewall dos-protection**

```
no
```

If previously enabled, disables Stateful Firewall protection for subscribers from all or specified DoS attack(s).

```
default
```

Configures this command with its default setting.
Default: Protection from all DOS attacks is disabled.

```
all
```

Enables protection against all DoS attacks supported by the Stateful Firewall in-line service.

```
flooding { icmp | tcp-syn | udp }
```

Enables protection against specified flooding attacks:

- **icmp**: Enables protection against ICMP Flood attacks
- **tcp-syn**: Enables protection against TCP SYN Flood attacks
- **udp**: Enables protection against UDP Flood attacks
ftp-bounce

Enables protection against FTP Bounce attacks. In an FTP Bounce attack, an attacker is able to use the PORT command to request access to ports indirectly through a user system as an agent for the request. This technique is used to port scan hosts discreetly, and to access specific ports that the attacker cannot access through a direct connection.

ip-unaligned-timestamp

Enables protection against IP Unaligned Timestamp attacks. In an IP Unaligned Timestamp attack, certain operating systems crash if they receive a frame with the IP timestamp option that is not aligned on a 32-bit boundary.

mime-flood

Enables protection against HTTP Multiple Internet Mail Extension (MIME) Header Flooding attacks. In a MIME Flood attack an attacker sends huge amount of MIME headers which consumes a lot of memory and CPU usage.

port-scan

Enables protection against Port Scan attacks.

tcp-window-containment

Enables protection against TCP Sequence Number Out-of-Range attacks. In a Sequence Number Out-of-Range attack the attacker sends packets with out-of-range sequence numbers forcing the system to wait for missing sequence packets.

source-router

Enables protection against IP Source Route IP Option attacks. Source routing is an IP option mainly used by network administrators to check connectivity. When an IP packet leaves a system, its path through various networks to its destination is controlled by the routers and their current configuration. Source routing provides a means to override the control of the routers. Strict source routing specifies the path through all the routers to the destination. The same path in reverse is used to return responses. Loose source routing allows the attacker to spoof both an address and sets the loose source routing option to force the response to return to the attacker's network.

teardrop

Enables protection against Teardrop attacks. In a Teardrop attack, overlapping IP fragments are exploited causing the TCP/IP fragmentation re-assembly to improperly handle overlapping IP fragments.

winnuke

Enables protection against WIN-NUKE attacks. This is a type of Nuke denial-of-service attack against networks consisting of fragmented or otherwise invalid ICMP packets sent to the target, achieved by using a modified ping utility to repeatedly send this corrupt data, thus slowing down the affected computer until it comes to a complete stop. The WinNuke exploits the vulnerability in the NetBIOS handler and a string of out-of-band data sent to TCP port 139 of the victim machine causing it to lock up and display a Blue Screen of Death.
**Usage**

Use this command to enable Stateful Firewall protection from different types of DoS attacks. This command can be used multiple times for different DoS attacks.

**Important:** The DoS attacks are detected only in the downlink direction.

**Example**

The following command enables Stateful Firewall protection from all supported DoS attacks:

```plaintext
firewall dos-protection all
```
**firewall flooding**

This command allows you to configure Stateful Firewall protection from Packet Flooding attacks.

**Important:** In StarOS 8.0, this command is available in the ACS Configuration Mode. In StarOS 8.1 and StarOS 8.3, use this command for Rulebase-based Firewall-and-NAT configuration. In StarOS 8.1 and StarOS 9.0 and later releases, for Policy-based Firewall-and-NAT configuration, this command is available in the Firewall-and-NAT Policy Configuration Mode.

**Product**
PSF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
firewall flooding { { protocol { icmp | tcp-syn | udp } packet limit packets } | { sampling-interval interval } }

default firewall flooding { { protocol { icmp | tcp-syn | udp } packet limit } | { sampling-interval } }
```

**default**

Configures this command the default setting for the specified keyword.

**protocol { icmp | tcp-syn | udp }**

Specifies the transport protocol:

- `icmp`: Configuration for ICMP protocol.
- `tcp-syn`: Configuration for TCP-SYN packet limit.
- `udp`: Configuration for UDP protocol.

**packet limit packets**

Specifies the maximum number of specified packets a subscriber can receive during a sampling interval. `packets` must be an integer from 1 through 4294967295. Default: 1000 packets per sampling interval for all protocols.

**sampling-interval interval**

Specifies the flooding sampling interval, in seconds. `interval` must be an integer from 1 through 60. Default: 1 second
Usage

Use this command to configure the maximum number of ICMP, TCP-SYN, / UDP packets allowed to prevent the packet flooding attacks to the host.

Example

The following command ensures a subscriber will not receive more than 1000 ICMP packets per sampling interval:

```
firewall flooding protocol icmp packet limit 1000
```

The following command ensures a subscriber will not receive more than 1000 UDP packets per sampling interval on different 5-tuples. That is, if an attacker is sending lot of UDP packets on different ports or using different spoofed IPs, those packets will be limited to 1000 packets per sampling interval. This way only “suspected” malicious packets are limited and not “legitimate” packets:

```
firewall flooding protocol udp packet limit 1000
```

The following command ensures a subscriber will not receive more than 1000 TCP-SYN packets per sampling interval:

```
firewall flooding protocol tcp-syn packet limit 1000
```

The following command specifies a flooding sampling interval of 1 second:

```
firewall flooding sampling-interval 1
```
firewall icmp-destination-unreachable-message-threshold

This command allows you to configure a threshold on the number of ICMP error messages sent by the subscriber for a particular data flow.

**Important:** In StarOS 8.0, this command is available in the ACS Configuration Mode. In StarOS 8.1 and StarOS 8.3, use this command for Rulebase-based Firewall-and-NAT configuration. In StarOS 8.1 and StarOS 9.0 and later releases, for Policy-based Firewall-and-NAT configuration, this command is available in the Firewall-and-NAT Policy Configuration Mode.

**Product**
PSF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
firewall icmp-destination-unreachable-message-threshold messages then-block-server
{ default | no } firewall icmp-destination-unreachable-message-threshold
```

<table>
<thead>
<tr>
<th>Default</th>
<th>Configuration with its default setting. Default: No limit</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>No</th>
<th>If previously configured, deletes the configuration from the current rulebase.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Messages</th>
<th>Specifies the threshold on the number of ICMP error messages sent by the subscriber for a particular data flow. Messages must be an integer from 1 through 100.</th>
</tr>
</thead>
</table>

**Usage**

Use this command to configure a threshold on the number of ICMP error messages sent by the subscriber for a particular data flow. After the threshold is reached, it is assumed that the server is not reacting properly to the error messages, and further downlink traffic to the subscriber on the unwanted flow is blocked. Some servers that run QChat ignore the ICMP error messages (Destination Port Unreachable and Host Unreachable) from the mobiles. So the mobiles continue to receive unwanted UDP traffic from the QChat servers, and their batteries get exhausted quickly.
Example

The following command configures a threshold of 10 ICMP error messages:

```
firweall icmp-destination-unreachable-message-threshold 10 then-block-server
```
firewall max-ip-packet-size

This command allows you to configure the maximum IP packet size (after IP reassembly) allowed over Stateful Firewall.

**Important:** In StarOS 8.0, this command is available in the ACS Configuration Mode. In StarOS 8.1 and StarOS 8.3, use this command for Rulebase-based Firewall-and-NAT configuration. In StarOS 8.1 and StarOS 9.0 and later releases, for Policy-based Firewall-and-NAT configuration, this command is available in the Firewall-and-NAT Policy Configuration Mode.

<table>
<thead>
<tr>

</tbody>
</table>

```sh
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
firewall max-ip-packet-size packet_size protocol { icmp | non-icmp }
```

```
default firewall max-ip-packet-size protocol { icmp | non-icmp }
```

**Default**

Configures the default maximum IP packet size configuration. Default: 65535 bytes (for both ICMP and non-ICMP)

**Packet Size**

Specifies the maximum packet size. `packet_size` must be an integer from 30000 through 65535.

**Protocol**

Specifies the transport protocol:

- `icmp`: Configuration for ICMP protocol.
- `non-icmp`: Configuration for protocols other than ICMP.

**Usage**

Use this command to configure the maximum IP packet size allowed for ICMP and non-ICMP packets to prevent packet flooding attacks to the host. Packets exceeding the configured size will be dropped for “Jolt Attack” and “Ping-Of-Death Attack”.

**Example**

// Example usage in the ACS Configuration Mode

```sh
firewall max-ip-packet-size 10000 non-icmp
```

// Configuration sequence for default settings

```sh
default firewall max-ip-packet-size 65535 non-icmp
```
The following command allows a maximum packet size of 60000 for ICMP protocol:

```plaintext
firewall max-ip-packet-size 60000 protocol icmp
```
**firewall mime-flood**

This command allows you to configure Stateful Firewall protection from Multipurpose Internet Mail Extensions (MIME) Flood attacks.

**Important**: In StarOS 8.0, this command is available in the ACS Configuration Mode. In StarOS 8.1 and StarOS 8.3, use this command for Rulebase-based Firewall-and-NAT configuration. In StarOS 8.1 and StarOS 9.0 and later releases, for Policy-based Firewall-and-NAT configuration, this command is available in the Firewall-and-NAT Policy Configuration Mode.

**Product**
PSF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

**Syntax**

```plaintext
firewall mime-flood { http-headers-limit max_limit | max-http-header-field-size max_size }

default firewall mime-flood { http-headers-limit | max-http-header-field-size }
```

**default**
Configures this command with its default setting.

**http-headers-limit max_limit**

Specifies the maximum number of headers allowed in an HTTP packet. If the number of HTTP headers in a page received is more than the specified limit, the request will be denied.

`max_limit` must be an integer from 1 through 256.

Default: 16

**max-http-header-field-size max_size**

Specifies the maximum header field size allowed in the HTTP header, in bytes. If the size of HTTP header in the received page is more than the specified number of bytes, the request will be denied.

`max_size` must be an integer from 1 through 8192.

Default: 4096 bytes

**Usage**

Use this command to configure the maximum number of headers allowed in an HTTP packet, and the maximum header field size allowed in the HTTP header to prevent MIME flooding attacks.
Example

The following command sets the maximum number of headers allowed in an HTTP packet to 100:

```
firewall mime-flood http-headers-limit 100
```

The following command sets the maximum header field size allowed in the HTTP header to 1000 bytes:

```
firewall mime-flood max-http-header-field-size 1000
```
firewall no-ruledef-matches

This command allows you to configure the default action for packets when no Stateful Firewall ruledef matches.

**Important:** In StarOS 8.0, this command is available in the ACS Configuration Mode. In StarOS 8.1 and StarOS 8.3, use this command for Rulebase-based Firewall-and-NAT configuration. In StarOS 8.1 and StarOS 9.0 and later releases, for Policy-based Firewall-and-NAT configuration, use the `access-rule no-ruledef-matches` command available in the Firewall-and-NAT Policy Configuration Mode.

**Product**
PSF
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
firewall no-ruledef-matches { downlink | uplink } action { deny [ charging-action charging_action_name ] | permit [ bypass-nat | nat-realm nat_realm_name ] }
```

```
default firewall no-ruledef-matches { downlink | uplink } action
```

**default**

Configures the default action for packets with no Stateful Firewall ruledef match.

```
downlink | uplink
```

Specifies the packet type:

- **downlink**: Downlink (from network to subscriber) packets with no Stateful Firewall ruledef match.
  
  Default: deny

- **uplink**: Uplink (from subscriber to network) packets with no Stateful Firewall ruledef match.
  
  Default: permit

```
action { deny [ charging-action charging_action_name ] | permit [ bypass-nat | nat-realm nat_realm_name ] }
```

Specifies the default action for packets with no Stateful Firewall ruledef match.

```
permit [ bypass-nat | nat-realm nat_realm_name ]: Permit packets.
```

**Important:** The `bypass-nat` keyword is only available in StarOS 8.3 and later releases.
Optionally specify:

- **bypass-nat**: Specifies to bypass Network Address Translation (NAT).
- **nat-realm nat_realm_name**: Specifies a NAT realm to be used for performing NAT on subscriber packets.
  
  `nat_realm_name` must be the name of a NAT realm, and must be an alphanumeric string of 1 through 31 characters.

**Important**: If neither `bypass-nat` or `nat-realm` are configured, NAT is performed if the `nat policy nat-required` CLI command is configured with the `default-nat-realm` option.

**deny [ charging-action charging_action_name ]**: Denies specified packets.

Optionally, a charging action can be specified.

`charging_action_name` must be the name of a charging action, and must be an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to configure the default action to be taken on packets with no Stateful Firewall ruledef matches.

If, for deny action, the optional charging action is configured, the action taken depends on what is configured in the charging action. For the Stateful Firewall rule, the “flow action”, “billing action”, and “content ID” of the charging action will be used to take action. If flow exists, flow statistics are updated.

Allowing/dropping of packets is determined in the following sequence:

- Check is done to see if the packet matches any pinholes. If yes, no rule matching is done and the packet is allowed.
- Stateful Firewall ruledef matching is done. If a rule matches, the packet is allowed or dropped as per the `firewall priority` configuration.
- If no Stateful Firewall ruledef matches, the packet is allowed or dropped as per the `no-ruledef-matches` configuration.

For a packet dropped due to Stateful Firewall ruledef match or no match (first packet of a flow), the charging action applied is the one configured in the `firewall priority` or the `firewall no-ruledef-matches` command respectively.

In StarOS 8.1, in the case of Policy-based Stateful Firewall, the charging action applied is the one configured in the `access-rule priority` or the `access-rule no-ruledef-matches` command respectively.

For action on packets dropped due to any error condition after data session is created, the charging action must be configured in the `flow any-error charging-action` command.

**Example**

The following command configures Stateful Firewall to permit downlink packets with no ruledef matches:

```
firwall no-ruledef-matches downlink action permit
```
**firewall policy**

This command allows you to enable/disable Stateful Firewall support for all subscribers using the current rulebase.

**Important:** In StarOS 8.0, this command is available in the APN/Subscriber Configuration Mode. In StarOS 8.1 and StarOS 8.3, use this command for Rulebase-based Firewall-and-NAT configuration. In StarOS 8.1 and StarOS 9.0 and later releases, for Policy-based Firewall-and-NAT configuration, this command is available in the Firewall-and-NAT Policy Configuration Mode.

**Product**

PSF

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

`[local]host_name(config-rule-base)#`

**Syntax**

```
firewall policy firewall-required

{ default | no } firewall policy
```

- **default**
  
  Configures this command with its default setting.
  
  Default: Stateful Firewall support is disabled for all subscribers using the current rulebase.

- **no**
  
  If previously enabled, disables Stateful Firewall support for all subscribers using the current rulebase.

- **firewall-required**
  
  Enables Stateful Firewall support for all subscribers using the current rulebase.

**Usage**

Use this command to enable/disable Stateful Firewall support for all subscribers using the current rulebase.

**Example**

The following command enables Stateful Firewall support:

```
firewall policy firewall-required
```

The following command disables Stateful Firewall support:

```
no firewall policy
```
firewall priority

This command allows you to add and specify the priority and type of a Stateful Firewall ruledef in the current rulebase, and allows you to configure a single or range of ports to be allowed on the server for auxiliary/data connections.

Important: In StarOS 8.1 and StarOS 9.0 and later releases, for Policy-based Firewall-and-NAT configuration, use the access-rule priority command available in the Firewall-and-NAT Policy Configuration Mode.

Product
PSF
NAT

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration
active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:
[local]host_name(config-rule-base)#

Syntax

firewall priority priority [ dynamic-only | static-and-dynamic ] firewall-ruledef
firewall_ruledef_name { { deny [ charging-action charging_action_name ] } | { permit [ nat-realm nat_realm_name | [ trigger open-port { aux_port_number | range start_port_number to end_port_number } direction { both | reverse | same } ] ] } ] }

no firewall priority priority

If previously configured, deletes the specified Stateful Firewall ruledef priority configuration from the current rulebase.

priority

Specifies the Stateful Firewall ruledef’s priority in the current rulebase.
priority must be a unique value in the current rulebase, and must be an integer from 1 through 65535.

[ dynamic-only | static-and-dynamic ] firewall-ruledef firewall_ruledef_name

Specifies the Stateful Firewall ruledef to add to the rulebase. Optionally, the Stateful Firewall ruledef type can be specified.

• dynamic-only: Firewall Dynamic Ruledef—Predefined ruledef that can be enabled/disabled by the policy server, and is disabled by default.

• static-and-dynamic: Firewall Static and Dynamic Ruledef—Predefined ruledef that can be disabled/enabled by the policy server, and is enabled by default.

firewall_ruledef_name must be the name of a Stateful Firewall ruledef, and must be an alphanumeric string of 1 through 63 characters.
deny [ charging-action charging_action_name ]

Denies packets if the rule is matched. An optional charging action can be specified. If a packet matches the deny rule, action is taken as configured in the charging action. For Stateful Firewall ruledefs, only the terminate-flow action is applicable, if configured in the specified charging action.

charging_action_name must be the name of a charging action, and must be an alphanumeric string of 1 through 63 characters.

permit [ nat-realm nat_realm_name | [ bypass-nat ] [ trigger open-port { aux_port_number | range start_port_number to end_port_number } ] ]

Permits packets.

•nat-realm nat_realm_name: Specifies the NAT realm to be used for performing NAT on subscriber packets matching the Stateful Firewall ruledef.

If the NAT realm is not specified, then NAT will be bypassed. That is, NAT will not be applied on subscriber packets that are matching a Stateful Firewall ruledef with no NAT realm name configured.

nat_realm_name must be the name of a NAT realm, and must be an alphanumeric string of 1 through 31 characters.

•bypass-nat: Specifies that packets bypass NAT.

Important: If the nat-realm is not configured, NAT is performed if the nat policy nat-required CLI command is configured with the default-nat-realm option.

•trigger open-port { aux_port_number | range start_port_number to end_port_number } : Permits packets if the rule is matched, and allows the creation of data flows for Stateful Firewall. Optionally a port trigger can be specified to be used for this rule to limit the range of auxiliary data connections (a single or range of port numbers) for protocols having control and data connections (like FTP). The trigger port will be the destination port of an association which matches a rule.

•aux_port_number: Specifies the number of auxiliary ports to open for traffic, and must be an integer from 1 through 65535.

•range start_port_number to end_port_number: Specifies the range of ports to open for subscriber traffic.

•start_port_number must be an integer from 1 through 65535. This is the start of the port range and must be less than end_port_number.

•end_port_number must be an integer from 1 through 65535. This is the end of the port range and must be greater than start_port_number.

direction { both | reverse | same }

Specifies the direction from which the auxiliary connection is initiated. This direction can be same as the direction of control connection, or the reverse of the control connection direction, or in both directions.

•both: Provides the trigger to open port for traffic in either direction of the control connection.

•reverse: Provides the trigger to open port for traffic in the reverse direction of the control connection (from where the connection is initiated).

•same: Provides the trigger to open port for traffic in the same direction of the control connection (from where the connection is initiated).
Usage

Use this command to add Stateful Firewall ruledefs to the rulebase and configure the priority, type, and port triggers. Port trigger configuration is optional. Port trigger can be configured only if a rule action is permit. The rulebase specifies the Stateful Firewall rules to be applied on the calls. The ruledefs within a rulebase have priorities, based on which priority matching is done. Once a rule is matched and the rule action is permit, if the trigger is configured, the appropriate check is made. The trigger port will be the destination port of an association which matches the rule.

Multiple triggers can be defined for the same port number to permit multiple auxiliary ports for subscriber traffic.

Once a rule is matched and if the rule action is deny, the action taken depends on what is configured in the specified charging action. If the flow exists, flow statistics are updated and action is taken as configured in the charging action:

- If the billing action is configured as EDR enabled, an EDR is generated.
- If the content ID is configured, UDR information is updated.
- If the flow action is configured as “terminate-flow”, the flow is terminated instead of just discarding the packet.

If the billing action, content ID, and flow action are not configured, no action is taken on the dropped packets.

Important: For Stateful Firewall ruledefs, only the terminate-flow action is applicable if configured in the specified charging action.

For a packet dropped due to Stateful Firewall ruledef match or no match (first packet of a flow), the charging action applied is the one configured in the firewall priority or the firewall no-ruledef-matches command respectively.

In StarOS 8.1, in the case of Policy-based Firewall, the charging action applied is the one configured in the access-rule priority or the access-rule no-ruledef-matches command respectively.

For action on packets dropped due to any error condition after data session is created, the charging action must be configured in the flow any-error charging-action command.

The GGSN can dynamically activate/deactivate dynamic Stateful Firewall ruledefs for a subscriber based on the rule name received from a policy server. At rule match, if a rule in the rulebase is a dynamic rule, and if the rule is enabled for the particular subscriber, rule matching is done for the rule. If the rule is disabled for the particular subscriber, rule matching is not done for the rule.

Example

The following command assigns a priority of 10 to the Stateful Firewall ruledef fw_rule1, adds it to the rulebase, and permits port trigger to be used for the rule to open ports in the range of 100 to 200 in either direction of the control connection:

```
firewall priority 10 firewall-ruledef fw_rule1 permit trigger open-port range 100 to 200 direction both
```

The following command configures the Stateful Firewall ruledef fw_rule2 as a dynamic ruledef:

```
firewall priority 7 dynamic-only firewall-ruledef fw_rule2 deny
```
**firewall tcp-first-packet-non-syn**

This command allows you to configure the action to take on TCP flows starting with a non-syn packet.

**Important:** In StarOS 8.1 and StarOS 8.3, use this command for Rulebase-based Firewall-and-NAT configuration. In StarOS 8.1 and StarOS 9.0 and later releases, for Policy-based Firewall-and-NAT configuration, this command is available in the Firewall-and-NAT Policy Configuration Mode.

```

**Syntax**

```bash
firewall tcp-first-packet-non-syn { drop | reset }
```

**default firewall tcp-first-packet-non-syn**

```
default
```

Configures this command with its default setting. Default: `drop`

```
drop
```

Specifies to drop the packet or session.

```
reset
```

Specifies to send reset.

**Usage**

Use this command to configure action to take on TCP flow starting with a non-syn packet.

**Example**

The following command configures action to take on TCP flow starting with a non-syn packet to drop:

```bash
firewall tcp-first-packet-non-syn drop
```
firewall tcp-idle-timeout-action

This command allows you to configure the Stateful Firewall action to be taken on TCP idle timeout expiry.

**Important:** In StarOS 8.1 and StarOS 8.3, use this command for Rulebase-based Firewall-and-NAT configuration. In StarOS 8.1 and StarOS 9.0 and later releases, for Policy-based Firewall-and-NAT configuration, this command is available in the Firewall-and-NAT Policy Configuration Mode.

active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
firewall tcp-idle-timeout-action { drop | reset }
default firewall tcp-idle-timeout-action
```

**default firewall tcp-idle-timeout-action**

```
default
Configures this command with its default setting.
Default: reset
```

```
drop
Specifies to drop the packet or session on TCP timeout expiry.
```

```
reset
Specifies to send reset on TCP timeout expiry.
```

**Usage**

Use this command to configure action to take on TCP idle timeout expiry.

**Example**

The following command configures action to take on TCP idle timeout expiry to drop:

```
firewall tcp-idle-timeout-action drop
```
ACS Rulebase Configuration Mode Commands

**firewall tcp-reset-message-threshold**

This command allows you to configure a threshold on the number of TCP reset messages sent by the subscriber for a particular data flow. After this threshold is reached, further downlink traffic to the subscriber on the unwanted flow is blocked.

**Important:** This command is only available in StarOS 8.3 and later releases. In StarOS 8.3, use this command for Rulebase-based Firewall-and-NAT configuration. In StarOS 9.0 and later releases, for Policy-based Firewall-and-NAT configuration, this command is available in the Firewall-and-NAT Policy Configuration Mode.

**Product**
PSF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration
active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

**Syntax**

```
fir         firewall tcp-reset-message-threshold messages then-block-server
{ default | no } firewall tcp-reset-message-threshold
```

| { default | no } | firewall tcp-reset-message-threshold |
|------------|-------------------------------------|
| **default** | Configures this command with its default setting. Default: no firewall tcp-reset-message-threshold |
| **no**      | If previously configured, deletes the firewall tcp-reset-message-threshold configuration from the current rulebase. |
| **messages**| Specifies the threshold on the number of TCP reset messages sent by the subscriber for a particular data flow. messages must be an integer from 1 through 100. |

**Usage**

Use this command to configure a threshold on the number of TCP reset messages sent by the subscriber for a particular data flow. After the threshold is reached, assuming the server is not reacting properly to the reset messages further downlink traffic to the subscriber on the unwanted flow is blocked. This configuration enables QCHAT noise suppression for TCP.

**Example**

The following command sets the threshold on the number of TCP reset messages to 10:
firewall tcp-reset-message-threshold 10 then-block-server
**firewall tcp-syn-flood-intercept**

This command allows you to configure the TCP intercept parameters to prevent TCP SYN flooding attacks by intercepting and validating TCP connection requests for DoS protection mechanism configured with the `dos-protection` command.

**Important:** In StarOS 8.0, this command is available in the ACS Configuration Mode. In StarOS 8.1 and StarOS 8.3, use this command for Rulebase-based Firewall-and-NAT configuration. In StarOS 8.1 and StarOS 9.0 and later releases, for Policy-based Firewall-and-NAT configuration, this command is available in the Firewall-and-NAT Policy Configuration Mode.

**Product**
PSF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
firewall tcp-syn-flood-intercept { mode { none | watch [ aggressive ] } | watch-timeout}

default firewall tcp-syn-flood-intercept { mode | watch-timeout }
```

**default**

Sets the default values of TCP intercept parameters for SYN Flood DoS protection.

**mode { none | watch [ aggressive ] }**

Specifies the TCP SYN flood intercept mode:

- **none:** Disables TCP SYN flood intercept feature.
- **watch:** Configures TCP SYN flood intercept feature in watch mode. Stateful Firewall passively watches to see if TCP connections become established within a configurable interval. If connections are not established within the timeout period, Stateful Firewall clears the half-open connections by sending RST to TCP client and server. The default watch-timeout for connection establishment is 30 seconds.
- **aggressive:** Configures TCP SYN flood Intercept or Watch feature for aggressive behavior. Each new connection request causes the oldest incomplete connection to be deleted. When operating in watch mode, the watch timeout is reduced by half. If the watch-timeout is 30 seconds, under aggressive conditions it becomes 15 seconds. When operating in intercept mode, the retransmit timeout is reduced by half (i.e. if the timeout is 60 seconds, it is reduced to 30 seconds). Thus the amount of time waiting for connections to be established is reduced by half (i.e. it is reduced to 150 seconds from 300 seconds under aggressive conditions).
Default: `none`

```
watch-timeout  intercept_watch_timeout
```

Specifies the TCP intercept watch timeout, in seconds.

*intercept_watch_timeout* must be an integer from 5 through 30.

Default: 30

**Usage**

This TCP intercept functionality provides protection against TCP SYN Flooding attacks. The system captures TCP SYN requests and responds with TCP SYN-ACKs. If a connection initiator completes the handshake with a TCP ACK, the TCP connection request is considered as valid by system and system forwards the initial TCP SYN to the valid target which triggers the target to send a TCP SYN-ACK. Now system intercepts with TCP SYN-ACK and sends the TCP ACK to complete the TCP handshake. Any TCP packet received before the handshake completion will be discarded.

**Example**

The following command sets the TCP intercept watch timeout setting to 5 seconds:

```
firewall tcp-syn-flood-intercept watch-timeout 5
```
flow any-error

This command allows you to specify the charging action to be used for packets dropped by Stateful Firewall due to any error conditions.

**Product**
PSF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
flow any-error charging-action charging_action_name

default flow any-error
```

```
default
```

Configures the default action for packets dropped by Stateful Firewall due to any errors.
Default: Update the flow statistics if flow is available

```
charging_action_name
```

Specifies the charging action based on which accounting action is taken on packets dropped by Stateful Firewall due to any errors.

*charging_action_name* must be the name of a charging action, and must be an alphanumeric string of 1 through 63 characters.

**Important:** The charging action specified here should preferably not be used for action on packets dropped due to Stateful Firewall ruledef match or no-match (in the firewall priority and firewall no-ruledef-matches commands) and the content ID within the charging action must be unique so that dropped counts will not interfere with other content IDs.

**Usage**

Use this command to configure the charging action for packets dropped by Stateful Firewall due to any error conditions, such as, a packet being inappropriate based on the state of the protocol of the packet's session, or DoS protection causing the packet to be discarded, and so on.

For a packet dropped due to Stateful Firewall ruledef match or no match (first packet of a flow), the charging action applied is the one configured in the firewall priority or the firewall no-ruledef-matches command respectively.

In StarOS 8.1, in the case of Policy-based Firewall, the charging action applied is the one configured in the access-rule priority or the access-rule no-ruledef-matches command respectively.
For a packet dropped due to any error condition after data session is created, the charging action used is the one configured in the \texttt{flow any-error charging-action} command. If the charging action applied on a packet is the one specified in the \texttt{flow any-error charging-action} command, flow statistics are updated and action is taken as configured in the charging action:

- If the billing action is configured as EDR enabled, an Event Data Record (EDR) is generated.
- If the content ID is configured, Usage Data Record (UDR) information is updated.
- If the flow action is configured as “terminate-flow”, the flow is terminated instead of just discarding the packet.

If the billing action, content ID, and flow action are not configured, no action is taken on the dropped packets.

\textbf{Example}

The following command specifies the charging action \textit{test2} for accounting action on packets dropped/discarded by Stateful Firewall due to any error:

\begin{verbatim}
flow any-error charging-action test2
\end{verbatim}
flow control-handshaking

This command allows you to specify how to charge for the control traffic associated with an application.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

 ACTIVE-CHARGING service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

flow control-handshaking { charge-to-application { [ all-packets ] [ initial-packets ] [ mid-session-packets ] [ tear-down-packets ] } | charge-separate-from-application }

default flow control-handshaking

no flow control-handshaking { charge-to-application }

default flow control-handshaking

Configures this command with its default setting.
Default: Same as no flow control-handshaking

no flow control-handshaking { charge-to-application }

If previously configured, deletes the flow control-handshaking configuration from the current rulebase. The control packets will use whatever content-id is determined by the normal use of the action commands.

In this command, the optional keyword charge-to-application is deprecated and has no effect.

charge-to-application { [ all-packets ] [ initial-packets ] [ mid-session-packets ] [ tear-down-packets ] }

Configures the charging action to include the flow control packets either during initial handshaking only or specified control packets during session for charging.

• all-packets: Specifies that the initial setup packets will wait until the application has been determined before assigning the content-id, and all mid-session ACK packets as well as the final tear-down packets will use that content-id.

• initial-packets: Specifies that only the initial setup packets will wait for content-id assignment.

• mid-session-packets: Specifies that the ACK packets after the initial setup will use the application's or content-id assignment.

• tear-down-packets: Specifies that the final tear-down packets (TCP or WAP) will use the application's or content-id assignment.
**flow control-handshaking**

---

### charge-separate-from-application

Configures the charging action to separate the charging of the initial control packets or all subsequent control packets from regular charging.

#### Usage

Use this command to configure how to charge for the control traffic associated with an application ruledef. Applications like HTTP use TCP to set up and tear down connections before the HTTP application starts. This command controls whether the packets that set up and tear down the connections should use the same content ID as the application's flow.

In normal mode 3-way handshake TCP packets (SYN, SYN-ACK, and ACK) and closing or intermittent packets (FIN, RST, etc.) directed and charged based on configured matched rules. This command makes the system to wait for the start and stop of layer 7 packet flow and content ID and charge the initial, intermittent, and closing TCP packets as configured to the same matching rules and content ID as of the flow.

This command also affects applications that do not use TCP but use other methods for control packets, for example WAP, where WTP/UDP may be used to set up and tear down connection-oriented WSP.

#### Example

Following command enables the charging for initial TCP handshaking control packets and wait for content-id of data traffic flow:

```
flow control-handshaking charge-to-application initial-packets
```

The following command enables charging all mid-session ACKs as well as tear-down packets to application:

```
flow control-handshaking charge-to-application mid-session-packets tear-down-packets
```
flow end-condition

This command allows you to configure the end condition of the session flows related to a user session and triggers EDR generation.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

Syntax

In StarOS 12.2 and later releases:

```
flow end-condition { content-filtering | hagr | handoff | normal-end-signaling | session-end | url-blacklisting | timeout } [ flow-overflow ] + { charging-edr
charging_edr_format_name | reporting-edr reporting_edr_format_name
}
```

```
no flow end-condition
```

In StarOS 12.1 and earlier releases:

```
flow end-condition { { content-filtering | normal-end-signaling | timeout + } | { { hagr
| handoff | session-end } [ flow-overflow ] + } [ url-blacklisting ] } edr
edr_format_name
```

```
no flow end-condition
```

no
If previously configured, deletes the flow end-condition configuration from the current rulebase.

content-filtering

Creates an EDR with the specified EDR format whenever a flow ends due to Category-based Content Filtering in-line service action. Possible actions include redirect-url, terminate-flow, content-insert.

hagr

Creates an EDR with the specified EDR format whenever a flow is terminated due to Inter-chassis Session Recovery action.

handoff

Creates an EDR with the specified EDR format whenever a flow ends due to hand-off. Whenever a handoff occurs, ACS closes the EDRs for all current flows using the specified EDR format, and begins new statistics collection for the flows for the EDRs that will be generated when the flows actually end.
**normal-end-signaling**

Creates an EDR with the specified EDR format whenever flow end is signaled normally, for example like detecting FIN and ACK for a TCP flow, or a WSP-DISCONNECT terminating a connection-oriented WSP flow over UDP) and create an EDR for the flow using the specified EDR format.

**session-end**

Creates an EDR with the specified EDR format whenever a subscriber session ends. By this option ACS creates an EDR with the specified format name for every flow that has had any activity since last EDR was created for the flow on session end.

**url-blacklisting**

Creates an EDR with the specified EDR format whenever flow ends due to URL Blacklisting action.

**timeout**

Creates an EDR with the specified EDR format whenever a flow ends due to a timeout condition.

**flow-overflow**

> **Important:** This keyword is only available in StarOS 8.3 and later releases. And, is only applicable when used with the `hagr`, `handoff`, and `session-end` keywords.

Creates an EDR with the specified EDR format whenever there is a flow-overflow condition. If any of the specified end-conditions that affect subscriber information stored at ACS (such as call line) is configured, the “flow-overflow” EDR is generated.

> +

Indicates that more than one of the keywords can be entered within a single command.

**edr edr_format_name**

> **Important:** This option is available only in the 12.1 and earlier releases. In 12.2 and later releases, this option is deprecated and is replaced by the `charging-edr` option.

Specifies the EDR format to record EDR for specified flow end condition. 
`edr_format_name` must be the name of an EDR format, and must be a unique alphanumeric string of 1 through 63 characters.

**charging-edr charging_edr_format_name**

> **Important:** This option is available only in 12.2 and later releases.

Specifies the charging EDR format. 
`charging_edr_format_name` must be the name of a charging EDR format, and must be an alphanumeric string of 1 through 63 characters.
reporting-edr reporting_edr_format_name

**Important:** This option is available only in 12.2 and later releases.

Specifies the reporting EDR format. `reporting_edr_format_name` must be the name of a reporting EDR format, and must be a unique alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to enable or disable the capturing of EDRs based on flow end condition.

**Example**

In 12.1 and earlier releases, the following command configures the flow end condition as “handoff” and creates a charging EDR with format named `EDR_format1`:

```
flow end-condition handoff edr-format EDR_format1
```

In 12.2 and later releases, the following command configures the flow end condition as handoff and creates a charging EDR with format named `EDR_format1`:

```
flow end-condition handoff charging-edr EDR_format1
```
flow limit-across-applications

This command allows you to limit the total number of simultaneous flows per Subscriber/APN sent to a rulebase regardless of the flow type, or limit flows based on the protocol type under the Session Control feature.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

Syntax

```
flow limit-across-applications { limit | non-tcp limit | tcp limit }

no flow limit-across-applications [ non-tcp | tcp ]
```

---

**no**

If previously configured, deletes the flow limit-across-applications configuration from the current rulebase.

```
flow limit-across-applications limit
```

Specifies the maximum number of flows across all applications for the rulebase. `limit` must be an integer from 1 through 4000000000.

Default: No limits

```
non-tcp limit
```

Specifies the maximum limit of non-TCP type flows. `limit` must be an integer from 1 through 4000000000.

Default: No limits

```
tcp limit
```

Specifies the maximum limit of TCP flows. `limit` must be an integer from 1 through 4000000000.

Default: No limits

---

Usage

Use this command to limit the total number of flows allowed for a rulebase regardless of flow type, or limit flows based on the protocol—non-TCP (connection-less) or TCP (connection-oriented).

If a subscriber attempts to exceed these limits the system discards the packets of new flow. This limit processing of this command has following aspects for UDP, TCP, ICMP and some of the exempted flows:
• UDP/ICMP: System waits for the flow timeout before updating the counter and removing it from the count of number of flows.

• TCP: After a TCP flow ends, system waits for a short period of time to accommodate the retransmission of any missed packet from one end. TCP flows those are ended, but are still in wait period for timeout are exempted for this limit processing.

• Exempted flows: System exempts all the other flows specified with the flow limit-for-flow-type command in the ACS Charging Action Configuration Mode set to no.

Example

The following command defines the maximum number of 200000 flows for the rulebase:

```
flow limit-across-applications 200000
```
**flow rtsp-all-pkts**

This command allows you to delay charge packets in an RTSP flow.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
[ no | default ] flow rtsp-all-pkts charge-to-application
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>If previously configured, deletes the flow rtsp-all-pkts configuration from the current rulebase.</td>
</tr>
<tr>
<td>default</td>
<td>Configures this command with its default setting. Default: Same as no flow rtsp-all-pkts charge-to-application.</td>
</tr>
</tbody>
</table>

**flow rtsp-all-pkts charge-to-application**

Configures delay charging for RTSP traffic. When this configuration is enabled, all packets (TCP control packets and RTSP packets) prior to the RTSP SETUP will be charged to application as per the application ruledef. In other words, they will be charged to the content-id established by the first SETUP of the RTSP flow.

**Usage**

Use this command to delay charge packets in a RTSP flow. All initial packets (TCP control packets (all packets including initial, mid-session, end-session) and RTSP packets prior to the first SETUP) can be delay charged. Apart from the initial packets, all intermittent TCP control packets are also charged to the last matched Ruledef for the given RTSP flow. This command is used in conjunction with the `rtsp initial-bytes-limit RTSP_bytes` command.

The following command enables the RTSP flow’s delay charging:

```
flow rtsp-all-pkts charge-to-application
```
fw-and-nat default-policy

This command allows you to configure the default Firewall-and-NAT policy for the current rulebase. This command must be used to configure the Policy-based Firewall-and-NAT feature.

**Important:** This command is only available in StarOS 8.1 and StarOS 9.0 and later releases.

**Product**
PSF
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
fw-and-nat default-policy fw_nat_policy_name

no fw-and-nat default-policy
```

- **no**
  
  If previously configured, deletes the Firewall-and-NAT default policy configuration from the current rulebase.

- **fw_nat_policy_name**
  
  Specifies the default Firewall-and-NAT policy for the current rulebase.
  
  `fw_nat_policy_name` must be the name of a Firewall-and-NAT policy, and must be an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to configure the default Firewall-and-NAT policy for a rulebase.

For subscribers using the current rulebase, the default Firewall-and-NAT policy will be used if in the APN/subscriber profile the `default fw-and-nat policy` command is configured, and a policy to use is not received from the AAA/OCS.

For more information, see the Personal Stateful Firewall Administration Guide.

**Example**

The following command configures a Firewall-and-NAT policy named `standard` to the rulebase:

```
fw-and-nat default-policy standard
```
**http header-parse-limit**

This command allows you to configure the HTTP header parse limit, on exceeding which the flow is marked as permanent failure and is matched and charged against `http error = TRUE` ruledef.

---

**Important:** This command is customer specific. For more information contact your Cisco account representative.

**Product**

ACS

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
http header-parse-limit parse_limit_bytes
```

{ default | no } http header-parse-limit

---

**default**

Configures the default setting for this command.

Default: 12000 bytes

---

**no**

If enabled, disables the header-parse-limit configuration in the current rulebase.

---

**Important:** Disabling header parse limit may lead to uncharged bytes (due to no rule-matching until header is complete) if header is not correctly terminated.

```
parse_limit_bytes
```

Specifies the header-parse-limit, number of bytes.

`parse_limit_bytes` must be an integer from 1 through 256000.

**Usage**

If a user sends HTTP LF terminated traffic instead of the usual HTTP CRLF terminated traffic, and similarly the server is responding with LF terminated traffic, the traffic does not result in any rule match, and rule match happens only at flow idle or at call clear when the quota for the same is not requested/updated. This results in a revenue hole for prepaid subscribers.
For operators who have Stateful Firewall in-line service enabled, and are okay if packets are dropped, a workaround is to configure the `firewall mime-flood` command in the ACS Configuration Mode, which enables to configure the maximum number of headers allowed in an HTTP packet and the maximum header field size allowed in the HTTP header (in bytes). However, a limitation of this workaround is that Stateful Firewall supports MIME flood detection only in the downlink direction.

The support for LF termination has been added in StarOS 14.0 and later releases. For this release, with the help of configurable maximum header length support, HTTP analyzer would be allowing such LF terminated HTTP request/responses to pass through without rule matching only until the configured maximum header length is reached. When this threshold is reached, immediately the analyzer marks such HTTP session as failure and rule match would occur for `http error = TRUE` for the current packet as well as for all the previous packets that passed through unmatched. At this point, the quota for all such packets will be requested and reported.

**Example**

The following command sets the HTTP header parse limit to 10000 bytes:

```bash
http header-parse-limit 10000
```
ip reassembly-timeout

This command allows you to configure how long to hold onto IP fragments for reassembly, while waiting for the complete packet to arrive.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

Syntax

```bash
ip reassembly-timeout timeout_duration

default ip reassembly-timeout
```

**Usage**

Use this command to configure duration for timeout timer to hold IP fragmented packets before reassembly is needed.

IP fragmented packet are retained, until either all fragmented packets have been received or the configured timeout has expired for the oldest fragment. If all fragments have been received, a temporary complete packet is reconstructed for analysis. Then all fragments are forwarded in order from first to last. If all fragments are not received, the fragments will be forwarded without being passed through the protocol analyzers, except for the IP analyzer.

**Example**

The following command sets the timeout timer to 15000 milliseconds:

```bash
ip reassembly-timeout 15000
```
ip reset-tos

This command allows you to reset the IP Type of Service (ToS) value of incoming packets to the default QCI value, before proceeding with the rest of ACS processing.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

[ default | no ] ip reset-tos

----------
default

Configures this command with its default setting.
Default: Disabled

----------
no

If previously configured, deletes the IP reset-tos configuration from the current rulebase.

Usage

Use this command to reset the ToS field of any packet after it reaches ACS, or to broaden the range of values that are used in the ToS field in the IP header of any packet.
**nat binding-record**

This command allows you to configure NAT Binding Record (NBR) generation.

---

**Important:** This command is only available in StarOS 8.3. In StarOS 9.0 and later releases this command is available in the Firewall-and-NAT Policy Configuration Mode.

---

**Product**
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
*Exec > ACS Configuration > Rulebase Configuration*

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
nat binding-record edr-format edr_format_name [ port-chunk-allocation ] [ port-chunk-release ] +

{ default | no } nat binding-record
```

---

**default**

Configures this command with its default setting.

Default: *port-chunk-release*

---

**no**

If previously configured, deletes the configuration from the current rulebase.

---

**edr-format edr_format_name**

Specifies the EDR format.

*edr_format_name* must be the name of an EDR format, and must be an alphanumeric string of 1 through 63 characters.

---

**port-chunk-allocation**

Specifies generating NBR when a port chunk is allocated.

---

**port-chunk-release**

Specifies generating NBR when a port chunk is released.
Nat binding-record

+ Indicates that more than one of the previous keywords can be entered within a single command.

Usage

Use this command to configure NBR generation.

Example

The following command configures an EDR format named test123 and specifies generating NBR when a port chunk is allocated, and when a port chunk is released:

    nat binding-record edr-format test123 port-chunk-allocation port-chunk-release
**nat policy**

This command allows you to enable/disable Network Address Translation (NAT) processing for all subscribers using the current rulebase.

**Important:** In StarOS 8.1 and StarOS 9.0 and later releases, for Policy-based Firewall-and-NAT, this command is available in the Firewall-and-NAT Policy Configuration Mode.

**Important:** Before enabling NAT processing for a subscriber, Stateful Firewall must be enabled for the subscriber. See the `firewall policy` CLI command.

**Product**
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
nat policy nat-required [ default-nat-realm nat_realm_name ]

{ default | no } nat policy
```

**default**

Configures this command with its default setting.
Default: NAT processing is disabled for all subscribers using the current rulebase.

**no**

If previously enabled, disables NAT processing for all subscribers using the current rulebase.

```
nat policy nat-required
```

Enables NAT processing for all subscribers using the current rulebase.

```
default-nat-realm nat_realm_name
```

**Important:** This keyword is only available in StarOS 8.3 and later releases.

Specifies the default NAT realm to be used if one is not already configured.

`nat_realm_name` must be the name of a NAT realm, and must be an alphanumeric string of 1 through 31 characters.
**Important:** Including the default NAT realm, a maximum of three NAT realms are supported.

---

**Usage**
Use this command to enable/disable NAT processing for all subscribers using the current rulebase. After NAT is enabled for a subscriber, the NAT IP address to be used is chosen from the NAT realms defined in the rule priority lines within the rulebase. See the `firewall priority` CLI command. NAT enable/disable status in the rulebase can be changed any time, however the changed NAT status will not be applied for active calls using the rulebase. The new NAT status is only applied to new calls.

**Example**
The following command enables NAT processing:

```
nat policy nat-required
```

The following command disables NAT processing:

```
no nat policy
```
nat suppress-aaa-update call-termination

This command allows you to suppress sending NAT Bind Updates (NBU) to the AAA server when a call gets terminated.

⚠️ **Important:** This command is customer-specific. For more information please contact your Cisco account representative. In release 9.0, this command is available in the Firewall-and-NAT Policy Configuration Mode.

**Product**
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-rule-base)#
```

**Syntax**

```
nat suppress-aaa-update call-termination

default nat suppress-aaa-update
```

```
default

Configures this command with its default setting.
Default: Disabled. No suppression of AAA updates.
```

**Usage**
Use this command to suppress the sending of NAT Bind Updates (NBU) to the AAA server when the call gets terminated, as these NBUs would be cleared at the AAA after receiving the accounting-stop. This enables to minimize the number of messages between the chassis and AAA server. When not configured, NBUs are sent to the AAA server whenever a port chunk is allocated, de-allocated, or the call is cleared (PPP disconnect).

**Example**
The following command suppresses the sending of NBU to the AAA server when PPP disconnect happens:

```
nat suppress-aaa-update call-termination
```
**p2p dynamic-flow-detection**

This command allows you to enable/disable the P2P analyzer to detect peer-to-peer (P2P) applications.

**Product**
ADC

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
[ default | no ] p2p dynamic-flow-detection
```

---

**default**

Configures this command with its default setting.
Default: Disabled

---

**no**

If previously enabled, disables P2P dynamic flow detection in the current rulebase.

---

**p2p dynamic-flow-detection**

Enables dynamic P2P flow detection.

**Usage**

Use this command to enable dynamic-flow detection. This allows the P2P analyzer to detect the P2P applications configured for the ACS.
pcp service

This command allows you to configure the PCP service for the current rulebase.

**Important:** This command is customer specific. Contact your Cisco account representative for more information.

**Product**
NAT
PSF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
pcp service pcp_service_name

no pcp service
```

- `no`  
  If previously configured, deletes the PCP service configuration from the current rulebase. This service is disabled by default.

```
pcp_service_name
```

Specifies the PCP service name for the current rulebase.

`pcp_service_name` must be the name of a PCP service, and must be an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to configure the PCP service for the current rulebase.

**Example**

The following command configures a PCP service named `pcp1` for the rulebase:

```
pcp service pcp1
```
post-processing dynamic

This command allows you to specify ruledefs/group-of-ruledefs as dynamic post-processing ruledefs/group-of-ruledefs. This allows the system to differentiate normal post-processing rules from preconfigured ones. By default, this configuration is disabled.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

post-processing dynamic { group-of-ruledefs ruledefs_group_name | ruledef ruledef_name }

charging-action charging_action_name [ description description ]

no post-processing dynamic { group-of-ruledefs ruledefs_group_name | ruledef ruledef_name }

---

no

If previously configured, deletes the specified configuration from the current rulebase.

group-of-ruledefs ruledefs_group_name

Adds the specified group-of-ruledefs to the current rulebase.

ruledefs_group_name must be the name of a group-of-ruledefs, and must be an alphanumeric string of 1 through 63 characters.

ruledef ruledef_name

Adds the specified ruledef to the current rulebase.

ruledef_name must be the name of a ruledef, and must be an alphanumeric string of 1 through 63 characters.

charging-action charging_action_name

Specifies the charging action.

charging_action_name must be the name of a charging action, and must be an alphanumeric string of 1 through 63 characters.

description description

Specifies an optional description for this configuration.

description must be an alphanumeric string of 1 through 31 characters.
Usage

Use this command to configure specific ruledefs/group-of-ruledefs as dynamic post-processing ruledefs/group-of-ruledefs. This allows the system to differentiate normal post-processing rules from the preconfigured ones. This makes possible enabling/disabling ruledefs/groups-of-ruledefs entry from an external server.

Example

The following command specifies the ruledef named `test_rule` as a dynamic post-processing ruledef configured with the charging action `ca13` and a description of `testing`:

```
post-processing dynamic ruledef test_rule charging-action ca13
description testing
```
post-processing policy

This command allows you to specify the post-processing policy to be applied on Limit-Reached packets.

Product
GGSN
PDSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Syntax
post-processing policy { always | not-for-dynamic-discard }

default post-processing policy

default
Configures this command with its default setting.
Default: not-for-dynamic-discard

always
Specifies to apply post-processing even if the Credit Control Application (CCA) decides to discard packets due to limit-reached condition. If there are post-processing priority-based rules, CCA will check for any redirection rules. Otherwise, by default, CCA will discard the packets. No other post-processing actions like forward, next-hop, or xheader-insertion will be applied on the limit-reached packets.

not-for-dynamic-discard
Specifies to apply post-processing only if CCA decides not to discard packet. Will directly discard the limit-reached context and will not apply post-processing priority based rules.

Usage
This command allows to enable post-processing priority based rules for content in blacklisted state. Whenever RADIUS/Diameter prepay server blacklists content the packets are generally discarded. To enable redirection of such content, post-processing should be enabled on the blacklisted content. With this command, RADIUS/Diameter Credit-Control application will decide whether to allow post-processing to be enabled or not for the blacklisted content.
The following is a sample configuration:
Example

The following command will enable post processing on Limit-Reached packets:

```
post-processing policy always
```
post-processing priority

This command allows you to configure the post-processing priority and action to be taken on specific ruledef in the current rulebase.

Important: This command is only available in StarOS 8.3 and later releases.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

post-processing priority priority { group-of-ruledefs ruledefs_group_name | ruledef ruledef_name } charging-action charging_action_name [ description description ]

no post-processing priority priority

no

If previously configured, deletes the specified post-processing priority configuration from the current rulebase.

priority priority

Specifies priority for the ruledef/group-of-ruledefs in the current rulebase.

priority must be a unique value in the current rulebase, and must be an integer from 1 through 65535.

group-of-ruledefs ruledefs_group_name

Specifies the group-of-ruledefs.

ruledefs_group_name must be the name of a group-of-ruledefs, and must be an alphanumeric string of 1 through 63 characters.

Important: The group-of-ruledefs specified must be configured for post-processing. See the group-of-ruledefs-application command in the ACS Group-Of-Ruledefs Configuration mode.

ruledef ruledef_name

Specifies the ruledef.

ruledef_name must be the name of a ruledef, and must be an alphanumeric string of 1 through 63 characters.
post-processing priority

**Important:** The ruledef specified must be configured for post-processing. See the `rule-application` command in the *ACS Ruledef Configuration Mode Commands* chapter.

```
charging-action charging_action_name
```

Specifies the charging action.

`charging_action_name` must be the name of a charging action, and must be an alphanumeric string of 1 through 63 characters.

```
description description
```

Specifies an optional description for this configuration.

`description` must be an alphanumeric string of 1 through 31 characters.

**Usage**

Use this command to configure the post-processing priority and action to be taken on a ruledef in the rulebase.

**Example**

The following command configures the ruledef named `test_ruledef` with a priority of 10, and the charging action named `test_ca` for post processing:

```
post-processing priority 10 ruledef test_ruledef charging-action test_ca
```
qos-renegotiate timeout

This command allows you to configure the timeout setting for the Quality of Service (QoS) Renegotiation feature.

**Important:** This command is license dependent. For more information contact your Cisco account representative.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
qos-renegotiate timeout timeout

no qos-renegotiate timeout
```

**Usage**

Use this command to configure timeout setting for the QoS Renegotiation feature.

**Example**

The following command sets the QoS renegotiate timeout period to 1000 seconds:

```
qos-renegotiate timeout 1000
```
radius threshold

This command allows you to configure the interval and volume thresholds to generate interim RADIUS Charging Data Records (CDRs) and write them to CDR file for ACS postpaid billing.

Product
HA
PDSN

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

Syntax

```
radius threshold { interval interval | volume total volume }
{ default | no } radius threshold { interval | volume total }
```

- **no**
  If previously configured, deletes the RADIUS threshold configuration from the current rulebase.

- **default**
  Configures this command with the default settings.
  Default: Disabled

- **interval interval**
  Specifies the time interval, in seconds, for generating RADIUS interim accounting requests.
  `interval` must be an integer from 60 through 40000000.
  Default: Disabled

- **volume total volume**
  Specifies the limit for the total number of octets (uplink+downlink) after which a stop-start pair will be sent to RADIUS.
  `volume` must be an integer from 100000 through 4000000000.
  Default: Disabled

Usage

Use this command to specify a time interval threshold to generate interim RADIUS CDRs and write it to RADIUS CDR file for postpaid billing.

Example

The following command configures a time threshold interval of 600 seconds for RADIUS CDRs:
radius threshold interval 600
retransmission-counted

Insert a sentence for your command description

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

```

```

Syntax

```
retransmissions-counted
```

```
no
```

Retransmissions will be counted for all the charging modules. This CLI will override the CLI at the charging action as well as the CLI pertaining to the retransmissions at the rulebase.

Usage

Use this command to count retransmissions for all the charging modules.

Example

With the following command, retransmissions will not be counted for any of the charging modules:

```
no retransmissions-counted
```
ran bandwidth optimize

This command is used to enable optimized calculation of [MBR, GBR] when a subscriber (voice) call is put on hold in case of VoLTE.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

[ default | no ] ran-bandwidth optimize

no
If previously configured, disables the optimization feature for calculating [MBR, GBR] values based on Flow-Status AVP value.

Usage

Use this command to enable optimized calculation of [MBR, GBR] values when a subscriber (voice) call is put on hold in case of VoLTE.

When the rule is installed and active, the system uses the GBR/MBR assigned in the rule for calculating the GBR / MBR values towards the bearers created. When more than one rule is installed, P-GW adds the GBR / MBR values from all the active and installed rules even if the flow of a certain rule is marked as disabled.

This current behavior is in accordance with 3GPP TS standard specification 29.212, and this might result in RAN bandwidth wastage. To avoid this wastage, some optimization is done while calculating MBR and GBR for GBR bearer.

This optimization feature provides the ability to configure a list of APNs, for which the optimized calculation of MBR, GBR can be enabled. By default, this optimized calculation should be enabled only for the IMS APN.

This feature further helps optimize the logic of aggregating MBR and GBR values, based on “Flow-Status” AVP value received in the rule definition through RAR.

During session setup, when a CCA-I is received, and if ran bandwidth optimize is configured for the associated rulebase, the system will aggregate [MBR, GBR] of only the rules which have flow-status='ENABLED'. This information will subsequently be sent to UE.

Important: The last used [MBR, GBR] for GBR bearer needs to be recovered in the event of a session manager or chassis switchover. Failure to do so can result in miscalculation of [MBR, GBR] after recovery.
By default, this CLI will be disabled. Any change in this configuration will not affect existing calls on the system. Optimized bandwidth calculation will be done only for the new calls established after enabling this CLI command.
route priority

This command allows you to configure the routing of packets to protocol analyzers.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration
active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

route priority route_priority ruledef ruledef_name analyzer { dns | file-transfer | ftp-control | ftp-data | h323 | http | imap | mms | pop3 | pptp | radius | rtcp | rtp | rtsp | sdp | secure-http | sip [ advanced | basic-and-advanced ] | smtp | tftp | wsp-connection-less | wsp-connection-oriented } [ description description ]

no route priority route_priority

If previously configured, deletes the specified route priority configuration from the current rulebase.

route priority route_priority

Specifies the route priority for the specified ruledef in the current rulebase.
route_priority must be an integer from 1 through 65535.
Lower numbered priorities are examined first. Up to 1024 instances can be configured across all rulebases.

ruledef ruledef_name

Specifies the ruledef to evaluate packets to determine analyzer.
ruledef_name specifies the name of the ruledef configured for the route application using the rule-application command in the ACS Ruledef Configuration Mode.
ruledef_name must be the name of a ruledef, and must be an alphanumeric string of 1 through 63 characters.

analyzer

Specifies the analyzer for the ruledef, and must be one of the following:
• dns: Route to DNS protocol analyzer.
• file-transfer: Route to file analyzer.
• ftp-control: Route to FTP control protocol analyzer.
• ftp-data: Route to FTP data protocol analyzer.
• **h323**: Route to H323 protocol analyzer.
• **http**: Route to HTTP protocol analyzer.
• **imap**: Route to IMAP protocol analyzer.
• **mms**: Route to MMS protocol analyzer.
• **pop3**: Route to POP3 protocol analyzer.
• **pptp**: Route to PPTP protocol analyzer.
• **radius**: Route to RADIUS protocol analyzer.
• **rtcp**: Route to RTCP protocol analyzer.
• **rtp**: Route to RTP protocol analyzer.
• **rtsp**: Route to RTSP protocol analyzer.
• **sdp**: Route to SDP protocol analyzer.
• **secure-http**: Route to secure HTTP protocol analyzer.
• **sip [ advanced | basic-and-advanced ]**: Route to SIP protocol analyzer.
  • **advanced**: For SIP calls to work with NAT/Stateful Firewall, a SIP Application-Level Gateway (ALG) is required to do payload translation of SIP packets and pin-hole (dynamic flow) creation for media packets. A SIP routing rule must be configured for routing the packets to the SIP ALG for processing. If the keyword `advanced` is configured, the packets matching the routing rule will be routed to SIP ALG for processing and not to ACS SIP analyzer. If not configured, then packets will not be routed to SIP ALG and will be routed to ACS SIP analyzer for processing.
  
  Also, see `firewall nat-alg` CLI command in the ACS Configuration Mode.
  
  • **basic-and-advanced**: For SIP ALG to co-exist with SIP Analyzer, the packets are routed through ACS SIP Analyzer and SIP ALG. The SIP packets can pass through ACS functionality (by ACS SIP Analyzer processing) and at the same time payload translation/pinhole-creation can happen successfully (by SIP ALG processing). If `basic-and-advanced` is configured, then the packets matching the routing rule will be routed through the SIP Analyzer and then through SIP ALG for processing.
• **tftp**: Route to TFTP protocol analyzer.
• **smtp**: Route to SMTP protocol analyzer.
• **wsp-connection-less**: Route to WSP connection-less protocol analyzer.
• **wsp-connection-oriented**: Route to WSP connection-oriented protocol analyzer.

**Important**: To route packets to the P2P analyzer, the ruledef should have rules to match all IP packets. Otherwise, the analyzer may not detect all P2P traffic.

**Important**: Use the `show active-charging analyzer statistics` command in the Exec Mode to see the list of supported analyzers.

```
description description
```

Enables to add a description to the rule and action for later reference in saved configuration file. `description` must be an alphanumeric string of 1 through 63 characters.
Usage

Instances of this CLI command control which packets are routed to which protocol analyzers. Packets sent to ACS are always passed through the IP protocol analyzer. This CLI command controls which higher layer analyzers are also invoked.

<td>secure-http</td>
<td>TCP destination port or source port is HTTPS (443). Note that HTTP may use the CONNECT method (see RFC 2817), in which case, the subscriber will be upgraded with transport layer security, but the traffic to/from the chassis will still be HTTP and be passed through the http rather than the secure-http analyzer (assuming that routing to the http analyzer has been configured).</td>
</tr>
<tr>
<td>sip</td>
<td>UDP destination port or source port is SIP (5060).</td>
</tr>
<tr>
<td>smtp</td>
<td>TCP destination port or source port is SMTP (25).</td>
</tr>
<tr>
<td>tcp</td>
<td>All IPv4 packets with IP protocol = TCP (6) are automatically routed here.</td>
</tr>
<tr>
<td>udp</td>
<td>All IPv4 packets with IP protocol = UDP (17) are automatically routed here.</td>
</tr>
<tr>
<td>wap2</td>
<td>TCP destination port or source port of the carrier-specific port number for WAP-2 (e.g. one carrier uses 8799); or, send all HTTP traffic to the wap2 analyzer if the carrier does not use a special port number.</td>
</tr>
<tr>
<td>wsp</td>
<td>UDP destination port or source port is connection-less WSP (9200) or connection-oriented WSP (9201).</td>
</tr>
<tr>
<td>wtp</td>
<td>Packets are automatically routed here, if you specified “wsp-connection-oriented” as described above.</td>
</tr>
</tbody>
</table>
Example

The following command assigns a route and rule action with the route priority of 23, a ruledef named test, and an analyzer test_analyzer with description as route_test1 to the current rulebase:

```
route priority 23 ruledef test analyzer test_analyzer description route_test1
```
rtp dynamic-flow-detection

This command allows you to enable/disable the Real Time Streaming Protocol (RTSP) and Session Description Protocol (SDP) analyzers to detect the start/stop of RTP and RTCP flows.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration
active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

[ default | no ] rtp dynamic-flow-detection

default

Configures this command with its default setting.
Default: Disabled; same as no rtp dynamic-flow-detection.

no

If previously configured, deletes this configuration from the current rulebase.

Usage
Use this command to enable the RTSP and SDP analyzer to detect the start/stop of RTP and RTCP flows. This command is used in conjunction with the route priority command.

Example
The following command enables RTP dynamic flow detection:

    rtp dynamic-flow-detection
rtsp initial-bytes-limit

This command allows to set the maximum number of uplink and downlink bytes, added together to accumulate, while rule matching and charging is being delayed for RTSP flows. The limit is per RTSP flow.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

rtsp initial-bytes-limit rtsp_bytes

default rtsp initial-bytes-limit

Syntax:

default

Contains the RTSP initial packets limit to 6000 bytes.

RTSP_bytes

Specifies the maximum number of uplink and downlink bytes limit. rtsp_bytes must be an integer from 1 through 256000.

Usage

Use this command to configure the maximum number of uplink and downlink bytes per RTSP flow that can be accumulated before the first SETUP request. The accumulated bytes include both TCP-control packets as well as RTSP packets. Once this limit is reached, rule matching occurs and charging is enforced on the flow. This command is used in conjunction with the flow rtsp-all-pkts charge-to-application command.

Example

The following command sets the RTSP initial bytes limit to 9000 bytes:

rtsp initial-bytes-limit 9000
ruledef-parsing

This command allows you to configure whether to consider or ignore the port number embedded in the application header (for example, the ":80" in www.star.com:80) when comparing the ruledef expressions to the packet contents.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```plaintext
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```plaintext
[local]host_name(config-rule-base)#
```

**Syntax**

```plaintext
[ no ] ruledef-parsing ignore-port-numbers-embedded-in-application-headers analyzers { http rtsp sip wsp }

default ruledef-parsing
```

- **no**
  If previously configured, deletes the ruledef-parsing configuration from the current rulebase.

- **default**
  Configures this command with its default setting.
  Default: Same as `no ruledef-parsing ignore-port-numbers-embedded-in-application-headers analyzers { http rtsp sip wsp }` — not ignoring port numbers that are embedded in application headers.

```plaintext
ignore-port-numbers-embedded-in-application-headers analyzers { http rtsp sip wsp }
```

Ignore the port numbers present in application header.
Specifies analyzers for which the port number must be ignored.

**Usage**
Use this command to make the HTTP, RTSP, SIP, and WSP analyzer ignore port numbers embedded in application headers.

**Example**
The following command makes the HTTP analyzer in the current rulebase ignore port numbers embedded in application headers:

```plaintext
ruledef-parsing ignore-port-numbers-embedded-in-application-headers analyzers http
```
tcp 2msl-timeout

This command allows you to configure how long to retain the TCP flow after the FIN has been acknowledged.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

tcp 2msl-timeout 2msl_timeout [ port-reuse ]

{ default | no } tcp 2msl-timeout

default

Configures this command with its default setting.
Default: 2 seconds

no

Disables the timeout and sets the system to delete the flow immediately upon seeing the FIN acknowledged.

tcp 2msl-timeout 2msl_timeout

Specifies the duration to keep the TCP flow.
2msl_timeout specifies the timeout duration, in seconds, and must be an integer from 1 through 20.

port-reuse

Allows the source port reuse to reopen the TCP flow in 2msl timeout.

Usage

Use this command to configure how long to retain the TCP flow after the FIN has been acknowledged. Acknowledgment to the FIN is not guaranteed to be received by the destination, then the FIN could be resent and re-acknowledged. In this scenario, it is desirable to still have the flow, so that the re-sends do not create a new flow.

Example

The following command sets the timeout to 4 seconds:

tcp 2msl-timeout 4 port-reuse
tcp check-window-size

This command allows you to enable/disable TCP window-size checking.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

[ default | no ] tcp check-window-size

---

**default**

Configures this command with its default setting.
Default: Enabled (packets after the erroneous packet (with size greater than the receiver’s window size) will hit tcp-error ruledef).

---

**no**

Disables the window-size check and continues with normal L7 parsing.

---

**tcp check-window-size**

Enables the window-size check and continues with normal L7 parsing.

---

Usage

Use this command to enable/disable TCP window-size check for packets out of TCP window.

Example

The following command enables TCP window-size check:

```
tcp check-window-size
```
tcp mss

This command allows you to configure the TCP Maximum Segment Size (MSS) in TCP SYN packets.

**Important:** This command is only available in StarOS 8.1 and later releases.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-rule-base)#
```

**Syntax**

```
tcp mss tcp_mss { add-if-not-present | limit-if-present } +
{ default | no } tcp mss
```

- **default**
  Configures this command with its default setting.
  Default: Disabled

- **no**
  If previously configured, deletes the TCP MSS configuration from the current rulebase.

- **tcp mss tcp_mss**
  Specifies the TCP MSS.
  `tcp_mss` must be an integer from 496 through 65535.

- **add-if-not-present**
  Specifies to add the TCP MSS if not present in the packet.

- **limit-if-present**
  Specifies to limit the TCP MSS if present in the packet.

**Usage**

Using this command, TCP MSS can be limited if already present in the TCP SYN packets. If there are no errors detected in IP header/TCP mandatory header and there are no memory allocation failures, TCP
optional header is parsed. If TCP MSS is present in the optional header and its value is greater than the configured MSS value, the value present in the TCP packet is replaced with the configured one. If the TCP optional header is not present in the SYN packet and there are no errors in already present TCP header, the TCP MSS value configured will be inserted while sending the current packet out.

Example

The following command limits the TCP maximum segment size to 3000, and if not present adds it to the packets:

```
tcp mss 3000 limit-if-present add-if-not-present
```
tcp out-of-order-timeout

Description This command has been deprecated, and is replaced by the tcp packets-out-of-order command.
tcp packets-out-of-order

This command allows you to configure processing of TCP packets that are out of order, while waiting for the earlier packet(s) to arrive.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local] host_name(config-rule-base) #

**Syntax**

tcp packets-out-of-order { timeout timeout_duration | transmit [ after-reordering | immediately ] }  
default tcp packets-out-of-order { timeout | transmit }

default

Configures this command with its default setting.

*timeout: 5000 milliseconds

*transmit: immediately

**timeout timeout_duration**

Specifies the timeout duration for re-assembly of TCP out-of-order packets. 

timeout_duration is the timeout duration, in milliseconds, and must be an integer from 100 through 30000.

Default: 5000 milliseconds

**transmit [ after-reordering | immediately ]**

Configures the TCP out-of-order segment behavior after buffering a copy.

*after-reordering: Delivers the TCP out-of-order segments in-sequence to the ECS analyzer after all packets are received and successfully reordered. The 'after-reordering' feature is doing this by buffering out-of-order packets, and only releasing them after the missing out-of-order packets are received (or after OOO timeout).

When the missing packet is received, complete deep packet inspection of all the packets and all relevant in-line services is done, and then the last packet is forwarded (as the latest). If reordering is not successful within the specified OOO timeout, all the subsequent received packets in that TCP flow are forwarded without being passed through the analysers (except the L3/L4 analyzer). As a consequence only L3/L4 rule matching will take place. If memory allocation fails or the received packet is partial retransmitted data, the packet will also be forwarded immediately without being passed through the protocol analyzers, except for the L3/L4 analyzers.
**Important:** On the outgoing interface, no in-sequence delivery is guaranteed. This feature is intended to:
- deliver the TCP segments in-order to the ECS analysers
- buffer the original packets during OOO conditions, such that application-based flow actions (ex: Header insertion) can still take place on the actual data packets
- Its not intended to put the packets in-sequence on the outgoing interface (although some improvement can be seen there as well) - the cost of this feature is additional delay for OOO packets (up to a maximum of the OOO timeout).

- **Immediately:** Delivers the TCP out-of-order segments in-sequence to the ECS analyzer after all packets are received and successfully reordered. The 'immediately' feature is accomplishing this by making a copy of out-of-order packets, and buffering those, while transmitting the original data packets through the outgoing interface immediately. When the missing packet is received, complete deep packet inspection of all the packets and all relevant in-line services is done, and then the last packet is forwarded.

  If reordering of the buffered packets is not successful within the specified OOO timeout, all the subsequent received packets in that TCP flow are forwarded without being passed through the analysers (except the L3/L4 analyzer). As a consequence only L3/L4 rule matching will take place.

  If memory allocation fails or the received packet is partial retransmitted data, the packet will also be forwarded immediately without being passed through the protocol analyzers, except for the L3/L4 analysers.

**Important:** This feature is not changing anything on the sequencing of the packets - This feature has the consequence that during OOO conditions, certain application-based flow actions (ex: Header insertion) could not take place as the original packets are already sent out by the time the ECS analyser receives the (copies of) in-sequence packets.

Default: **immediately**

**Usage**

Use this command to configure how to process TCP packets that are out of order, while waiting for the earlier packet(s) to arrive.

**Example**

The following command sets the timeout timer to 10000 milliseconds:

```
tcp packets-out-of-order timeout 10000
```
**tcp proxy-mode**

This command allows you to enable/disable TCP Proxy mode for all subscribers using the current rulebase.

**Product**
- ACS
- CF
- MVG

**Privilege**
- Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
tcp proxy-mode { dynamic { all | content-filtering | dcca | ip-readdressing | nexthop-readdressing | xheader-insert } + | static [ port [ port_number [ to port_number ] ] ] } } 

default tcp proxy-mode

no tcp proxy-mode { dynamic { content-filtering | dcca | ip-readdressing | nexthop-readdressing | xheader-insert } + | static [ port [ port_number [ to port_number ] ] ] } ]
```

**default**
Configures this command with its default setting.
Default: Disabled

**no**
If previously enabled, disables TCP Proxy mode.
Optionally, TCP Proxy can be disabled for specific options that were previously enabled.

```
dynamic { all | content-filtering | dcca | ip-readdressing | nexthop-readdressing | xheader-insert } +
```

Enables TCP proxy for subscriber-initiated TCP flows under the specified condition(s).
- **all**: Specifies that subscriber-initiated TCP flows be proxied if all/any of the following conditions are satisfied.
- **content-filtering**: Specifies that subscriber-initiated TCP flows be proxied if a URL is requested, and that URL is checked because Category-based Content Filtering is enabled in the rulebase.
- **dcca**: Specifies that subscriber-initiated TCP flows be proxied if DCCA is enabled in the charging action.
- **ip-readdressing**: Specifies that subscriber-initiated TCP flows be proxied if IP Readdressing feature is enabled in the charging action.
• **nexthop-readdressing**: Specifies that subscriber-initiated TCP flows be proxied if Nexthop Readdressing feature is enabled in the charging action.

• **xheader-insert**: Specifies that subscriber-initiated TCP flows be proxied if x-Header Insertion feature is enabled in the charging action.

```plaintext
static [ port [ port_number [ to port_number ] ] ]
```

Enables static TCP proxy for every subscriber-initiated TCP flow, unless specific ports are specified.

```plaintext
port [ port_number [ to port_number ] ]
```

Specifies port numbers and/or range of port numbers.

*port_number* must be an integer from 1 through 65535.

---

**Important**: Up to 32 port numbers and eight port ranges can be specified.

---

**Usage**

**Important**: In release 11.0, TCP Proxy functions only in Static mode. Dynamic TCP Proxy mode is supported only in 12.0 and later releases.

Use this command to enable/disable TCP Proxy mode for all subscribers using this ACS rulebase. Optionally, TCP Proxy can be enabled/disabled for specific ACS features. Note that enabling/disabling the TCP Proxy feature for any of the optional ACS features, does not affect that feature.

Note that the last command overwrites any previous configuration. For example, when the following commands are applied in sequence:

```plaintext
tcp proxy-mode dynamic nexthop-readdressing
tcp proxy-mode dynamic xheader-insert
```

The nexthop configuration is overwritten by the x-header configuration.

---

**Example**

The following command enables TCP proxy for subscriber-initiated TCP flows whenever next-hop-forwarding-address is configured in the charging action:

```plaintext
tcp proxy-mode dynamic nexthop-readdressing
```
**tethering-detection**

This command allows you to enable/disable the Tethering Detection feature for the current rulebase, and specifies the database to use.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
tethering-detection { os-db-only | ua-db-only }
{ default | no } tethering-detection
```

---

**default**

Configures this command with its default setting.

Default: By default, the Tethering Detection feature is disabled. When enabled, unless a specific database is specified to be used, by default tethering detection will make use of both the databases.

---

**no**

If previously configured, deletes the tethering detection configuration from the current rulebase.

---

**os-db-only**

Specifies to perform tethering detection using only the OS signature database.

---

**ua-db-only**

Specifies to perform tethering detection using only the UA signature database.

---

**Usage**

Use this command to enable/disable the Tethering Detection feature for a rulebase, and configures the database to use.

Changing the configuration does not affect existing flows of the subscriber. If Tethering Detection was disabled and is turned enabled, it will be applied only to new flows of subscribers using the rulebase.

Also, see the `tethering-database` command in the *ACS Configuration Mode Commands* chapter.

---

**Example**

The following command enables the Tethering Detection feature in the rulebase, and specifies to use only the OS database:

```
tethering-detection os-db-only
```
tft-notify-ue-def-bearer

This command allows you to control whether TFT updates are sent to UE or not for default bearer for the specified rulebase.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-rule-base) #
```

**Syntax**

```
{ default | no } tft-notify-ue-def-bearer
```

- **default**
  The default behavior is to send the TFT updates of default bearer for the specified APN to UE.

- **no**
  This keyword controls the TFT updates of default bearer for the APN attached to the chassis, from being sent to the UE.

**Usage**

Use this command at the rulebase level to control whether TFT updates are sent to UE or not for default bearer for the specified rulebase.

This feature provides the operator the flexibility to configure this per Rulebase and also configure to suppress TFT updates only. The CLI command allows sending other QoS updates to the UE and controls only the TFT related updates. This CLI is supported only for default bearer.

In releases prior to 15.0, the "no policy-control update-default-bearer" CLI command is used to suppress all the TFT updates to the UE on the default bearer including the initial TFTs sent in the Create Session Response. Also, this configuration is available for the entire system and not per rulebase.

Additionally, this CLI command suppresses all the QoS related updates (including change in bit rate) to the UE.
**timestamp rounding**

This command allows you to enable/disable timestamp rounding in EDRs or eG-CDRs.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
timestamp rounding { edr | egcdr } { ceiling | floor | round-off }

{ default | no } timestamp rounding { edr | egcdr }
```

---

**default**

Configures this command with its default setting.

Default: `round-off`

---

**no**

Disables timestamp rounding.

---

**edr**

Enables timestamp rounding for EDRs.

---

**egcdr**

Enables timestamp rounding for eG-CDRs.

---

**ceiling**

If the fractional part of the seconds is greater than 0, adds 1 to the number of seconds and discards the fraction.

---

**floor**

Discards the fractional part of the second.

---

**round-off**

Sets the fractional part of the seconds to nearest integer value. If the fractional value is greater than or equal to 0.5, it adds 1 to the number of seconds and discards the fractional part of second.
Usage

Use this command to configure the timestamp rounding setting. The specified rounding will be performed before system attempts any calculation. For example using round-off, if the start time is 1.4, and the end time is 1.6, then the calculated duration will be 1 (for example, 2 – 1 = 1).

This command may be repeated for each type of EDR or eG-CDR.

Example

The following command sets the EDR timestamp to nearest integer value second; for example, 34:12.23 to 34:12.00:

```
timestamp rounding edr round-off
```
tpo default-policy

The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
**transactional-rule-matching**

This command allows you to enable or disable transactional rule matching (TRM) which allows the Enhanced Charging Service (ECS) to bypass per-packet rule matching on a transaction once the transaction is fully classified.

---

**Important:** The TRM feature is supported in SSI platform; earlier it was restricted only to ASR5500.

---

**Product**
- ACS
- ADC

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:
```
[local]host_name(config-rule-base)#
```

**Syntax**

```
transactional-rule-matching

[ default | no ] transactional-rule-matching

default

Configures this command with its default setting.
Default: Disabled.

no

If already configured, disables transactional rule matching.
```

**Usage**

Use this command to enable or disable transactional rule matching. This allows the Enhanced Charging Service (ECS) to bypass per-packet rule matching on a transaction once the transaction is fully classified. A transaction for TRM can be defined as the entire UDP flow, the ACK of the 3-way handshake to the FIN/RST of a TCP flow, or the HTTP request to the next HTTP request, or HTTP request to the FIN/RST for the final request of the flow. Rule matching can be performed on IP L4 rules (UDP, TCP), HTTP, and HTTPS.

In 16.0 and later releases, ADC and TRM/FP can be enabled together. ADC flows will be considered for TRM optimization. Most VoIP applications that require all packets of the flow do not support TRM. When TRM/FP is enabled with ADC, such protocols will not take TRM/FP.
**Important:** From 16.0 release, Transactional Rule Matching and Fastpath functionalities have been merged, and will be governed by only the `transactional-rule-matching` keyword alone. The keyword `fastpath` independently can no longer be used to turn on or turn off this functionality.

**Example**

The following command enables transactional rule matching:

```
transactional-rule-matching
```
transport-layer-checksum

This command allows you to enable/disable checksum verification for TCP and UDP packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
[ no ] transport-layer-checksum verify-during-packet-inspection [ tcp | udp ]
```

**default transport-layer-checksum**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ no ]</td>
<td>Disables the checksum calculation for the specified packet type.</td>
</tr>
<tr>
<td>default</td>
<td>Configures this command with its default setting. Default: Same as <code>transport-layer-checksum verify-during-packet-inspection</code>—to perform the checksum verification calculation on all TCP and UDP packets.</td>
</tr>
<tr>
<td>[ tcp</td>
<td>udp ]</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to disable or enable performing checksum verification calculations on TCP or UDP packets.

If the checksum is not verified, the packets will go through the TCP/UDP analyzers (and deeper analyzers, if so configured via the `route` command) regardless of the value of the TCP/UDP checksum.

If the checksum is verified, only packets with good checksums will go through the TCP/UDP analyzers (and deeper analyzers, if so configured).

**Example**

The following command disables checksum verification calculations on all TCP and UDP packets:

```
no transport-layer-checksum verify-during-packet-inspection
```
**udr threshold**

This command allows you to configure the threshold limit to generate Usage Data Records (UDRs) that provide Comma Separated Value (CSV) records written periodically in a fixed schema designed to reflect a total billable quantity.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
udr threshold { interval interval | volume { downlink bytes [ uplink bytes ] | total bytes | downlink bytes [ uplink bytes ] } }

default udr threshold { interval | volume }

no udr threshold { interval | volume { downlink [ uplink ] | total | uplink [ downlink ] } }
```

---

**no**

If previously configured, deletes the UDR threshold configuration from the current rulebase.

---

**default**

Configures this command with its default setting.

Default: Disabled; same as `no udr threshold interval` and `no udr threshold volume`.

---

**interval interval**

Specifies the time interval, in seconds, for closing the UDR if the minimum time duration thresholds are satisfied. By default, this option is disabled.

Default: 0 (Disabled)

---

**volume**

Specifies uplink/downlink volume octet counts for the generation of interim UDRs.

- **downlink bytes**: Specifies the limit for the number of downlink octets after which the UDR is closed.

  `bytes` must be an integer from 100000 through 4000000000.

  Default: 4000000000

- **total bytes**: Specifies the limit for the total number of octets (uplink+downlink) after which the UDR is closed.
bytes must be an integer from 100000 through 4000000000.
Default: Disabled

- **uplink bytes**: Specifies the limit for the number of uplink octets after which the UDR is closed.
  
  bytes must be an integer from 100000 through 4000000000.
  
  Default: 4000000000

UDR records are generated whenever either threshold is reached.

**Usage**

Use this command to enable thresholds for generation of UDRs.

**Example**

The following command specifies that UDR records should be generated every 10 minutes (600 seconds):

```
udr threshold interval 600
```
udr trigger

This command allows you to configure additional triggers for generating UDRs.

Important: This command is only available in StarOS 8.3 and later releases.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration

active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

udr trigger first-hit-content-id | tariff-time minute minutes hour hours

no udr trigger first-hit-content-id | tariff-time

default udr trigger

no
Disables first-hit-content-id UDR trigger.

default
Configures this command with its default setting.
Default: Disabled; no additional triggers.

first-hit-content-id

Specifies to generate interim UDR on first packet hit per rating group/content ID.

tariff-time minute minutes hour hours

This keyword allows to configure tariff time trigger to close ongoing UDR buckets and save all data traffic up to tariff time in a single UDR file. By default, this CLI keyword is disabled.
Configuring this keyword enables the PDSN/PCEF to generate content base UDR record for each concurrent online subscriber in each of day cross and place them in a single UDR file. The charging records include content based service (by duration and by volume).
Tariff time is stored at rulebase level. Therefore if the tariff time is updated while there are ongoing calls in the network, the old tariff time will be ignored and the new tariff time will be applied to the existing as well as upcoming calls.
At the end of the “Tariff Time” period, the UDR files are created and the next set of records are stored in a new UDR file.
**Usage**

This command enables to assign first packet trigger to interim UDRs—for generating UDR for first packet hit per rating group/content ID. The first-hit-content-id trigger when configured causes an UDR to be generated as soon as a packet hits a Charging Action with a content ID. UDR generation will be triggered when this command is configured and present in the rulebase.

**Example**

The following command assigns first packet trigger to interim UDRs, for generating UDR for first packet hit per rating group/content ID:

```
udr trigger first-hit-content-id
```
url-blacklisting action

This command allows you to enable/disable URL Blacklisting functionality for the current rulebase, and configures the action to be taken when there is a URL match.

**Product**
CF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**
```
url-blacklisting action { discard | redirect-url url | terminate-flow | www-reply-code-and-terminate-flow reply_code } [ content-id content_id ]
{ default | no } url-blacklisting action
```

- **default**
  Disables URL Blacklisting in the current rulebase.

- **no**
  If previously configured, deletes the URL Blacklisting action configuration from the current rulebase.

- **discard**
  Configures URL Blacklisting “discard” action.

- **redirect-url url**
  Configures URL Blacklisting “redirect-url” action.
  `url` specifies the redirect URL/URI, which must be a fully qualified URL/URI, and must be an alphanumeric string of 1 through 1023 characters.

- **terminate-flow**
  Configures URL Blacklisting “terminate-flow” action.

- **www-reply-code-and-terminate-flow reply_code**
  Configures URL Blacklisting “terminate-flow” action with reply code.
  `reply_code` specifies the reply code, and must be an integer from 100 through 599.
**url-blacklisting action**

```
content-id content_id
```

### Usage

Use this command to enable/disable URL Blacklisting at the rulebase level, and configure the action to be taken.

### Example

The following command enables URL Blacklisting in the rulebase, and configures the terminate-flow action with reply code 300:

```
url-blacklisting action www-reply-code-and-terminate-flow 300
```

The following command disables URL Blacklisting feature in the rulebase:

```
no url-blacklisting action
```
url-preprocessing

This command allows you to enable/disable a group-of-prefixed-urls for preprocessing of embedded URLs.

Important: This command is customer specific. For more information, please contact your Cisco account representative.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration
active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-rule-base)#

Syntax

[ no ] url-preprocessing bypass group-of-prefixed-urls prefixed_urls_group_name

no
If previously configured, deletes the URL-preprocessing bypass configuration from the current rulebase.

group-of-prefixed-urls prefixed_urls_group_name
Specifies the group-of-prefixed-urls. prefixed_urls_group_name must be the name of a group-of-prefixed-urls, and must be an alphanumeric string of 1 through 63 characters.

Usage
Use this command to enable/disable a group-of-prefixed-urls for preprocessing of embedded URLs. This command can be issued multiple times to enable multiple groups. If an embedded URL begins with the string specified within any of the groups, that prefix text will be removed from the URL.

Example
The following command enables looking for prefixed URLs of the group-of-prefixed-urls named test5:

url-preprocessing bypass group-of-prefixed-urls test5
video optimization-preprocessing cae-readdressing

This command allows you to enable/disable CAE readdressing at the rulebase level.

Product
ACS
MVG

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Rulebase Configuration
active-charging service service_name > rulebase rulebase_name

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

Syntax

```
video optimization-preprocessing cae-readdressing
[ default | no ] video optimization-preprocessing
```

- **default**
  Configures this command with its default setting.

- **no**
  If already configured, disables CAE readdressing.

Usage

Use this command to configure ACS to readdress the flows to CAE.
websocket flow-detection

This command allows you to enable or disable websocket flow detection at rulebase level.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
[ no ] websocket flow-detection [ protocol1 | protocol2 | protocol3 | ... ]
```

- **no**
  Disables the websocket flow detection.

```
[ protocol 1 | protocol2 | protocol3 | ... ]
```

Specifies protocol for detection.
If both protocol1 and protocol2 are specified, then specifies protocol detection of both protocols.

**Usage**
Use this command to disable or enable websocket flow detection identification of protocols.

**Important:** Currently, websocket is only using HTTP protocol as a transport layer, so the CLI will have only http as option.

**Example**
The following command disables websocket flow detection identification of protocols:

```
no websocket flow-detection [proto1 | proto2 | proto3 ]
```
**wtp out-of-order-timeout**

**Description** This command has been deprecated, and is replaced by the `wtp packets-out-of-order` command.
**wtp packets-out-of-order**

This command allows you to configure how to process Wireless Transaction Protocol (WTP) packets that are out of order, while waiting for the earlier packet(s) to arrive.

**Product**

ACS

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Rulebase Configuration

`active-charging service service_name > rulebase rulebase_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
wtp packets-out-of-order { out-of-order-timeout timeout | transmit [ after-reordering | immediately ] }
default wtp packets-out-of-order { out-of-order-timeout | transmit }
```

**default**

Configures this command with its default setting.

- `out-of-order-timeout`: 5000 milliseconds
- `transmit`: immediately

**out-of-order-timeout timeout**

Specifies the maximum duration for which WTP out-of-order packets are retained, before reassembly is needed.

`timeout` is the timeout duration, in milliseconds, and must be an integer from 100 through 30000.

Default: 5000 milliseconds

**transmit [ after-reordering | immediately ]**

Specifies the WTP out-of-order segment behavior after buffering a copy:

- `after-reordering`: Sends WTP out-of-order segment after it becomes ordered
- `immediately`: Sends WTP out-of-order segment immediately after buffering a copy

Default: immediately

**Usage**

Use this command to configure TCP out-of-order segment options.

If out-of-order-timeout is specified, out-of-order packets are retained, until either all packets have been received or the configured timeout has expired for the oldest packet. If all packets have been received, a temporary complete packet is reconstructed for analysis. Then all packets are forwarded in order from first to
last. If all packets are not received, the packets will be forwarded without being passed through the protocol analyzers, except for the IP analyzer.

If **after-reordering** transmitting is specified, the packets are held onto and reordered. After successfully reordering the packets, they are processed in the proper order. If reordering is not successful due to timeout (wtp out-of-order-timeout), the received packets are forwarded without being passed through the protocol analyzers.

If **immediately** is specified, the packets are transmitted as they are received without any in-line services or Charging Action processing, however a copy of each packet is retained. When the missing packet is received, complete deep packet inspection of all the packets and all relevant in-line services is undertaken, and then the last packet is forwarded (unless otherwise configured by the in-line services or Charging Action).

**Example**

The following command sets the timeout timer to 10000 milliseconds:

```
wtp out-of-order-timeout 10000
```
xheader-encryption

This command allows you to configure X-Header Encryption feature’s parameters.

**Important:** This command is license dependent. For more information please contact your Cisco account representative.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Rulebase Configuration

```
active-charging service service_name > rulebase rulebase_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-rule-base)#
```

**Syntax**

```
xheader-encryption { certificate-name certificate_name | re-encryption period period }

default xheader-encryption re-encryption period

no xheader-encryption { certificate-name | re-encryption }
```

**default**

Configures this command with its default setting.
Default: Disabled

**no**

If previously configured, deletes the configuration from the current rulebase.

**certificate-name certificate_name**

Specifies the encryption certificate to use for the X-Header Encryption feature.
`certificate_name` must be the name of an encryption certificate, and must be an alphanumeric string of 1 through 63 characters.
Default: Disabled; no encryption certificate

**re-encryption period period**

Specifies how often to re-generate the encryption keys.
`period` specifies the re-encryption time period in minutes, and must be an integer from 1 through 10000.
Default: Disabled; no re-encryption
Usage
Use this command to configure the X-Header Encryption feature’s certificate and re-encryption parameters.

Example
The following command configures the X-Header Encryption feature to use the certificate named testcert:

```
xheader-encryption certificate-name testcert
```
Chapter 19
ACS Ruledef Configuration Mode Commands

The ACS Ruledef Configuration Mode is used to create and manage rule expressions in individual rule definitions (ruledefs).

**Important:** In 14.1 and earlier releases, up to 10 rule expressions can be configured in one ruledef. In 15.0 and later releases, up to 32 rule expressions can be configured in one ruledef.

**Mode**

Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**bearer 3gpp apn**

This command allows you to define rule expressions to match Access Point Name (APN) of the bearer flow.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] bearer 3gpp apn [ case-sensitive ] operator apn_name
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **apn_name**
  Specifies name of the APN to match.
  `apn_name` must be an alphanumeric string of 1 through 62 characters and may contain punctuation characters.
**Usage**

Use this command to define rule expressions to match an APN in the bearer flow.

**Example**

The following command defines a rule expression to match user traffic based on APN named `apn12`:

```
bearer 3gpp = apn12
```
bearer 3gpp imsi

This command allows you to define rule expressions to match International Mobile Station Identification (IMSI) number in the bearer flow.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local] host_name(config-acs-ruledef) #

Syntax

[ no ] bearer 3gpp imsi { operator imsi | { !range | range } imsi_pool imsi_pool_name }

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  *operator* must be one of the following:
  - `!=`: Does not equal
  - `=`: Equals

- **imsi**
  Specifies the IMSI number to match.

- **!range | range**
  - `!range`: Not in the range of
  - `range`: In the range of

- **imsi_pool imsi_pool_name**
  Specifies the IMSI pool.
  *imsi_pool_name* must be the name of an IMSI pool, and must be an alphanumeric string of 1 through 63 characters.

Usage
Use this command to define rule expressions to match an IMSI.

Example
The following command defines a rule expression to analyze user traffic for the IMSI number 9198838330912:

```bash
bearer 3gpp imsi = 9198838330912
```
**bearer 3gpp rat-type**

This command allows you to define rule expressions to match Radio Access Technology (RAT) in the bearer flow.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] bearer 3gpp rat-type operator rat_type
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `==`: Equals

- **rat_type**
  Specifies the RAT type to match.
  `rat_type` must be one of the following:
  - `geran`: GSM EDGE Radio Access Network type
  - `utran`: UMTS Terrestrial Radio Access Network type
  - `wlan`: Wireless LAN type

**Usage**
Use this command to define rule expressions to match a RAT type.

**Example**
The following command defines a rule expression to match user traffic based on RAT type `wlan`:

```
bearer 3gpp rat-type = wlan
```
**bearer 3gpp sgsn-address**

This command allows you to define rule expressions to match SGSN address associated in the bearer flow.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```active-charging service service_name > ruledef ruledef_name```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] bearer 3gpp sgsn-address operator ipv4/ipv6_address
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `=`: Equals

- **ipv4/ipv6_address**
  Specifies the SGSN IP address to match.
  `ipv4/ipv6_address` must be in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

**Usage**

Use this command to define rule expressions to match IP address of an SGSN node. This command replaces the `bearer sgsn-address` command.

**Example**

The following command defines a rule expression to analyze user traffic for an SGSN node with IP address 10.1.1.1:

```
bearer 3gpp sgsn-address = 10.1.1.1
```
**bearer 3gpp2 bsid**

This command allows you to define rule expressions to match Base Station Identifier (BSID) associated with the bearer.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] bearer 3gpp2 bsid [ case-sensitive ] [ use-group-of-objects ] operator string
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **use-group-of-objects**
  Specifies using a group-of-objects as a qualifier to match this rule.

- **operator**
  Specifies how to match.
  
  *operator* must be one of the following:
  - !=: Does not equal
  - !=contains: Does not contain
  - !=ends-with: Does not end with
  - !=starts-with: Does not start with
  - =: Equals
  - contains: Contains
  - ends-with: Ends with
  - starts-with: Starts with

- **string**
  Specifies the name of a group-of-objects to match.
  If the **use-group-of-objects** keyword is not included in the command, **string** specifies name of the matching 3GPP2 service Base Station ID (BSID) in bearer flow.
If the `use-group-of-objects` keyword is included in the command, `string` must be the name of the group-of-objects to use. In this case, it is checked if the rule is satisfied for either one or none of the objects in the group-of-objects depending upon the operator used. For example, if the `operator` is `contains`, the expression would be true if any of the objects in the specified object group is contained in the BSID. If the `operator` is `!contains`, then the expression would be true if none of the objects in the object group is contained in the BSID.

`string` must be an alphanumeric string of 1 through 16 characters, and may contain punctuation characters.

**Usage**

Use this command to define rule expressions to match a 3GPP2 Base Station Identifier (BSID).

**Example**

The following command defines a rule expression to analyze user traffic for 3GPP2 BSID named `bs001_xyz`:

```
bearer 3gpp2 bsid = bs001_xyz
```
bearer 3gpp2 service-option

This command allows you to define rule expressions to match 3GPP2 service with service options associated with the bearer.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] bearer 3gpp2 service-option operator service_option_code

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• <=: Lesser than or equals
• ==: Equals
• >=: Greater than or equals

service_option_code
Specifies the 3GPP2 service option code to match.
service_option_code must be an integer from 0 through 1000.

Usage
Use this command to define rule expressions to match a 3GPP2 service’s service option code.

Example
The following command defines a rule expression to analyze user traffic for a 3GPP2 service’s service option matching 1034:

 bearer 3gpp2 service-option = 1034
**bearer apn**

This command allows you to define rule expressions to match the APN used for the subscriber session.

> **Important:** In 8.1 and later releases, this command is deprecated and is replaced by the `bearer 3gpp apn` command.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
 Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acis-ruledef)#
```

**Syntax**

```
[ no ] bearer apn [ case-sensitive ] operator apn_name
```

**no**
If previously configured, deletes the specified rule expression from the current ruledef.

**case-sensitive**
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

**operator**
Specifies how to match.

`operator` must be one of the following:

- `!=`: Does not equal
- `!contains`: Does not contain
- `!ends-with`: Does not end with
- `!starts-with`: Does not start with
- `=`: Equals
- `contains`: Contains
- `ends-with`: Ends with
- `starts-with`: Starts with

**apn_name**
Specifies the APN to match.
**Bearer Apn Configuration Mode Commands**

**Usage**

Use this command to define rule expressions to match APN used for subscriber session.

**Example**

The following command defines a rule expression to match user traffic based on APN name `apn12`:

```
bearer apn = apn12
```
bearer imsi

This command allows you to define rule expressions to match IMSI number of the subscriber.

**Important:** In 8.1 and later releases, this command is deprecated and is replaced by the `bearer 3gpp imsi` command.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] bearer imsi { operator imsi | { !range | range } imsi-pool imsi_pool_name }
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `=`: Equals

- **imsi**
  Specifies the IMSI number to match.

- **!range | range**
  Specifies the range criteria:
  - `!range`: Not in the range of
  - `range`: In the range of

- **imsi-pool imsi_pool_name**
  Specifies an IMSI pool.
  `imsi_pool_name` must be the name of an IMSI pool, and must be an alphanumeric string of 1 through 63 characters.
**Usage**

Use this command to define rule expressions to match IMSI number of subscriber.

**Example**

The following command defines a rule expression to match user traffic based on IMSI number 9198838330912:

```
bearer imsi = 9198838330912
```
bearer rat-type

This command allows you to define rule expressions to match Radio Access Technology (RAT) in the bearer flow.

**Important:** In 8.1 and later releases, this command is deprecated and is replaced by the `bearer 3gpp rat-type` command.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```

**Syntax**

```
[ no ] bearer rat-type operator rat_type
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.

  - `!=`: Does not equal
  - `=`: Equals

- **rat_type**
  Specifies the RAT type to match.

  - `geran`: GSM EDGE Radio Access Network type
  - `utran`: UMTS Terrestrial Radio Access Network type
  - `wlan`: Wireless LAN type

**Usage**

Use this command to define rule expressions to match a RAT type.

**Example**

The following command defines a rule expression to match user traffic based on RAT type `wlan`:

```
bearer rat-type = wlan
```
bearer sgsn-address

This command allows you to define rule expressions to match IP address of the SGSN (in acting as GGSN) / P-GW (if acting as S-GW) in the bearer flow.

⚠️ Important: In 8.1 and later releases, this command is deprecated and is replaced by the bearer 3gpp sgsn-address command.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

Syntax

[ no ] bearer sgsn-address operator ipv4/ipv6_address

- no
  If previously configured, deletes the specified rule expression from the current ruledef.

- operator
  Specifies how to match.
  operator must be one of the following:
  - !=: Does not equal
  - ==: Equals

- ipv4/ipv6_address
  Specifies the SGSN IP address to match.
  ipv4/ipv6_address must be in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

Usage
Use this command to define rule expressions to match IP address of the SGSN (in acting as GGSN) / P-GW (if acting as S-GW).

Example
The following command defines a rule expression to match user traffic based on SGSN node IP address 10.1.1.1:

    bearer sgsn-address = 10.1.1.1
bearer traffic-group

This command allows you to define rule expressions to match traffic group number associated with the subscriber session.

Important: This functionality is available only if the Content Access Control license has been installed on the chassis.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] bearer traffic-group operator group_number

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:

- !=: Does not equal
- <=: Lesser than or equals
- ==: Equals
- >=: Greater than or equals

group_number
Specifies the traffic group number to match.
group_number must be an integer from 1 through 255.

Usage

Use this command to define rule expressions to match traffic group of the subscriber session. See the fa-ha-spi command in the HA Service Configuration Mode Commands chapter for more information.

Example

The following command defines a rule expression to analyze all traffic groups assigned a value greater or equal to 23:
bearer traffic-group

bearer traffic-group >= 23
**cca quota-state**

Specifies the quota state of a subscriber for prepaid credit control service. In release 12.0 and later, this command should be used as a post-processing rule. For more information on post-processing policy command, refer to the ACS Rulebase Configuration Mode Commands chapter in this guide.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```plaintext
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] cca quota-state operator { limit-reached | lower-bandwidth }
```

- **no**
  Disables the configured credit control quota state.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `<=`: Lesser than or equals
  - `=`: Equals
  - `>=`: Greater than or equals

- **limit-reached**
  This state matches an affirmative end-of-quota indication for the current ruledef from the prepay server.

- **lower-bandwidth**
  This state matches the lower-bandwidth quota state of a rating group.

**Usage**

This command supports URL redirection and creates a rule for subscriber prepaid quota state as exhausted or not exhausted.

If a subscriber has exhausted the quota but has not exhausted the qualified period, a different charging-action can be applied via the `cca quota-state` command.

**Example**

This page does not contain any example.
The following command defines a rule expression to match user traffic based on the Credit-Control Application (CCA) quota state `limit-reached`:

```
cca quota-state = limit-reached
```
**cca redirect-indicator**

This command allows you to define rule expressions to match redirect-indicator state of the Credit Control Application. In release 12.0 and later, this command should be used as a post-processing rule. For more information on post-processing policy command, refer to *ACS Rulebase Configuration Mode Commands* chapter in this reference.

<tr>
<td>redirect_indicator</td>
<td>Specifies the redirect indicator for the AVP used for redirection of the URL in the RADIUS dictionary for prepaid service. It must be an integer from 0 through 4294967295.</td>
</tr>
</tbody>
</table>

**Important:** For the RADIUS server configured with different values to return for this AVP, the ACS requires ruledefs to match the different values for system to associate with charging actions that have different redirect URLs configured.

**Usage**

This command is used to configure an AVP to be used from a dictionary that defines the AVP for the redirect-indicator. For example, a RADIUS dictionary specifies the 3gpp2-release-indicator to be used for the redirect indicator when RADIUS is used as the Credit-Control Application. In this case, the value for 3gpp2-release-indicator
that is returned by the RADIUS prepaid server for a quota request for a given content ID is retained by system and associated with the flow.

Example

The following command defines a rule expression to match redirect indicator 1234 for the URL Redirect AVP:

```plaintext
cca redirect-indicator = 1234
```
copy-packet-to-log

This command allows you to print every packet that hits the current ruledef to a log statement.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] copy-packet-to-log

no
Disables the copy-packet-to-log feature.

copy-packet-to-log
Specifies to print packets hitting the current ruledef to a log.

Usage
Use this command to print every packet that hits a ruledef to a log statement. This facilitates debugging.
description

Sets the descriptive text for the object.

Product
All

Privilege
Security Administrator, Administrator

Syntax

description text

no description

no

Clears the description for the object.

text

Specifies the descriptive text as an alphanumeric string of 1 to 79 characters. If you include spaces between words in the description, you must enclose the text within double quotation marks (" "), for example, “AAA BBBB”.

Usage

The description should provide useful information on the object’s primary function, services, endusers, etc.
**dns answer-name**

This command allows you to define rule expressions to match answer name in the answer section of DNS response messages.

**Product**  
ACS

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acns-ruledef)#
```

**Syntax**

```
[ no ] dns answer-name [ case-sensitive ] operator value
```

- **no**  
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**  
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**  
  Specifies how to match.  
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **value**  
  Specifies the value to match.  
  `value` must be an alphanumeric string of 1 through 255 characters and may contain punctuation characters.
Usage

Use this command to define rule expressions to match an answer name from the answer section of DNS response messages. The answer section of a DNS response may contain more than one answer. A maximum of seven answers from the response packet are parsed. For the equality expressions (=, contains, starts-with, ends-with) a match is sought from any of the answers in the packet (up to the first seven answers). For the inequality expressions (!=, !contains, !starts-with, !ends-with), a non-match is sought from all answers (up to the first seven answers).

Example

The following command defines a rule expression to match user traffic for answer name test:

```
  dns answer-name = test
```
dns any-match

This command allows you to define rule expressions to match all DNS packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] dns any-match operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  - **!=**: Does not equal
  - **==**: Equals

- **condition**
  Specifies the condition to match.
  - **FALSE**
  - **TRUE**

**Usage**

Use this command to define an any-match rule expression to match all DNS packets.

**Example**

The following command defines an any-match rule expression to match all DNS packets:

```
dns any-match = TRUE
```
**dns previous-state**

This command allows you to define rule expressions to match previous state of the DNS FSM.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name >.ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] dns previous-state operator dns_previous_state
```

- **no**
  
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  
  Specifies how to match.
  
  `operator` must be one of the following:
  
  - !=: Does not equal
  - ==: Equals

- **dns_previous_state**
  
  Specifies the previous state to match.
  
  `dns_previous_state` must be one of the following:
  
  - `dns-timeout`
  - `init`
  - `req-sent`
  - `resp-error`
  - `resp-success`

**Usage**

Use this command to define rule expressions to match previous state of DNS FSM.

**Example**

The following command defines a rule expression to match the DNS FSM previous state `req-sent`:

```
dns previous-state = req-sent
```
dns query-name

This command allows you to define rule expressions to match query name in DNS request messages.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] dns query-name [ case-sensitive ] operator query_name
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.

  - `operator` must be one of the following:
    - `!=`: Does not equal
    - `!contains`: Does not contain
    - `!ends-with`: Does not end with
    - `!starts-with`: Does not start with
    - `=`: Equals
    - `contains`: Contains
    - `ends-with`: Ends with
    - `starts-with`: Starts with

- **query_name**
  Specifies the query name to match.

  *query_name* must be an alphanumeric string of 1 through 255 characters and may contain punctuation characters.
Usage
Use this command to define rule expressions to match query name in DNS request messages.

Example
The following command defines a rule expression to match DNS query name test:

```
dns query-name = test
```
dns return-code

This command allows you to define rule expressions to match response code in DNS response messages.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acns-ruledef)#

Syntax

[ no ] dns return-code { operator return_code }

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• ==: Equals

return_code
Specifies the response code to match.
return_code must be one of the following:
• format-error
• name-error
• no-error
• not-implemented
• refused
• server-failure

Usage
Use this command to define rule expressions to match response code in DNS response messages.

Example
The following command defines a rule expression to match a DNS response code refused:

    dns return-code = refused
**dns state**

This command allows you to define rule expressions to match current state of DNS FSM.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] dns state operator dns_current_state
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `==`: Equals

- **dns_current_state**
  Specifies the current state to match.
  `dns_current_state` must be one of the following:
  - `dns-timeout`
  - `init`
  - `req-sent`
  - `resp-error`
  - `resp-success`

**Usage**

Use this command to define rule expressions to match DNS FSM current state.

**Example**

The following command defines a rule expression to match DNS FSM current state of `req-sent`:

```
dns state = req-sent
```
**dns tid**

This command allows you to define rule expressions to match Transaction Identifier (TID) field in DNS messages.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acss-ruledef)#
```

**Syntax**

```
[ no ] dns tid operator tid_value
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  
  - `!=`: Does not equal
  - `<=`: Lesser than or equals
  - `=:` Equals
  - `>=`: Greater than or equals

- **tid_value**
  Specifies the DNS transaction identifier to match.
  `tid_value` must be an integer from 1 through 65535.

**Usage**

Use this command to define rule expressions to match a TID field of DNS messages.

**Example**

The following command defines a rule expression to match DNS TID field value of test:

```
dns tid = test
```
email

This command allows you to define rule expressions to match generic e-mail message parameters. These expressions will be applicable for IMAP, MMS, POP3, and SMTP protocols.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] email { cc | content { class | type } | from | size | subject | to } [ case-sensitive ] operator value
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **cc**
  Specifies to match the “cc” field of standard e-mail message.

- **content { class | type }**
  Specifies to match the “content-type” or “content-class” field of standard e-mail message.

- **from**
  Specifies to match the “from” field of standard e-mail message.

- **subject**
  Specifies to match the “subject” field of standard e-mail message.

- **to**
  Specifies to match the “to” field of standard e-mail message.

- **size**
  Specifies to match with the total size of e-mail message specified in bytes.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.
operator

Specifies how to match.

operator must be one of the following except for size:

- !=: Does not equal
- !contains: Does not contain
- !ends-with: Does not end with
- !starts-with: Does not start with
- =: Equals
- contains: Contains
- ends-with: Ends with
- starts-with: Starts with

operator must be one of the following for size:

- !=: Does not equal
- <=: Lesser than or equals
- =: Equals
- >=: Greater than or equals

value

Specifies the value to match.

value must be an alphanumeric string and can contain punctuation characters.

- cc: A string of 1 through 512 characters
- content: A string of 1 through 128 characters
- from: A string of 1 through 64 characters
- size: A range of bytes from 1 through 4000000000 bytes
- subject: A string of 1 through 128 characters
- to: A string of 1 through 512 characters

Usage

Use this command to define rule expressions to match different fields/parameters within standard e-mail messages.

Example

The following command defines a rule expression to analyze user traffic for the occurrence of `triangle` in the “cc” field of e-mail messages:

```
email cc contains triangle@xyz.com
```
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
file-transfer any-match

This command allows you to define rule expressions to match all file-transfer packets. This expression applies to file transfers that use the FTP or HTTP protocols.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] file-transfer any-match operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `==`: Equals

- **condition**
  Specifies the condition to match.
  `condition` must be one of the following:
  - `FALSE`
  - `TRUE`

**Usage**

Use this command to define rule expressions to match all file-transfer packets. This expression applies to file transfers that use the FTP or HTTP protocols.

**Example**

The following command defines a rule expression to match all file-transfer packets:

```
file-transfer any-match = TRUE
```
file-transfer chunk-number

This command allows you to define rule expressions to match the total number of chunks in an HTTP file as determined by the File Transfer analyzer.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] file-transfer chunk-number operator chunks_number

---

**no**

If previously configured, deletes the specified rule expression from the current ruledef.

---

**operator**

Specifies how to match.

* operator must be one of the following:
  - !=: Does not equal
  - <=: Lesser than or equals
  - =: Equals
  - >=: Greater than or equals

---

**chunks_number**

Specifies the number of chunks to match.

* chunks_number must be an integer from 1 through 65535.

Usage

Use this command to define rule expressions to match the total number of chunks in an HTTP file as determined by the File Transfer analyzer.

Example

The following command defines a rule expression to match 150 number of chunks:

```
file-transfer chunk-number = 150
```
**file-transfer current-chunk-length**

This command allows you to define rule expressions to match the length of an HTTP chunk currently in the File Transfer analyzer.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acos-ruledef)#
```

**Syntax**

```
[ no ] file-transfer current-chunk-length operator current_chunk_length
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  - operator must be one of the following:
    - `!=`: Does not equal
    - `<=`: Lesser than or equals
    - `==`: Equals
    - `>=`: Greater than or equals

- **current_chunk_length**
  Specifies the current chunk length value (in bytes) to match.
  - current_chunk_length must be an integer from 1 through 4000000.

**Usage**

Use this command to define rule expressions to match the length of an HTTP chunk currently in the File Transfer analyzer.

**Example**

The following command defines a rule expression to match length of current HTTP chunk as 1500000 bytes:

```
file-transfer current-chunk-length = 1500000
```
file-transfer declared-chunk-length

This command allows you to define rule expressions to match the declared length of an HTTP chunk currently in the File Transfer analyzer.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] file-transfer declared-chunk-length operator declared_chunk_length

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
  • !=: Does not equal
  • <=: Lesser than or equals
  • ==: Equals
  • >=: Greater than or equals

declared_chunk_length
Specifies the declared chunk length value (in bytes) to match.
declared_chunk_length must be an integer from 1 through 4000000.

Usage
Use this command to define rule expressions to match the declared length of an HTTP chunk currently in the File Transfer analyzer.

Example
The following command defines a rule expression to match declared length of the current HTTP chunk as 2500000 bytes:

file-transfer declared-chunk-length = 2500000
file-transfer declared-file-size

This command allows you to define rule expressions to match the declared file size by the File Transfer analyzer decoding the FTP handshake.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acis-ruledef)#
```

**Syntax**

```
[ no ] file-transfer declared-file-size operator declared_file_size
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  * operator must be one of the following:
    - !==: Does not equal
    - <=: Lesser than or equals
    - ==: Equals
    - >=: Greater than or equals

- **declared_file_size**
  Specifies the declared file size (in bytes) to match.
  **declared_file_size** must be an integer from 1 through 4000000.

**Usage**

Use this command to define rule expressions to match the declared file size by the File Transfer analyzer decoding the FTP handshake.

**Example**

The following command defines a rule expression to match declared file size as 2500000 bytes:

```
file-transfer declared-file-size = 2500000
```
file-transfer filename

This command allows you to define rule expressions to match file name.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] file-transfer filename [ case-sensitive ] operator file_name

no
If previously configured, deletes the specified rule expression from the current ruledef.

case-sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

operator
Specifies how to match.
operator must be one of the following:
  • !=: Does not equal
  • !contains: Does not contain
  • !ends-with: Does not end with
  • !starts-with: Does not start with
  • =: Equals
  • contains: Contains
  • ends-with: Ends with
  • starts-with: Starts with

file_name
Specifies the file name to match.
file_name must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
file-transfer filename

Usage
Use this command to define rule expressions to match file name in file-transfer.

Example
The following command defines a rule expression to match file name containing `star1`:

```
file-transfer filename contains star1
```
file-transfer previous-state

This command allows you to define rule expressions to match previous state of File Transfer FSM.

Product

ACS

Privilege

Security Administrator, Administrator

Mode

Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] file-transfer previous-state operator file_transfer_previous_state

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• ==: Equals

file_transfer_previous_state
Specifies the previous state to match.
file_transfer_previous_state must be one of the following:
• init: Specifies previous state as initialization.
• request-sent: Specifies previous state as request sent.
• transfer-error: Specifies previous state as transfer error.
• transfer-ok: Specifies previous state as transfer ok.

Usage

Use this command to define rule expressions to match previous state of File Transfer FSM.

Example

The following command defines a rule expression to match previous state of init:

file-transfer previous-state = init
file-transfer state

This command allows you to define rule expressions to match the current state of File Transfer FSM.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] file-transfer state operator file_transfer_current_state

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
  • !=: Does not equal
  • ==: Equals

file_transfer_current_state
Specifies the current state to match.
file_transfer_current_state must be one of the following
  • init: Specifies current state as initialization.
  • request-sent: Specifies current state as request sent.
  • transfer-error: Specifies current state as transfer error.
  • transfer-ok: Specifies current state as transfer ok.

Usage
Use this command to define rule expressions to match current state of File Transfer FSM.
The following table describes details of File Transfer FSM states with event:

<table>
<thead>
<tr>
<th>Event</th>
<th>init</th>
<th>request-sent</th>
<th>transfer-ok</th>
<th>transfer-err</th>
</tr>
</thead>
<tbody>
<tr>
<td>FTP “RETR” command or HTTP “GET” request received with chunk encoding</td>
<td></td>
<td>request-sent</td>
<td>Discarded</td>
<td>Discarded</td>
</tr>
<tr>
<td>HTTP 2xx response received</td>
<td></td>
<td>transfer-ok</td>
<td>Discarded</td>
<td>Discarded</td>
</tr>
</tbody>
</table>
### ACS Ruledef Configuration Mode Commands

**file-transfer state**

<table>
<thead>
<tr>
<th>Event</th>
<th>init</th>
<th>request-sent</th>
<th>transfer-ok</th>
<th>transfer-err</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP 4xx or HTTP 5xx response received</td>
<td>transfer-error</td>
<td>Discarded</td>
<td>Discarded</td>
<td>Discarded</td>
</tr>
<tr>
<td>FTP reply received with reply status as file-transfer complete/successful</td>
<td>Discarded</td>
<td>transfer-ok</td>
<td>Discarded</td>
<td>Discarded</td>
</tr>
<tr>
<td>FTP reply received with reply status as file-transfer unsuccessful</td>
<td>Discarded</td>
<td>transfer-error</td>
<td>Discarded</td>
<td>Discarded</td>
</tr>
</tbody>
</table>

**Example**

The following command defines a rule expression to match file-transfer current state of `init`:

```
file-transfer state = init
```
file-transfer transferred-file-size

This command allows you to define rule expressions to match the size of a file that has been transferred so far, as detected by the File Transfer analyzer.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] file-transfer transferred-file-size operator transferred_file_size
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  - **operator** must be one of the following:
    - !=: Does not equal
    - <=: Lesser than or equals
    - ==: Equals
    - >=: Greater than or equals

- **transferred_file_size**
  Specifies the transferred file size (in bytes) to match.
  **transferred_file_size** must be an integer from 1 through 4000000000.

**Usage**
Use this command to define rule expressions to match the size of the file that has been transferred so far, as detected by the File Transfer analyzer.

**Example**
The following command defines a rule expression to match file transferred size of 2500 bytes:

```
file-transfer transferred-file-size = 2500
```
ftp any-match

This command allows you to define rule expressions to match all FTP packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] ftp any-match operator condition

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• ==: Equals

condition
Specifies the condition to match.
condition must be one of the following:
• FALSE
• TRUE

Usage
Use this command to define a rule expression to match all FTP packets.

Example
The following command defines a rule expression to match all FTP packets:

ftp any-match = TRUE
**ftp client-ip-address**

This command allows you to define rule expressions to match IP address of the FTP client.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acis-ruledef)#
```

**Syntax**

```
[ no ] ftp client-ip-address operator ipv4/ipv6_address
```

- **no**
  
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  
  Specifies how to match.
  
  `operator` must be one of the following:
  
  - `!=`: Does not equal
  - `<=`: Lesser than or equals
  - `==`: Equals
  - `>=`: Greater than or equals

- **ipv4/ipv6_address**
  
  Specifies the FTP client IP address to match.
  
  `ipv4/ipv6_address` must be in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

**Usage**

Use this command to define rule expressions to match an FTP client IP address, which will be either the IP source address or the IP destination address, depending on the direction.

**Example**

The following command defines a rule expression to match client IP address `10.1.1.1`:

```
ftp client-ip-address = 10.1.1.1
```
**ftp client-port**

This command allows you to define rule expressions to match port number of the FTP client.

**Product**

ACS

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Ruledef Configuration

```text
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] ftp client-port operator port_number
```

- **no**
  
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  
  Specifies how to match.
  
  `operator` must be one of the following:
  
  - `!=`: Does not equal
  
  - `<=`: Lesser than or equals
  
  - `==`: Equals
  
  - `>=`: Greater than or equals

- **port_number**
  
  Specifies the client port number to match.
  
  `port_number` must be an integer from 1 through 65535.

**Usage**

Use this command to define rule expressions to match port number of the FTP client, which will be either the TCP source port or the TCP destination port, depending on the direction.

**Example**

The following command defines a rule expression to match FTP client port number 10:

```
ftp client-port = 10
```
**ftp command args**

This command allows you to define rule expressions to match arguments within an FTP command.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

`[local]host_name(config-acs-ruledef)#`

**Syntax**

```
[ no ] ftp command args [ case-sensitive ] operator argument
```

**no**

If previously configured, deletes the specified rule expression from the current ruledef.

**case-sensitive**

Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

**operator**

Specifies how to match.

- `!=`: Does not equal
- `!contains`: Does not contain
- `!ends-with`: Does not end with
- `!starts-with`: Does not start with
- `=`: Equals
- `contains`: Contains
- `ends-with`: Ends with
- `starts-with`: Starts with

**argument**

Specifies the argument to match.

`argument` must be an alphanumeric string of 1 through 127 characters.

**Usage**

Use this command to define rule expressions to match arguments within an FTP command.
Example

The following command defines a rule expression to match argument *ascii* within an FTP command:

```bash
ftp command args = ascii
```
ftp command id

This command allows you to define rule expressions to match FTP command ID.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

Syntax

[ no ] ftp command id operator command_id

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:

- !=: Does not equal
- <=: Lesser than or equals
- >=: Greater than or equals
- =: Equals

command_id
Specifies the command identifier to match.
In 8.3 and earlier releases, command_id must be an integer from 0 through 15.
In 9.0 and later releases, command_id must be an integer from 0 through 18.

Usage
Use this command to define rule expressions to match FTP command ID.

Example
The following command defines a rule expression to match the FTP command ID 10:

ftp command id = 10
**ftp command name**

This command allows you to define rule expressions to match FTP command name.

**Product**

ACS

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] ftp command_name operator command_name
```

- **no**
  - If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  - Specifies how to match.
  - `operator` must be one of the following:
    - `!=`: Does not equal
    - `=`: Equals

- **command_name**
  - Specifies the command name to match.
  - `command_name` must be one of the following:
    - `abor`: Abort command
    - `cwd`: Current working directory command
    - `eprt`: eprt command
    - `epsv`: epsv command
    - `list`: List command
    - `mode`: Transfer mode command
    - `pass`: Password command
    - `pasv`: Passive command
    - `port`: Port command
    - `quit`: Quit command
    - `rest`: Restore command
    - `retr`: Retry command
• **stor**: Store command
• **stru**: File structure command
• **syst**: System command
• **type**: Type command
• **user**: User command

---

**Usage**

Use this command to define rule expressions to match FTP command name.

**Example**

The following command defines a rule expression to match FTP command name **list**:

```
ftp command name = list
```
ftp connection-type

This command allows you to define rule expressions to match FTP connection type.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acos-ruledef)#
```

Syntax

```
[ no ] ftp connection-type operator connection_type

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match. `operator` must be one of the following:
- `!=`: Does not equal
- `<=`: Lesser than or equals
- `=`: Equals
- `>=`: Greater than or equals

connection_type
Specifies the connection type to match. `connection_type` must be one of the following:
- `0`: Unknown
- `1`: Control connection
- `2`: Data connection
```

Usage

Use this command to define rule expressions to match an FTP connection type.

Example

The following command defines a rule expression to match FTP connection type 1:

```
ftp connection-type = 1
```
**ftp data-any-match**

This command allows you to define rule expressions to match all FTP data packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec &gt; ACS Configuration &gt; Ruledef Configuration

```
active-charging service service_name &gt; ruledef ruledef_name

</tr>
</tbody>
</table>

**Usage**

Use this command to define rule expressions to match all FTP data packets.

**Example**

The following command defines a rule expression to match all FTP data packets:

```
ftp data-any-match = TRUE
```
ftp filename

This command allows you to define rule expressions to match FTP file name.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acsl-ruledef)#

Syntax

[ no ] ftp filename [ case-sensitive ] operator file_name

- **no**
  - If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  - Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  - Specifies how to match.

  * operator must be one of the following:
    - !=: Does not equal
    - !contains: Does not contain
    - !ends-with: Does not end with
    - !starts-with: Does not start with
    - =: Equals
    - contains: Contains
    - ends-with: Ends with
    - starts-with: Starts with

- **file_name**
  - Specifies the file name to match.

  * file_name must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
**Usage**

Use this command to define rule expressions to match an FTP file name.

**Example**

The following command defines a rule expression to match a file named `testtransfer`:

```plaintext
ftp filename = testtransfer
```
ftp pdu-length

This command allows you to define rule expressions to match the length of a current FTP packet.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] ftp pdu-length operator pdu_length

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.

operator must be one of the following:
• !=: Does not equal
• <=: Lesser than or equals
• ==: Equals
• >=: Greater than or equals

pdu_length
Specifies the FTP PDU length (in bytes) to match.
pdu_length must be an integer from 0 through 65535.

Usage
Use this command to define rule expressions to match the length of a current FTP packet, that is, FTP PDU length (FTP header + FTP payload).

Example
The following command defines a rule expression to match an FTP PDU length of 9647 bytes:

ftp pdu-length = 9647
ftp pdu-type

This command allows you to define rule expressions to match FTP Protocol Data Unit (PDU) type.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] ftp pdu-type operator pdu_type

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
- !=: Does not equal
- <=: Lesser than or equals
- >=: Greater than or equals

pdu_type
Specifies the PDU type to match.
pdu_type must be one of the following:
- 0: Unknown
- 1: Command
- 2: Reply

Usage
Use this command to define rule expressions to match a PDU type of FTP packet.

Example
The following command defines a rule expression to match FTP PDU type 1:

ftp pdu-type = 1
ftp previous-state

This command allows you to define rule expressions to match previous state of FTP session.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] ftp previous-state operator ftp_previous_state
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `=`: Equals

- **ftp_previous_state**
  Specifies the previous state to match.
  `ftp_previous_state` must be one of the following:
  - `command-sent`
  - `init`
  - `response-error`
  - `response-ok`

**Usage**

Use this command to define rule expressions to match a previous state of FTP session.

**Example**

The following command defines a rule expression to match previous FTP state `init`:

```
ftp previous-state = init
```
**ftp reply code**

This command allows you to define rule expressions to match FTP reply code.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] ftp reply code operator reply_code
```

- **no**
  - If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  - Specifies how to match.
    - `!=`: Does not equal
    - `<=`: Lesser than or equals
    - `==`: Equals
    - `>=`: Greater than or equals

- **reply_code**
  - Specifies the FTP reply code to match.
    - `reply_code` must be an integer from 100 through 599.

**Usage**
Use this command to define rule expressions to match an FTP reply code.

**Example**
The following command defines a rule expression to match FTP reply code 150:

```
ftp reply code = 150
```
**ftp server-ip-address**

This command allows you to define rule expressions to match FTP server IP address.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

**Syntax**

```
[ no ] ftp server-ip-address operator ipv4/ipv6_address
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `<=`: Lesser than or equals
  - `=`: Equals
  - `>=`: Greater than or equals

- **ipv4/ipv6_address**
  Specifies IP address of the server to match
  `ipv4/ipv6_address` must be in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

**Usage**

Use this command to define rule expressions to match an FTP server IP address, which will be either the IP source address or the IP destination address, depending on the direction.

**Example**

The following command defines a rule expression to match the FTP server IP address `10.1.1.1`:

```
ftp server-ip-address = 10.1.1.1
```
**ftp server-port**

This command allows you to define rule expressions to match FTP server port number.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] ftp server-port operator port
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `<=`: Lesser than or equals
  - `=`: Equals
  - `>=`: Greater than or equals

- **port**
  Specifies the FTP server port number to match.
  `port` must be an integer from 1 through 65535.

**Usage**

Use this command to define rule expressions to match an FTP server port number, which will be either the TCP source port or the TCP destination port, depending on the direction.

**Example**

The following command defines a rule expression to analyze user traffic for FTP server port 21:

```
ftp server-port = 21
```
### ftp session-length

This command allows you to define rule expressions to match the total number of bytes sent on an FTP control connection.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] ftp session-length operator session_length
```

<table>

<tbody>
<tr>
<td>Specifies the FTP session length (in bytes) to match.</td>
</tr>
<tr>
<td>session_length must be an integer from 1 through 400000000.</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to define rule expressions to match the total number of bytes sent on an FTP control connection.

**Example**

The following command defines a rule expression to match FTP session length of 40000 bytes:

```
ftp session-length = 40000
```
ftp state

This command allows you to define rule expressions to match the current state of an FTP session.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] ftp state operator ftp_state

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:

- !=: Does not equal
- ==: Equals

ftp_state
Specifies the FTP state to match.
ftp_state must be one of the following:

- close: FTP transmissions that are in closed state.
- command-sent: FTP transmissions that are in command-sent state.
- response-error: FTP transmissions that are in response-error state.
- response-ok: FTP transmissions that are in response-ok state.

Usage
Use this command to define rule expressions to match the current state of an FTP session.

Example
The following command defines a rule expression to match FTP current state close:

ftp state = close
ftp url

This command allows you to define rule expressions to match the FTP URL/path of a file being transferred.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] ftp url [ case-sensitive ] operator url
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **url**
  Specifies the URL to match.
  `url` must be an alphanumeric string of 1 through 127 characters.

**Usage**

Use this command to define rule expressions to match the FTP URL/path of a file being transferred.
Example

The following command defines a rule expression to match the URL ftp://rfc.ietf.org/rfc/rfc1738.txt:

```text
ftp url = ftp://rfc.ietf.org/rfc/rfc1738.txt
```
ftp user

This command allows you to define rule expressions to match the user name FTP command packet.

</tr>
</tbody>
</table>
Usage

Use this command to define rule expressions to match a user name FTP command.

Example

The following command defines a rule expression to match FTP user name user1:

ftp user = user1
http any-match

This command allows you to define rule expressions to match all HTTP and HTTPS Connect Method packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

**Syntax**

[ no ] http any-match operator condition

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  operator must be one of the following:
  - !=: Does not equal
  - ==: Equals

- **condition**
  Specifies the condition to match.
  condition must be one of the following:
  - FALSE
  - TRUE

**Usage**

Use this command to define rule expressions to match all HTTP packets.

**Example**

The following command defines a rule expression to match all HTTP packets:

    http any-match = TRUE
http attribute-in-data

This command allows you to define rule expressions to match any arbitrary attribute in the payload following the HTTP headers.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **attribute**
  `attribute` must be an alphanumeric string of 1 through 31 characters.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **value**
  Specifies the value as an alphanumeric string of 1 through 127 characters.
Usage

Use this command to define rule expressions to match arbitrary attribute in the payload following the HTTP headers.

In 14.0 and later releases, the ECS HTTP analyzer supports both CRLF and LF as valid terminators for HTTP header fields.
http attribute-in-url

This command allows you to define rule expressions to match arbitrary attribute in the combined Host+URI HTTP headers.

Product
ACС

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

---

no
If previously configured, deletes the specified rule expression from the current ruledef.

attribute
attribute must be an alphanumeric string of 1 through 31 characters.

case-sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

operator
Specifies how to match.
operator must be one of the following:

• !=: Does not equal
• !contains: Does not contain
• !ends-with: Does not end with
• !starts-with: Does not start with
• ==: Equals
• contains: Contains
• ends-with: Ends with
• starts-with: Starts with

value
Specifies the value as an alphanumeric string of 1 through 127 characters.
Usage
Use this command to configure rule expression to match an arbitrary attribute in the combined Host+URI HTTP headers.
In 14.0 and later releases, the ECS HTTP analyzer supports both CRLF and LF as valid terminators for HTTP header fields.
http content disposition

This command allows you to define rule expressions to match optional content-disposition field of HTTP entity header.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acg-ruledef)#
```

**Syntax**

```
[ no ] http content disposition [ case-sensitive ] operator content_disposition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **content_disposition**
  This field offers a mechanism for the sender to transmit presentational information to the recipient, allowing each component of a message to be tagged with an indication of its desired presentation semantics.
  `content_disposition` must be an alphanumeric string of 1 through 127 characters, and may contain punctuation characters.
Usage
Use this command to define rule expressions to match optional content-disposition field of HTTP entity header. This feature supports RFC 2616 for HTTP and RFC 1806 for Content Disposition.
In 14.0 and later releases, the ECS HTTP analyzer supports both CRLF and LF as valid terminators for HTTP header fields.

Example
The following command defines a rule expression to match content disposition successful:

```
http content disposition = successful
```
http content length

This command allows you to define rule expressions to match the value in HTTP Content-Length entity-header field.

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
- !=: Does not equal
- <=: Lesser than or equals
- ==: Equals
- >=: Greater than or equals

content_length
Specifies the HTTP body length (in bytes) to match.
content_length must be an integer from 1 through 4000000000.

Usage
Use this command to define rule expressions to match value in HTTP Content-Length entity-header field.
In 14.0 and later releases, the ECS HTTP analyzer supports both CRLF and LF as valid terminators for HTTP header fields.

Example
The following command defines a rule expression to match value of 10000 bytes in HTTP Content-Length entity-header field:

http content length = 10000
http content range

This command allows you to define rule expressions for CAE re-addressing to verify if the HTTP Response has content-range header or not.

Product
ACS
MVG

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] http content range = TRUE

no

If previously configured, deletes the specified rule expression from the current ruledef.

Usage

Use this command to define rule expressions for CAE re-addressing to verify if the HTTP Response has content-range header or not. This header is useful in detecting HTTP video requests when using ECS DPI ruledefs based on HTTP headers/URI.
http content type

This command allows you to define rule expressions to match value in HTTP Content-Type entity-header field.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

<tr>
<td>content_type must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.</td>
</tr>
</tbody>
</table>
Usage
Use this command to define rule expressions to match value in HTTP Content-Type entity-header field.
In 14.0 and later releases, the ECS HTTP analyzer supports both CRLF and LF as valid terminators for HTTP header fields.

Example
The following command defines a rule expression to match `abc100` in HTTP Content-Type entity-header field:

```
http content type = abc100
```
http cookie

This command allows you to define rule expressions to match strings in the HTTP cookie header.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)>
```

**Syntax**

```
[ no ] http cookie [ case-sensitive ] operator cookie_string
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - !=: Does not equal
  - !contains: Does not contain
  - !ends-with: Does not end with
  - !starts-with: Does not start with
  - =: Equals
  - contains: Contains
  - ends-with: Ends with
  - starts-with: Starts with

- **cookie_string**
  Specifies the string to match in the HTTP cookie header.
  `cookie_string` must be an alphanumeric string of 1 through 127 characters.

**Usage**

Use this command to define rule expressions to match strings in an HTTP cookie header.
The cookie match ruleline can be combined with other rulelines having different match criteria. Multiple line cookie header strings can be combined together using a comma (,) separator.

**Important:** The HTTP parser can parse up to a maximum of 4096 bytes in the cookie header. In the case of multiple line cookie headers, the maximum of 4096 bytes includes the total size of all cookie header values, and the separators added to combine them.

**Example**

The following command defines a rule expression to match the HTTP cookie header with the string *tollfree*:

```
http cookie = tollfree
```
http domain

This command allows you to define rule expressions to match the domain portion of URIs in HTTP packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] http domain [ case-sensitive ] operator domain
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  ```
  • !=: Does not equal
  • !contains: Does not contain
  • !ends-with: Does not end with
  • !starts-with: Does not start with
  • ==: Equals
  • contains: Contains
  • ends-with: Ends with
  • starts-with: Starts with
  ```

- **domain**
  Specifies the domain to match.
  `domain` must be an alphanumeric string of 1 through 127 characters.

**Usage**

Use this command to define rule expressions to match the domain portion of URIs in HTTP packets.
From the URL, after http:// (if present) is removed, everything until the first "/" is the domain.

Example

The following command defines a rule expression to match user traffic based on domain name `testdomain`:

```
http domain = testdomain
```
http error

This command allows you to define rule expressions to match for errors in HTTP packets (for example, invalid HTTP header) and errors in the HTTP analyzer FSM (Finite State Machine) while parsing HTTP packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration  
active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

**Syntax**

```
[ no ] http error operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `==`: Equals

- **condition**
  Specifies the condition to match.
  `condition` must be one of the following:
  - `FALSE`
  - `TRUE`

**Usage**

Use this command to define rule expressions to match for errors in HTTP packets and other errors in HTTP analyzer FSM while parsing HTTP packets. For example, FSM error, invalid header field values, ACS memory and buffer limit, packet related errors, and so on.

ACS supports pipelining of up to 32 HTTP requests on the same TCP connection. Pipeline overflow requests are not analyzed. Such overflow requests are treated as HTTP error. The billing system, based on this information, decides to charge or not charge, or refund the subscriber accordingly.

In 14.0 and later releases, the ECS HTTP analyzer supports both CRLF and LF as valid terminators for HTTP header fields.

**Example**

The following command defines a rule expression to match user traffic based on HTTP error status of **TRUE**: 
http error = TRUE
http first-request-packet

This command allows you to define rule expressions to match the GET or POST request, if it is the first HTTP request for the subscriber's session.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] http first-request-packet operator condition
```

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
<tbody>
<tr>
<td>If previously configured, deletes the specified rule expression from the current ruledef.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>operator</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies how to match.</td>
</tr>
<tr>
<td><strong>operator</strong> must be one of the following:</td>
</tr>
</tbody>
</table>

  - `!=`: Does not equal
  - `==`: Equals

<table>
<thead>
<tr>
<th>condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the condition to match.</td>
</tr>
<tr>
<td><strong>condition</strong> must be one of the following:</td>
</tr>
</tbody>
</table>

  - `FALSE`
  - `TRUE`

**Usage**

Use this command to define rule expressions to match the GET or POST request, if it is the first HTTP request for the subscriber's session.

This expression can be connected with a charging action, so the subscriber is redirected to a splash page for the first Web access attempted.

**Example**

The following command defines a rule expression to match first-request-packet:

```
http first-request-packet = TRUE
```
http header-length

This command allows you to define rule expressions to match HTTP header length.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] http header-length operator header_length

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
- !=: Does not equal
- <=: Lesser than or equals
- =: Equals
- >=: Greater than or equals

header_length
Specifies the HTTP header length (in bytes) to match.
header_length must be an integer from 0 through 65535.

Usage
Use this command to define rule expressions to match the length of an HTTP header.
In 14.0 and later releases, the ECS HTTP analyzer supports both CRLF and LF as valid terminators for HTTP header fields.

Example
The following command defines a rule expression to match an HTTP header length of 8000:

http header-length = 8000
http host

This command allows you to define rule expressions to match value in HTTP Host request-header field.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] http host [ case-sensitive ] operator host_name

no
If previously configured, deletes the specified rule expression from the current ruledef.

case-sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

operator
Specifies how to match.
operator must be one of the following:
  • !=: Does not equal
  • !contains: Does not contain
  • !ends-with: Does not end with
  • !starts-with: Does not start with
  • =: Equals
  • contains: Contains
  • ends-with: Ends with
  • regex: Regular expression
  • starts-with: Starts with

host_name
Specifies the host name to match.
host_name must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
Usage
Use this command to define rule expressions to match value in HTTP Host request-header field.
In 14.0 and later releases, the ECS HTTP analyzer supports both CRLF and LF as valid terminators for HTTP
header fields.
The following table lists the special characters that you can use in regex rule expressions. For more
information on regex support, refer to the Enhanced Charging Service Administration Guide.

Table 6. Special Characters Supported in Regex Rule Expressions

<table>
<thead>
<tr>
<th>Regex Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Zero or more characters</td>
</tr>
<tr>
<td>+</td>
<td>Zero or more repeated instances of the token preceding the +</td>
</tr>
<tr>
<td>?</td>
<td>Match zero or one character</td>
</tr>
</tbody>
</table>

**Important:** The CLI does not support configuring “?” directly, you must instead use “\077”.

For example, if you want to match the string “xyz<any one character>pqr”, you must configure it as:

```
http host regex "xyz\077pqr"
```

In another example, if you want to exactly match the string “url?resource=abc”, you must configure it as:

```
http uri regex "url\077resource=abc"
```

Where, the first “\” (backslash) is for the escaping of “?” and then “\077” for specifying “?” to the CLI.

<table>
<thead>
<tr>
<th>\character</th>
<th>Escaped character</th>
</tr>
</thead>
<tbody>
<tr>
<td>?</td>
<td>Match the question mark (&lt;ctrl-v&gt;??)</td>
</tr>
<tr>
<td>+</td>
<td>Match the plus character</td>
</tr>
<tr>
<td>*</td>
<td>Match the asterisk character</td>
</tr>
<tr>
<td>\a</td>
<td>Match the Alert (ASCII 7) character</td>
</tr>
<tr>
<td>\b</td>
<td>Match the Backspace (ASCII 8) character</td>
</tr>
<tr>
<td>\f</td>
<td>Match the Form-feed (ASCII 12) character</td>
</tr>
<tr>
<td>\n</td>
<td>Match the New line (ASCII 10) character</td>
</tr>
<tr>
<td>\r</td>
<td>Match the Carriage return (ASCII 13) character</td>
</tr>
<tr>
<td>\t</td>
<td>Match the Tab (ASCII 9) character</td>
</tr>
<tr>
<td>\v</td>
<td>Match the Vertical tab (ASCII 11) character</td>
</tr>
<tr>
<td>\0</td>
<td>Match the Null (ASCII 0) character</td>
</tr>
<tr>
<td>\</td>
<td>Match the backslash character</td>
</tr>
<tr>
<td>Bracketed range [0-9]</td>
<td>Match any single character from the range</td>
</tr>
</tbody>
</table>

A leading ^ in a range | Do not match any in the range. All other characters represent themselves.
**regex Character** | **Description**
--- | ---
\x## | Any ASCII character as specified in two-digit hex notation. For example, \x5A yields a “Z”.
| | Specify OR regular expression operator

**Important:** When using the regex operator “|” in regex expressions, always wrap the string in double quotes.

For example, if you want to match the string "pqr" OR "xyz", you must configure it as:

```
http host regex "pqr|xyz"
```

**Example**

The following command defines a rule expression to match `host1` in HTTP Host request-header field:

```
http host = host1
```

The following command defines a regex rule expression to match either of the following values in the HTTP Host request-header field: `host1`, `host23w01`.

```
http host regex "host1|host23w01"
```
http payload-length

This command allows you to define rule expressions to match HTTP payload length.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] http payload-length operator payload_length

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:

• !=: Does not equal
• <=: Lesser than or equals
• ==: Equals
• >=: Greater than or equals

payload_length
Specifies the HTTP payload (data) length (in bytes) to match.
payload_length must be an integer from 1 through 400000000.

Usage
Use this command to define rule expressions to match HTTP payload (data) length (pdu-length - header-length).

Example
The following command defines a rule expression to match HTTP payload length of 100000 bytes:

http payload-length = 100000
http pdu-length

This command allows you to define rule expressions to match the total length of a single HTTP packet.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] http pdu-length operator pdu_length

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
- !=: Does not equal
- <=: Lesser than or equals
- ==: Equals
- >=: Greater than or equals

pdu_length
Specifies the HTTP PDU length (in bytes) to match.
pdu_length must be an integer from 0 through 65535.

Usage
Use this command to define rule expressions to match the total length of a single HTTP packet. This will also match packets with partial HTTP message (due to fragmentation).

Example
The following command defines a rule expression to match an HTTP PDU length of 10000 bytes:

http pdu-length = 10000
http previous-state

This command allows you to define rule expressions to match previous state of HTTP sessions.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```plaintext
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```plaintext
[ no ] http previous-state operator http_previous_state
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  - `!=`: Does not equal
  - `==`: Equals

- **http_previous_state**
  Specifies the previous state to match.
  - `init`: Initialized state
  - `response-error`: Response error state
  - `response-ok`: Response ok state
  - `waiting-for-response`: Waiting for response state

**Usage**

Use this command to define rule expressions to match a previous state of HTTP sessions.

**Example**

The following command defines a rule expression to match HTTP previous state `response-ok`:

```plaintext
http previous-state = response-ok
```
http referer

This command allows you to define rule expressions to match the value in the HTTP Referer request-header field.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] http referer [ case-sensitive ] operator referer_name

no
If previously configured, deletes the specified rule expression from the current ruledef.

case-sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• !contains: Does not contain
• !ends-with: Does not end with
• !starts-with: Does not start with
• =: Equals
• contains: Contains
• ends-with: Ends with
• regex: Regular expression
• starts-with: Starts with

referer_name
Specifies the HTTP referer name to match.
referer_name must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
Usage

Use this command to define rule expressions to match value in HTTP Referer request-header field. This feature allows an operator to collect or track all URLs visited during a particular subscriber session. These URLs include the entire string of visited URLs, including all referral links. This information is output in an Event Data Record (EDR) format to support reporting or billing functions.

For example, if a subscriber begins a mobile web session and clicks on the “Sports” link from the home deck, and then selects ESPN and moves to an advertiser link, the operator can capture all URLs for that entire session. During this period ACS collects the URLs for a particular subscriber session; collection can be limited by time duration or number of URLs visited.

ACS generates EDRs that contain HTTP URL and the HTTP referer fields along with other fields. In 14.0 and later releases, the ECS HTTP analyzer supports both CRLF and LF as valid terminators for HTTP header fields.

The following table lists the special characters that you can use in regex rule expressions. For more information on regex support, refer to the Enhanced Charging Service Administration Guide.

### Table 7. Special Characters Supported in Regex Rule Expressions

<table>
<thead>
<tr>
<th>Regex Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>*</code></td>
<td>Zero or more characters</td>
</tr>
<tr>
<td><code>+</code></td>
<td>Zero or more repeated instances of the token preceding the +</td>
</tr>
<tr>
<td><code>?</code></td>
<td>Match zero or one character</td>
</tr>
</tbody>
</table>

**Important:** The CLI does not support configuring “?” directly, you must instead use “\077”.

For example, if you want to match the string “xyz<any one character>pqr”, you must configure it as: `http host regex "xyz\077pqr"`

In another example, if you want to exactly match the string “url?resource=abc”, you must configure it as: `http uri regex "url\077resource=abc"`

Where, the first “\” (backslash) is for the escaping of “?” and then “\077” for specifying “?” to the CLI.

<table>
<thead>
<tr>
<th><code>\</code>character</th>
<th>Escaped character</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>\?</code></td>
<td>Match the question mark (&lt;ctrl-v&gt;?) character</td>
</tr>
<tr>
<td><code>\+</code></td>
<td>Match the plus character</td>
</tr>
<tr>
<td><code>\*</code></td>
<td>Match the asterisk character</td>
</tr>
<tr>
<td><code>\a</code></td>
<td>Match the Alert (ASCII 7) character</td>
</tr>
<tr>
<td><code>\b</code></td>
<td>Match the Backspace (ASCII 8) character</td>
</tr>
<tr>
<td><code>\f</code></td>
<td>Match the Form-feed (ASCII 12) character</td>
</tr>
<tr>
<td><code>\n</code></td>
<td>Match the New line (ASCII 10) character</td>
</tr>
<tr>
<td><code>\r</code></td>
<td>Match the Carriage return (ASCII 13) character</td>
</tr>
<tr>
<td><code>\t</code></td>
<td>Match the Tab (ASCII 9) character</td>
</tr>
<tr>
<td><code>\v</code></td>
<td>Match the Vertical tab (ASCII 11) character</td>
</tr>
<tr>
<td><code>\0</code></td>
<td>Match the Null (ASCII 0) character</td>
</tr>
</tbody>
</table>
## Regex Character Description

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\</td>
<td>Match the backslash character</td>
</tr>
<tr>
<td>Bracketed range [0-9]</td>
<td>Match any single character from the range</td>
</tr>
<tr>
<td>A leading ^ in a range</td>
<td>Do not match any in the range. All other characters represent themselves.</td>
</tr>
<tr>
<td>\x##</td>
<td>Any ASCII character as specified in two-digit hex notation. For example, \x5A yields a “Z”.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Important:** When using the regex operator “|” in regex expressions, always wrap the string in double quotes.

For example, if you want to match the string "pqr" OR “xyz”, you must configure it as:

```plaintext
http host regex "pqr|xyz"
```

### Example

The following command defines a rule expression to match the HTTP referer `cricket.espn.com`:

```plaintext
http referer = cricket.espn.com
```
http reply code

This command allows you to define rule expressions to match status code associated with HTTP response packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

**Syntax**

```
[ no ] http reply code operator reply_code
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  * operator must be one of the following:
    - !=: Does not equal
    - <=: Lesser than or equals
    - =: Equals
    - >=: Greater than or equals

- **reply_code**
  Specifies the HTTP reply code to match.
  * reply_code must be an integer from 100 through 599.

**Usage**
Use this command to define rule expressions to match status code associated with HTTP response codes.

**Example**
The following command defines a rule expression to match HTTP response code 204:

```
http reply code = 204
```
http reply payload

This command allows you to define rule expressions to enable video detection using HTTP payload content.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration
active-<charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] http reply payload type = video

no

If previously configured, deletes the specified rule expression from the current ruledef.

Usage
Use this command to enable inspection for video in HTTP Response payload. Request payloads will not be inspected.
http request method

This command allows you to define rule expressions to match HTTP request method.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] http request method operator request_method

- no
  If previously configured, deletes the specified rule expression from the current ruledef.

- operator
  Specifies how to match.
  operator must be one of the following:
  - !=: Does not equal
  - =: Equals

- request_method
  Specifies the HTTP request method to match.
  request_method must be one of the following:
  - connect
  - delete
  - get
  - head
  - options
  - post
  - put
  - trace

Usage

Use this command to define rule expressions to match an HTTP request method.

Example
The following command defines a rule expression to match user traffic based on HTTP request method `connect`:

```
http request method = connect
```
http session-length

This command allows you to define rule expressions to match HTTP session length.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] http session-length operator session_length

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• <=: Lesser than or equals
• ==: Equals
• >=: Greater than or equals

session_length
Specifies the HTTP total session length (in bytes) to match.
session_length must be an integer from 1 through 400000000.

Usage
Use this command to define rule expressions to match a total HTTP session length.

Example
The following command defines a rule expression to match an HTTP session length of 200000:

http session-length = 200000
This command allows you to define rule expressions to match current state of an HTTP session.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] http state operator current_state
```

- **no**
  - If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  - Specifies how to match.
  - `operator` must be one of the following:
    - `!=`: Does not equal
    - `==`: Equals

- **current_state**
  - Specifies the current state of HTTP session to match.
  - `current_state` must be one of the following:
    - `close`: Closed state
    - `response-error`: Response error state
    - `response-ok`: Response ok state
    - `waiting-for-response`: Waiting for response state

**Usage**

Use this command to define rule expressions to match a current state of an HTTP session.

**Example**

The following command defines a rule expression to match current state `close`:

```
http state = close
```
http transaction-length

This command allows you to define rule expressions to match HTTP transaction length (combined length of one HTTP GET Request message and its associated response messages).

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

Syntax

```
[ no ] http transaction-length { operator transaction_length | { { range | !range } range_from to range_to } }
```

**no**
If previously configured, deletes the specified rule expression from the current ruledef.

**operator**
Specifies how to match.
Operator must be one of the following:

- !=: Does not equal
- <=: Lesser than or equals
- ==: Equals
- >=: Greater than or equals

**transaction_length**
Specifies the HTTP transaction length (in bytes) to match.
Transaction_length must be an integer from 1 through 4000000000.

**{ range | !range } range_from to range_to**
Enables or disables the range criteria for length of transaction.

- range: Enables the range criteria for HTTP transaction length.
- !range: Disables the range criteria for HTTP transaction length.
- range_from: Specifies the start of range (in bytes) for HTTP transaction length.
- range_to: Specifies the end of range (in bytes) for HTTP transaction length.
Usage

Use this command to define rule expressions to match an HTTP transaction length [one HTTP GET Request message + associated response message(s)] in bytes.

Example

The following command defines a rule expression to match an HTTP transaction length of 10200 bytes:

```
http transaction-length = 10200
```
http transfer-encoding

This command allows you to define rule expressions to match the value in HTTP Transfer-Encoding general-header field.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] http transfer-encoding [ case-sensitive ] operator transfer_encoding

---

no
If previously configured, deletes the specified rule expression from the current ruledef.

---

case-sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

---

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
  • !contains: Does not contain
  • !ends-with: Does not end with
  • !starts-with: Does not start with
• =: Equals
  • contains: Contains
  • ends-with: Ends with
  • starts-with: Starts with

---

transfer_encoding
Specifies the HTTP transfer encoding to match.
transfer_encoding must be an alphanumeric string of 1 through 127 characters, and may contain punctuation characters.
Usage

Use this command to define rule expressions to match the value in HTTP Transfer-Encoding general-header field.
In 14.0 and later releases, the ECS HTTP analyzer supports both CRLF and LF as valid terminators for HTTP header fields.

Example

The following command defines a rule expression to match the value `chunked` in HTTP Transfer-Encoding general-header field:

```
http transfer-encoding = chunked
```
http uri

This command allows you to define rule expressions to match HTTP URI.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```bash
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```bash
[ no ] http uri [ case-sensitive ] operator uri
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  - `operator` must be one of the following:
    - `!=`: Does not equal
    - `!contains`: Does not contain
    - `!ends-with`: Does not end with
    - `!starts-with`: Does not start with
    - `=`: Equals
    - `contains`: Contains
    - `ends-with`: Ends with
    - `regex`: Regular expression
    - `starts-with`: Starts with

- **uri**
  Specifies the HTTP URI to match.
  - `uri` must be an alphanumeric string of 1 through 127 characters, and can contain punctuation characters, and excludes the “host” portion.
## Usage

Use this command to define rule expressions to match an HTTP URI, excluding the host portion. The following table lists the special characters that you can use in regex rule expressions. For more information on regex support, refer to the Enhanced Charging Service Administration Guide.

<table>
<thead>
<tr>
<th>Regex Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Zero or more characters</td>
</tr>
<tr>
<td>+</td>
<td>Zero or more repeated instances of the token preceding the +</td>
</tr>
<tr>
<td>?</td>
<td>Match zero or one character</td>
</tr>
</tbody>
</table>

### Important:
The CLI does not support configuring “?” directly, you must instead use “\077”.

For example, if you want to match the string “xyz<any one character>pqr”, you must configure it as:

```
http host regex "xyz\077pqr"
```

In another example, if you want to exactly match the string “url?resource=abc”, you must configure it as:

```
http uri regex "url\077resource=abc"
```

Where, the first “\” (backslash) is for the escaping of “?” and then “\077” for specifying “?” to the CLI.

<table>
<thead>
<tr>
<th>Bracketed range</th>
<th>Match any single character from the range</th>
</tr>
</thead>
<tbody>
<tr>
<td>A leading ^ in a range</td>
<td>Do not match any in the range. All other characters represent themselves.</td>
</tr>
<tr>
<td>\x##</td>
<td>Any ASCII character as specified in two-digit hex notation. For example, \x5A yields a “Z”.</td>
</tr>
</tbody>
</table>
### Important

When using the regex operator "|" in regex expressions, always wrap the string in double quotes.

For example, if you want to match the string “pqr” OR “xyz”, you must configure it as:

```plaintext
http host regex "pqr|xyz".
```

### Example

The following command defines a rule expression to match the HTTP URI string

```plaintext
http://www.somehost.com
```

```plaintext
http uri = http://www.somehost.com
```

The following command defines a regex rule expression to match either of the following or similar values in the HTTP URI string: http://server19.com/search?form=zip, http://server20.com/search?form=pdf

```plaintext
```
http url

This command allows you to define rule expressions to match HTTP URL.

**Product**  
ACS

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
```

- **no**
  - If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  - Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  - Specifies how to match.
    - **operator** must be one of the following:
      - `!=`: Does not equal
      - `!contains`: Does not contain
      - `!ends-with`: Does not end with
      - `!starts-with`: Does not start with
      - `==`: Equals
      - `contains`: Contains
      - `ends-with`: Ends with
      - `regex`: Regular expression
      - `starts-with`: Starts with

- **url**
  - Specifies the HTTP URL to match.
    - **url** must be an alphanumeric string of 1 through 127 characters, that allows punctuation characters and includes “host + URI” for HTTP PDUs.
    - For example, in case of the URL “http://www.google.fr/”, the host is “http://www.google.fr”, and the URI is “/”. 

Hypertext Transfer Protocol
GET / HTTP/1.1
Request Method: GET
Request URI: /
Request Version: HTTP/1.1
Accept: */*
Accept-Language: fr
Accept-Encoding: gzip, deflate
User-Agent: Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.1; SV1)
Host: www.google.fr
Connection: Keep-Alive

Usage
Use this command to define rule expressions to match HTTP URL.
The following table lists the special characters that you can use in regex rule expressions. For more information on regex support, refer to the Enhanced Charging Service Administration Guide.

Table 9. Special Characters Supported in Regex Rule Expressions

<table>
<thead>
<tr>
<th>Regex Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Zero or more characters</td>
</tr>
<tr>
<td>+</td>
<td>Zero or more repeated instances of the token preceding the +</td>
</tr>
<tr>
<td>?</td>
<td>Match zero or one character</td>
</tr>
</tbody>
</table>

**Important:** The CLI does not support configuring “?” directly, you must instead use “\077”.

For example, if you want to match the string “xyz<any one character>pqr”, you must configure it as: `http host regex "xyz\077pqr"`
In another example, if you want to exactly match the string “url?resource=abc”, you must configure it as: `http uri regex "url\077resource=abc"`
Where, the first “\" (backslash) is for the escaping of “?” and then “\077” for specifying “?” to the CLI.

<table>
<thead>
<tr>
<th>\character</th>
<th>Escaped character</th>
</tr>
</thead>
<tbody>
<tr>
<td>?</td>
<td>Match the question mark (&lt;ctl-v&gt;? character</td>
</tr>
<tr>
<td>+</td>
<td>Match the plus character</td>
</tr>
<tr>
<td>Regex Character</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>*</td>
<td>Match the asterisk character</td>
</tr>
<tr>
<td>\a</td>
<td>Match the Alert (ASCII 7) character</td>
</tr>
<tr>
<td>\b</td>
<td>Match the Backspace (ASCII 8) character</td>
</tr>
<tr>
<td>\f</td>
<td>Match the Form-feed (ASCII 12) character</td>
</tr>
<tr>
<td>\n</td>
<td>Match the New line (ASCII 10) character</td>
</tr>
<tr>
<td>\r</td>
<td>Match the Carriage return (ASCII 13) character</td>
</tr>
<tr>
<td>\t</td>
<td>Match the Tab (ASCII 9) character</td>
</tr>
<tr>
<td>\v</td>
<td>Match the Vertical tab (ASCII 11) character</td>
</tr>
<tr>
<td>\0</td>
<td>Match the Null (ASCII 0) character</td>
</tr>
<tr>
<td>\</td>
<td>Match the backslash character</td>
</tr>
<tr>
<td>Bracketed range [0-9]</td>
<td>Match any single character from the range</td>
</tr>
<tr>
<td>A leading ^ in a range</td>
<td>Do not match any in the range. All other characters represent themselves.</td>
</tr>
<tr>
<td>\x##</td>
<td>Any ASCII character as specified in two-digit hex notation. For example, \x5A yields a “Z”.</td>
</tr>
<tr>
<td></td>
<td>Specify OR regular expression operator</td>
</tr>
</tbody>
</table>

**Important:** When using the regex operator “|” in regex expressions, always wrap the string in double quotes.

For example, if you want to match the string "pqr" OR “xyz”, you must configure it as:

```plaintext
http host regex "pqr|xyz"
```

**Example**

The following command defines a rule expression to match the HTTP URL `http://rfc.ietf.org/rfc/rfc1738.txt`:

```plaintext
http url = http://rfc.ietf.org/rfc/rfc1738.txt
```

The following command defines a regex rule expression to match either of the following or similar values in the HTTP URL string: `http://yahoo.com`, `http://www.yahoo.co.in`, `http://yahoo.com/news`.

```plaintext
http url regex "(http://|http://www).yahoo.(co.in|com)"
```
http user-agent

This command allows you to define rule expressions to match the User-Agent request-header field of HTTP packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

**Syntax**

[ no ] http user-agent [ case-sensitive ] operator user_agent

---

**no**
If previously configured, deletes the specified rule expression from the current ruledef.

---

**case-sensitive**
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

---

**operator**
Specifies how to match.

* operator must be one of the following:
  - !=: Does not equal
  - !contains: Does not contain
  - !ends-with: Does not end with
  - !starts-with: Does not start with
  - =: Equals
  - contains: Contains
  - ends-with: Ends with
  - starts-with: Starts with

---

**user_agent**
Specifies the HTTP user agent value to match.

* user_agent must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
**Usage**

Use this command to define rule expressions to match value in HTTP user-agent header field. In 14.0 and later releases, the ECS HTTP analyzer supports both CRLF and LF as valid terminators for HTTP header fields.

**Example**

The following command defines a rule expression to match `xyz.123` in HTTP user-agent header field:

```
http user-agent = xyz.123
```
http version

This command allows you to define rule expressions to match version information in HTTP headers.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```command
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
```

---

**no**
If previously configured, deletes the specified rule expression from the current ruledef.

---

**case-sensitive**
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

---

**operator**
Specifies how to match.

**operator** must be one of the following:

- `!=`: Does not equal
- `!contains`: Does not contain
- `!ends-with`: Does not end with
- `!starts-with`: Does not start with
- `=`: Equals
- `contains`: Contains
- `ends-with`: Ends with
- `starts-with`: Starts with

---

**http_version**
Specifies this HTTP version value to match.

**http_version** must be an alphanumeric string of 1 through 127 characters, and may contain punctuation characters.
Usage

Use this command to define rule expressions to match HTTP version.

Example

The following command defines a rule expression to match HTTP version http4.2:

```
http version = http4.2
```
http x-header

This command allows you to define rule expressions to match specified field within extension-headers (x-headers).

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] http x-header field_name [ case-sensitive ] operator string

no
If previously configured, deletes the specified rule expression from the current ruledef.

field_name
field_name must be an alphanumeric string of 1 through 31 characters.

case-sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• !contains: Does not contain
• !ends-with: Does not end with
• !starts-with: Does not start with
• =: Equals
• contains: Contains
• ends-with: Ends with
• starts-with: Starts with

string
Specifies the HTTP x-header value to match.
string must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
Usage
Use this command to define rule expressions to match specified fields within x-headers. The extension-header can be any header field not specified in RFCs. All x-header fields must begin with "x-". In 14.0 and later releases, the ECS HTTP analyzer supports both CRLF and LF as valid terminators for HTTP header fields.

Example
The following command defines a rule expression to match the extension-header test_field for the value test_string:

```
http x-header test_field = test_string
```
### icmp any-match

This command allows you to define rule expressions to match all ICMP packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```plaintext
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```plaintext
[ no ] icmp any-match operator condition
```

---

**no**
If previously configured, deletes the specified rule expression from the current ruledef.

---

**operator**
Specifies how to match.

- `!` = Does not equal
- `=` = Equals

---

**condition**
Specifies the condition to match.

- `FALSE`
- `TRUE`

**Usage**
Use this command to define rule expressions to match all ICMP packets.

**Example**
The following command defines a rule expression to match all ICMP packets:

```
icmp any-match = TRUE
```
icmp code

This command allows you to define rule expressions to match value in the Code field of ICMP packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] icmp code operator code

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• <=: Lesser than or equals
• ==: Equals
• >=: Greater than or equals

code
Specifies the ICMP code to match.
code must be an integer from 0 through 255.

Usage
Use this command to define rule expressions to match a code field of ICMP packets.

Example
The following command defines a rule expression to match ICMP code 11:

    icmp code = 11
**icmp type**

This command allows you to define rule expressions to match value in Type field of ICMP packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] icmp type operator type
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `<=`: Lesser than or equals
  - `==`: Equals
  - `>=`: Greater than or equals

- **type**
  Specifies the ICMP type to match.
  `type` must be an integer from 0 through 255. For example, 0 for Echo Reply, 3 for Destination Unreachable, and 5 for Redirect.

**Usage**

Use this command to define rule expressions to match a type field of ICMP packets.

**Example**

The following command defines a rule expression to match user traffic based on ICMP type 3:

```
icmp type = 3
```
**icmpv6 any-match**

This command allows you to define rule expressions to match all ICMPv6 packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

**Syntax**

```
[ no ] icmpv6 any-match operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `=`: Equals

- **condition**
  Specifies the condition to match.
  `condition` must be one of the following:
  - `FALSE`
  - `TRUE`

**Usage**

Use this command to define rule expressions to match all ICMPv6 packets.

**Example**

The following command defines a rule expression to match all ICMPv6 packets:

```
icmpv6 any-match = TRUE
```
icmpv6 code

This command allows you to define rule expressions to match value in Code field of ICMPv6 packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] icmpv6 code operator code

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• <=: Lesser than or equals
• ==: Equals
• >=: Greater than or equals

code
Specifies the ICMPv6 code to match.
code must be an integer from 0 through 255.

Usage
Use this command to define rule expressions to match a code field of ICMPv6 packets.

Example
The following command defines a rule expression to match ICMPv6 code 134:

icmpv6 code = 134
icmpv6 type

This command allows you to define rule expressions to match type field of ICMPv6 packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] icmpv6 type operator type

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• <=: Lesser than or equals
• ==: Equals
• >=: Greater than or equals

type
Specifies the ICMPv6 type to match.
type must be an integer from 0 through 255. For example, 129 for Echo Reply, 3 for Time Exceeded, and 137 for Redirect Message.

Usage
Use this command to define rule expressions to match type field of ICMPv6 packets.

Example
The following command defines a rule expression to match ICMPv6 type 133:

icmpv6 type = 133
**if-protocol**

This command allows you to associate different content IDs with the same ruledef, depending on the protocol being used.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
if-protocol { http | wsp-connection-less | wsp-connection-oriented } content-id content_id
no if-protocol { http | wsp-connection-less | wsp-connection-oriented }
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **http**
  Specifies HTTP protocol.
  This is the same as the rule expression `http any-match = true`.

- **wsp-connection-less**
  Specifies WSP connection-less protocol.
  This is the same as requiring “wsp any-match = true” but “wtp any-match = false” (that is, connection-less WAP1.x).

- **wsp-connection-oriented**
  Specifies WSP connection-oriented protocol.
  This is the same as the combined rule expression “wsp any-match = true” and “wtp any-match = true” (that is, connection-oriented WAP1.x).

- **content-id content_id**
  Specifies the content ID for the specified protocol.
  In 12.1 and earlier releases, `content_id` must be an integer from 1 through 65535.
  In 12.2 and later releases, `content_id` must be an integer from 1 through 2147483647.
Usage

Use this command to associate different content IDs with the same ruledef, depending on the protocol being used.
This command is only effective for charging ruledefs. See the `rule-application` command for information on how to configure charging ruledefs.
If a particular ruledef should have three different values for content-id, depending on whether the traffic is connection-oriented WAP1.x, connection-less WAP1.x, or WAP2.0, within the ruledef we should have configuration similar to the following:

```
if-protocol wsp-connection-oriented content-id 1
if-protocol wsp-connection-less content-id 2
if-protocol http content-id 3
```

Presumably, the ruledef would have another configurable like “www url contains foo”, which would cause it to use different content IDs when "foo" was accessed, depending upon the protocol being used.

Example

The following command associates HTTP protocol and a content ID of 23:

```
if-protocol http content-id 23
```
imap any-match

This command allows you to define rule expressions to match all IMAP packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

Syntax

[ no ] imap any-match operator condition

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `=`: Equals

- **condition**
  Specifies the condition to match.
  `condition` must be one of the following:
  - `FALSE`
  - `TRUE`

Usage
Use this command to define rule expressions to match all IMAP packets.

Example
The following command defines a rule expression to match all IMAP packets:

```
imap any-match = TRUE
```
imap cc

This command allows you to define rule expressions to match recipient address in the Carbon Copy (cc) field of e-mails in IMAP messages.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-acs-ruledef) #
```

**Syntax**

```
[ no ] imap cc [ case-sensitive ] operator cc_address
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  `- operator` must be one of the following:
  - !=: Does not equal
  - !contains: Does not contain
  - !ends-with: Does not end with
  - !starts-with: Does not start with
  - =: Equals
  - contains: Contains
  - ends-with: Ends with
  - starts-with: Starts with

- **cc_address**
  Specifies the e-mail “cc” address/name to match.
  `- cc_address` must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
**Usage**

Use this command to define rule expressions to match recipient address in the “cc” field of e-mails in IMAP messages.

**Example**

The following command defines a rule expression to match recipient address `triangle@xyz.com` in the “cc” field of e-mails in IMAP messages:

```
imap cc contains triangle@xyz.com
```
imap command

This command allows you to define rule expressions to match embedded IMAP commands in IMAP messages.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

**Syntax**

```
[ no ] imap command operator command
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `=`: Equals

- **command**
  Specifies the command to match.
  `command` must be one of the following:
  - `append`
  - `authenticate`
  - `capability`
  - `check`
  - `close`
  - `copy`
  - `create`
  - `delete`
  - `examine`
  - `expunge`
  - `fetch`
  - `list`
Usage

Use this command to define rule expressions to match an embedded command in the IMAP message.

Example

The following command defines a rule expression to match close command in IMAP messages:

```
imap command = close
```
imap content class

This command allows you to define rule expressions to match the content-class field of e-mails in IMAP messages.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] imap content class [ case-sensitive ] operator content_class

---

no

If previously configured, deletes the specified rule expression from the current ruledef.

---

case-sensitive

Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

---

operator

Specifies how to match.

operator must be one of the following:

- !=: Does not equal
- !contains: Does not contain
- !ends-with: Does not end with
- !starts-with: Does not start with
- =: Equals
- contains: Contains
- ends-with: Ends with
- starts-with: Starts with

---

content_class

Specifies the content class to match.

content_class must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
Usage

Use this command to define rule expressions to match the content-class field of e-mails in IMAP messages.

Example

The following command defines a rule expression to analyze user traffic matching content class `javax.mail.internet.MimeMultipart` in the content-class field of e-mails in IMAP messages:

```
imap content class contains javax.mail.internet.MimeMultipart
```
imap content type

This command allows you to define rule expressions to match the content-type field of e-mails in IMAP messages.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

`[local]host_name(config-acs-ruledef)#`

**Syntax**

```
[ no ] imap content type [ case-sensitive ] operator content_type
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **content_type**
  Specifies the content type field to match.
  `content_type` must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
Usage

Use this command to define rule expressions to match the content-type field of e-mails in IMAP messages.

Example

The following command defines a rule expression to analyze user traffic matching content type
`text/plain; charset=iso-8859-1` in the content-type field of e-mails in IMAP messages:

```
imap content type contains text/plain; charset=iso-8859-1
```
imap date

This command allows you to define rule expressions to match the Date field of e-mails in IMAP messages.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] imap date [ case-sensitive ] operator date
```

---

**no**

If previously configured, deletes the specified rule expression from the current ruledef.

---

**case-sensitive**

Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

---

**operator**

Specifies how to match. 

Operator must be one of the following:

- !=: Does not equal
- !contains: Does not contain
- !ends-with: Does not end with
- !starts-with: Does not start with
- ==: Equals
- contains: Contains
- ends-with: Ends with
- starts-with: Starts with

---

**date**

Specifies the date to match. 

Date must be an alphanumeric string of 1 through 127 characters that may include punctuation marks and spaces as shown in the example below.
Usage

Use this command to define rule expressions to match the date field of e-mails in IMAP messages.

Example

The following command defines a rule expression to analyze user traffic matching date Fri, 20 Jan 2012 11:00:00 -0600 in the “date” field of e-mails in IMAP messages:

```
imap date contains Fri, 21 Jan 2012 11:00:00 -0600
```
imap final-reply

This command allows you to define rule expressions to match final-reply value for the last IMAP final-reply message.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] imap final-reply operator final_reply

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
  • !=: Does not equal
  • ==: Equals

final_reply
Specifies the “final-reply” condition to match.
final_reply must be one of the following:
  • bad: Final reply is invalid or bad.
  • no: There is no final reply.
  • ok: Final reply is valid.
```

**Usage**

Use this command to define rule expressions to match a final-reply value for the last IMAP final-reply message.

**Example**

The following command defines a rule expression to analyze user traffic matching the final-reply condition `bad` in the last IMAP final-reply message:

```
imap final-reply = bad
```
imap from

This command allows you to define rule expressions to match the from field of e-mails in IMAP messages.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] imap from [ case-sensitive ] operator from_address
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **from_address**
  Specifies the “from” address/value to match.
  `from_address` must be an alphanumeric string of 1 through 127 characters.

**Usage**

Use this command to define rule expressions to match the from field of e-mails in IMAP messages.
Example

The following command defines a rule expression to analyze user traffic matching *triangle* in the “from” field of e-mails in the IMAP messages:

```
imap from contains triangle
```
**imap mail-size**

This command allows you to define rule expressions to match IMAP e-mail users that have e-mails of a specified size in their mailboxes.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] imap mail-size operator mail_size
```

---

**no**

If previously configured, deletes the specified rule expression from the current ruledef.

---

**operator**

Specifies how to match.

* operator must be one of the following:
  
  - `!`: Does not equal
  
  - `<=`: Lesser than or equals
  
  - `=`: Equals
  
  - `>=`: Greater than or equals

---

**mail_size**

Specifies the total size of mail, in bytes, to match.

* mail_size must be an integer from 0 through 4000000000.

**Usage**

Use this command to define rule expressions to discover the number of IMAP e-mail users that have e-mails of a specified size in their mailboxes.

**Example**

The following command defines a rule expression to match users with e-mail size less than or equal to 23400 bytes:

```
imap mail-size <= 23400
```
imap mailbox-size

This command allows you to define rule expressions to match IMAP e-mail user having a specified number of messages in their mailboxes.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] imap mailbox-size operator number_of_email
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  - !=: Does not equal
  - <=: Lesser than or equals
  - =: Equals
  - >=: Greater than or equals

- **number_of_email**
  Specifies the total number of e-mail messages in mailbox of an IMAP user to match.
  - **number_of_email** must be an integer from 0 through 65535.

**Usage**

Use this command to define rule expressions to match the number of IMAP e-mail users having a specified number of messages in their mailboxes.

**Example**

The following command defines a rule expression to match e-mail users having less than or equal to 1024 e-mail messages in their mailboxes:

```
imap mailbox-size <= 1024
```
imap message-type

This command allows you to define rule expressions to match the type of IMAP packet.

<tr>
<td>• final-reply: Message is of final reply type.</td>
</tr>
<tr>
<td>• request: There is of request type.</td>
</tr>
<tr>
<td>• untagged-reply: Message of reply type, but without any tag.</td>
</tr>
</tbody>
</table>

Usage

Use this command to define rule expressions to match the IMAP message type.

Example

The following command defines a rule expression to match IMAP sessions with message type request:

imap message-type = request
imap previous-state

This command allows you to define rule expressions to match the previous state of IMAP request sessions.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] imap previous-state operator imap_previous_state

---

no

If previously configured, deletes the specified rule expression from the current ruledef.

---

operator

Specifies how to match.
operator must be one of the following:

-!=: Does not equal
-=: Equals

---

imap_previous_state

Specifies the previous state to match.
imap_previous_state must be one of the following:

- init: Message in initialization state.
- request-sent: Message in request-sent state.

Usage

Use this command to define rule expressions to match previous state of IMAP request session.

Example

The following command defines a rule expression to match IMAP sessions with previous state init:

imap previous-state = init
imap session-length

This command allows you to define rule expressions to match the total length of an IMAP session.

Product
ACS

Privilege
Security Administrator, Administrator

Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] imap session-length operator session_length

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match. 
operator must be one of the following:
• !=: Does not equal
• <=: Lesser than or equals
• ==: Equals
• >=: Greater than or equals

session_length
Specifies the total length of IMAP session (in bytes) to match. 
session_length must be an integer from 1 through 400000000.

Usage
Use this command to define rule expressions to match the total length of IMAP sessions. The session length is calculated by adding together the IP payloads (that is, starting after the IP header) of all relevant IMAP session packets.

Example
The following command defines a rule expression to match IMAP sessions with length less than or equal to 4000 bytes:

imap session-length <= 4000
imap session-previous-state

This command allows you to define rule expressions to match the previous state of an IMAP session.

**Product**

[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] imap session-previous-state operator imap_session_previous_state
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - !=: Does not equal
  - ==: Equals

- **imap_session_previous_state**
  Specifies the previous state of IMAP session to match.
  `imap_session_previous_state` must be one of the following:
  - `authenticated`: Session authenticated
  - `connected`: Session connected
  - `init`: Session initialized
  - `mailbox-selected`: Mailbox selected

**Usage**
Use this command to define rule expressions to match the previous state of IMAP sessions.

**Example**
The following command defines a rule expression to match IMAP sessions with previous state `init`:

```
imap session-previous-state = init
```
imap session-state

This command allows you to define rule expressions to match the current state of IMAP sessions.

Product

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] imap session-state operator session_current_state

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• ==: Equals

session_current_state
Specifies the current state to match.
session_current_state must be one of the following:
• authenticated: Session authenticating.
• connected: Session connecting.
• logout: Session logged out.
• mailbox-selected: Mailbox selecting.

Usage
Use this command to define rule expressions to match the current state of IMAP sessions.

Example
The following command defines a rule expression to match IMAP sessions with current state connected:

imap session-state = connected
imap state

This command allows you to define rule expressions to match the current state of IMAP sessions.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] imap state operator current_state

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• ==: Equals

current_state
Specifies current state of IMAP session to match.
current_state must be one of the following:
• request-sent: Request message sent
• response-fail: Request response failed
• response-ok: Request response is good

Usage
Use this command to define rule expressions to match the current state of IMAP session.

Example
The following command defines a rule expression to match IMAP sessions with current state response-fail:

imap state = response-fail
imap subject

This command allows you to define rule expressions to match the subject field of e-mails in IMAP messages.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] imap subject [ case-sensitive ] operator subject
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  **operator** must be one of the following:
  - !=: Does not equal
  - !contains: Does not contain
  - !ends-with: Does not end with
  - !starts-with: Does not start with
  - ==: Equals
  - contains: Contains
  - ends-with: Ends with
  - starts-with: Starts with

- **subject**
  Specifies the “subject” to match.
  **subject** must be an alphanumeric string of 1 through 127 characters, and may contain punctuation characters and space as shown in the example below.
Usage
Use this command to define rule expressions to match “subject” field of e-mail in IMAP message.

Example
The following command defines rule expression to match occurrence of the string My test in the “subject” field of e-mails in IMAP message:

imap subject contains My test
imap to

This command allows you to define rule expressions to match the “to” field of e-mails in IMAP messages.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] imap to [ case-sensitive ] operator to

no
If previously configured, deletes the specified rule expression from the current ruledef.

case-sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

operator
Specifies how to match.
operator must be one of the following:

• !=: Does not equal
• !contains: Does not contain
• !ends-with: Does not end with
• !starts-with: Does not start with
• =: Equals
• contains: Contains
• ends-with: Ends with
• starts-with: Starts with

to
Specifies the “to” field value to match.
to must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.

Usage

Use this command to define rule expressions to match “to” field of e-mails in IMAP messages.
Example

The following command defines a rule expression to analyze user traffic matching the occurrence `xyz.com` in the “to” field of e-mails in the IMAP message:

```
imap to contains xyz.com
```
ip any-match

This command allows you to define rule expressions to match all IPv4/IPv6 packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acst-ruledef)#

Syntax

[ no ] ip any-match operator condition

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  **operator** must be one of the following:
  - !=: Does not equal
  - ==: Equals

- **condition**
  Specifies the condition to match.
  **condition** must be one of the following:
  - FALSE
  - TRUE

Usage
Use this command to define rule expressions to match IPv4/IPv6 packets.

Example

The following command defines a rule expression to match IPv4/IPv6 packets:

```
ip any-match = TRUE
```
ip dscp

This command enables you to configure a ruledef with the DSCP value and match it with the DSCP value in the incoming IP packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration
active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local] host_name(config-acs-ruledef)#

Syntax

[ no ] ip dscp { operator } IPv4_ToS_value | IPv6_TC_value [ mask mask_value ]

- **no**
  
  If previously configured, removes the specified DSCP value and the mask from the configuration.

- **operator**
  
  Specifies how to match.
  
  **operator** must be one of the following:
  
  - !=: Does not equal
  - =: Equals

- IPv4_ToS_value | IPv6_TC_value
  
  Specifies the DSCP value to match with the incoming IP packets.
  
  The **IPv4_ToS_value** or **IPv6_TC_value** must be an integer from 0 through 63.

- mask mask_value
  
  Specifies the mask for the number of bits in the DSCP value to be considered for matching.
  
  **mask_value** must be an integer from 0 through 63. The default mask value is 63.

Usage

Use this command to check if the DSCP value in the IPv4 ToS or IPv6 TC field of incoming IP packet matches with configured ToS/TC value.

Example

The following command will match all incoming packets which has DSCP value 20:

```
ip dscp = 20 mask 31
```
ip downlink

This command allows you to define rule expressions to match downlink (network to subscriber) packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] ip downlink operator condition

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  * operator must be one of the following:
    - !=: Does not equal
    - =: Equals

- **condition**
  Specifies the condition to match.
  * condition must be one of the following:
    - FALSE
    - TRUE

Usage

Use this command to define rule expressions to match downlink (to subscriber) IP packets.

Example

The following command defines a rule expression to match IP packet in downlink direction:

   ip downlink = TRUE
ip dst-address

This command allows you to define rule expressions to match IP destination address field within IP headers.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acd-ruledef)#
```

**Syntax**

```
[ no ] ip dst-address { operator { ipv4/ipv6_address | ipv4/ipv6_address/mask } | { !range | range } host-pool host_pool_name }
```

- **operator**: Specifies how to match.  
  - !=: Does not equal  
  - <=: Lesser than or equals  
  - =: Equals  
  - >=: Greater than or equals

- **ipv4/ipv6_address**: Specifies the IP address of the destination node for outgoing traffic. `ipv4/ipv6_address` must be an IP address in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

- **ipv4/ipv6_address/mask**: Specifies the IP address of the destination node for outgoing traffic. `ipv4/ipv6_address/mask` must be an IP address in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation with subnet mask bit. The mask bit is a numeric value which corresponding to the number of bits in the subnet mask.

- **{ !range | range } host-pool host_pool_name**: Specifies the name of the host pool. `host_pool_name` must be an alphanumeric string of 1 through 63 characters.
**Usage**

Use this command to define rule expressions to match the IP destination address field within IP headers.

**Example**

The following command defines a rule expression to match user traffic based on the IPv4 destination address 10.1.1.1:

```
ip dst-address = 10.1.1.1
```
**ip error**

This command allows you to define rule expressions to match user traffic for invalid IP packets and other errors, for example IP header error, while parsing IP packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-consuming service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```

```

**Syntax**

```
[ no ] ip error operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

```
operator
```

Specifies how to match.

- **! =**: Does not equal
- **=**: Equals

```
condition
```

Specifies the condition to match.

- **FALSE**
- **TRUE**

**Usage**

Use this command to define rule expressions to match invalid IP packets and any other errors while parsing IP packets.

**Example**

The following command defines a rule expression to match user traffic for invalid IP packets and other errors:

```
ip error = TRUE
```
ip protocol

This command allows you to define rule expressions to match the protocol field in IP headers.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

**Syntax**

```
[ no ] ip protocol operator { protocol_assignment_no | protocol }
```

*no*

If previously configured, deletes the specified rule expression from the current ruledef.

*operator*

Specifies how to match.

*operator* must be one of the following:

- !=: Does not equal
- <=: Lesser than or equals—available only in 8.1 and later releases
- =: Equals
- >=: Greater than or equals—available only in 8.1 and later releases

*protocol_assignment_no*

Specifies the protocol by assignment number.

*protocol_assignment_no* must be an integer from 0 through 255.
For example, 1 for ICMP, 6 for TCP, and 17 for UDP.

*protocol*

Specifies the protocol by name.

*protocol* must be one of the following:

- ah
- esp
- gre
- gre
- icmp
- icmpv6
- tcp
Usage

Use this command to define rule expressions to match protocol field in IP packet headers.

Example

The following command defines a rule expression to match protocol assignment number 1:

```
ip protocol = 1
```
ip server-domain-name

This command allows you to define rule expressions to match host names (domain names).

Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acis-rudedef)#

Syntax

[ no ] ip server-domain-name operator domain_name

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• =: Equals
• contains: Contains
• ends-with: Ends with
• starts-with: Starts with

domain_name
Specifies the domain name to match.
domain_name must be an alphanumeric string of 1 through 127 characters.

Usage
Use this command to define rule expressions to match full or partial host names (domain names).
The rule will be matched for the learnt IP addresses resolved from DNS queries to the specified domain names. DNS responses for the specified domain names will be snooped and the learnt IP addresses stored. Besides being used for standard rule matching, this command also enables the DNS Snooping feature if the rulebase references any ruledefs with this configuration. The DNS protocol analyzer must also be enabled in the rulebase.

Example
The following command defines a rule expression to match domain name values containing star:

    ip server-domain-name contains star
ip server-ip-address

This command allows you to define rule expressions to match the IP address of the destination end of the connection.

Product
ACS

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] ip server-ip-address { operator { ipv4/ipv6_address | ipv4/ipv6_address/mask } | { !range | range } host-pool host_pool_name }

no

If previously configured, deletes the specified rule expression from the current ruledef.

operator

operator: Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• <=: Lesser than or equals
• ==: Equals
• >=: Greater than or equals

ipv4/ipv6_address

Specifies the server IP address. For uplink packets (subscriber to network), this field matches the destination IP address in the IP header. For downlink packets (network to subscriber), this field matches the source IP address in the IP header. ipv4/ipv6_address must be an IP address in IPv4 dotted-decimal notation or IPv6 colon-separated-hexadecimal notation.

ipv4/ipv6_address/mask

Specifies the server IP address with subnet mask bit. For uplink packets (subscriber to network), this field matches the destination IP address in the IP header. For downlink packets (network to subscriber), this field matches the source IP address in the IP header. ipv4/ipv6_address/mask must be an IP address in IPv4 dotted-decimal notation or IPv6 colon-separated-hexadecimal notation with subnet mask bit. The mask bit is a numeric value which is the number of bits in the subnet mask.

{ !range | range } host-pool host_pool_name

!range | range: Specifies the range criteria:
**Command**

Command Line Interface Reference, StarOS Release 16

**Usage**

Use this command to define rule expressions to match the IP address of the destination end of the connection. For uplink packets, this field matches the destination IP address in the IP header. For downlink packets, this field matches the source IP address in the IP header.

**Example**

The following command defines a rule expression to match user traffic based on IPv4 server address 10.1.1.1:

```
    ip server-ip-address = 10.1.1.1
```
ip src-address

This command allows you to define rule expressions to match the source IP address field within IP headers.

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] ip src-address { operator { ipv4/ipv6_address | ipv4/ipv6_address/mask } | { !range | range } host-pool host_pool_name }
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  **operator** must be one of the following:
  - !=: Does not equal
  - <=: Lesser than or equals
  - =: Equals
  - >=: Greater than or equals

- **ipv4/ipv6_address**
  Specifies IP address of the source node for incoming traffic. **ipv4/ipv6_address** must be an IP address in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

- **ipv4/ipv6_address/mask**
  Specifies the IP address of the source node for incoming traffic with subnet mask bit. **ipv4/ipv6_address/mask** must be an IP address in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation with subnet mask bit. The mask bit is a numeric value which corresponds to the number of bits in the subnet mask.

- **{ !range | range } host-pool host_pool_name**
  **!range** | **range**: Specifies the range criteria:
  - !range: Not in the range of
  - range: In the range of
**Usage**

Use this command to define rule expressions to match IP source address field within IP header.

**Example**

The following command defines a rule expression to match user traffic based on IPv4 source address 10.1.1.1:

```plaintext
ip src-address = 10.1.1.1
```
ip subscriber-ip-address

This command allows you to define rule expressions to match the IP address of the subscriber, which will be either the source or destination address depending on the direction.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

Exec > ACS Configuration > Ruledef Configuration

    active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

    [local]host_name(config-acns-ruledef)#

**Syntax**

    [ no ] ip subscriber-ip-address { operator { ipv4/ipv6_address | ipv4/ipv6_address/mask } | { !range | range } host-pool host_pool_name }

**no**
If previously configured, deletes the specified rule expression from the current ruledef.

**operator**
operator: Specifies how to match.
operator must be one of the following:
- !=: Does not equal
- <=: Lesser than or equals
- =: Equals
- >=: Greater than or equals

**ipv4/ipv6_address**
Specifies the subscriber IP address. Depending on the direction of packet this IP address will be either the IP source address or the IP destination address. *ipv4/ipv6_address* must be an IP address in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

**ipv4/ipv6_address/mask**
Specifies the subscriber IP address with subnet mask bit. Depending on the direction of packet this IP address will either be the IP source address or the IP destination address. *ipv4/ipv6_address/mask* must be an IP address in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation with subnet mask bit. The mask bit is a numeric value which corresponds to the number of bits in the subnet mask.

**{ !range | range } host-pool host_pool_name**

!range | range: Specifies the range criteria:
- !range: Not in the range of
ACS Ruledef Configuration Mode Commands

ip subscriber-ip-address

- **range**: In the range of
  
  **host-pool host_pool_name**: Specifies the name of the host pool. `host_pool_name` must be an alphanumeric string of 1 through 63 characters.

---

**Usage**

Use this command to define rule expressions to match the IP address of the subscriber, which will be either the source or destination address depending on the direction.

**Example**

The following command defines a rule expression to match user traffic based on subscriber IPv4 address 10.1.1.1:

```
   ip subscriber-ip-address = 10.1.1.1
```
ip total-length

This command allows you to define rule expressions to match the total length field in IP headers.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

Syntax

[ no ] ip total-length operator total_length

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
- !=: Does not equal
- <=: Lesser than or equals
- -: Equals
- >=: Greater than or equals

total_length
Specifies the total length of the IP packet (including payload) to match.
total_length must be an integer from 0 through 4096.

Usage
Use this command to define rule expressions to match the total length field in IP headers.

Example
The following command defines a rule expression to match user traffic based on IP total length of 2000 bytes:

    ip total-length = 2000
**ip uplink**

This command allows you to define rule expressions to match uplink (subscriber to network) IP packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] ip uplink operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  - !=: Does not equal
  - ==: Equals

- **condition**
  Specifies the condition to match.
  - FALSE
  - TRUE

**Usage**
Use this command to define rule expressions to match uplink (subscriber to network) IP packets.

**Example**
The following command defines a rule expression to match uplink packets:

```
   ip uplink = TRUE
```
ip version

This command allows you to define rule expressions to match the version number in IP headers.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] ip version operator ip_version

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be = (equals).

ip_version
Specifies the IP version to match.
ip_version must be one of the following:
● ipv4
● ipv6

Usage
Use this command to define rule expressions to match version number in IP header.

Example
The following command defines a rule expression to match user traffic for the IP version ipv6:

ip version = ipv6
mms any-match

This command allows you to define rule expressions to match all Multimedia Messenging Service (MMS) packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] mms any-match operator condition

---

no
If previously configured, deletes the specified rule expression from the current ruledef.

---

operator
Specifies how to match.
operator must be one of the following:

- !=: Does not equal
- ==: Equals

---

condition
Specifies the condition to match.
condition must be one of the following:

- FALSE
- TRUE

Usage
Use this command to define rule expressions to match all MMS packets.

Example
The following command defines a rule expression to match all MMS packets:

mms any-match = TRUE
**mms bcc**

This command allows you to define rule expressions to match recipient addresses in the bcc field of MMS messages.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] mms bcc [ case-sensitive ] operator bcc_address
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **bcc_address**
  Specifies the “bcc” address/value to match.
  `bcc_address` must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters and space.
Usage

Use this command to define rule expressions to match recipient address in the “bcc” field of MMS messages.

Example

The following command defines a rule expression to match recipient address containing `test1` in “bcc” field of MMS messages:

```
mms bcc contains test1
```
mms cc

This command allows you to define rule expressions to match recipient addresses in the cc field of MMS messages.

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] mms cc [ case-sensitive ] operator cc_address

no
If previously configured, deletes the specified rule expression from the current ruledef.

case-sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

operator
Specifies how to match.
operator must be one of the following:
  • !=: Does not equal
  • !contains: Does not contain
  • !ends-with: Does not end with
  • !starts-with: Does not start with
  • =: Equals
  • contains: Contains
  • ends-with: Ends with
  • starts-with: Starts with

cc_address
Specifies the “cc” address/value to match.
cc_address must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters and space.
Usage
Use this command to define rule expressions to match recipient addresses in “cc” field of MMS messages.

Example
The following command defines a rule expression to match recipient address containing \texttt{test1} in the “cc” field of MMS messages:

\texttt{mms cc contains test1}
**mms content location**

This command allows you to define rule expressions to match the content-location field of MMS messages.

**Syntax**

```plaintext
[ no ] mms content location [ case-sensitive ] operator string
```

- **no**
  
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  
  Specifies how to match.
  
  **operator** must be one of the following:
  
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **string**
  
  Specifies the value to match.
  
  **string** must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters and space.
**Usage**
Use this command to define rule expressions to match the content-location field of MMS messages.

**Example**
The following command defines a rule expression to match `test1` in content-location field of MMS messages:

```
mms content location contains test1
```
mms content type

This command allows you to define rule expressions to match the content-type field of MMS messages.

Product

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] mms content type [ case-sensitive ] operator content_type

no
If previously configured, deletes the specified rule expression from the current ruledef.

case-sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

operator
Specifies how to match.

operator must be one of the following:

• !=: Does not equal
• !contains: Does not contain
• !ends-with: Does not end with
• !starts-with: Does not start with
• =: Equals
• contains: Contains
• ends-with: Ends with
• starts-with: Starts with

c content_type
Specifies the MMS content type to match.

content_type must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters and space.
Usage

Use this command to define rule expressions to match content-type field of MMS messages.

Example

The following command defines a rule expression to match image in content-type field of MMS messages:

```
mms content type contains image
```
mms downlink

This command allows you to define rule expressions to match downlink (network to subscriber) MMS packets.

**Product**
ACS

**Privilege**

```

**Syntax**

```
[ no ] mms downlink operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `==`: Equals

- **condition**
  Specifies the downlink (from the Mobile Node direction) status to match.
  `condition` must be one of the following:
  - `FALSE`
  - `TRUE`

**Usage**

Use this command to define rule expressions to match downlink MMS packets.

**Example**

The following command defines a rule expression to match all downlink MMS packets:

```
mms downlink = TRUE
```
mms from

This command allows you to define rule expressions to match the “from” field in MMS messages.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-accs-ruledef)#

Syntax

[ no ] mms from [ case-sensitive ] operator from_address

---

no
If previously configured, deletes the specified rule expression from the current ruledef.

---

case-sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

---

operator
Specifies how to match.
operator must be one of the following:

• !=: Does not equal

• !contains: Does not contain

• !ends-with: Does not end with

• !starts-with: Does not start with

• =: Equals

• contains: Contains

• ends-with: Ends with

• starts-with: Starts with

---

from_address
Specifies the “from” address/value to match.

from_address must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters and space.
Usage
Use this command to define rule expressions to match the “from” field of MMS messages.

Example
The following command defines a rule expression to match test1 in the “from” field of MMS messages:

```
mms from contains test1
```
mms message-id

This command allows you to define rule expressions to match the message ID field of MMS messages.

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```bash
[ no ] mms message-id [ case-sensitive ] operator message_id
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **message_id**
  Specifies the MMS message ID to match.
  `message_id` must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
Usage

Use this command to define rule expressions to match the “message ID” field of MMS messages.

Example

The following command defines a rule expression to match `test1` in the “message ID” field of MMS messages:

```
mms message-id contains test1
```
mms pdu-type

This command allows you to define rule expressions to match Protocol Data Unit (PDU) type in the current MMS packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration
active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] mms pdu-type operator pdu_type

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
- !: Does not equal
- =: Equals

pdu_type
Specifies the MMS PDU type to match.
pdu_type must be one of the following:
- mms-pdu-type-m-acknowledge-ind
- mms-pdu-type-m-delivery-ind
- mms-pdu-type-m-http-get
- mms-pdu-type-m-notification-ind
- mms-pdu-type-m-notify-rsp-ind
- mms-pdu-type-m-retrieve-conf
- mms-pdu-type-m-send-conf
- mms-pdu-type-m-send-request
- mms-pdu-type-m-wsp-get
- mms-pdu-type-response: This option is deprecated. Use the mms_pdu_type_m_retrieve_conf option instead.
Usage
Use this command to define rule expressions to match the PDU type in the current MMS packet.

Example
The following command defines a rule expression to match PDU type `mms-pdu-type=m-http-get` in the current MMS packet:

```
mms pdu-type = mms-pdu-type=m-http-get
```
**mms previous-state**

This command allows you to define rule expressions to match the previous state of MMS sessions.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] mms previous-state operator mss_previous_state
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `=`: Equals

- **mms_previous_state**
  Specifies the previous state to match.
  
  `mms_previous_state` must be one of the following:
  - `delayed-ack-pending`: This option is deprecated, use `retrieve-conf-received`.
  - `delayed-m-notify-rsp-sent`: This option is deprecated, use `notify-rsp-sent`.
  - `delayed-retrieval-pending`: This option is deprecated, use `retrieval-pending`.
  - `immediate-retrieval-pending`: This option is deprecated, use `retrieval-pending`.
  - `init`
  - `m-send-conf-rcvd`: This option is deprecated, use `send-success`.
  - `m-send-req-sent`
  - `notification-ind-rcvd`
  - `notify-rsp-sent`
  - `retrieval-pending`
  - `retrieve-conf-received`
  - `send-success`
Usage

Use this command to define rule expressions to match the previous state of MMS sessions.

Example

The following command defines a rule expression to match user traffic based on MMS previous state of *retrieval-pending*:

```
mms previous-state = retrieval-pending
```
mms response status

This command allows you to define rule expressions to match the response status code of MMS messages.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] mms response status operator status_code

- no
  If previously configured, deletes the specified rule expression from the current ruledef.

- operator
  Specifies how to match.
  operator must be one of the following:
  • !=: Does not equal
  • ==: Equals

- status_code
  Specifies the status code to match.
  status_code must be an integer from 128 through 136.

Usage
Use this command to define rule expressions to match response status code of MMS messages.

Example
The following command defines a rule expression to match user traffic based on MMS response status code 129:

mms response status = 129
mms state

This command allows you to define rule expressions to match the current state of MMS sessions.

Product

```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match. `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **subject_string**
  Specifies the value to match. `subject_string` must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters and space.
### Usage

Use this command to define rule expressions to match “subject” field of MMS messages.

### Example

The following command defines a rule expression to match `test1` in the “subject” field of MMS messages:

```
mms subject contains test1
```
mms tid

This command allows you to define rule expressions to match the “Transaction Identifier” (TID) field of MMS messages.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] mms tid [ case-sensitive ] operator transaction_id
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match. 
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `==`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **transaction_id**
  Specifies the MMS TID to match. 
  `transaction_id` must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
Usage

Use this command to define rule expressions to match TID field of MMS messages.

Example

The following command defines a rule expression to match test in TID field of MMS messages:

```
mms tid = test
```
mms to

This command allows you to define rule expressions to match the “to” field of MMS messages.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acd-ruledef)#

Syntax

[ no ] mms to [ case-sensitive ] operator to_address

no
If previously configured, deletes the specified rule expression from the current ruledef.

case-sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

operator
Specifies how to match.
operator must be one of the following:

bullet !=: Does not equal
bullet !contains: Does not contain
bullet !ends-with: Does not end with
bullet !starts-with: Does not start with
bullet =: Equals
bullet contains: Contains
bullet ends-with: Ends with
bullet starts-with: Starts with

to_address
Specifies the “to” address/name to match.
to_address must be an alphanumeric string of 1 through 127 characters, and may contain punctuation characters and space.
Usage

Use this command to define rule expressions to match “to” field of MMS messages.

Example

The following command defines a rule expression to match user traffic based on test in “to” field of MMS messages:

```
mms to = test
```
mms uplink

This command allows you to define rule expressions to match uplink (subscriber to network) MMS packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] mms uplink operator condition

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
- !=: Does not equal
- ==: Equals

condition
Specifies the uplink (from the Mobile Node direction) status to match.
condition must one of the following:
- FALSE
- TRUE

Usage
Use this command to define rule expressions to match uplink MMS packets.

Example

The following command defines a rule expression to match uplink MMS packets:

    mms uplink = TRUE
mms version

This command allows you to define rule expressions to match the MMS version in MMS packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] mms version operator version
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `==`: Equals

- **version**
  Specifies the MMS version to match.
  `version` must be an integer from 1 through 65535.

---

**Important:** MMS protocol analyzer supports decoding of only MMS version 1.0.

**Usage**

Use this command to define rule expressions to match MMS version in MMS packets.

**Example**

The following command defines a rule expression to match MMS version 1.0 in MMS packets:

```
mms version = 1
```
multi-line-or all-lines

This command applies the OR operator to all lines in the current ruledef.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] multi-line-or all-lines

no
If previously configured, deletes this configuration in the current ruledef.

multi-line-or all-lines
Applies the OR operator to all lines in the current ruledef.

Usage

When a ruledef is evaluated, if the multi-line-or all-lines command is configured, the logical OR operator is applied to all the rule expressions in the ruledef to decide if the ruledef matches or not. If the multi-line-or all-lines command is not configured, the logical AND operator is applied to all the rule expressions.

The intent of this command is to allow a single ruledef to specify multiple URL expressions. Otherwise, multiple ruledefs need to be created, each with one URL expression. When this CLI command is used, each expression in the ruledef impacts the total number of ruledefs allowed. So from a "maximum number of possible ruledefs" perspective, it makes no difference whether there are N ruledefs with one expression each, or one ruledef with N expressions.
**p2p any-match**

This command allows you to define rule expressions to match all Peer-to-Peer (P2P) packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] p2p any-match operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  
  **operator** must be one of the following:
  
  - **=**: Equals

- **condition**
  Specifies the condition to match.
  
  **condition** must be one of the following:
  
  - **TRUE**: The rule matches any P2P traffic.
  - **FALSE**: The rule does not match any P2P traffic.

**Usage**
Use this command to define rule expressions to match all P2P packets.

**Example**

The following command defines a rule expression to match all P2P packets:

```
p2p any-match = TRUE
```
p2p behavioral

This command allows you to define rule expressions to match behavioral detection type — P2P, Video, VoIP, Behavioral Upload or Behavioral Download.

Product
ACS, ADC

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] p2p behavioral operator behavioral_list

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
- !=: Does not equal
- ==: Equals

behavioral_list
Specifies the behavior to match. The behavioral list is the list of supported behavioral detection logic populated from the currently loaded ADC plugin.
behavioral_list must be one of the following:
- download: Detects unknown flows which are data download using behavioral analysis
- p2p: Detects P2P/file sharing protocols using behavioral analysis
- upload: Detects unknown flows which are data upload using behavioral analysis
- video: Detects video flows using behavioral analysis
- voip: Detects VoIP (voice and video) protocols using behavioral analysis

Usage
Use this command to define rule expressions to detect behavioral protocols. Behavioral P2P and behavioral VoIP are meant for zero day detection of P2P/file sharing protocols and VoIP traffic respectively. Behavioral upload/download is similar to client-server upload/download using HTTP, FTP, SFTP, etc. It must also detect flows of non-standard ports which ECS cannot detect and falls under the client-server model. This feature is
disabled by default and meant only for statistical purposes (not for charging purposes). For detection purposes use the `p2p-detection behavioral` command in the ACS Configuration Mode.

**Example**

The following command specifies to configure behavioral VoIP:

```
p2p behavioral = voip
```
**p2p protocol**

This command allows you to define rule expressions to match P2P protocol. This command must be used for charging purposes. It must **not** be used for detection purposes.

**Product**

ACS

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] p2p protocol operator protocol
```

---

**no**

If previously configured, deletes the specified rule expression from the current ruledef.

---

**operator**

Specifies how to match.

`operator` must be `=` (equals).

---

**protocol**

Specifies the protocol to match.

`protocol` must be one of the following:

- `actionvoip`
- `actsync`
- `adobeconnect`
- `aimini`
- `amazoncloud`
- `antsp2p`
- `apple-push`
- `apple-store`
- `applejuice`

Usage
Use this command to define rule expressions to detect P2P protocols for charging purposes. For detection purposes use the `p2p-detection protocol` command in the ACS Configuration Mode.

Example
The following command specifies to detect orb protocol for charging purposes:

```
p2p protocol = orb
```
p2p protocol-group

This command allows you to define rule expressions to match ADC application/protocol group.

Product
ACS, ADC

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

</tr>
</tbody>
</table>
• **p2p-anon-filesharing**: Peer to Peer application/protocols used for anonymous filesharing.
• **remote-control**: Peer to Peer application/protocols used for filesharing.
• **social-nw-game**: Application/Protocols used for remote management.
• **social-nw-generic**: Application/Protocols used for social networking games.
• **social-nw-videoconf**: Application/Protocols used for social networking.
• **standard**: Application/Protocols used for social network video conference.
• **streaming**: Application/Protocols used for streaming audio and video.
• **untagged**: Default group for protocols not otherwise classified.

**Usage**

Use this command to define rule expressions to match ADC protocol group. The list of P2P applications/protocols is populated from the currently loaded P2P plugin.

**Example**

The following command specifies to detect the `gaming` protocol group:

```
p2p protocol-group = gaming
```
p2p traffic-type

This command allows you to define rule expressions to match the traffic type.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```plaintext
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```plaintext
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```plaintext
[ no ] p2p traffic-type operator traffic_type
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `=`: Equals

- **traffic_type**
  Specifies the traffic type to match.
  In 11.0 and later releases, `traffic_type` must be one of the following:
  - `audio`
  - `file-transfer`
  - `im`
  - `unclassified`
  - `video`
  - `voipout`

  In 10.0 and earlier releases, the supported `traffic_type` was `voice`.

**Usage**

Use this command to configure the system to detect voice or non-voice P2P traffic. When the detection of a protocol is enabled then the detection of sub-type is enabled by default.

**Example**

The following command configures the system to detect video traffic:
p2p traffic-type = video
pop3 any-match

This command allows you to define rule expressions to match all Post Office Protocol 3 (POP3) packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-accs-ruledef)#
```

**Syntax**

```
[ no ] pop3 any-match operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  **operator** must be one of the following:
  - !=: Does not equal
  - ==: Equals

- **condition**
  Specifies the condition to match.
  **condition** must be one of the following:
  - FALSE
  - TRUE

**Usage**

Use this command to define rule expressions to match all POP3 packets.

**Example**

The following command defines a rule expression to match all POP3 packets:

```
pop3 any-match = TRUE
```
pop3 command args

This command allows you to define rule expressions to match POP3 command arguments.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local] host_name(config-acd-ruledef) #

Syntax

[ no ] pop3 command args [ case-sensitive ] operator argument

no
If previously configured, deletes the specified rule expression from the current ruledef.

case-sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

operator
Specifies how to match.
operator must be one of the following:
- !: Does not equal
- !contains: Does not contain
- !ends-with: Does not end with
- !starts-with: Does not start with
- =: Equals
- contains: Contains
- ends-with: Ends with
- starts-with: Starts with

argument
Specifies the command argument to match.
argument must be an alphanumeric string of 1 through 40 characters, and may contain punctuation characters.
Usage
Use this command to define rule expressions to match POP3 command argument.

Example
The following command defines a rule expression to match POP3 command argument test:

```
pop3 command args = test
```
pop3 command id

This command allows you to define rule expressions to match POP3 command ID.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] pop3 command id operator command_id

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• <=: Lesser than or equals
• >=: Greater than or equals

command_id
Specifies the command ID to match.
command_id must be an integer from 1 through 12.

Usage
Use this command to define rule expressions to match a POP3 command ID.

Example
The following command defines a rule expression to match POP3 command ID 8:

    pop3 command id = 8
pop3 command name

This command allows you to define rule expressions to match command sent within a POP3 packet.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] pop3 command_name operator command_name

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:

- !=: Does not equal
- ==: Equals

command_name
Specifies the command name to match.
command_name must be one of the following:

- apop
- dele
- list
- noop
- pass
- quit
- retr
- reset
- stat
- top
- uidl
- user
Usage
Use this command to define rule expressions to match commands sent within POP3 packets.

Example
The following command defines a rule expression to match the `list` command sent in POP3 packets:

```
pop3 command name = list
```
pop3 mail-size

This command allows you to define rule expressions to match POP3 mail size.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local] host_name(config-acs-ruledef)#

Syntax

[ no ] pop3 mail-size { operator mail_size | { range | !range } range_from to range_to }

- no
  If previously configured, deletes the specified rule expression from the current ruledef.

- operator
  Specifies how to match.
  operator must be one of the following:
  • !=: Does not equal
  • <=: Lesser than or equals
  • =: Equals
  • >=: Greater than or equals

- { range | !range } range_from to range_to
  Enables or disables the range criteria.
  • range: Enables the range criteria.
  • !range: Disables the range criteria.

- range_from
  Specifies start of the range.
  range_from must be an integer from 1 through 4000000000.

- range_to
  Specifies the end range.
  range_to must be an integer from 1 through 4000000000, and must be greater than range_from.

- mail_size
  Specifies the mail size to match.
  mail_size must be an integer from 1 through 4000000000.
Usage
Use this command to define rule expressions to match POP3 mail size.

Example
The following command defines a rule expression to match POP3 mail size of 40000:

```
pop3 mail-size = 40000
```
**pop3 pdu-length**

This command allows you to define rule expressions to match the Protocol Data Unit (PDU) length of POP3 packets equal to the POP3 header plus POP3 payload.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Ruledef Configuration

```plaintext
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```plaintext
[ no ] pop3 pdu-length { operator pdu_length | { { range | !range } range_from to range_to } }
```

- **no**
  
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**

  Specifies how to match.

  * operator must be one of the following:
    
    - `!=`: Does not equal
    - `<=`: Lesser than or equals
    - `==`: Equals
    - `>=`: Greater than or equals

- **{ range | !range } range_from to range_to**

  Enables or disables the range criteria.

  - **range**: Enables the range criteria.
  - **!range**: Disables the range criteria.

  * **range_from**: Specifies the start of range as an integer from 0 through 65535.
  * **range_to**: Specifies the end range. range_to must be an integer from 0 through 65535, and must be greater than range_from.

- **pdu_length**

  Specifies the POP3 PDU length to match.

  * pdu_length must be an integer from 0 through 65535.
Usage
Use this command to define rule expressions to match POP3 PDU length (header + payload) in bytes.

Example
The following command defines a rule expression to match PDU length of 1000 bytes:

```
pop3 pdu-length = 1000
```
**pop3 pdu-type**

This command allows you to define rule expressions to match POP3 Protocol Data Unit (PDU) type.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

Active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] pop3 pdu-type operator pdu_type
```

- **no**
  
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  
  Specifies how to match.
  
  - !=: Does not equal
  - ==: Equals

- **pdu_type**
  
  Specifies the POP3 PDU type to match.
  
  - command-packet
  - data-packet
  - relay-packet

**Usage**

Use this command to define rule expressions to match POP3 PDU type.

**Example**

The following command defines a rule expression to match POP3 PDU type relay-packet:

```
pop3 pdu-type = relay-packet
```
**pop3 previous-state**

This command allows you to define rule expressions to match the previous state of POP3 sessions.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acis-ruledef)#
```

**Syntax**

```
[ no ] pop3 previous-state operator pop3_previous_state
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  
  `operator` must be one of the following:

  - `!=`: Does not equal
  - `==`: Equals

- **pop3_previous_state**
  Specifies the previous state to match.
  
  `pop3_previous_state` must be one of the following:

  - `connected`: Connected state
  - `data transaction`: Data transaction state
  - `init`: Initialized state
  - `reply-error`: Reply error state
  - `reply-ok`: Response ok state
  - `waiting-for-reply`: Waiting for reply state

**Usage**

Use this command to define rule expressions to match a POP3 previous state.

**Example**

The following command defines a rule expression to match user traffic for a POP3 previous state of `connected`:

```
pop3 previous-state = connected
```
pop3 reply args

This command allows you to define rule expressions to match specified arguments with POP3 reply.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] pop3 reply args [ case-sensitive ] operator argument
```

- **no**
  - If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  - Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  - Specifies how to match. `operator` must be one of the following:
    - `!=`: Does not equal
    - `!contains`: Does not contain
    - `!ends-with`: Does not end with
    - `!starts-with`: Does not start with
    - `=`: Equals
    - `contains`: Contains
    - `ends-with`: Ends with
    - `starts-with`: Starts with

- **argument**
  - Specifies the reply argument to match.
  - In 11.0 and earlier releases, `argument` must be an alphanumeric string of 1 through 512 characters, and may contain punctuation characters.
  - In 12.0 and later releases, `argument` must be an alphanumeric string of 1 through 127 characters, and may contain punctuation characters.
pop3 reply args

Usage
Use this command to define rule expressions to match specified arguments within a POP3 reply.

Example
The following command defines a rule expression to match the argument test with POP3 replies:

```
pop3 reply args = test
```
**pop3 reply id**

This command allows you to define rule expressions to match POP3 reply ID.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```plaintext
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```plaintext
[ no ] pop3 reply id operator reply_id
```

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>If previously configured, deletes the specified rule expression from the current ruledef.</td>
</tr>
<tr>
<td>operator</td>
<td>Specifies how to match.</td>
</tr>
<tr>
<td>reply_id</td>
<td>Specifies the POP3 reply ID to match.</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to define rule expressions to match POP3 reply ID.

**Example**

The following command defines a rule expression to match POP3 reply ID of 2:

```plaintext
pop3 reply id = 2
```
pop3 reply status

This command allows you to define rule expressions to match POP3 reply status.

Product
ACS

Privilege
Security Administrator, Administrator

</tr>
<tr>
<td>reply_status must be one of the following:</td>
</tr>
<tr>
<td>• +OK: Reply OK</td>
</tr>
<tr>
<td>• -ERR: Reply error</td>
</tr>
</tbody>
</table>

Usage
Use this command to define rule expressions to match POP3 reply status.

Example
The following command defines a rule expression to match POP3 reply status +OK:

    pop3 reply status = +OK
**pop3 session-length**

This command allows you to define rule expressions to match POP3 session-length.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] pop3 session-length { operator session_length | { range | !range } range_from to range_to }
```

---

**no**

If previously configured, deletes the specified rule expression from the current ruledef.

---

**operator**

Specifies how to match.

- `!`: Does not equal
- `<=`: Lesser than or equals
- `=`: Equals
- `>=`: Greater than or equals

---

**session_length**

Specifies the POP3 session length to match.

- `session_length` must be an integer from 1 through 4000000000.

---

```
{ range | !range } range_from to range_to
```

Enables or disables the range criteria for POP3 session length.

- `range`: Enables the range criteria for POP3 session length.
- `!range`: Disables the range criteria for POP3 session length.

- `range_from`: Specifies the start of range of POP3 session as an integer from 1 through 4000000000, but less than or equal to `range_to`.
- `range_to`: Specifies the end of range of POP3 session as an integer from 1 through 4000000000, but greater than or equal to `range_from`. 
Usage

Use this command to define rule expressions to match the total length of POP3 sessions.

Example

The following command defines a rule expression to match a POP3 session length of 40000:

```
pop3 session-length = 40000
```
**pop3 state**

This command allows you to define rule expressions to match the current state of POP3 sessions.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] pop3 state operator current_state
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `=`: Equals

- **current_state**
  Specifies the current state to match.
  `current_state` must be one of the following:
  - `close`
  - `connected`
  - `data-transaction`
  - `reply-error`
  - `reply-ok`
  - `waiting-for-reply`

**Usage**

Use this command to define rule expressions to match the current state of POP3 sessions.

**Example**

The following command defines a rule expression to match the POP3 current state `close`:

```
pop3 state = close
```
**pop3 user-name**

This command allows you to define rule expressions to match POP3 user name.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] pop3 user-name [ case-sensitive ] operator user_name
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  **operator** must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **user_name**
  Specifies the POP3 user name to match.
  **user_name** must be an alphanumeric string of 1 through 64 characters, and may contain punctuation characters and space.
Usage

Use this command to define rule expressions to match POP3 user name.

Example

The following command defines a rule expression to match POP3 user name `test`:

```
pop3 user-name = test
```
**pptp any-match**

This command allows you to define a rule expression to match all Point-to-Point Tunneling Protocol (PPTP) packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] pptp any-match operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `=`: Equals

- **condition**
  Specifies the condition to match.
  `condition` must be one of the following:
  - `FALSE`
  - `TRUE`

**Usage**
Use this command to specify a ruledef to analyze user traffic based on the PPTP any match status.

**Example**
The following command creates a PPTP ruledef for analyzing user traffic using a PPTP any match status of `FALSE`:

```
pptp any-match = FALSE
```
pptp ctrl-msg-type

This command allows you to define rule expressions to match control message type in PPTP packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] pptp ctrl-msg-type = message_type

no

If previously configured, deletes the specified rule expression from the current ruledef.

message_type

message_type must be one of the following:

• call-clear-request
• call-disconnect-notify
• echo-reply
• echo-request
• incoming-call-connected
• incoming-call-reply
• incoming-call-request
• outgoing-call-reply
• outgoing-call-request
• set-link-info
• start-control-connection-reply
• start-control-connection-request
• stop-control-connection-reply
• stop-control-connection-request
• wan-error-notify

Usage

Use this command to define rule expressions to match the control message type in PPTP packets.
Example

The following command specifies to match `echo-reply` message type:

```
pptp ctrl-msg-type = echo-reply
```
**pptp gre any-match**

This command allows you to define rule expressions to match all PPTP Generic Routing Encapsulation (GRE) packets.

**Product**

ACS

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] pptp gre any-match = condition
```

- **no**
  
  If previously configured, deletes the specified rule expression from the current ruledef.

- **condition**
  
  `condition` must be one of the following:
  
  - **FALSE**
  - **TRUE**

**Usage**

Use this command to define rule expressions to match all PPTP GRE packets.

**Example**

The following command defines a rule expression to match all PPTP GRE packets:

```
pptp gre any-match = TRUE
```
radius state

This command allows you to define rule expressions to match the current state of an RADIUS session.

Product
GGSN
PDSN
P-GW

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration
active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] radius state operator radius_state

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !: Does not equal
• =: Equals

radius_state
Specifies the RADIUS state to match.
radius_state must be one of the following:
• auth-req-rcvd: Analyzer received the Access-Request message from the client.
• auth-rsp-fail: Analyzer received the Access-reject message from the server.
• auth-rsp-success: Analyzer received the Access-Accept message from the server as a reply to Access-request.

Usage
Use this command to define rule expressions to match the current state of an RADIUS session.

Example
The following command defines a rule expression to match RADIUS current state close:

radius state = close
rtcp any-match

This command allows you to define rule expressions to match all Real-Time Transport Control Protocol (RTCP) packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] rtcp any-match operator condition

- **no**
  - If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  - Specifies how to match.
  - `operator` must be one of the following:
    - `!`: Does not equal
    - `=`: Equals

- **condition**
  - Specifies the condition to match.
  - `condition` must be one of the following:
    - `TRUE`: The rule matches any RTCP traffic.
    - `FALSE`: The rule does not match any RTCP traffic.

Usage
Use this command to define rule expressions to match all RTCP packets.

Example
The following command defines a rule expression to match all RTCP packets:

```
rtcp any-match = TRUE
```
rtcp jitter

This command allows you to define rule expressions to match the jitter parameter in RTCP packets.

**Product**  
ACS

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > ACS Configuration > Ruledef Configuration

```plaintext
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] rtcp jitter operator jitter
```

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>If previously configured, deletes the specified rule expression from the current ruledef.</td>
</tr>
<tr>
<td>operator</td>
<td>Specifies how to match. operator must be one of the following:</td>
</tr>
<tr>
<td>!=</td>
<td>Does not equal</td>
</tr>
<tr>
<td>&lt;=</td>
<td>Lesser than or equals</td>
</tr>
<tr>
<td>=</td>
<td>Equals</td>
</tr>
<tr>
<td>&gt;=</td>
<td>Greater than or equals</td>
</tr>
<tr>
<td>jitter</td>
<td>Specifies the RTCP inter-arrival jitter value (in milliseconds) to match. jitter must be an integer from 0 through 4294967295.</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to define rule expressions to match jitter parameter found in the RTCP sender report or receiver report packets.

**Example**

The following command matches packets for jitter greater than or equal to 1295 milliseconds:

```
rtcp jitter >= 1295
```
**rtcp parent-proto**

This command allows you to define rule expressions to match the parent protocol of the RTCP flow.

---

**Important:** This command is available only in 8.1 and 9.0 and later releases.

---

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] rtcp parent-proto operator parent_protocol
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  - **operator** must be one of the following:
    - `!=`: Does not equal
    - `==`: Equals

- **parent_protocol**
  Specifies the RTCP parent protocol to match.
  - **parent_protocol** must be one of the following:
    - `rtsp`: Real Time Streaming Protocol
    - `sip`: Session Initiation Protocol

---

**Usage**

Use this command to define rule expressions to match user traffic based on the parent protocol of the RTCP flow.

**Example**

The following command defines a rule expression to match user traffic based on SIP being the parent protocol of the RTCP flow:

```
rtcp parent-proto = sip
```
**rtcp pdu-length**

This command allows you to define rule expressions to match Protocol Data Unit (PDU) length of RTCP packets, (RTCP header + RTCP payload).

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] rtcp pdu-length operator pdu_length
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `<=`: Lesser than or equals
  - `=`: Equals
  - `>=`: Greater than or equals

- **pdu_length**
  Specifies the RTCP length (in bytes) to match.
  In 8.1 and later releases, `pdu_length` must be an integer from 1 through 65535.
  In 8.0, `pdu_length` must be an integer from 1 through 2000.

**Usage**

Use this command to define rule expressions to match RTCP PDU length (header + payload) in bytes.

**Example**

The following command defines a rule expression to match user traffic based on an RTCP PDU length of 10000 bytes:

```
rtcp pdu-length = 10000
```
**rtcp rtsp-id**

This command allows you to define rule expressions to match user traffic based on a Real-time Streaming Protocol (RTSP) ID associated with an RTCP flow.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[llocal]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] rtcp rtsp-id [ case-sensitive ] operator rtsp_id
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **rtsp_id**
  Specifies the value to match.
  `rtsp_id` must be an alphanumeric string of 1 through 32 characters.
rtcp rtsp-id

Usage
Use this command to define rule expressions to match an RTSP ID associated with an RTCP flow.

Example
The following command defines a rule expression to match user traffic containing RTSP message ID of test1:

      rtcp rtsp-id contains test1
**rtcp session-length**

This command allows you to define rule expressions to match the total length of RTCP sessions.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] rtcp session-length operator session_length
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.

  **operator** must be one of the following:
  - !=: Does not equal
  - <=: Lesser than or equals
  - =: Equals
  - >=: Greater than or equals

- **session_length**
  Specifies the RTCP total session length (in bytes) to match.
  In 8.1 and later releases, **session_length** must be an integer from 1 through 4000000000.
  In 8.0, **session_length** must be an integer from 1 through 40000000.

**Usage**

Use this command to define rule expressions to match RTCP total session length.

**Example**

The following command defines a rule expression to match user traffic for a total RTCP session length of 200000:

```
rtcp session-length = 200000
```
rtcp uri

This command allows you to define rule expressions to match URI associated with RTCP flows.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] rtcp uri [ case-sensitive ] operator uri
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  
  **operator** must be one of the following:
  
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **uri**
  Specifies the URI to match.
  
  **uri** must be an alphanumeric string of 1 through 127 characters and may include punctuation characters.

**Usage**

Use this command to define rule expressions to match URI associated with RTCP flow.
Example

The following command defines a rule expression to match user traffic for RTCP URI rtsp://www.example.org:

\[ \text{rtcp uri} = \text{rtsp://www.example.org} \]
rtp any-match

This command allows you to define rule expressions to match all Real-time Transport Protocol (RTP) packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] rtp any-match operator condition

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• ==: Equals

condition
Specifies the condition to match.
condition must be one of the following:
• FALSE
• TRUE

Usage
Use this command to define rule expressions to match all RTP packets.

Example
The following command defines a rule expression to match all RTP packets:

rtp any-match = TRUE
rtp parent,proto

This command allows you to define rule expressions to match the parent protocol of the RTP flow.

**Important:** This command is available only in 8.1 and in 9.0 and later releases.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```plaintext
active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```plaintext
[ no ] rtp parentproto operator parent_protocol
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  ```plaintext
  operator must be one of the following:
  • !=: Does not equal
  • ==: Equals
  ```

- **parent_protocol**
  Specifies the RTP parent protocol to match.
  ```plaintext
  parent_protocol must be one of the following:
  • rtsp: Real Time Streaming Protocol
  • sip: Session Initiation Protocol
  ```

**Usage**

Use this command to define rule expressions to match user traffic based on the parent protocol of the RTP flow.

**Example**

The following command defines a rule expression to match user traffic with parent protocol of the RTP flow being SIP:

```
rtp parentproto = sip
```
rtp pdu-length

This command allows you to define rule expressions to match PDU length of RTP packets, equal to the RTP header + RTP payload.

Product

ACS

Privilege

Security Administrator, Administrator

Mode

Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] rtp pdu-length operator pdu_length

no

If previously configured, deletes the specified rule expression from the current ruledef.

operator

Specifies how to match.

operator must be one of the following:

• !=: Does not equal
• <=: Lesser than or equals
• ==: Equals
• >=: Greater than or equals

pdu_length

Specifies the RTP PDU length (in bytes) to match.

In 8.1 and later releases, pdu_length must be an integer from 1 through 65535.

In 8.0, pdu_length must be an integer from 1 through 2000.

Usage

Use this command to define rule expressions to match PDU length (header + payload) of RTP packets in bytes.

Example

The following command defines a rule expression to match an RTP PDU length of 1000 bytes:

rtp pdu-length = 1000
rtp rtsp-id

This command allows you to define rule expressions to match RTSP ID associated with RTP flows.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

[local] host_name(config-acos-ruledef) #

**Syntax**

```plaintext
[ no ] rtp rtsp-id [ case-sensitive ] operator rtsp_id
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `==`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **rtsp_id**
  Specifies the RTSP ID to match.
  `rtsp_id` must be an alphanumeric string of 1 through 32 characters.

**Usage**

Use this command to define rule expressions to match RTSP ID associated with RTP flows.
Example

The following command defines a rule expression to match RTSP message ID of *test1*:

```
rtp rtsp-id contains test1
```
rtp session-length

This command allows you to define rule expressions to match the total length of RTP sessions.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] rtp session-length operator session_length

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match. 
operator must be one of the following:
  * !=: Does not equal
  * <=: Lesser than or equals
  * =: Equals
  * >=: Greater than or equals

session_length
Specifies the RTP total session length (in bytes) to match.
In 8.1 and later releases, session_length must be an integer from 1 through 4000000000.
In release 8.0, session_length must be an integer from 1 through 40000000.

Usage
Use this command to define rule expressions to match the RTP total session length. The session-length is calculated by adding together the “rtp pdu-length” values of all relevant packets.

Example

The following command defines a rule expression to match a total RTP session length of 200000:

rtp session-length = 200000
**rtp uri**

This command allows you to define rule expressions to match the media URI associated with RTP flows.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

*active-charging service service_name > ruledef ruledef_name*

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
(no ) rtp uri [ case-sensitive ] operator uri
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  *operator* must be one of the following:
  - !=: Does not equal
  - !contains: Does not contain
  - !ends-with: Does not end with
  - !starts-with: Does not start with
  - =: Equals
  - contains: Contains
  - ends-with: Ends with
  - starts-with: Starts with

- **uri**
  Specifies the RTP URI to match.
  *uri* must be an alphanumeric string of 1 through 127 characters. *uri* allows punctuation characters and excludes the "host" portion.
Usage
Use this command to define rule expressions to match media URI associated with RTP flow.

Example
The following command defines a rule expression to match the RTP URI string
rtsp://www.example.org:

\[ rtp \text{ uri } = \text{ rtsp://www.example.org } \]
rtsp any-match

This command allows you to define rule expressions to match all Real Time Streaming Protocol (RTSP) packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] rtsp any-match operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  * operator must be one of the following:
    - !=: Does not equal
    - ==: Equals

- **condition**
  Specifies the condition to match.
  * condition must be one of the following:
    - FALSE
    - TRUE

**Usage**
Use this command to define rule expressions to match all RTSP packets.

**Example**
The following command defines a rule expression to match all RTSP packets:

```
rtsp any-match = TRUE
```
**rtsp content length**

This command allows you to define rule expressions to match the content length field in RTSP header.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**

[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] rtsp content length operator content_length
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match. `operator` must be one of the following:
  - `!`: Does not equal
  - `<=`: Lesser than or equals
  - `=`: Equals
  - `>=`: Greater than or equals

- **content_length**
  Specifies the content length (in bytes) to match. `content_length` must be an integer from 0 through 65535.

**Usage**

Use this command to define rule expressions to match “content length” field in RTSP headers.

**Example**

The following command defines a rule expression to match content length of `10000` in RTSP headers:

```
rtsp content length = 10000
```
rtsp content type

This command allows you to define rule expressions to match the content type field in RTSP headers.

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] rtsp content type [ case-sensitive ] operator content_type

no
If previously configured, deletes the specified rule expression from the current ruledef.

case_sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

operator
Specifies how to match.
operator must be one of the following:

- !=: Does not equal
- !contains: Does not contain
- !ends-with: Does not end with
- !starts-with: Does not start with
- =: Equals
- contains: Contains
- ends-with: Ends with
- starts-with: Starts with

content_type
Specifies the content type to match.
content_type must be an alphanumeric string of 1 through 127 characters, and may contain punctuation characters.
**Usage**

Use this command to define rule expressions to match “content type” field in RTSP headers.

**Example**

The following command defines a rule expression to match RTSP content type `abc100`:

```
rtsp content type = abc100
```
rtsp date

This command allows you to define rule expressions to match the date field in the RTSP message headers.

**Product**

```

**Syntax**

```
[ no ] rtsp date [ case-sensitive ] operator date
```

- **no**
  
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  
  Specifies how to match. `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **date**
  
  Specifies the date in RTSP header to match. `date` must be an alphanumeric string of 1 through 127 characters, and may contain punctuation characters.

**Usage**

Use this command to define rule expressions to match the “date” field in the RTSP message headers.
Example

The following command defines a rule expression to match the date 12_04_2006 in RTSP message headers:

```
rtsp date = 12_04_2006
```
rtsp previous-state

This command allows you to define rule expressions to match the previous state of RTSP sessions.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] rtsp reply code operator reply_code
```

- **no**
  
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**

  Specifies how to match.

  - !=: Does not equal
  - <=: Lesser than or equals
  - ==: Equals
  - >=: Greater than or equals

- **reply_code**

  Specifies the RTSP reply code to match.

  `reply_code` must be an integer from 100 through 599.

**Usage**

Use this command to define rule expressions to match the return code in RTSP response.

**Example**

The following command defines a rule expression to match RTSP return code **302**:

```
rtsp reply code = 302
```
rtsp request method

This command allows you to define rule expressions to match the method in RTSP responses.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)\#

Syntax

[ no ] rtsp request method operator request_method

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
- !=: Does not equal
- ==: Equals

request_method
Specifies the RTSP request method to match.
request_method must be one of the following requests:
- announce
- describe
- get-parameter
- options
- pause
- play
- record
- redirect
- set-parameter
- setup
- teardown
Usage

Use this command to define rule expressions to match the method in RTSP responses.

Example

The following command defines a rule expression to match RTSP request method announce:

```bash
rtsp request method = announce
```
rtsp request packet

This command allows you to define rule expressions to match all RTSP request messages.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

[local] host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] rtsp request packet operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `==`: Equals

- **condition**
  Specifies the condition to match.
  `condition` must be one of the following:
  - `TRUE`: Is request
  - `FALSE`: Is response

**Usage**

Use this command to define rule expressions to match all RTSP request messages.

**Example**

The following command defines a rule expression to match all RTSP request messages:

```
rtsp request packet = TRUE
```
**rtsp rtp-seq**

This command allows you to define rule expressions to match the “seq” field in the RTP-Info header of RTSP responses.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

**Syntax**

\[
\text{[ no ] rtsp rtp-seq } \text{ operator sequence_number}
\]

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  \( \text{operator} \) must be one of the following:
  - \( \neq \): Does not equal
  - \( \leq \): Lesser than or equals
  - \( = \): Equals
  - \( \geq \): Greater than or equals

- **sequence_number**
  Specifies the sequence number in the RTSP RTP-Info field to match.
  \( \text{sequence_number} \) must be an alphanumeric string of 0 through 65535 characters in Normal Play Time (NPT) time format.

**Usage**
Use this command to define rule expressions to match user traffic matching the “seq” field in the RTP-Info header of RTSP response for a PLAY request.

**Example**
The following command defines a rule expression to match user traffic based on RTP-seq number \( npt-12:34:59 \):

\[
\text{rtsp rtp-seq } = \text{npt-12:34:59}
\]
**rtsp rtp-time**

This command allows you to define rule expressions to match the “time” field in RTP-Info header of RTSP responses.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```shell
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```shell
[ no ] rtsp rtp-time operator time
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `<=`: Lesser than or equals
  - `=`: Equals
  - `>=`: Greater than or equals

- **time**
  Specifies the time to match.
  `time` must be an alphanumeric string of 1 through 2147483647 characters in Normal Play Time (NPT) time format.

**Usage**

Use this command to define rule expressions to match the “time” field in the RTP-Info header of RTSP response for a PLAY request.

**Example**

The following command defines a rule expression to match RTP timestamp of `20120123T153600Z`:

```
rtsp rtp-time = 20120123T153600Z
```
rtsp rtp-uri

This command allows you to define rule expressions to match the URI field in the RTP-Info header of RTSP responses.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] rtsp rtp-uri [ case-sensitive ] operator uri

- no
  If previously configured, deletes the specified rule expression from the current ruledef.

- case-sensitive
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- operator
  Specifies how to match.
  operator must be one of the following:
  • !=: Does not equal
  • !contains: Does not contain
  • !ends-with: Does not end with
  • !starts-with: Does not start with
  • =: Equals
  • contains: Contains
  • ends-with: Ends with
  • starts-with: Starts with

- uri
  Specifies the value to match with the URI in RTP-Info header of the RTSP message.
  uri must be an alphanumeric string of 1 through 127 characters. uri allows punctuation characters and excludes the “host” portion.
rtsp rtp-uri

Usage
Use this command to define rule expressions to match the URI field in the RTP-Info header of the RTSP response for a PLAY request.

Example
The following command defines a rule expression to match user traffic based on RTP-URI string rtsp://www.foo.com in the RTP-info header of RTSP packet:

```
rtsp rtp-uri = rtsp://www.foo.com
```
rtsp session-id

This command allows you to define rule expressions to match the session ID in RTSP messages.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] rtsp session-id [ case-sensitive ] operator session_id

no
If previously configured, deletes the specified rule expression from the current ruledef.

case-sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

operator
Specifies how to match.
operator must be one of the following:
  • !=: Does not equal
  • !contains: Does not contain
  • !ends-with: Does not end with
  • !starts-with: Does not start with
  • ==: Equals
  • contains: Contains
  • ends-with: Ends with
  • starts-with: Starts with

session_id
Specifies the session ID to match.
session_id must be an alphanumerics string of 1 through 127 characters.

Usage

Use this command to define rule expressions to match the session ID in RTSP messages.
Example

The following command defines a rule expression to match the RTSP session ID 0123abc100:

```
rtsp session-id = 0123abc100
```
rtsp session-length

This command allows you to define rule expressions to match the total length of RTSP sessions.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acds-ruledef)#

Syntax

[ no ] rtsp session-length operator session_length

- no
  If previously configured, deletes the specified rule expression from the current ruledef.

- operator
  Specifies how to match.
  operator must be one of the following:
  - !=: Does not equal
  - <=: Lesser than or equals
  - =: Equals
  - >=: Greater than or equals

- session_length
  Specifies the RTSP session length (in bytes) to match.
  session_length must be an integer from 1 through 4000000.

Usage

Use this command to define rule expressions to match the total length of RTSP sessions. That is, the sum of the “rtsp pdu-length” values of all relevant packets.

Example

The following command defines a rule expression to match RTSP session length of 3000000 bytes:

rtsp session-length = 3000000
rtsp state

This command allows you to define rule expressions to match the current state of RTSP sessions.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

localhost@host_name(config-acs-ruledef)#

Syntax

\[
\text{[ no ] rtsp state \ operator current\_state}
\]

\text{no}

If previously configured, deletes the specified rule expression from the current ruledef.

\text{operator}

Specifies how to match.
\text{operator} must be one of the following:
- \text{!=: Does not equal}
- \text{=: Equals}

\text{current\_state}

Specifies the current state to match.
\text{current\_state} must be one of the following:
- \text{end}
- \text{init}
- \text{open}
- \text{play}
- \text{ready}
- \text{record}

Usage
Use this command to define rule expressions to match the current state of RTSP sessions.

Example
The following command defines a rule expression to match RTSP current state \text{init}:

\text{rtsp state = init}
rtsp uri

This command allows you to define rule expressions to match URI in RTSP request message.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] rtsp uri [ case-sensitive ] operator uri

no
If previously configured, deletes the specified rule expression from the current ruledef.

case-sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

operator
Specifies how to match.
operator must be one of the following:

• !=: Does not equal
• !contains: Does not contain
• !ends-with: Does not end with
• !starts-with: Does not start with
• ==: Equals
• contains: Contains
• ends-with: Ends with
• regex: Regular expression
• starts-with: Starts with

uri
Specifies the URI to match.
uri must be an alphanumeric string of 1 through 127 characters. uri allows punctuation characters and excludes the “host” portion.
Usage
Use this command to define rule expressions to match URI in RTSP request. The following table lists the special characters that you can use in regex rule expressions. For more information on regex support, refer to the Enhanced Charging Service Administration Guide.

<table>
<thead>
<tr>
<th>Regex Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Zero or more characters</td>
</tr>
<tr>
<td>+</td>
<td>Zero or more repeated instances of the token preceding the +</td>
</tr>
<tr>
<td>?</td>
<td>Match zero or one character</td>
</tr>
</tbody>
</table>

**Important:** The CLI does not support configuring “?” directly, you must instead use “\077”.

For example, if you want to match the string “xyz<any one character>pqr”, you must configure it as:

```
http host regex "xyz\077pqr"
```

In another example, if you want to exactly match the string “url?resource=abc”, you must configure it as:

```
http uri regex "url\077resource=abc"
```

Where, the first “\” (backslash) is for the escaping of “?” and then “\077” for specifying “?” to the CLI.

<table>
<thead>
<tr>
<th>Character</th>
<th>Escaped character</th>
</tr>
</thead>
<tbody>
<tr>
<td>?</td>
<td>Match the question mark (&lt;ctrl-v&gt;) character</td>
</tr>
<tr>
<td>+</td>
<td>Match the plus character</td>
</tr>
<tr>
<td>*</td>
<td>Match the asterisk character</td>
</tr>
<tr>
<td>\a</td>
<td>Match the Alert (ASCII 7) character</td>
</tr>
<tr>
<td>\b</td>
<td>Match the Backspace (ASCII 8) character</td>
</tr>
<tr>
<td>\f</td>
<td>Match the Form-feed (ASCII 12) character</td>
</tr>
<tr>
<td>\n</td>
<td>Match the New line (ASCII 10) character</td>
</tr>
<tr>
<td>\r</td>
<td>Match the Carriage return (ASCII 13) character</td>
</tr>
<tr>
<td>\t</td>
<td>Match the Tab (ASCII 9) character</td>
</tr>
<tr>
<td>\v</td>
<td>Match the Vertical tab (ASCII 11) character</td>
</tr>
<tr>
<td>\0</td>
<td>Match the Null (ASCII 0) character</td>
</tr>
<tr>
<td>\</td>
<td>Match the backslash character</td>
</tr>
<tr>
<td>[0-9]</td>
<td>Match any single character from the range</td>
</tr>
<tr>
<td>^</td>
<td>Do not match any in the range. All other characters represent themselves.</td>
</tr>
<tr>
<td>\x##</td>
<td>Any ASCII character as specified in two-digit hex notation. For example, \x5A yields a “Z”.</td>
</tr>
</tbody>
</table>
### ACS Ruledef Configuration Mode Commands

**rtsp uri**

<table>
<thead>
<tr>
<th>Regex Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>specify OR regular expression operator</td>
</tr>
</tbody>
</table>

**Important:** When using the regex operator “|” in regex expressions, always wrap the string in double quotes.

For example, if you want to match the string "pqr" OR "xyz", you must configure it as:

```
http host regex "pqr|xyz".
```

### Example

The following command defines a rule expression to match user traffic based on RTSP URI

```
rtsp://www.example.com:554/twister/audiotrack:
```

```
rtsp uri = rtsp://www.example.com:554/twister/audiotrack
```

The following command defines a regex rule expression to match either of the following or similar values in the RTSP URI string: rtsp://pvs29p.cvf.fr:554/t1/live/Oui17, rtsp://pvs00p.cvf.fr:554/t1/live/Nrj12, rtsp://pvs90p.cvf.fr:554/t1/live/France24_fr.

```
rtsp uri regex "rtsp://pvs([0-9][0-9])p.cvf.fr:554/t1/live/(Gulli|Tf1|Tmc|Nrj12|Star|France24_fr|Oui17)*"
```
rtsp uri sub-part

This command allows you to define rule expressions to match user traffic by parsing sub-parts of the URI in an RTSP request message.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax
[ no ] rtsp uri sub-part { { absolute-path | host | query } [ case-sensitive ] operator string | port { port_operator port_value | { range | !range } range_from to range_to } }

no
If previously configured, deletes the specified rule expression from the current ruledef.

absolute-path
Specifies the absolute path matching criteria to RTSP URI in an RTSP request message.

host
Specifies the host name matching criteria to RTSP URI in an RTSP request message.

query
Specifies the query string matching criteria to RTSP URI in an RTSP request message.

case-sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

operator
Specifies how to match.
operator must be one of the following:
  • !=: Does not equal
  • !contains: Does not contain
  • !ends-with: Does not end with
  • !starts-with: Does not start with
  • =: Equals
contains: Contains
ends-with: Ends with
starts-with: Starts with

string
Specifies the absolute path/host name or query string to match with the URI in RTSP header. 
string must be an alphanumeric string of 1 through 127 characters. string allows punctuation characters and excludes the “host” portion.

port
Specifies the port related matching for RTSP URI in an RTSP request message.

port_operator
Specifies how to match. 
operator must be one of the following:
• !=: Does not equal
• <: Lesser than or equals
• <=: Equals
• >=: Greater than or equals

port_value
Specifies the RTSP port number to match with port rule in the RTSP flow as an integer from 0 through 65535.

{ range | !range } range_from to range_to
Enables or disables the range criteria for RTSP flow ports.
• range: Enables the range criteria for RTSP flow ports.
• !range: Disables the range criteria for RTSP flow ports.
• range_from: Specifies the start of range of RTSP flow ports as an integer from 0 through 65535, but less than or equal to range_to.
• range_to: Specifies the end of range of RTSP flow ports as an integer from 0 through 65535, but more than or equal to range_from.

Usage
Use this command to define rule expressions to match URI sub parts like host, absolute path, port, and query in RTSP request messages.

Example
The following command defines a URI sub part rule expression to analyze user traffic based on an RTSP URI port number between 1023 and 1068:

rtsp uri sub-part port range 1023 to 1068
**rtsp user-agent**

This command allows you to define rule expressions to match the user-agent field in RTSP headers.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] rtsp user-agent [ case-sensitive ] operator user_agent
```

- **no**
  - If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  - Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  - Specifies how to match.
    - `operator` must be one of the following:
      - `!=`: Does not equal
      - `!contains`: Does not contain
      - `!ends-with`: Does not end with
      - `!starts-with`: Does not start with
      - `==`: Equals
      - `contains`: Contains
      - `ends-with`: Ends with
      - `starts-with`: Starts with

- **user_agent**
  - Specifies the user agent to match.
  - `user_agent` must be an alphanumeric string of 1 through 127 characters.

**Usage**

Use this command to define rule expressions to match the “user-agent” field in RTSP header.
Example

The following command defines a rule expression to match test in “user-agent” field of RTSP header:

```
rtsp user-agent = test
```
**rtsp-stream any-match**

This command allows you to define rule expressions to match all user traffic of type RTSP, RTCP, and RTP to achieve an unified charging for RTSP correlated flows.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```plaintext
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```plaintext
[ no ] rtsp-stream any-match operator condition
```

- **no**
  - If previously configured, deletes the rtsp-stream any match rule definition.

- **operator**
  - Specifies how to logically match the information in the analyzed field.
  - **operator** must be one of the following:
    - `!=`: Does not equal
    - `=`: Equals

- **condition**
  - Specifies the condition to match.
  - **condition** must be one of the following:
    - `FALSE`
    - `TRUE`

**Usage**
Use this command to specify a rule definition to analyze all RTSP, RTCP, and RTP traffic.

**Example**
The following command defines a rule expression to match all RTSP, RTCP, and RTP user traffic:

```plaintext
rtsp-stream any-match = TRUE
```
rtsp-stream first-setup-url

This command allows you to define rule expressions to match user traffic of type RTSP, RTCP, and RTP on the first setup URL of the parent RTSP flow to achieve an unified charging for RTSP correlated flows.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

- **no**
  If previously configured, deletes the rtsp-stream any match rule definition.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to logically match the information in the analyzed field.

  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: contains
  - `ends-with`: Ends with
  - `regex`: Regular expression
  - `starts-with`: Starts with

- **url**
  Specifies the URL to match.

  `url` must be an alphanumeric string of 1 through 127 characters.
Usage

Use this command to specify a rule definition to analyze RTSP, RTCP, and RTP traffic based on the first setup URL of the parent RTSP flow.

The following table lists the special characters that you can use in regex rule expressions. For more information on regex support, refer to the Enhanced Charging Service Administration Guide.

<table>
<thead>
<tr>
<th>Regex Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Zero or more characters</td>
</tr>
<tr>
<td>+</td>
<td>Zero or more repeated instances of the token preceding the +</td>
</tr>
<tr>
<td>?</td>
<td>Match zero or one character</td>
</tr>
</tbody>
</table>

**Important**: The CLI does not support configuring “?” directly, you must instead use “\077”.

For example, if you want to match the string “xyz<any one character>pqr”, you must configure it as: `http host regex "xyz\077pqr"`

In another example, if you want to exactly match the string “url?resource=abc”, you must configure it as: `http uri regex "url\\077resource=abc"`

Where, the first “\” (backslash) is for the escaping of “?”, and then “\077” for specifying “?” to the CLI.

<table>
<thead>
<tr>
<th>\ character</th>
<th>Escaped character</th>
</tr>
</thead>
<tbody>
<tr>
<td>?</td>
<td>Match the question mark (&lt;ctrl-v&gt;?) character</td>
</tr>
<tr>
<td>+</td>
<td>Match the plus character</td>
</tr>
<tr>
<td>*</td>
<td>Match the asterisk character</td>
</tr>
<tr>
<td>\a</td>
<td>Match the Alert (ASCII 7) character</td>
</tr>
<tr>
<td>\b</td>
<td>Match the Backspace (ASCII 8) character</td>
</tr>
<tr>
<td>\f</td>
<td>Match the Form-feed (ASCII 12) character</td>
</tr>
<tr>
<td>\n</td>
<td>Match the New line (ASCII 10) character</td>
</tr>
<tr>
<td>\r</td>
<td>Match the Carriage return (ASCII 13) character</td>
</tr>
<tr>
<td>\t</td>
<td>Match the Tab (ASCII 9) character</td>
</tr>
<tr>
<td>\v</td>
<td>Match the Vertical tab (ASCII 11) character</td>
</tr>
<tr>
<td>\0</td>
<td>Match the Null (ASCII 0) character</td>
</tr>
<tr>
<td>\</td>
<td>Match the backslash character</td>
</tr>
</tbody>
</table>

Bracketed range \[0-9\] Match any single character from the range

A leading ^ in a range Do not match any in the range. All other characters represent themselves.

\x## Any ASCII character as specified in two-digit hex notation. For example, \x5A yields a “Z”.

---

**Table 11. Special Characters Supported in Regex Rule Expressions**
ACS Ruledef Configuration Mode Commands

rtsp-stream first-setup-url

<table>
<thead>
<tr>
<th>Regex Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Specify OR regular expression operator</td>
</tr>
</tbody>
</table>

**Important:** When using the regex operator “|” in regex expressions, always wrap the string in double quotes.

For example, if you want to match the string "pqr" OR “xyz”, you must configure it as:

```
http host regex "pqr|xyz".
```

**Example**

The following command defines a rule expression to match all RTSP, RTCP, and RTP traffic when the parent RTSP’s first setup URL contains `cisco.com`:

```
rtsp-stream first-setup-url contains cisco.com
```

The following command defines a rule expression to match all RTSP, RTCP, and RTP traffic when the parent RTSP’s first setup URL matches the given regular expression: `rtsp://tvs100.google.fr/t1/M6`

```
rtsp-stream first-setup-url regex rtsp://tvs(a|l|b)[0-9][0-9].google.(fr|:554)/t1/(M6|W9_)*
```
rule-application

This command allows you to specify the purpose of a ruledef, such as for charging, post-processing, routing, and so on.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

Syntax

rule-application { charging | post-processing | routing | tpo }

no rule-application

Syntax

no
Disables the rule application configuration.

charging
Specifies that the current ruledef is for charging purposes.
Up to 2,048 rule definitions can be defined for the charging application in an Active Charging Service.
Default: Enabled

Important: The post-processing keyword is available only in 8.3 and later releases.

post-processing

Important: The Traffic Performance Optimization (TPO) in-line service is not supported in this release.

Important: The post-processing keyword is available only in 8.3 and later releases.

Important: The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
Usage

Use this command to specify the rule application for a rule definition. If, when configuring a ruledef, the rule-application is not specified, by default the system configures the ruledef as a charging ruledef.

Example

The following command configures the rule application “charging” to the current rule definition:

```plaintext
rule-application charging
```
sdp any-match

This command allows you to define rule expressions to match all packets that contain Session Description Protocol (SDP) descriptions.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] sdp any-match operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `==`: Equals

- **condition**
  Specifies the condition to match.
  `condition` must be one of the following:
  - `FALSE`
  - `TRUE`

**Usage**

Use this command to define rule expressions to match all packets containing SDP descriptions.

**Example**

The following command defines a rule expression to match all packets containing SDP descriptions:

```
sdp any-match = TRUE
```
sdp connection-ip-address

This command allows you to define rule expressions to match the IP address in the connection field of SDP descriptions.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

Syntax
[

no

] sdp connection-ip-address operator ipv4_address

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• ==: Equals

ipv4_address
Specifies the IP address to match.
ipv4_address must be in IPv4 dotted-decimal notation.

Usage
Use this command to define rule expressions to match IP address in the connection field of SDP descriptions.

Example
The following command defines a rule expression to match the IP address 10.1.1.1 in the connection field of SDP descriptions:

sdp connection-ip-address = 10.1.1.1
sdp media-audio-port

This command allows you to define rule expressions to match media audio ports specified in the media sections of SDP descriptions.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] sdp media-audio-port operator port

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:

- $!$: Does not equal
- $=$: Equals

port
Specifies the port number to match.
port must be an integer from 0 through 65535.

Usage
Use this command to define rule expressions to match media audio ports specified in the media sections of SDP descriptions.

Example
The following command defines a rule expression to match media audio port 100 in the media sections of SDP descriptions:

    sdp media-audio-port = 100
sdp media-video-port

This command allows you to define rule expressions to match media video ports specified in the media sections of SDP descriptions.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] sdp media-video-port operator port

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - !=: Does not equal
  - ==: Equals

- **port**
  Specifies the port number to match.
  `port` must be an integer from 0 through 65535.

Usage

Use this command to define rule expressions to match media video ports specified in the media sections of SDP descriptions.

Example

The following command defines a rule expression to match media video port 100 in the media sections of SDP descriptions:

```
    sdp media-video-port = 100
```
sdp uplink

This command allows you to define rule expressions to match SDP descriptions in the uplink (subscriber to network) direction.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] sdp uplink operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

  **operator**
  Specifies how to match.

  **condition**
  Specifies the condition to match.

**Usage**

Use this command to define rule expressions to match SDP descriptions in uplink direction.

**Example**

The following command defines a rule expression to match all SDP descriptions in the uplink direction:

```
sdp uplink = TRUE
```
secure-http any-match

This command allows you to define rule expressions to match all Secure HTTP (HTTPS) packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] secure-http any-match operator condition

---

no
If previously configured, deletes the specified rule expression from the current ruledef.

---

operator
Specifies how to match.
operator must be one of the following:
- !=: Does not equal
- ==: Equals

---

condition
Specifies the condition to match.
condition must be one of the following:
- FALSE
- TRUE

---

Usage
Use this command to define rule expressions to match all Secure HTTP packets.

Example
The following command defines a rule expression to match all HTTPS packets:

    secure-http any-match = TRUE
secure-http uplink

This command allows you to define rule expressions to match uplink (subscriber to network) HTTPS packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] secure-http uplink operator condition

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
- !=: Does not equal
- ==: Equals

condition
Specifies the condition to match.
condition must be one of the following:
- FALSE: Is not uplink
- TRUE: Is uplink

Usage
Use this command to define rule expressions to match uplink HTTPS packets.

Example
The following command defines a rule expression to match all uplink HTTPS packets:

secure-http uplink = TRUE
sips any-match

This command allows you to define rule expressions to match all Session Initiation Protocol (SIP) packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] sip any-match operator condition

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• ==: Equals

condition
Specifies the condition to match.
condition must be one of the following:
• FALSE
• TRUE

Usage
Use this command to define rule expressions to match all SIP packets.

Example
The following command defines a rule expression to match all SIP packets:

sips any-match = TRUE
**sip call-id**

This command allows you to define rule expressions to match the Call ID in SIP messages.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

**Syntax**

```
[ no ] sip call-id [ case-sensitive ] operator call_id
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **call-id**
  Specifies the call ID to match.
  `call-id` must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
Usage
Use this command to define rule expressions to match the call ID in SIP messages.

Example
The following command defines a rule expression to match the call ID `test` in SIP messages:

```
sip call-id = test
```
sip content length

This command allows you to define rule expressions to match the content-length field in SIP headers.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] sip content length operator content_length

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• <=: Lesser than or equals
• =: Equals
• >=: Greater than or equals

content_length
Specifies the SIP content length to match.
content_length must be an integer from 0 through 65535.

Usage
Use this command to define rule expressions to match the content-length field in SIP headers.

Example
The following command defines a rule expression to match the content length 10000 in SIP headers:

sip content length = 10000
**sip content type**

This command allows you to define rule expressions to match the content type field in SIP headers.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```plaintext
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```plaintext
[ no ] sip content type [ case-sensitive ] operator content_type
```

- **no**
  - If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  - Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  - Specifies how to match. `operator` must be one of the following:
    - `!=`: Does not equal
    - `!contains`: Does not contain
    - `!ends-with`: Does not end with
    - `!starts-with`: Does not start with
    - `=`: Equals
    - `contains`: Contains
    - `ends-with`: Ends with
    - `starts-with`: Starts with

- **content_type**
  - Specifies the content type to match. `content_type` must be an alphanumeric string of 1 through 127 characters.

**Usage**

Use this command to define rule expressions to match the content type field in SIP headers.
Example

The following command defines a rule expression to match content type `download_string` in SIP headers:

```
sip content type = download_string
```
**sip from**

This command allows you to define rule expressions to match the from field in SIP messages.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```plaintext
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] sip from [ case-sensitive ] operator string
```

- **no**

  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**

  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**

  Specifies how to match.

  The `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **string**

  Specifies the value to match.

  The `string` must be an alphanumeric string of 1 through 127 characters, and may contain punctuation characters.

**Usage**

Use this command to define rule expressions to match the “from” field in SIP messages.
Example

The following command defines a rule expression to match `test1` in the “from” field in SIP messages:

```
sip from contains test1
```
**sip previous-state**

This command allows you to define rule expressions to match previous state of SIP sessions.

<table>
<thead>
<tr>
<th>Product</th>

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] sip previous-state operator sip_previous_state
```

- **no**
  - If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  - Specifies how to match.
  - **operator** must be one of the following:
    - !=: Does not equal
    - ==: Equals

- **sip_previous_state**
  - Specifies the previous state to match.
  - **sip_previous_state** must be one of the following:
    - init
    - provisional-response
    - request-sent
    - response-fail
    - response-ok

**Usage**

Use this command to define rule expressions to match a previous state of SIP sessions.

**Example**

The following command defines a rule expression to match user traffic based on the SIP previous state of request-sent:

```
sip previous-state = request-sent
```

**sip reply code**

This command allows you to define rule expressions to match the reply code in SIP responses.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] sip reply code operator reply_code
```

- **no**  
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**  
  Specifies how to match.  
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `<=`: Lesser than or equals
  - `==`: Equals
  - `>=`: Greater than or equals

- **reply_code**  
  Specifies the SIP reply code to match.  
  `reply_code` must be an integer from 100 through 699.

**Usage**
Use this command to define rule expressions to match the reply code in SIP responses.

**Example**

The following command defines a rule expression to match `180` in the reply code in SIP responses:

```
sip reply code = 180
```
sip request method

This command allows you to define rule expressions to match the method in SIP requests.

**Product**  
ACS

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > ACS Configuration > Ruledef Configuration

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] sip request method operator method
```

- **no**  
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**  
  Specifies how to match.  
  `operator` must be one of the following:
  - `!=`: Does not equal  
  - `==`: Equals

- **method**  
  Specifies the SIP method to match.  
  `method` must be one of the following:
  - `ack`  
  - `bye`  
  - `cancel`  
  - `invite`  
  - `options`  
  - `register`

**Usage**

Use this command to define rule expressions to match the method in SIP requests.

**Example**

The following command defines a rule expression to match the method `bye` in SIP request messages:

```
sip request method = bye
```
**sip request packet**

This command allows you to define rule expressions to match all SIP request packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] sip request packet operator condition
```

---

**no**

If previously configured, deletes the specified rule expression from the current ruledef.

---

**operator**

Specifies how to match.

- **operator** must be one of the following:
  - **=**: Equals
  - **!=**: Does not equal

---

**condition**

Specifies the condition to match.

- **condition** must be one of the following:
  - **FALSE**: Is a response
  - **TRUE**: Is a request

---

**Usage**

Use this command to define rule expressions to match all SIP request packets.

**Example**

The following command defines a rule expression to match all SIP request packets:

```
sip request packet = TRUE
```
**sip state**

This command allows you to define rule expressions to match current state of the SIP session.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-acs-ruledef) #
```

**Syntax**

```
[ no ] sip state operator current_state
```

- **no**
  - If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  - Specifies how to match.
  - *operator* must be one of the following:
    - !=: Does not equal
    - ==: Equals

- **current_state**
  - Specifies the current state to match.
  - *current_state* must be one of the following:
    - ack-received
    - provisional-response
    - request-sent
    - response-fail
    - response-ok

**Usage**
Use this command to define rule expressions to match the current SIP session.

**Example**
The following command defines a rule expression to match user traffic based on SIP current state request-sent:

```
sip state = request-sent
```
sip to

This command allows you to define rule expressions to match the “to” field in SIP messages.

**Product**

ACS

**Privilege**

Security Administrator, Administrator

[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] sip to [ case-sensitive ] operator to_address
```

- **no**
  - If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  - Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  - Specifies how to match.
  - `operator` must be one of the following:
    - `!=`: Does not equal
    - `!contains`: Does not contain
    - `!ends-with`: Does not end with
    - `!starts-with`: Does not start with
    - `=`: Equals
    - `contains`: Contains
    - `ends-with`: Ends with
    - `starts-with`: Starts with

- **to_address**
  - Specifies the “to” address/name to match.
  - `to_address` must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
Usage
Use this command to define rule expressions to match the “to” field in SIP messages.

Example
The following command defines a rule expression to match test1 in the “to” field of SIP messages:

```
sip to contains test1
```
sip uri

This command allows you to define rule expressions to match the URI in SIP messages.

Product

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] sip uri [ sub-part { headers | host | parameters | port | userinfo } ] [ case-sensitive ] operator uri

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
</table>
| If previously configured, deletes the specified rule expression from the current ruledef.

| sub-part { headers | host | parameters | port | userinfo } |
|---|
| This is an optional keyword that defines what sub-part of a SIP URI to check.  
  • headers: Apply the rule to SIP URI header field.  
  • host: Apply the rule the SIP URI host field.  
  • parameters: Apply the rule to the SIP URI parameters field.  
  • port: Apply the rule to the SIP URI port field.  
  • userinfo: Apply the rule to the SIP URI userinfo field.

<table>
<thead>
<tr>
<th>case-sensitive</th>
</tr>
</thead>
</table>
| Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

<table>
<thead>
<tr>
<th>operator</th>
</tr>
</thead>
</table>
| Specifies how to match.  
 operator must be one of the following:  
  • !=: Does not equal  
  • !contains: Does not contain  
  • !ends-with: Does not end with  
  • !starts-with: Does not start with  
  • =: Equals  
  • contains: Contains
• **ends-with**: Ends with
• **starts-with**: Starts with

The string for sub-part keyword **port** must be an integer and requires different operators. Use the following operators with the **port** keyword:

- ![]: Does not equal
- <=: Is less than
- =: Equals
- >=: Is greater than

**uri**

Specifies the SIP URI to match. **uri** must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters. The string for sub-part keyword **port** must be an integer from 0 through 65535.

**Usage**

Use this command to define rule expressions to match the URI in SIP messages.

**Example**

The following command defines a rule expression to match the URI string `sip:10.1.1.1:5060` in SIP messages:

```
sip uri = sip:10.1.1.1:5060
```

The following command defines a rule expression to match the URI string `sip:nnnn@host:5060;user=phone` in SIP messages:

```
sip uri = sip:nnnn@host:5060;user=phone
```
smtp any-match

This command allows you to define rule expressions to match all Simple Mail Transfer Protocol (SMTP) packets.

Product

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] smtp any-match operator condition

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
  • !=: Does not equal
  • ==: Equals

condition
Specifies the condition to match.
condition must be one of the following:
  • FALSE
  • TRUE

Usage
Use this command to define rule expressions to match all SMTP packets.

Example
The following command defines a rule expression to match all SMTP packets:

smtp any-match = TRUE
smtp command arguments

This command allows you to define rule expressions to match SMTP command arguments.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

```

**Syntax**

```
[ no ] smtp command arguments [ case-sensitive ] operator argument
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match. `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **argument**
  Specifies the command argument to match. `argument` must be an alphanumeric string of 1 through 63 characters and may contain punctuation characters.
smtp command arguments

Usage
Use this command to define rule expressions to match SMTP command arguments.

Example
The following command defines a rule expression to match SMTP command argument test:

```
smtp command arguments = test
```
smtp command id

This command allows you to define rule expressions to match SMTP command IDs.

**Product**

```

**Syntax**

```
[ no ] smtp command id operator command_id
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  - `!=`: Does not equal
  - `<=`: Lesser than or equals
  - `==`: Equals
  - `>=`: Greater than or equals

- **command_id**
  Specifies the command argument to match.
  - `command_id` must be an integer from 0 through 10.

**Usage**

Use this command to define rule expressions to match SMTP command IDs.

**Example**
The following command defines a rule expression to match SMTP command ID 8:

```
smtp command id = 8
```
smtp command name

This command allows you to define rule expressions to match commands sent in SMTP packets.

Syntax

[ no ] smtp command name operator command_name

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• ==: Equals

cmd_name
Specifies the command name to match.
cmd_name must be one of the following:
• bdat
• data
• ehlo
• expn
• helo
• mail-from
• noop
• quit
• rcpt-to
• rset
• vrfy
ACS Ruledef Configuration Mode Commands

Usage
Use this command to define rule expressions to match commands sent in SMTP packets.

Example
The following command defines a rule expression to match `data` command in SMTP packets:

`smtp command name = data`
smtp mail-size

This command allows you to define rule expressions to match the size of mail sent by a SMTP client.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acis-ruledef)#
```

**Syntax**

```
[ no ] smtp mail-size { operator mail_size | { range | !range } range_from to range_to }
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  - `!=`: Does not equal
  - `<=`: Lesser than or equals
  - `==`: Equals
  - `>=`: Greater than or equals

- **mail_size**
  Specifies the mail size (in bytes) to match.
  - `mail_size` must be an integer from 1 through 40000000.

- `{ range | !range } range_from to range_to`
  Enables or disables the range criteria.
  - `range`: Enables the range criteria.
  - `!range`: Disables the range criteria.
  - `range_from`: Specifies the start of range as an integer from 1 through 40000000.
  - `range_to`: Specifies the end range. `range_to` must be an integer from 1 through 40000000, and must be greater than `range_from`. 
Usage

Use this command to define rule expressions to match the size of mail sent by an SMTP client.

Example

The following command defines a rule expression to match mail size of 40000 bytes:

```
smtp mail-size = 40000
```
smtp pdu-length

This command allows you to define rule expressions to match the Protocol Data Unit (PDU) length of SMTP packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

</tbody>
</table>

<table>
<thead>
<tr>
<th>pdu_length</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the SMTP PDU length (in bytes) to match.</td>
</tr>
<tr>
<td><code>pdu_length</code> must be an integer from 1 through 65535.</td>
</tr>
</tbody>
</table>

| { range | !range } range_from to range_to |
|---|
| Enables or disables the range criteria. |
| • `range`: Enables the range criteria. |
| • `!range`: Disables the range criteria. |
| • `range_from`: Specifies the start of range as an integer from 1 through 65535. |
| • `range_to`: Specifies the end range. `range_to` must be an integer from 1 through 65535, and must be greater than `range_from`. |
Usage
Use this command to define rule expressions to match PDU length of SMTP packets, that is headers + payload.

Example
The following command defines a rule expression to match a PDU length of 1600 bytes:

```
smtp pdu-length = 1600
```
smtp previous-state

This command allows you to define rule expressions to match previous state of SMTP command sessions.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] smtp previous-state operator smtp_previous_state

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
  • !=: Does not equal
  • ==: Equals

smtp_previous_state
Specifies the previous state to match.
smtp_previous_state must be one of the following:
  • close: Closed state
  • init: Initialized state
  • response-error: Reply error state
  • response-ok: Response ok state
  • waiting-for-response: Waiting for response state

Usage
Use this command to define rule expressions to match a previous state of SMTP command sessions.

Example
The following command defines a rule expression to match user traffic based on SMTP previous state close:

smtp previous-state = close
smtp recipient

This command allows you to define rule expressions to match the recipient e-mail ID in the current SMTP transaction.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] smtp recipient [ case-sensitive ] operator argument

---

no

If previously configured, deletes the specified rule expression from the current ruledef.

---

case-sensitive

Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

---

operator

Specifies how to match.

operator must be one of the following:

• !=: Does not equal
• !contains: Does not contain
• !ends-with: Does not end with
• !starts-with: Does not start with
• ==: Equals
• contains: Contains
• ends-with: Ends with
• starts-with: Starts with

---

argument

Specifies the response argument to match.

argument must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
Usage

Use this command to define rule expressions to match the recipient e-mail ID in the current SMTP transaction.

Example

The following command defines a rule expression to match recipient e-mail ID containing test in the current SMTP transaction:

```
smtp recipient contains test
```
**smtp reply arguments**

This command allows you to define rule expressions to match the arguments within SMTP responses.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] smtp reply arguments [ case-sensitive ] operator argument
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  ```
  operator must be one of the following:
  - !=: Does not equal
  - !contains: Does not contain
  - !ends-with: Does not end with
  - !starts-with: Does not start with
  - =: Equals
  - contains: Contains
  - ends-with: Ends with
  - starts-with: Starts with
  ```

- **argument**
  Specifies the reply argument to match.
  ```
  argument must be an alphanumeric string of 1 through 63 characters and may contain punctuation characters.
  ```
Usage

Use this command to define rule expressions to match the arguments with SMTP response.

Example

The following command defines a rule expression to match reply argument \texttt{forward-path} in SMTP response:

\begin{verbatim}
smtp reply arguments = forward-path
\end{verbatim}
smtp reply id

This command allows you to define rule expressions to match reply ID assigned to SMTP responses.

**Product**

```

**Syntax**

```
[ no ] smtp reply id operator reply_id
```

---

**no**
If previously configured, deletes the specified rule expression from the current ruledef.

---

**operator**
Specifies how to match.

* operator must be one of the following:
  * `!=`: Does not equal
  * `==`: Equals

---

**reply_id**
Specifies the reply ID to match.

* reply_id must be one of the following:
  * `0`: +NO reply
  * `1`: +OK reply
  * `2`: -ERR reply

---

**Usage**
Use this command to define rule expressions to reply ID assigned to SMTP response.

**Example**
The following command defines a rule expression to match reply ID 2 assigned to SMTP response:

```
smtplib reply id = 2
```
smtp reply status

This command allows you to define rule expressions to match the reply status in SMTP packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] smtp reply status operator reply_status

- no
  If previously configured, deletes the specified rule expression from the current ruledef.

- operator
  Specifies how to match.
  operator must be one of the following:
  - !=: Does not equal
  - ==: Equals

- reply_status
  Specifies the SMTP reply status to match.
  reply_status must be one of the following:
  - +OK: Response OK
  - -ERR: Response error

Usage

Use this command to define rule expressions to match reply status in SMTP packets.

Example

The following command defines a rule expression to match reply status +OK in SMTP packets:

smtp reply status = +OK
smtp sender

This command allows you to define rule expressions to match sender e-mail ID in the current SMTP transaction.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

Syntax

[ no ] smtp sender [ case-sensitive ] operator sender

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **sender**
  Specifies the sender value to match.
  `sender` must be an alphanumeric string of 1 through 127 characters.

Usage
Use this command to define rule expressions to match sender e-mail ID in the current SMTP transaction.
Example

The following command defines a rule expression to match sender e-mail ID containing `test` in the current SMTP transaction:

```
smtplib_sender contains test
```
smtp session-length

This command allows you to define rule expressions to match total length of SMTP sessions.

**Product**
ACS

[local]host_name(config-acs-ruledef)#
```

**Syntax**

```plaintext
[ no ] smtp session-length { operator session_length | { range | !range } range_from to range_to }
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  ```plaintext
  operator
  ```
  ```plaintext
  operator must be one of the following:
  - !=: Does not equal
  - <=: Lesser than or equals
  - ==: Equals
  - >=: Greater than or equals
  ```

- **session_length**
  Specifies the session length to match.
  ```plaintext
  session_length
  ```
  ```plaintext
  session_length must be an integer from 1 through 40000000.
  ```

- **{ range | !range } range_from to range_to**
  Enables or disables the range criteria.
  ```plaintext
  { range | !range } range_from to range_to
  ```
  ```plaintext
  Enables the range criteria.
  ```
  ```plaintext
  !range: Disables the range criteria.
  ```
  ```plaintext
  range_from: Specifies the start of range as an integer from 1 through 40000000.
  ```
  ```plaintext
  range_to: Specifies the end range. range_to must be an integer from 1 through 40000000, and must be greater than range_from.
  ```
**Usage**

Use this command to define rule expressions to match total length of SMTP session.

**Example**

The following command defines a rule expression to match SMTP session length of 4000000:

```
smtp session-length = 4000000
```
smtp state

This command allows you to define rule expressions to match current state of a SMTP command session.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] smtp state  

no

If previously configured, deletes the specified rule expression from the current ruledef.

operator

Specifies how to match.

operator must be one of the following:

• !=: Does not equal
• ==: Equals

current_state

Specifies the current state to match.

current_state must be one of the following:

• close: Closed state
• init: Initialized state
• response-error: Response of error state
• response-ok: Response of ok state
• waiting-for-response: Waiting for response state

Usage

Use this command to define rule expressions to match current state of SMTP command session.

Example

The following command defines a rule expression to match current state as close of SMTP command session:

    smtp state = close
tcp analyzed out-of-order

This command allows you to define rule expressions to determine whether the received TCP packet was received before all of the earlier sequenced packets have been received. This functionality is for whether the packet was analyzed or discarded because the earlier sequenced packet(s) was (were) not received before a timeout expired.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] tcp analyzed out-of-order operator condition

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• ==: Equals

condition
Specifies the condition to match.
condition must be one of the following:
• FALSE: Not analyzed
• TRUE: Analyzed

Usage
This command is used to set the status flag to 'analyzed' or 'not analyzed' for all TCP packets received at the ACSMgr/SessMgr prior to their earlier packets.
When a packet reaches ACSMgr/SessMgr prior to earlier packet(s), it and subsequent packets are buffered at ACSMgr/SessMgr as TCP out-of-order packets and ACSMgr/SessMgr waits for missing packet(s) until the time-out duration expires. If the packet(s) with the missing sequence number(s) arrives within the time-out duration, all buffered packets with the correct sequence will be presented to upper layers (HTTP etc.) for analysis; otherwise buffered TCP out-of-order packets will be sent to charging with analysis done flag at the TCP/IP layer only.
If this command is enabled the TCP out-of-order packets are marked and sent to TCP analyzer as analyzed for charging action, otherwise they are discarded.

**Example**

The following command sets to analyze TCP out-of-order packets:

```
tcp analyzed out-of-order = TRUE
```
tcp any-match

This command allows you to define rule expressions to match all TCP packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] tcp any-match operator condition

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
  • !=: Does not equal
  • ==: Equals

c condition
Specifies the condition to match.
condition must be one of the following:
  • FALSE: Not analyzed
  • TRUE: Analyzed

Usage
Use this command to define rule expressions to match all TCP packets.

Example
The following command defines a rule expression to match all TCP packets:

tcp any-match = TRUE
tcp connection-initiator

This command allows you to define rule expressions to match the TCP connection initiator.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] tcp connection-initiator operator subscriber
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  **operator** must be one of the following:
  - !=: Does not equal
  - ==: Equals

- **subscriber**
  Specifies that the connection is being initiated by the subscriber.

**Usage**

Use this command to define rule expressions to match the TCP connection initiator, and to allow the operator to differentiate when the connection initiated by subscriber or the subscriber is acting as a Transaction Control Server (TCS) server.

**Example**

The following command defines a rule expression to match user traffic based on TCP connection initiator subscriber:

```
tcp connection-initiator = subscriber
```
tcp downlink

This command allows you to define rule expressions to match downlink (network to subscriber) TCP packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name

[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] tcp downlink operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  **operator** must be one of the following:
  - !=: Does not equal
  - =: Equals

- **condition**
  Specifies the condition to match.
  **condition** must be one of the following:
  - FALSE
  - TRUE

**Usage**

Use this command to define rule expressions to match downlink (to subscriber) TCP packets.

**Example**

The following command defines a rule expression to match downlink TCP packets:

```
tcp downlink = TRUE
```
tcp dst-port

This command allows you to define rule expressions to match destination port number in TCP headers.

Product

</tr>
<tr>
<td>• end_range must be an integer from 1 through 65535, and must be greater than start_range.</td>
</tr>
</tbody>
</table>
port-map port_map_name

Specifies the port map for the port range. port_map_name must be an alphanumeric string of 1 through 63 characters.

Usage

Use this command to define rule expressions to match destination port number in TCP headers.

Example

The following command defines a rule expression to match destination port number 10 in TCP headers:

```
tcp dst-port = 10
```
**tcp duplicate**

This command allows you to define rule expressions to match TCP retransmissions.

**Product**  
ACS

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > ACS Configuration > Ruledef Configuration

```ini
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] tcp duplicate operator condition
```

- **no**  
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**  
  Specifies how to match.  
  `operator` must be one of the following:
  ```
  • !=: Does not equal  
  • ==: Equals
  ```

- **condition**  
  Specifies the condition to match.  
  `condition` must be one of the following:
  ```
  • FALSE: Not duplicated/retransmitted  
  • TRUE: Duplicated/retransmitted
  ```

**Usage**

Use this command to specify rule expressions to match TCP retransmission.

**Example**

The following command defines a rule expression to match TCP retransmissions:

```ini
tcp duplicate = TRUE
```
tcp either-port

This command allows you to define rule expressions to match either a destination or source port number in TCP headers.

**Product**

ACS

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] tcp either-port { operator port_number | !range | range } { start_range to end_range | port-map port_map_name } }
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `<=`: Lesser than or equals
  - `==`: Equals
  - `>=`: Greater than or equals

- **port_number**
  Specifies the port number to match.
  `port_number` must be an integer from 1 through 65535.

- **range | !range**
  Specifies the range criteria:
  - `!range`: Not in the range
  - `range`: In the range

- **start_range to end_range**
  Specifies the starting and ending port numbers for the port range.
  - `start_range` must be an integer from 1 through 65535.
  - `end_range` must be an integer from 1 through 65535, and must be greater than `start_range`. 
port-map port_map_name

Specifies the port map for the port range. port_map_name must be an alphanumeric string of 1 through 63 characters.

Usage

Use this command to define rule expressions to match either a destination or source port number in TCP headers.
This command expression allows you to create a single ruledef using either-port, rather than needing two ruledefs (one with dst-port and one with src-port).

Example

The following command defines a rule expression to match destination/source port number 10 in TCP header:

```
tcp either-port = 10
```
**tcp error**

This command allows you to define rule expressions to identify errors, either in the packet (for example, TCP checksum error) or in the TCP analyzer's Finite State Machine (FSM).

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] tcp error operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  - `!=`: Does not equal
  - `=`: Equals

- **condition**
  Specifies the condition to match.
  - `FALSE`
  - `TRUE`

**Usage**

Use this command to define a rule expression to identify errors, either in the packet (for example, TCP checksum error) or in the TCP analyzer's FSM.

**Example**

The following command defines a rule expression to match TCP errors:

```
tcp error = TRUE
```
**tcp flag**

This command allows you to define rule expressions to match bit within the flag field of TCP headers.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] tcp flag operator flag
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!contains`: Does not contain
  - `contains`: Contains
  - `!=`: Does not equal
  - `=`: Equals

- **flag**
  Specifies the flag value to match.
  `flag` must be one of the following:
  - `ack`: TCP FLAG ACK
  - `fin`: TCP FLAG FIN
  - `push`: TCP FLAG PUSH
  - `reset`: TCP FLAG RESET
  - `syn`: TCP FLAG SYN

**Usage**

Use this command to define rule expressions to match a bit within the flag field of TCP headers.

**Example**

The following command defines a rule expression to match `reset` within flag field of TCP headers:

```
```
tcp flag = reset
**tcp initial-handshake-lost**

This command allows you to define rule expressions to match data packets when there has been no TCP handshaking to establish TCP connection.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```plaintext
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```plaintext
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] tcp initial-handshake-lost operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match. 
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `=`: Equals

- **condition**
  Specifies the condition to match. 
  `condition` must be one of the following:
  - `FALSE`
  - `TRUE`

**Usage**
Use this command to define rule expressions to match data packets when there has been no TCP handshaking to establish TCP connection.

**Example**
The following command defines a rule expression to identify TCP flow where the initial handshake was not seen:

```plaintext
tcp initial-handshake-lost = TRUE
```
### tcp payload

This command allows you to define rule expressions to match hexadecimal or ASCII string content in the payload protocol-signature field of the TCP payload.

**Product**
- ACS

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] tcp payload starts-with { hex-signature hex_string | string-signature string }
```

- **no**
  - If previously configured, deletes the specified rule expression from the current ruledef.

- **hex-signature hex_string**
  - Specifies hexadecimal protocol signature in payload field.
  - `hex_string` must be a dash-delimited list of hex data of size smaller than 32.

- **string-signature string**
  - Specifies protocol signature in payload field.
  - `string` must be an alphanumeric string of 1 through 32 characters.

**Usage**

Use this command to define rule expressions to match for Hex/ASCII string content in payload protocol-signature field.

This rule expression is useful for detecting certain applications.

**Example**

The following command defines a rule expression to identify user traffic based on TCP protocol signature `tcp1`:

```
tcp payload starts-with string-signature tcp1
```
tcp payload-length

This command allows you to define rule expressions to match the length of a TCP payload.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration
active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] tcp payload-length operator payload_length

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match. 
operator must be one of the following:
- !=: Does not equal
- <=: Lesser than or equals
- =: Equals
- >=: Greater than or equals

payload_length
Specifies the TCP payload length to match. 
payload_length must be an integer from 0 through 40000000.

Usage
Use this command to define rule expressions to match length of TCP payload, excluding the TCP or lower layer headers.
To match TCP control packets configure a payload-length of 0 (zero).

Example
The following command defines a rule expression to match TCP payload length of 10000:

tcp payload-length = 10000
tcp previous-state

This command allows you to define rule expressions to match previous state of TCP connections.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] tcp previous-state operator tcp_previous_state

no

If previously configured, deletes the specified rule expression from the current ruledef.

operator

Specifies how to match.
operator must be one of the following:
- !=: Does not equal
- ==: Equals

tcp_previous_state

Specifies the previous state to match.
tcp_previous_state must be one of the following:
- close
- close-wait
- closing
- established
- fin-wait1
- fin-wait2
- last-ack
- listen
- syn-received
- syn-sent
- time-wait
Usage
Use this command to define rule expressions to match a TCP previous state.

Example
The following command defines a rule expression to match user traffic based on previous state $\text{time\text{-}wait}$:

$$
tcp \text{ previous\text{-}state} = \text{time\text{-}wait}
$$
**tcp proxy-prev-state**

This command allows you to define rule expressions to match TCP previous state on the ingress side of the TCP proxy.

**Product**  
ACS

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > ACS Configuration > Ruledef Configuration

```plaintext
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```plaintext
[ no ] tcp proxy-prev-state operator previous_state
```

---

**no**

If previously configured, deletes the specified rule expression from the current ruledef.

---

**operator**

Specifies how to match.  
**operator** must be one of the following:

- `!=`: Does not equal
- `=`: Equals

---

**previous_state**

Specifies the previous state to match.  
**previous_state** must be one of the following:

- `close`
- `close-wait`
- `closing`
- `established`
- `fin-wait1`
- `fin-wait2`
- `last-ack`
- `listen`
- `syn-received`
- `syn-sent`
- `time-wait`
Usage

If there is no TCP proxy configured, this configuration is not applicable. For proxy-enabled flows, TCP state handling interprets the ingress side as the radio side and the egress side as the Internet side of the TCP connection.

\texttt{tcp state} and \texttt{tcp prev-state} is the state of the client stack, which would be either the state of the subscriber's stack (if flow is not proxy enabled) or the MS state of proxy on the egress-side (if flow is proxy-enabled).

\texttt{tcp proxy-state} and \texttt{tcp proxy-prev-state} is the state of the embedded TCP proxy server, that is the proxy ingress-side.

So, depending on the use case, if using \texttt{tcp state} and \texttt{tcp prev-state} an existing configuration may work fine regardless of whether proxy is enabled. For other use cases, other ruledefs may have to be created. Both \texttt{tcp state} and \texttt{tcp proxy-state} can be used in the same ruledef. If proxy was being used, they would map to the egress-side and ingress-side, respectively. If proxy was not being used, then this would not match ruledef because proxy state would not be applicable.

Example

The following command defines a rule expression to match user traffic based on TCP proxy previous state of established:

\begin{verbatim}
tcp proxy-prev-state = established
\end{verbatim}
**tcp proxy-state**

This command allows you to define rule expressions to match the TCP state on the ingress side of the TCP proxy.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

*active-charging service service_name > ruledef ruledef_name*

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] tcp proxy-state operator state
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.

  - **operator** must be one of the following:
    - !=: Does not equal
    - ==: Equals

- **state**
  Specifies the state to match.

  - **state** must be one of the following:
    - close
    - close-wait
    - closing
    - established
    - fin-wait1
    - fin-wait2
    - last-ack
    - listen
    - syn-received
    - syn-sent
    - time-wait
Usage

If there is no TCP proxy configured, this configuration is not applicable.

For proxy-enabled flows, TCP state handling interprets the ingress side as the radio side and the egress side as the Internet side of the TCP connection.

- `tcp state` and `tcp prev-state` is the state of the client stack, which would be either the state of the subscriber's stack (if flow is not proxy enabled) or the MS state of proxy on egress-side (if flow is proxy-enabled).
- `tcp proxy-state` and `tcp proxy-prev-state` is the state of the embedded TCP proxy server, that is the proxy ingress-side.

So, depending on the use case, if using `tcp state` and `tcp prev-state` an existing configuration may work fine regardless of whether proxy is enabled. For other use cases, other ruledefs may have to be created. Both `tcp state` and `tcp proxy-state` can be used in the same ruledef. If proxy was being used, they would map to the egress-side and ingress-side, respectively. If proxy was not being used, then this would not match the ruledef because proxy state would not be applicable.

Example

The following command defines a rule expression to match user traffic based on TCP proxy previous state of established:

```
tcp proxy-state = established
```
tcp session-length

This command allows you to define rule expressions to match the total length of a TCP session.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

activate-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] tcp session-length operator session_length

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:

• !=: Does not equal
• <=: Lesser than or equals
• =: Equals
• >=: Greater than or equals

session_length
Specifies the TCP session length (in bytes) to match as be an integer from 0 through 4000000000.

Usage
Use this command to define rule expressions to match the total length of a TCP session.
The session-length is calculated by adding together the TCP payload-length values of all relevant packets.

Example
The following command defines a rule expression to match user traffic based on TCP session length of 2000 bytes:

tcp session-length = 2000
**tcp src-port**

This command allows you to define rule expressions to match source a port number in TCP headers.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] tcp src-port { operator port_number | { !range | range } { start_range to end_range | port-map port_map_name } }
```

---

**no**

If previously configured, deletes the specified rule expression from the current ruledef.

---

**operator**

Specifies how to match.

*operator* must be one of the following:

- !=: Does not equal
- <=: Lesser than or equals
- ==: Equals
- >=: Greater than or equals

---

**port_number**

Specifies the port number to match.

*port_number* must be an integer from 1 through 65535.

---

**range | !range**

Specifies the range criteria:

- !range: Not in the range
- range: In the range

---

**start_range to end_range**

Specifies the starting and ending port numbers for the port range.

- *start_range* must be an integer from 1 through 65535.
- *end_range* must be an integer from 1 through 65535, and must be greater than *start_range*.
**port-map port_map_name**

Specifies the port map for the port range. *port_map_name* must be an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to define rule expressions to match source a port number in TCP headers.

**Example**

The following command defines a rule expression to analyze user traffic matching TCP source port 10:

```
tcp src-port = 10
```
**tcp state**

This command allows you to define rule expressions to match current state of TCP connections.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] tcp state operator current_state
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  ```
  operator must be one of the following:
  • !=: Does not equal
  • ==: Equals
  ```

- **current_state**
  Specifies the current state to match.
  ```
  current_state must be one of the following:
  • close
  • close-wait
  • closing
  • established
  • fin-wait1
  • fin-wait2
  • last-ack
  • listen
  • syn-received
  • syn-sent
  • time-wait
  ```
**Usage**

Use this command to define rule expressions to match a current state of TCP connections.

**Example**

The following command defines a rule expression to match user traffic based on current state `close`:

```
tcp state = close
```
**tcp uplink**

This command allows you to define rule expressions to match uplink (subscriber to network) TCP packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
=localhost host_name(config-acs-ruledef) #
```

**Syntax**

```
[ no ] tcp uplink operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  - !: Does not equal
  - =: Equals

- **condition**
  Specifies the condition.
  - FALSE
  - TRUE

**Usage**

Use this command to define rule expressions to uplink TCP packets.

**Example**

The following command defines a rule expression to uplink TCP packets:

```
tcp uplink = TRUE
```
tethering-detection

This command allows you to define rule expressions to match tethered or non-tethered flows.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-acs-ruledef)#
```

**Syntax**

```
tethering-detection { flow-not-tethered | flow-tethered }

no tethering-detection
```

```
no
```

Deletes the tethering detection configuration from the ruledef.

```
flow-not-tethered
```

Specifies to match if tethering is not detected on flow.

```
flow-tethered
```

Specifies to match if tethering is detected on flow.

**Usage**

Use this command to define rule expressions to match tethered/non-tethered flows.

Note that in order for the rule containing the tethering-detection configuration to get matched, at least one valid rule line has to be present in it.

This configuration is treated in a special manner by the rule matching engine in that it is excluded from the condition **multi-line-or all-lines**. For example, if there are three rule-lines in a ruledef and multi-line-or is enabled as follows:

```
ruledef all-tethered-web-traffic

   http any-match = TRUE

   wsp any-match = TRUE

   multi-line-or all-lines
```

```
tethering-detection flow-tethered
```

In this case, if for a packet only the rule line `tethering-detection flow-tethered` matches, it is not sufficient to result in a rule match even though `multi-line-or all-lines` is enabled in the ruledef.

**Example**

The following command defines a rule expression to match tethered flows:

```
tethering-detection flow-tethered
```
**tftp any-match**

This command allows you to define rule expressions to match all Trivial File Transfer Protocol (TFTP) packets.

**Product**

ACS

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] tftp any-match operator condition
```

- **no**
  
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  
  Specifies how to match.
  
  `operator` must be one of the following:
  
  - `!=`: Does not equal
  - `=`: Equals

- **condition**
  
  Specifies the condition to match.
  
  `condition` must be one of the following:
  
  - `FALSE`: Not analyzed
  - `TRUE`: Analyzed

**Usage**

Use this command to define rule expressions to match all TFTP packets.

**Example**

The following command defines a rule expression to match all TFTP packets:

```
tftp any-match = TRUE
```
### tftp data-any-match

This command allows you to define rule expressions to match all TFTP data packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] tftp data-any-match operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `=`: Equals

- **condition**
  Specifies the condition to match.
  `condition` must be one of the following:
  - `FALSE`: Not analyzed
  - `TRUE`: Analyzed

**Usage**

Use this command to define rule expressions to match all TFTP data packets.

**Example**

The following command defines a rule expression to match all TFTP data packets:

```
tftp data-any-match = TRUE
```
**udp any-match**

This command allows you to define rule expressions to match all UDP packets.

**Product**

ACS

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > reuledef ruledef_name`

Exec > ACS Configuration > Ruledef Configuration

active - charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] udp downlink operator condition

no

If previously configured, deletes the specified rule expression from the current ruledef.

operator

Specifies how to match.
operator must be one of the following:
  • =: Equals

condition

Specifies the condition to match.
condition must be one of the following:
  • FALSE
  • TRUE

Usage

Use this command to define rule expressions to match downlink UDP packets.

Example

The following command defines a rule expression to match downlink UDP packets:

    udp downlink = TRUE
**udp dst-port**

This command allows you to define rule expressions to match destination port number in UDP headers.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] udp dst-port { operator port_number | { !range | range | start_range to end_range | port-map port_map_name } }
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  - `operator` must be one of the following:
    - `!=`: Does not equal
    - `<=`: Lesser than or equals
    - `==`: Equals
    - `>=`: Greater than or equals

- **port_number**
  Specifies the port number to match.
  - `port_number` must be an integer from 1 through 65535.

- **!range | range**
  Specifies the range criteria.
  - `!range`: Not in the range
  - `range`: In the range

- **start_range to end_range**
  Specifies the starting and ending port numbers for the port range.
  - `start_range` must be an integer from 1 through 65535.
  - `end_range` must be an integer from 1 through 65535, and must be greater than `start_range`.
<table>
<thead>
<tr>
<th>Command</th>
<th>Port-Map Port-Map Name</th>
</tr>
</thead>
</table>

Specifies the port map for the port range. `port_map_name` must be an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to define rule expressions to match destination port number in UDP headers.

**Example**

The following command defines a rule expression to match user traffic based on destination port number 10:

```
udp dst-port = 10
```
udp either-port

This command allows you to define rule expressions to match either a destination or source port number in UDP headers.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] udp either-port { operator port_number | !range | range } { start_range to end_range | port-map port_map_name }

no

If previously configured, deletes the specified rule expression from the current ruledef.

operator

Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• <=: Lesser than or equals
• ==: Equals
• >=: Greater than or equals

port_number

Specifies the port number to match.
port_number must be an integer from 1 through 65535.

!range | range

Specifies the range criteria.
• !range: Not in the range
• range: In the range

start_range to end_range

Specifies the starting and ending port numbers for the port range.
start_range must be an integer from 1 through 65535.
end_range must be an integer from 1 through 65535, and must be greater than start_range.
port-map port_map_name

Specifies the port map for the port range. `port_map_name` must be an alphanumeric string of 1 through 63 characters.

Usage

Use this command to define rule expressions to match either destination or source port number in UDP headers.

Example

The following command defines a rule expression to match user traffic based on match either source/destination port number 10:

```
udp either-port = 10
```
udp payload starts-with

This command allows you to define rule expressions to match hex/ASCII string content in UDP payload protocol-signature field.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] udp payload starts-with { hex-signature hex_string | string-signature string }

no

If previously configured, deletes the specified rule expression from the current ruledef.

hex-signature hex_string

Specifies hexadecimal protocol signature in payload field.

hex_string must be a dash-delimited list of hex data of size smaller than 32.

string-signature string

Specifies protocol signature in payload field.

string must be an alphanumeric string of 1 through 32 characters.

Usage
Use this command to define rule expressions to match for Hex/ASCII string content in UDP payload protocol-signature field.

This rule expression is useful for detecting certain applications.

Example

The following command defines a UDP rule expression to analyze user traffic based on UDP protocol signature udp1:

    udp payload starts-with string-signature udp1
udp src-port

This command allows you to define rule expressions to match source port number in UDP headers.

**Product**

<tr>
<td><code>end_range</code> must be an integer from 1 through 65535, and must be greater than <code>start_range</code>.</td>
</tr>
</tbody>
</table>
**port-map**  *port_map_name*

Specifies the port map for the port range. *port_map_name* must be an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to define rule expressions to match source port number in UDP headers.

**Example**

The following command defines a rule expression to match source port number 10 in UDP headers:

```
udp src-port = 10
```
udp uplink

This command allows you to define rule expressions to match uplink (subscriber to network) UDP packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] udp uplink operator condition

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
  • =: Equals

condition
 Specifies the condition to match.
condition must be one of the following:
  • FALSE
  • TRUE

Usage
Use this command to define rule expressions to match uplink UDP packets.

Example
The following command defines a rule expression to match uplink (from subscriber) UDP packets:

    udp uplink = TRUE
**wsp any-match**

This command allows you to define rule expressions to match all Wireless Session Protocol (WSP) packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```bash
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] wsp any-match operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  - `!=`: Does not equal
  - `=`: Equals

- **condition**
  Specifies the condition to match.
  - `FALSE`
  - `TRUE`

**Usage**

Use this command to specify a rule expression to match all WSP packets.

**Example**

The following command defines a rule expression to match all WSP packets:

```
wsp any-match = TRUE
```
wsp content type

This command allows you to define rule expressions to match the content type field in WSP headers.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] wsp content type [ case-sensitive ] operator content_type

no
If previously configured, deletes the specified rule expression from the current ruledef.

case-sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

operator
Specifies how to match.
operator must be one of the following:

• !=: Does not equal
• !contains: Does not contain
• !ends-with: Does not end with
• !starts-with: Does not start with
• ==: Equals
• contains: Contains
• ends-with: Ends with
• starts-with: Starts with

content_type
Specifies content type to match.
content_type must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
Usage

Use this command to define rule expressions to match "content type" field in WSP headers.

Example

The following command defines a rule expression to WSP content type test:

```
wsp content type = test
```
wsp domain

This command allows you to define rule expressions to match domain portion of the URI for WSP packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] wsp domain [ case-sensitive ] operator domain

no

If previously configured, deletes the specified rule expression from the current ruledef.

case-sensitive

Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

operator

Specifies how to match. operator must be one of the following:

• !=: Does not equal
• !contains: Does not contain
• !ends-with: Does not end with
• !starts-with: Does not start with
• =: Equals
• contains: Contains
• ends-with: Ends with
• starts-with: Starts with

domain

Specifies the domain to match. domain must be an alphanumeric string of 1 through 127 characters.

Usage

Use this command to define rule expressions to match the domain portion of URIs in WSP packets.
Example

From the URL, after http:// (if present) is removed, everything until the first "/" is the domain.

The following command defines a rule expression to match user traffic based on domain name testdomain:

```
wsp domain = testdomain
```
**wsp downlink**

This command allows you to define rule expressions to match downlink (network to subscriber) WSP packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```plaintext
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] wsp downlink operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `==`: Equals

- **condition**
  Specifies the downlink (from the Mobile Node direction) status to match.
  `condition` must be one of the following:
  - `FALSE`
  - `TRUE`

**Usage**
Use this command to define rule expressions to match downlink WSP packets.

**Example**

The following command defines a rule expression to match downlink WSP packets:

```
wsp downlink = TRUE
```
wsp first-request-packet

This command allows you to define rule expressions to match WSP first-request-packet.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] wsp first-request-packet operator condition

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• ==: Equals

collection
Specifies the condition to match.
collection must be one of the following:
• FALSE
• TRUE

Usage
Use this command to define rule expressions to match the GET or POST request, if it is the first WSP request for the subscriber's session.

Example
The following command defines a rule expression to match WSP first-request-packet:

wsp first-request-packet = TRUE
wsp host

This command allows you to define rule expressions to match the host name header field in WSP headers.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] wsp host [ case-sensitive ] operator host_name

no
If previously configured, deletes the specified rule expression from the current ruledef.

case-sensitive
Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

operator
Specifies how to match.
operator must be one of the following:
- !=: Does not equal
- !contains: Does not contain
- !ends-with: Does not end with
- !starts-with: Does not start with
- =: Equals
- contains: Contains
- ends-with: Ends with
- starts-with: Starts with

host_name
Specifies the WSP host name to match.
host_name must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
Usage
Use this command to define rule expressions to match host name header field in WSP headers.

Example
The following command defines a rule expression to match host name `host1` in WSP headers:

```plaintext
wsp host contains host1
```
wsp pdu-length

This command allows you to define rule expressions to match WSP PDU length.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] wsp pdu-length operator pdu_length

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• <=: Lesser than or equals
• ==: Equals
• >=: Greater than or equals

pdu_length
Specifies the WSP PDU length (in bytes) to match.
pdu_length must be an integer from 1 through 65535.

Usage
Use this command to define rule expressions to match WSP PDU length (header + payload) in bytes.

Example
The following command defines a rule expression to match user traffic based on WSP PDU length of 10000 bytes:

wsp pdu-length = 10000
**wsp pdu-type**

This command allows you to define rule expressions to match WSP PDU type in the current packet.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] wsp pdu-type operator pdu_type
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `==`: Equals

- **pdu_type**
  Specifies the WSP PDU type to match.
  `pdu_type` must be one of the following:
  - `confirmed push`
  - `connect-reply`
  - `connect-request`
  - `data-fragment`
  - `delete`
  - `disconnect`
  - `get`
  - `head`
  - `options`
  - `post`
  - `push`
  - `put`
wsp pdu-type

• redirect
• reply
• resume
• suspend
• trace

Usage
Use this command to define rule expressions to match WSP PDU type value in current packet.

Example
The following command defines a rule expression to match WSP PDU type `resume`:

```
   wsp pdu-type resume
```
wsp previous-state

This command allows you to define rule expressions to match previous WSP method invocation state.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] wsp previous-state operator wsp_previous_state
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  - !: Does not equal
  - =: Equals

- **wsp_previous_state**
  Specifies the previous state to match.
  - init
  - response-error
  - response-ok
  - waiting-for-response

**Usage**

Use this command to define rule expressions to match WSP previous state.

**Example**

The following command defines a rule expression to match WSP previous state of response-ok:

```
wsp previous-state = response-ok
```
**wsp reply code**

This command allows you to define rule expressions to match WSP reply code.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] wsp reply code operator reply_code
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  - `!=`: Does not equal
  - `<=`: Lesser than or equals
  - `=`: Equals
  - `>=`: Greater than or equals

- **reply_code**
  Specifies the WSP reply code to match.
  `reply_code` must be an integer from 0 through 101.

**Usage**

Use this command to define rule expressions to match WSP reply code.

**Example**

The following command defines a rule expression to match WSP reply code of 50:

```
wsp reply code = 50
```
wsp session-length

This command allows you to define rule expressions to match total length of a WSP session.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

**Syntax**

[ no ] wsp session-length operator session_length

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  *operator* must be one of the following:
  - !=: Does not equal
  - <=: less than equals
  - ==: Equals
  - >=: greater than equals

- **session_length**
  Specifies the WSP session length (in bytes) to match.
  *session_length* must be an integer from 1 through 65535.

**Usage**
Use this command to define rule expressions to match total length of WSP session.

**Example**
The following command defines a rule expression to match WSP session length of 2000 bytes:

```
wsp session-length = 2000
```
**wsp session-management**

This command allows you to define rule expressions to match WSP Session Management state.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] wsp session-management { previous-state | state } operator state
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **previous-state**
  Specifies the previous WSP Session Management state.

- **state**
  Specifies current WSP Session Management Finite State Machine (FSM) state.

- **operator**
  Specifies how to match.
  **operator** must be one of the following:
  - !=: Does not equal
  - ==: Equals

- **state**
  Specifies the state to match.
  For **previous-state**, **state** must be one of the following:
  - connected
  - connecting
  - init
  - resuming
  - suspended
  For **state**, **state** must be one of the following:
  - close
wsp session-management

• connected
• connecting
• init
• resuming
• suspended

**Usage**

Use this command to define rule expressions to match a WSP Session Management state.

**Example**

The following command defines a rule expression to match previous WSP Session Management state of connecting:

```
wsp session-management previous-state = connecting
```
wsp state

This command allows you to define rule expressions to match WSP Method Invocation state.

Product
ACS

Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] wsp state operator current_state

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
- !=: Does not equal
- ==: Equals

current_state
Specifies the current state to match.
current_state must be one of the following:
- close
- response-error
- response-ok
- waiting-for-response

Usage
Use this command to define rule expressions to match WSP Method Invocation state.

Example

The following command defines a rule expression to match a WSP Method Invocation state close:

wsp state = close
wsp status

This command has been deprecated. See the `wsp reply-code` command.
**wsp tid**

This command allows you to define rule expressions to match Transaction Identifier (TID) field for connection-less WSP.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**
```
[ no ] wsp tid operator transaction_id
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.  
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `=`: Equals

- **transaction_id**
  Specifies the transaction identifier to match.  
  `transaction_id` must be an integer from 0 through 255.

**Usage**
Use this command to define rule expressions to match TID field for connection-less WSP.

**Example**
The following command defines a rule expression to match a TID value of 22 for connection-less WSP:

```
wsp tid = 22
```
wsp total-length

This command has been deprecated. See the wsp session-length command.
wsp transfer-encoding

This command allows you to define rule expressions to match transfer encoding present in WSP headers.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

table

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] wsp transfer-encoding [ case-sensitive ] operator transfer_encoding
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.

  - **operator** must be one of the following:
    - !==: Does not equal
    - !contains: Does not contain
    - !ends-with: Does not end with
    - !starts-with: Does not start with
    - ==: Equals
    - contains: Contains
    - ends-with: Ends with
    - starts-with: Starts with

- **transfer_encoding**
  This must be an alphanumeric string of 1 through 127 characters.

**Usage**

Use this command to define rule expressions to match transfer encoding present in WSP header.
The following command defines a rule expression to match user traffic based on WSP transfer encoding 7:

```
wsp transfer-encoding contains 7
```
wsp uplink

This command allows you to define rule expressions to match uplink (subscriber to network) WSP packets.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] wsp uplink operator condition

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match. 
operator must be one of the following:
  • !=: Does not equal
  • ==: Equals

condition
Specifies the uplink (to the Mobile Node direction) status to match.
condition must be one of the following:
  • FALSE
  • TRUE

Usage
Use this command to define rule expressions to match uplink WSP packets.

Example

The following command defines a rule expression to match uplink WSP packets:

wsp uplink = TRUE
**wsp url**

This command allows you to define rule expressions to match WSP URL.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acd-ruledef)#
```

**Syntax**

```
[ no ] wsp url [ case-sensitive ] operator url
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.

  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `regex`: Regular expression
  - `starts-with`: Starts with

- **url**
  Specifies the URL to match.

  - `url` must be an alphanumerical string of 1 through 127 characters.
Usage

Use this command to define rule expressions to match the complete URL, including the host portion. The following table lists the special characters that you can use in regex rule expressions. For more information on regex support, refer to the Enhanced Charging Service Administration Guide.

<table>
<thead>
<tr>
<th>Regex Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Zero or more characters</td>
</tr>
<tr>
<td>+</td>
<td>Zero or more repeated instances of the token preceding the +</td>
</tr>
<tr>
<td>?</td>
<td>Match zero or one character</td>
</tr>
</tbody>
</table>

**Important:** The CLI does not support configuring “?” directly, you must instead use “\?”. For example, if you want to match the string “xyz<any one character>pqr”, you must configure it as: `http host regex "xyz\077pqr"`

In another example, if you want to exactly match the string “url?resource=abc”, you must configure it as: `http uri regex "url\077resource=abc"`

Where, the first “\“ (backslash) is for the escaping of “?” and then “\077” for specifying “?” to the CLI.

<table>
<thead>
<tr>
<th>\character</th>
<th>Escaped character</th>
</tr>
</thead>
<tbody>
<tr>
<td>?</td>
<td>Match the question mark (&lt;ctrl-v&gt;?) character</td>
</tr>
<tr>
<td>+</td>
<td>Match the plus character</td>
</tr>
<tr>
<td>*</td>
<td>Match the asterisk character</td>
</tr>
<tr>
<td>\a</td>
<td>Match the Alert (ASCII 7) character</td>
</tr>
<tr>
<td>\b</td>
<td>Match the Backspace (ASCII 8) character</td>
</tr>
<tr>
<td>\f</td>
<td>Match the Form-feed (ASCII 12) character</td>
</tr>
<tr>
<td>\n</td>
<td>Match the New line (ASCII 10) character</td>
</tr>
<tr>
<td>\r</td>
<td>Match the Carriage return (ASCII 13) character</td>
</tr>
<tr>
<td>\t</td>
<td>Match the Tab (ASCII 9) character</td>
</tr>
<tr>
<td>\v</td>
<td>Match the Vertical tab (ASCII 11) character</td>
</tr>
<tr>
<td>\0</td>
<td>Match the Null (ASCII 0) character</td>
</tr>
<tr>
<td>\</td>
<td>Match the backslash character</td>
</tr>
<tr>
<td>Bracketed range [0-9]</td>
<td>Match any single character from the range</td>
</tr>
<tr>
<td>A leading ^ in a range</td>
<td>Do not match any in the range. All other characters represent themselves.</td>
</tr>
<tr>
<td>\x##</td>
<td>Any ASCII character as specified in two-digit hex notation. For example, \x5A yields a “Z”.</td>
</tr>
</tbody>
</table>
### Important

When using the regex operator "|" in regex expressions, always wrap the string in double quotes.

For example, if you want to match the string "pqr" OR "xyz", you must configure it as:

```
http host regex "pqr|xyz".
```

#### Example

The following command defines a rule expression to match user traffic based on WSP URL

```
wsp://wiki.tcl.tk:
```

```
wsp url = wsp://wiki.tcl.tk
```

The following command defines a regex rule expression to match any of the following or similar values in the WSP URL string: wsp://home.opera.yahoo.com, wsp://dwld.yahoo.com, wsp://dwld2.yahoo.com.

```
wsp url regex "wsp://(dwld|opera|home.opera|dwld[1-3]).yahoo.com"
```
wsp user-agent

This command allows you to define rule expressions to match user agent field in WSP headers.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] wsp user-agent [ case-sensitive ] operator user_agent

- **no**
  - If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  - Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  - Specifies how to match.
  - **operator** must be one of the following:
    - !=: Does not equal
    - !contains: Does not contain
    - !ends-with: Does not end with
    - !starts-with: Does not start with
    - =: Equals
    - contains: Contains
    - ends-with: Ends with
    - starts-with: Starts with

- **user_agent**
  - Specifies the WSP user agent to match.
  - **user_agent** must be an alphanumeric string of 1 through 127 characters.

Usage

Use this command to define rule expressions to match a user agent field in WSP headers.
Example

The following command defines a rule expression to match value \textit{test} in user agent field in WSP headers:

\begin{verbatim}
wsp user-agent contains test
\end{verbatim}
**wsp x-header**

This command allows you to define rule expressions to match WSP extension-headers (x-headers).

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] wsp x-header name [ case-sensitive ] operator string
```

- **no**
  - If previously configured, deletes the specified rule expression from the current ruledef.

- **name**
  - Specifies the x-header value as an alphanumeric string of 1 through 31 characters.

- **case-sensitive**
  - Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  - Specifies how to match.
  - **operator** must be one of the following:
    - !=: Does not equal
    - !contains: Does not contain
    - !ends-with: Does not end with
    - !starts-with: Does not start with
    - =: Equals
    - contains: Contains
    - ends-with: Ends with
    - starts-with: Starts with

- **string**
  - Specifies the value of the extension header as an alphanumeric string of 1 through 127 characters.
Usage

Use this command to configure any x-header field in WSP and parse it. The extension-header mechanism allows additional header fields to be defined without changing the protocol. The extension-header can be any header fields that are not specified in the RFC standard.

Example

The following command defines a rule expression to analyze user traffic containing WSP extension-header of test_field and value of test_string:

```
  wsp x-header test_field = test_string
```
wtp any-match

This command allows you to define rule expressions to match all Wireless Transaction Protocol (WTP) packets.

active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] wtp any-match operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.
- **operator**
  Specifies how to match. 
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `=`: Equals
- **condition**
  Specifies the condition to match. 
  `condition` must be one of the following:
  - `FALSE`
  - `TRUE`

**Usage**

Use this command to define rule expressions to match all WTP packets.

**Example**

The following command defines a rule expression to match all WTP packets:

```
wtp any-match = TRUE
```
**wtp downlink**

This command allows you to define rule expressions to match downlink (network to subscriber) WTP packets.

**Product**

```

**Syntax**

```
[ no ] wtp downlink operator condition
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `=`: Equals

- **condition**
  Specifies the downlink (from the Mobile Node direction) status to match.
  `condition` must be one of the following:
  - `FALSE`
  - `TRUE`

**Usage**

Use this command to define rule expressions to match downlink WTP packets.

**Example**

The following command defines a rule expression to match all downlink WTP packets:

```
wtp downlink = TRUE
```
**wtp gtr**

This command allows you to define rule expressions to match Group Transmission (GTR) flag in the current WTP PDU.

**Product**

ACS

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

```

**Syntax**

```
[ no ] wtp gtr operator condition
```

- **no**
  - If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  - Specifies how to match.
  - `operator` must be one of the following:
    - `!=`: Does not equal
    - `==`: Equals

- **condition**
  - Specifies the condition to match.
  - `condition` must be one of the following:
    - `FALSE`
    - `TRUE`

**Usage**

Use this command to define rule expressions to match the GTR flag (that indicates the last packet of a packet group) in the current WTP PDU.

**Example**

The following command defines a rule expression to match WTP user traffic based on WTP GTR:

```
wtp gtr = TRUE
```
wtp pdu-length

This command allows you to define rule expressions to match WTP PDU length.

</table>
| Specifies how to match. operator must be one of the following:
  - !=: Does not equal
  - ==: Equals

<table>
<thead>
<tr>
<th>pdu_length</th>
</tr>
</thead>
</table>
| Specifies the WTP PDU length (in bytes) to match. pdu_length must be an integer from 1 through 65535.

Usage
Use this command to define rule expressions to match WTP PDU length (header + payload) in bytes.

Example
The following command defines a rule expression to match WTP PDU length of 9647 bytes:

wtp pdu-length = 9647
**wtp pdu-type**

This command allows you to define rule expressions to match WTP PDU type.

**Product**
ACS

```

**Syntax**

```
[ no ] wtp pdu-type operator pdu_type
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  - `!=`: Does not equal
  - `=`: Equals

- **pdu_type**
  Specifies the WTP PDU type to match.
  - `abort`
  - `ack`
  - `invoke`
  - `negative-ack`
  - `result`
  - `segment-involve`
  - `segment-result`

**Usage**
Use this command to define rule expressions to match WTP PDU type.

**Example**

The following command defines a rule expression to match the WTP PDU type `result`:
wtp pdu-type = result
**wtp previous-state**

This command allows you to define rule expressions to match previous WTP state.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] wtp previous-state operator wtp_previous_state
```

**no**
If previously configured, deletes the specified rule expression from the current ruledef.

**operator**
Specifies how to match.
operator must be one of the following:
- `!=`: Does not equal
- `=`: Equals

**wtp_previous_state**
Specifies the previous state to match.
wtp_previous_state must be one of the following:
- `ack-sent`
- `init`
- `invoke-sent`
- `rcvd`
- `result-rcvd`

**Usage**
Use this command to define rule expressions to match WTP previous state.

**Example**
The following command defines a rule expression to match user traffic based on WTP previous state of `ack-sent`:

```
wtp previous-state = ack-sent
```
wtp rid

This command allows you to define rule expressions to match Re-transmission Indicator (RID) flag set in WTP traffic.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  - `!=`: Does not equal
  - `==`: Equals

- **condition**
  Specifies the condition to match.
  - `FALSE`
  - `TRUE`

**Usage**
Use this command to define rule expressions to match WTP RID flag.

**Example**
The following command defines a rule expression to match user traffic containing WTP RID flag:

```
wtp rid = TRUE
```
wtp state

This command allows you to define rule expressions to match current WTP state.

**Product**
ACS

</tr>
<tr>
<td>• init</td>
</tr>
<tr>
<td>• invoke-sent</td>
</tr>
<tr>
<td>• rcvd</td>
</tr>
<tr>
<td>• result-rcvd</td>
</tr>
</tbody>
</table>

**Usage**
Use this command to define rule expressions to match current WTP state.

**Example**
The following command defines a rule expression to match user traffic based on current WTP state close:

```
wtp state = close
```
wtp tid

This command allows you to define rule expressions to match WTP Transaction Identifier (TID).

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

Syntax

[ no ] wtp tid operator transaction_id

**no**
If previously configured, deletes the specified rule expression from the current ruledef.

**operator**
Specifies how to match.
operator must be one of the following:

- !=: Does not equal
- ==: Equals

**transaction_id**
Specifies the transaction identifier to match.
transaction_id must be an integer from 0 through 65535.

Usage
Use this command to define rule expressions to match WTP TID. This expression ignores the high order bit in the protocol that indicates the direction.

Example
The following command defines a rule expression to match user traffic containing WTP TID value of 22:

wtp tid = 22
wtp transaction class

This command allows you to define rule expressions to match WTP Transaction Class (TCL) state.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] wtp transaction class operator transaction_class

no
If previously configured, deletes the specified rule expression from the current ruledef.

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• ==: Equals

transaction_class
Specifies the WTP TCL to match.
transaction_class must be an integer from 0 through 2.

Usage
Use this command to define rule expressions to match WTP transaction class.

Example
The following command defines a rule expression to match WTP traffic based on WTP transaction class 2:

wtp transaction class = 2
wtp ttr

This command allows you to define rule expressions to match WTP Trailer Transmission (TTR) flag.

Product

ACS

Privilege

Security Administrator, Administrator

Mode

Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] wtp ttr operator condition

---

no

If previously configured, deletes the specified rule expression from the current ruledef.

operator

Specifies how to match.
operator must be one of the following:
- !=: Does not equal
- ==: Equals

condition

Specifies the condition to match.
condition must be one of the following:
- FALSE
- TRUE

Usage

Use this command to define rule expressions to match TTR flag (used to indicate the last packet in a segmented message) in the current WTP PDU.

Example

The following command defines a rule expression to match WTP traffic based on the presence of the WTP TTR flag:

wtp ttr = TRUE
**wtp uplink**

This command allows you to define rule expressions to match uplink (subscriber to network) WTP packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

**Syntax**

```
[wtp uplink [no]]
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `=`: Equals

- **condition**
  Specifies the condition to match.
  `condition` must be one of the following:
  - `FALSE`
  - `TRUE`

**Usage**
Use this command to define rule expressions to match uplink WTP packets.

**Example**
The following command defines a rule expression to match all uplink WTP packets:

```
  wtp uplink = TRUE
```
www any-match

This command allows you to define rule expressions to match all WWW packets. It is true for HTTP, WAP1.x, and WAP2.0 protocols.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

<tr>
<td>Specifies the condition to match.</td>
</tr>
<tr>
<td>condition must be one of the following:</td>
</tr>
<tr>
<td>• FALSE</td>
</tr>
<tr>
<td>• TRUE</td>
</tr>
</tbody>
</table>

Usage
Use this command to define rule expressions to match all WWW packets. This expression is true for HTTP, WAP1.x, and WAP2.0 protocols

Example
The following command defines a rule expression to match all WWW packets:

www any-match = TRUE
www content type

This command allows you to define rule expressions to match the Content-Type field of HTTP/WSP headers.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] www content type [ case-sensitive ] operator content_type

- **no**
  - If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  - Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  - Specifies how to match.
  - **operator** must be one of the following:
    - !=: Does not equal
    - !contains: Does not contain
    - !ends-with: Does not end with
    - !starts-with: Does not start with
    - =: Equals
    - contains: Contains
    - ends-with: Ends with
    - starts-with: Starts with

- **content_type**
  - Specifies the value to match.
  - **content_type** must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
Usage

Use this command to define rule expressions to match the “content type” field of HTTP/WSP header.

Example

The following command defines a rule expression to match the WWW content type \textit{Accept}:

\begin{verbatim}
www content type = Accept
\end{verbatim}
**www domain**

This command allows you to define rule expressions to match the domain portion of URIs in WSP/HTTP packets.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

```

**Syntax**

```
[ no ] www domain [ case-sensitive ] operator domain
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  
  `operator` must be one of the following:
  
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equals
  - `contains`: Contains
  - `ends-with`: Ends with
  - `starts-with`: Starts with

- **domain**
  Specifies the domain to match.
  
  `domain` must be an alphanumeric string of 1 through 127 characters.

**Usage**

Use this command to define rule expressions to match the domain portion of URIs in WSP/HTTP packets.
From the URL, after http:// (if present) is removed, everything until the first "/" is the domain.

Example

The following command defines a rule expression to match user traffic based on domain name testdomain:

```
www domain = testdomain
```
www downlink

This command allows you to define rule expressions to match downlink (network to subscriber) HTTP/WSP packets.

Product

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```text
[ no ] www payload-length operator payload_length
```

- `no`
  If previously configured, deletes the specified rule expression from the current ruledef.

- `operator`
  Specifies how to match.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `<=`: Lesser than or equals
  - `==`: Equals
  - `>=`: Greater than or equals

- `payload_length`
  Specifies the payload length (in bytes) to match.
  `payload_length` must be an integer from 1 through 4000000000.

**Usage**

Use this command to define rule expressions to match WWW payload length.

**Example**

The following command defines a rule expression to match user traffic based on WWW payload length of 10000:

```
www payload-length = 10000
```
**www pdu-length**

This command allows you to define rule expressions to match WWW PDU length.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] www pdu-length operator pdu_length
```

- **no**
  
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  
  Specifies how to match. 
  
  **operator** must be one of the following:
  
  - `!`: Does not equal
  - `<=`: Lesser than or equals
  - `=`: Equals
  - `>=`: Greater than or equals

- **pdu_length**
  
  Specifies the WWW PDU length (in bytes) to match. 
  
  **pdu_length** must be an integer from 0 through 65535.

**Usage**

Use this command to define rule expressions to match WWW PDU length (header + payload) in bytes.

**Example**

The following command defines a rule expression to match user traffic based on WWW PDU length of 9767 bytes:

```
www pdu-length = 9767
```
**www previous-state**

This command allows you to define rule expressions to match previous HTTP/WSP(HTTP) state.

**Product**

ACS

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Ruledef Configuration

`active-charging service service_name > ruledef ruledef_name`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] www previous-state operator www_previous_state
```

- **no**
  
  If previously configured, deletes the specified rule expression from the current ruledef.

- **operator**
  
  Specifies how to match.
  
  `operator` must be one of the following:
  
  - `!=`: Does not equal
  - `==`: Equals

- **www_previous_state**
  
  Specifies the previous state to match.
  
  `www_previous_state` must be one of the following:
  
  - `init`
  - `response-error`
  - `response-ok`
  - `waiting-for-response`

**Usage**

Use this command to define rule expressions to match a previous HTTP/WSP(HTTP) state.

**Example**

The following command defines a rule expression to match user traffic based on WWW previous state `init`:

```
www previous-state = init
```
www reply code

This command allows you to define rule expressions to match WWW reply code arguments.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] www reply code operator reply_code

---

no
If previously configured, deletes the specified rule expression from the current ruledef.

---

operator
Specifies how to match.
operator must be one of the following:
• !=: Does not equal
• <=: Lesser than or equals
• ==: Equals
• >=: Greater than or equals

---

reply_code
Specifies the reply code to match.
reply_code must be an integer from 100 through 599.

Usage
Use this command to define rule expressions to match HTTP 1.1 status code, or WSP status code that has been remapped to the corresponding HTTP value.
WSP status codes 0 – 101 are automatically remapped to the HTTP status code values, as defined by Table 36 WAP-230-WSP Version 5.

Example
The following command defines a rule expression to analyze WWW user traffic based on reply code of 125:

www reply code = 125
www state

This command allows you to define rule expressions to match current HTTP/WSP(HTTP) state.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

\texttt{active-charging service service_name > ruledef ruledef_name}

Entering the above command sequence results in the following prompt:

[local]\texttt{host_name(config-acs-ruledef)#}

Syntax

\texttt{[ no ] www state operator current_state}

\underline{no}

If previously configured, deletes the specified rule expression from the current ruledef.

\underline{operator}

Specifies how to match.
\texttt{operator} must be one of the following:
\begin{itemize}
  \item \texttt{!}: Does not equal
  \item \texttt{=} : Equals
\end{itemize}

\underline{current_state}

Specifies the current state to match.
\texttt{current_state} must be one of the following:
\begin{itemize}
  \item \texttt{close}
  \item \texttt{response-error}
  \item \texttt{response-ok}
  \item \texttt{waiting-for-response}
\end{itemize}

Usage
Use this command to define rule expressions to match current HTTP/WSP state.

Example

The following command defines a rule expression to match user traffic based on the current WWW state close:

\texttt{www state = close}
www transfer-encoding

This command allows you to define rule expressions to match the transfer encoding field present in HTTP/WSP(HTTP) headers.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Ruledef Configuration

active-charging service service_name > ruledef ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-ruledef)#

Syntax

[ no ] www transfer-encoding [ case-sensitive ] operator transfer_encoding

---

no

If previously configured, deletes the specified rule expression from the current ruledef.

---

case-sensitive

Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

---

operator

Specifies how to match.

operator must be one of the following:

• !=: Does not equal
• !contains: Does not contain
• !ends-with: Does not end with
• !starts-with: Does not start with
• =: Equals
• contains: Contains
• ends-with: Ends with
• starts-with: Starts with

---

transfer_encoding

Specifies the WWW transfer encoding to match.

transfer_encoding must be an alphanumeric string of 1 through 127 characters and may contain punctuation characters.
**Usage**

Use this command to define rule expressions to match the “transfer encoding” field present in HTTP/WSP(HTTP) headers.

**Example**

The following command defines a rule expression to match user traffic based on the WWW transfer encoding `user1`:

```
www transfer-encoding = user1
```
**www url**

This command allows you to define rule expressions to match URL for any Web protocol analyzer—HTTP, WAP1.X, WAP2.0.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Ruledef Configuration

```
active-charging service service_name > ruledef ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-ruledef)#
```

**Syntax**

```
[ no ] www url [ case-sensitive ] operator url
```

- **no**
  If previously configured, deletes the specified rule expression from the current ruledef.

- **case-sensitive**
  Specifies that the rule expression be case-sensitive. By default, rule expressions are not case-sensitive.

- **operator**
  Specifies how to match.
  **operator** must be one of the following:
  - `!=`: Does not equal
  - `!contains`: Does not contain
  - `!ends-with`: Does not end with
  - `!starts-with`: Does not start with
  - `=`: Equality
  - `contains`: Contains
  - `ends-with`: Ends with
  - `regex`: Regular expression
  - `starts-with`: Starts with

- **url**
  Specifies the URL to match.
  **url** must be an alphanumerical string of 1 through 127 characters and may contain punctuation characters.
Usage

Use this command to define rule expressions to match the URL for any Web protocol analyzer—HTTP, WAP1.X, WAP2.0.

The following table lists the special characters that you can use in regex rule expressions. For more information on regex support, refer to the Enhanced Charging Service Administration Guide.

Table 13. Special Characters Supported in Regex Rule Expressions

<table>
<thead>
<tr>
<th>Regex Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Zero or more characters</td>
</tr>
<tr>
<td>+</td>
<td>Zero or more repeated instances of the token preceding the +</td>
</tr>
<tr>
<td>?</td>
<td>Match zero or one character</td>
</tr>
</tbody>
</table>

**Important:** The CLI does not support configuring “?” directly, you must instead use “\077”.

For example, if you want to match the string “xyz<any one character>pqr”, you must configure it as: `http host regex "xyz\077pqr"`

In another example, if you want to exactly match the string “url?resource=abc”, you must configure it as: `http uri regex "url\077resource=abc"`

Where, the first “\” (backslash) is for the escaping of “?”, and then “\077” for specifying “?” to the CLI.

<table>
<thead>
<tr>
<th>\character</th>
<th>Escaped character</th>
</tr>
</thead>
<tbody>
<tr>
<td>?</td>
<td>Match the question mark (&lt;ctrl-v&gt;?) character</td>
</tr>
<tr>
<td>+</td>
<td>Match the plus character</td>
</tr>
<tr>
<td>*</td>
<td>Match the asterisk character</td>
</tr>
<tr>
<td>\a</td>
<td>Match the Alert (ASCII 7) character</td>
</tr>
<tr>
<td>\b</td>
<td>Match the Backspace (ASCII 8) character</td>
</tr>
<tr>
<td>\f</td>
<td>Match the Form-feed (ASCII 12) character</td>
</tr>
<tr>
<td>\n</td>
<td>Match the New line (ASCII 10) character</td>
</tr>
<tr>
<td>\r</td>
<td>Match the Carriage return (ASCII 13) character</td>
</tr>
<tr>
<td>\t</td>
<td>Match the Tab (ASCII 9) character</td>
</tr>
<tr>
<td>\v</td>
<td>Match the Vertical tab (ASCII 11) character</td>
</tr>
<tr>
<td>\0</td>
<td>Match the Null (ASCII 0) character</td>
</tr>
<tr>
<td>\</td>
<td>Match the backslash character</td>
</tr>
</tbody>
</table>

Bracketed range [0-9] Match any single character from the range

A leading ^ in a range Do not match any in the range. All other characters represent themselves.

\x## Any ASCII character as specified in two-digit hex notation. For example, \x5A yields a “Z”.
### Regex Character

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Specify OR regular expression operator</td>
</tr>
</tbody>
</table>

**Important:** When using the regex operator “|” in regex expressions, always wrap the string in double quotes.

For example, if you want to match the string "pqr" OR "xyz", you must configure it as: `http host regex "pqr|xyz"`.

**Example**

The following command defines a rule expression to match user traffic based on WWW URL `www.abc.com`:

```
www url = www.abc.com
```

```
www url regex
"http://(tp2.site.com|134.210.11.3)/httppvc_clnsssite.com.wap.symphonieserver.musicwaver.com/"
```
Chapter 20
ACS Timedef Configuration Mode Commands

The ACS Timedef Configuration Mode enables configuring the Time-of-Day Activation/Deactivation feature.

Important: This configuration mode is only available in StarOS 8.1 and in StarOS 9.0 and later releases.

Mode

Exec > ACS Configuration > Timedef Configuration

active-charging service service_name > timedef timedef_name

Entering the above command sequence results in the following prompt:

[local] host_name(config-acs-timedef)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Use this command to return to the Exec mode.
**exit**

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
exit
```

**Usage**
Use this command to return to the parent configuration mode.
start

This command allows you to configure timeslots in the current timedef.

⚠️ **Important**: This command is only available in StarOS 8.1 and in StarOS 9.0 and later releases.

⚠️ **Important**: A maximum of 24 timeslots can be specified within a timedef.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Timedef Configuration

```
active-charging service service_name > timedef timedef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-timedef)#
```

**Syntax**

```
[ no ] start day { friday | monday | saturday | sunday | thursday | tuesday | wednesday } time hh mm ss end day { friday | monday | saturday | sunday | thursday | tuesday | wednesday } time hh mm ss
```

```
[ no ] start time hh mm ss end time hh mm ss
```

**no**

If previously configured, removes the specified timeslot from the current timedef.

```
start day { friday | monday | saturday | sunday | thursday | tuesday | wednesday } time hh mm ss end day { friday | monday | saturday | sunday | thursday | tuesday | wednesday } time hh mm ss
```

Specifies a timeslot with a start day and time, and an end day and time.

- **start day**: Specifies the start day and start time.
- **end day**: Specifies the end day and end time.
- **time hh mm ss**: Specifies the start/end time:
  - **hh**: Specifies the start/end hour, and must be an integer from 0 through 23.
  - **mm**: Specifies the start/end minute, and must be an integer from 0 through 59.
  - **ss**: Specifies the start/end second, and must be an integer from 0 through 59.

```
start time hh mm ss end time hh mm ss
```

Specifies a timeslot with a start time and an end time to be applicable for all days of the week.
In specifying the start/end time:
- **hh**: Specifies the start/end hour, and must be an integer from 0 through 23.
- **mm**: Specifies the start/end minute, and must be an integer from 0 through 59.
- **ss**: Specifies the start/end second, and must be an integer from 0 through 59.

### Usage

Use this command to create timeslots in a timedef during which rules have to be active. Timedefs enable activation/deactivation of ruledefs/groups-of-ruledefs such that they are available for rule matching only when they are active.

When a packet is received, and a ruledef/group-of-ruledefs is eligible for rule matching, if a timedef is associated with the ruledef/group-of-ruledefs, before rule matching, the packet-arrival time is compared with the timeslots configured in the timedef. If the packet arrived in any of the timeslots configured in the associated timedef, rule matching is undertaken, else the next ruledef/group-of-ruledefs is considered.

**Important**: The time considered for timedef matching is the system’s local time.

This release does not support configuring a timeslot for a specific date. If in a timeslot, only the time is specified that timeslot will be applicable for all days.

If for a timeslot “start time” is after “end time”, that rule will span midnight and be considered to be active from the current day until the next day.

If for a timeslot, “start day” is after “end day”, that rule will span the current week until the end day in the next week.

In the following cases a rule will be active all the time:
- A timedef is not configured in an action priority
- A timedef is configured in an action priority, but the named timedef is not defined
- A timedef is defined but without timeslots

### Example

The following command specifies a timeslot that starts on **Tuesday at 09:00:00** and ends on **Friday at 21:30:00**:

```
start day tuesday time 9 0 0 end day friday time 21 30 0
```

The following command specifies a timeslot that starts at **15:00:00** and ends at **17:00:00** on all days of the week:

```
start time 15 0 0 end time 17 0 0
```

The following command specifies a timeslot that starts on **Friday at 22:00:00** and ends on **Tuesday at 08:00:00**. This timeslot spans the complete week until the end day, up to **Tuesday**.

```
start day friday time 22 0 0 end day tuesday time 8 0 0
```

The following command specifies a timeslot that starts at **16:00:00** and ends at **09:00:00** on all days of the week. Also, as start time > end time, this timeslot spans midnight too (that is, from **16:00:00 to 23:59:59** and from **00:00:00 to 09:00:00**).

```
start time 16 0 0 end time 9 0 0
```
Chapter 21
ACS x-Header Format Configuration Mode Commands

The ACS x-header Format Configuration Mode is used to create and configure extension-header (x-header) formats.

⚠️ *Important:* This feature is license dependent. Please contact your Cisco sales representative for more information.

**Mode**

Exec > ACS Configuration > ACS xheader Format Configuration

```
active-charging service service_name > xheader-format format_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-acs-xheader)#
```

⚠️ *Important:* The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
**exit**

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
insert

This command allows you to configure the x-header fields to be inserted in HTTP/WSP GET and POST request packets.

**Important:** This command is license dependent. Please contact your Cisco accounts representative for more information.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > ACS xheader Format Configuration

`active-charging service service_name > xheader-format format_name`

Entering the above command sequence results in the following prompt:

```
> {context_name}host_name(config-acs-xheader)#
```

**Syntax**

In StarOS 8.1, StarOS 9.0, and later releases:

```
insert xheader_field_name { string-constant xheader_field_value | variable { bearer { 3gpp { apn | charging-characteristics | charging-id | imei | imsi | qos | rat-type | s-mcc-mnc | ggsn-address } | acr | congestion-level | customer-id | dest-server-ip-address-port | ggsn-address | mdn | msisdn-no-cc radius-string | radius-calling-station-id | session-id | sn-rulebase | subscriber-ip-address | time-of-day | username } [ encrypt ] | http { host | url } } [ delete-existing ] }
```

```
no insert xheader_field_name
```

In StarOS 8.0:

```
insert xheader_field_name { string-constant xheader_field_value | variable { bearer { 3gpp charging-id | ggsn-address | imsi | radius-string | radius-calling-station-id | ggsn-address | sn-rulebase | subscriber-ip-address } | http { host | url } }
```

```
no insert xheader_field_name
```

**no**

If previously configured, removes the specified x-header field configuration.

<table>
<thead>
<tr>
<th>xheader_field_name</th>
</tr>
</thead>
</table>

Specifies the x-header field name to be inserted in the packets.

**xheader_field_name** must be an alphanumeric string of 1 through 31 characters.

Up to ten fields can be inserted in each x-header format.
string-constant \textit{xheader\_field\_value} \\
Specifies constant a string value for x-header field to be inserted in the packets. \textit{xheader\_field\_value} must be the x-header field value, and must be an alphanumeric string of 1 through 63 characters.

\textbf{variable} \\
Specifies name of the x-header field whose value must be inserted in the packets.

\texttt{bearer \{ 3gpp \{ apn | charging-characteristics | charging-id | imei | imsi | qos | rat-type | s-mcc-mnc | ggsn-address \} | acr | congestion-level | customer-id | dest-server-ip-address-port | ggsn-address | mdn | msisdn-no-cc | radius-string | radius-calling-station-id | session-id | sn-rulebase | subscriber-ip-address | time-of-day | username \} [ encrypt ]} \\
Specifies value of x-header field to be inserted:

\begin{itemize}
\item \texttt{3gpp}: 3GPP service.
\end{itemize}

\begin{itemize}
\item \texttt{apn}: APN of the bearer flow. This field is deprecated from under \texttt{bearer apn} and has been added within \texttt{bearer 3gpp apn}. The APN added via \texttt{bearer 3gpp apn}.
\item \texttt{charging-characteristics}: Charging characteristics of the bearer flow.
\item \texttt{charging-id}: Charging ID of the bearer flow.
\item \texttt{imei}: IMEI or IMEISV (depending on the case) associated with the bearer flow.
\item \texttt{imsi}: Specific Mobile Station Identification number.
\item \texttt{qos}: EPC QoS associated with the bearer flow.
\end{itemize}

The inserted x-header is seen as:
\begin{verbatim}
x-bearer-qos: 020400000100000002000000010000000200
\end{verbatim}

\begin{itemize}
\item \texttt{rat-type}: This field is deprecated from under \texttt{bearer rat-type} and has been added within \texttt{bearer 3gpp rat-type}. The RAT type as added via \texttt{bearer 3gpp rat-type}.
\item \texttt{s-mcc-mnc}: 3GPP serving node MCC + MNC associated with the bearer.
\end{itemize}

The inserted x-header is seen as:
\begin{verbatim}
x-s-mcc-mnc: 123765
\end{verbatim}

\begin{itemize}
\item \texttt{ggsn-address}: SGSN associated with the bearer flow.
\end{itemize}

\begin{itemize}
\item \texttt{acr}: Anonymous Customer Reference. Only MSISDN part of this is encrypted, if encrypt flag is set.
\item \texttt{congestion-level}: Cell level congestion currently experienced by the subscriber.
\item \texttt{customer-id}: Customer ID of the bearer.
\item \texttt{dest-server-ip-address-port}: The IPv4 or IPv6 address of the Origin Server, and the TCP port of the HTTP request to the Origin Server.
\item \texttt{ggsn-address}: GGSN IP address field.
\item \texttt{imsi}: This field is deprecated from within \texttt{bearer imsi} and has been moved within \texttt{bearer 3gpp imsi}. The IMSI as added via \texttt{bearer 3gpp imsi}.
\item \texttt{mdn}: MDN of the bearer flow.
\item \texttt{msisdn-no-cc}: MSISDN of the mobile handling the flow without the country code.
\end{itemize}
 ACS x-Header Format Configuration Mode Commands

- **radius-string**: SN-Transparent-Data Attribute received in RADIUS ACCESS ACCEPT message.
- **radius-calling-station-id**: Calling Station ID of the mobile handling the flow. Use this for MSISDN of the mobile handling the flow with the country code.
- **session-id**: Accounting session ID of the bearer flow.
- **sn-rulebase**: Name of the ACS rulebase.
- **sgsn-address**: This field is deprecated from under **bearer sgsn-address** and has been moved within **bearer 3gpp sgsn-address**. The SGSN address as added via **bearer 3gpp sgsn-address**.
- **subscriber-ip-address**: Subscriber IP address.
- **time-of-day**: The current date, time, and time zone offset of the subscriber.
- **username**: User name of the bearer flow.

**encrypt**: Specifies encryption of x-header field configuration. This option must only be configured when x-header encryption is enabled.

```
http { host | url }
```

Specifies value of the x-header field to be inserted:
- **host**: Host
- **url**: Uniform Resource Locator

**delete-existing**

Specifies enabling detection of spoofing in x-header fields. The x-header field configured with this keyword will be removed from the HTTP header if it already exists, and only the gateway inserted field will remain. By default, anti spoofing is disabled, and if required, should be enabled at a field level.

**Usage**

Use this command to configure the x-header fields to be inserted in HTTP/WSP GET and POST request packets. The x-headers would be inserted at the end of the HTTP/WSP header. This CLI command may be used up to 10 times. There is no control over the order of the fields that are to be inserted. Any of the indicated ruledef variables may be inserted using the variable option, or a static string may be inserted using the string-constant option.

Operators may insert x-headers in some HTTP/WSP packets, for which some rules will be configured. The charging-action associated with these rules will contain the list of x-headers to be inserted in the packets.

**Example**

The following command configures an x-header field named **test12** with a constant string value of **testing** to be inserted in HTTP/WSP GET and POST request packets:

```
insert test12 string-constant testing
```
Chapter 22
ALCAP Configuration Mode Commands

The ALCAP Service Configuration Mode is used to create, provide, and manage the Access Link Control Application Part (ALCAP) on HNB-GW to support IuCS-over-ATM connectivity to HNB subscriber in a 3G UMTS networks towards CS core network.

Mode

Exec > Global Configuration > Context Configuration > ALCAP Service Configuration

configure > context context_name > alcap-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-alcap-service-service_name)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**aal2-node**

This command creates/configures AAL2 node configuration to defined AAL2 node properties for IuCS-over-ATM function.

**Product**  
HNB-GW

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > Global Configuration > Context Configuration > ALCAP Service Configuration

configure > context context_name > alcap-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-alcap-service-service_name)#
```

**Syntax**

```
aal2-node aal2_node_name [-noconfirm]

no aal2-node aal2_node_name
```

`no`

Removes the configured AAL2 node from ALCAP service configuration.

```
aal2_node_name
```

Identifies the name of the AAL2 node name to configure the AAL2 node parameters. The `aal2_node_name` must be an alphanumerical string from 1 through 63 characters.

**Usage**

Use this command to create/configure the AAL2 node configuration and switch to AAL2 Node Configuration mode.

Entering this command results in the following prompt:

```
[context_name]host_name(config-alcap-service-service_name)#
```

A maximum of TBD AAL2 node can be configured in one ALCAP service.

**Important:** The AAL2 Node configured here will be used to bind with ATM port in PVC Configuration sub-mode of ATM Configuration mode for IuCS-over-ATM functionality.

**Important:** For more information on AAL2 node configuration, refer *AAL2 Node Configuration Mode Commands*.

**Example**

Following command creates AAL2 node configuration mode named `aal2_1` within the specific ALCAP service for IuCS-over-ATM support towards CS core networks and switch the user to AAL2 Node Configuration Mode named `aal2_1`:
aal2-node aal2_node_name -noconfirm
**aal2-route**

This command defines a route for each ATM Endpoint Service Address (AESA) with which it can have transport layer communication. This route actually maps an AESA to one or more AAL2 paths which will be used to setup an end to end communication path.

**Product**

HNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > ALCAP Service Configuration

```bash
configure > context context_name > alcap-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-alcap-service-service_name) #
```

**Syntax**

```
    aal2-route end-point {AESA_address | default} aal2-node aal2_node_name
    no aal2-route end-point {AESA_address | default} [aal2-node aal2_node_name]
```

**Usage**

Use this command to create a mapping between ATM endpoint and adjacent node for AAL2 connection routing purposes.

It defines a route for each ATM Endpoint Service Address (AESA) with which it can have transport layer communication. This route actually maps an AESA to one or more AAL2 paths which will be used to setup an end to end communication path.
The `default` keyword can be used to configure a default `aal2-route` which will match any AESA received from MSC and for which AESA specific route is not configured. When a connection is established an AESA specific route will have higher priority than default route.

**Important:** The default route shall not be used when AESA specific route exists.

If an HNB-GW configured with a route for `MGW1` which consists of `AAL2_path_A` and `AAL2_path_B` for `AAL2 switch-A` and `AAL2 switch-B` switch respectively then similarly `AAL2 switch-A` and `AAL2 switch-B` need to be configured with routes for `MGW1`.

A maximum of `TBD` AAL2 routes can be configured in one ALCAP service.

**Example**

Following command create a mapping between ATM endpoint `MGW1` and AAL2 node `aal2_1` for AAL2 connection routing purposes:

```
  aal2-route end-point MGW1 aal2-node aal2_1
```
### associate

This command associates a previously configured SS7 routing domain with this ALCAP service on HNB-GW node which will be used to define the SS7 routing domain in 3G UMTS networks.

**Product**

HNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > ALCAP Service Configuration

`configure > context context_name > alcap-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-alcap-service-service_name)#
```

**Syntax**

```
associate ss7-routing-domain ss7_rd_id

no associate ss7-routing-domain
```

**no**

Removes the associated SS7 routing domain id from this ALCAP service configuration.

**ss7_rd_id**

Identifies the SS7 routing domain index configured in Global configuration mode to associate with ALCAP service for IuCS-over-ATM support.

The `ss7_rd_id` must be an integer from 1 through 12.

**Important:** For SS7 routing domain configuration, refer to the `SS7 Routing Domain Configuration Commands Mode` chapter.

**Usage**

Use this command to associate a preconfigured SS7 routing domain index to provide IuCS-over-ATM support towards CS core network for HNB subscriber.

A maximum of `TBD` SS7 routing domains can be configured in one ALCAP service.

**Example**

Following command associates a predefined SS7 routing domain id 3 with ALCAP service to define routing domain for IuCS-over-ATM support towards CS core networks:

```
associate ss7-routing-domain 3
```
**end**

Exits the current mode and returns to the Exec Mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Change the mode back to the Exec mode.
exit

Exits the current mode and returns to the previous mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the previous mode.
maximum reset-retransmission

This command sets the maximum number of retries allowed for transmission of RESET message to reset the AAL2 path.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > ALCAP Service Configuration

configure > context context_name > alcap-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-alcap-service-service_name)#

Syntax

maximum reset-retransmissions retries

default maximum reset-retransmissions

default

Sets the number of RESET message retries to default value of 1.

retries

Sets the maximum number of retries allowed for transmission of RESET message to reset the AAL2 path by ALCAP service.

retries must be an integer value from 0 through 4. When 0 is used retransmission will be disabled.
Default: 1

Usage

Use this command to sets the maximum number of retries allowed for transmission of RESET message by ALCAP service to reset the AAL2 path when Timer_RES expires. Once the maximum number of RESET retries have been performed the ALCAP service shall stop the RESET procedure for the affected path and path will become available for connections.

Example

The following command configures ALCAP service to send maximum number of 2 RESET messages after expiry of RESET timer for AAL2 path RESET procedure:

maximum reset-retransmissions 2
**self-point-code**

This command specifies the SS7 point code address for ALCAP service.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ALCAP Service Configuration

```
configure > context context_name > alcap-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-alcap-service-service_name)#
```

**Syntax**

```
self-point-code point_code

no self-point-code

no
```

Deletes the configured self point code for this ALCAP service.

```
point_code
```

Defines the point code to assign to this ALCAP service.

**point_code:** value entered must adhere to the point code variant selected when the ALCAP service instance was defined:

- ITU Range 0.0.1 to 7.255.7
- ANSI Range 0.0.1 to 255.255.255
- TTC Range 0.0.1 to 15.31.255
- a string of 1 to 11 combined digits and period.

**Usage**

Use this command to assign the self point code to use for this ALCAP service.

**Example**

The following command sets an ITU-based point code for this ALCAP service:

```
self-pointcode 4.121.5
```

The following command removes the configured self-point code:

```
no self-pointcode
```
timeout alcap

This command configures the timeout duration for various ALCAP procedure timers in ALCAP service.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > ALCAP Service Configuration

configure > context context_name > alcap-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-alcap-service-service_name)#
```

**Syntax**

```
timeout alcap {blo blo_timer_value | erq erq_timer_value | mod mod_timer_value | rel rel_timer_value | res res_timer_value | ubl ubl_timer_value}

default timeout alcap {blo | erq | mod | rel | res | ubl}
```

default

Sets the timer values to default duration for specific ALCAP procedure in an ALCAP service.

**blo**

```
blo blo_timer_value
```

Specifies the maximum time, in seconds, the system waits for response from adjacent AAL2 node before reporting the failure of AAL2 Path Block procedure. When a request to block a particular AAL2 path is received by ALCAP service, the ALCAP service sends ALCAP-BLOCK-REQUEST message to AAL2 node/peer ALCAP Manage and starts Timer_BLO timer. The timer waits for specified timeout duration \( blo\_timer\_value \) for ALCAP-BLOCK-CONFIRM message before reporting error in procedure. If AAL2 Node responds with ALCAP-BLOCK-CONFIRM message the timer will stop before the expiry of timeout duration and system reports the successful completion of the procedure.

\( blo\_timer\_value \) must be an integer value from 2 through 60.

Default: 5

**erq**

```
erq erq_timer_value
```

Specifies the maximum time, in seconds, the system waits for response from adjacent AAL2 node before reporting the failure of AAL2 Establish Request procedure. When a request to establish a connection through ALCAP-ESTABLISH-REQUEST message is sent to AAL2 node the system starts the Timer_ERQ timer. The timer waits for specified timeout duration \( erq\_timer\_value \) for ALCAP-ESTABLISH-CONFIRM message before reporting error in procedure and system requests ALCAP Manager to free the AAL2-channel used for connection and also indicates to start the RESET procedure for this channel.

If AAL2 Node responds with ALCAP-ESTABLISH-CONFIRM message the timer will stop before the expiry of timeout duration and system reports the successful completion of the procedure.

\( erq\_timer\_value \) must be an integer value from 5 through 30.

Default: 5
mod  mod_timer_value

Specifies the maximum time, in seconds, the system waits for response from adjacent AAL2 node before reporting the failure of AAL2 Modify Request procedure. When a request to modify a connection or channel through ALCAP-MODIFY-REQUEST message is sent to AAL2 node the system starts the Timer_MOD timer. The timer waits for specified timeout duration mod_timer_value for ALCAP-MODIFY-CONFIRM message before reporting error in procedure and system requests ALCAP Manager to initiate the RESET or any other appropriate procedure for this channel and HNB-GW shall release the RUA connection towards HNB and SCCP connection towards CN.

If AAL2 Node responds with ALCAP-MODIFY-CONFIRM message the timer will stop before the expiry of timeout duration and system reports the successful completion of the procedure.

mod_timer_value must be an integer value from 5 through 30.

Default: 5

rel  rel_timer_value

Specifies the maximum time, in seconds, the system waits for response from adjacent AAL2 node before reporting the failure of AAL2 Release Request procedure. When a request to release a connection or channel through ALCAP-RELEASE-REQUEST message is sent to AAL2 node the system starts the Timer_REL timer and sends RAB-ASST-REQ to HNB. The timer waits for specified timeout duration rel_timer_value for ALCAP-RELEASE-CONFIRM message before reporting error in procedure and system requests ALCAP Manager to release the AAL2 channel. System also indicates to start RESET procedure for this channel.

If AAL2 Node responds with ALCAP-RELEASE-CONFIRM message the timer will stop before the expiry of timeout duration and system reports the successful completion of the procedure.

rel_timer_value must be an integer value from 2 through 60.

Default: 2

res  res_timer_value

Specifies the maximum time, in seconds, the system waits for response from adjacent AAL2 node before reporting the failure of AAL2 Reset Request procedure. When a request to reset a connection or channel through ALCAP-RESET-REQUEST message is sent to AAL2 node the system starts the Timer_RES timer. The timer waits for specified timeout duration res_timer_value for ALCAP-RESET-CONFIRM message before retrying the RESET procedure. The system will retry the RESET procedure for configured number of times and on completion of retry limit the stops the RESET procedure for the affected path and path will become available for connections.

If AAL2 Node responds with ALCAP-RESET-CONFIRM message the timer will stop before the expiry of timeout duration and system reports the successful completion of the procedure.

res_timer_value must be an integer value from 2 through 60.

Default: 2

ubl  ubl_timer_value

Specifies the maximum time, in seconds, the system waits for response from adjacent AAL2 node before reporting the failure of AAL2 Path UnBlock procedure. When a request to unblock a particular AAL2 path is received by ALCAP service, the ALCAP service sends ALCAP-UNBLOCK-REQUEST message to AAL2 node/peer ALCAP Manager and start Timer_BLO timer. The timer waits for specified timeout duration ubl_timer_value for ALCAP-UNBLOCK-CONFIRM message before reporting error in procedure.

If AAL2 node/peer ALCAP Manager responds with ALCAP-BLOCK-CONFIRM message the timer will stop before the expiry of timeout duration and system reports the successful completion of the procedure.

ubl_timer_value must be an integer value from 2 through 60.

Default: 2
**Usage**

Use this command to configure the timeout duration for various ALCAP procedures in ALCAP service.

**Example**

The following command sets the timeout duration of 10 seconds for ALCAP-MODIFY-REQUEST procedure:

```
  timeout alcap mod 10
```
timeout stc

This command configures the timeout duration for STC long (T30) and and STC short (T29) timers used in congestion indication procedure at Signaling Transport Converter (STC) layer in ALCAP service.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > ALCAP Service Configuration
configure > context context_name > alcap-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-alcap-service-service_name)#

Syntax

timeout stc {long long_timer_value | short short_timer_value}
default timeout stc {long | short}

Sets the timer values to default duration for specific STC procedure in an ALCAP service.

long long_timer_value

Specifies the duration in milliseconds for STC long timer. This timer is used by the congestion indication procedure. Receipt of a repeated congestion indication from MTP3B before the expiry of this timer is interpreted as the congestion situation. On the other hand, if no congestion indication is received from MTP3B before expiry of this timer, the congestion situation is considered to have improved.

long_timer_value must be an integer value from 5000 through 10000.
Default: 5000

short short_timer_value

Specifies the duration in milliseconds for STC short timer. This timer is used by the congestion indication procedure. The role of this timer is to avoid overreacting if multiple congestion indications are received from MTP3B in quick succession.

short_timer_value must be an integer value from 300 through 600.
Default: 300

Usage

Use this command to configure the long (T30) and short (T29) timer for congestion indication procedure in ALCAP service.

When the first congestion indication is received by, the traffic load into the affected destination point code is reduced and the same time two timers STC short timer (T29) and STC long timer (T30) are started. During STC short timer all received congestion indications for the same destination point code are ignored in order
not to reduce traffic too rapidly. Reception of a congestion indication after the expiry of STC short timer, but still during STC long timer, will decrease the traffic load by one more step and restart both the timers again. If STC long timer expires (i.e. no congestion indications having been received during the STC long timer period), traffic will be increased by one step and STC long timer will be restarted unless full traffic load has been resumed.

Example

The following command sets the timeout duration of 5000 milliseconds for STC long timer:

```
default timeout stc long
```

The following command sets the timeout duration of 300 milliseconds for STC short timer:

```
default timeout stc short
```
Chapter 23
APN Configuration Mode Commands

The Access Point Name (APN) Configuration Mode is used to create and configure APN profiles within the current system context of an UMTS/LTE service.

Mode

Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
aaa

This command configures Authentication, Authorization, and Accounting (AAA) functionality at the Access Point Name (APN) level.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name] host_name(config-apn) #

Syntax

aaa { group aaa_group_name | secondary-group aaa_group_name }
default aaa { group | secondary-group aaa_group_name }
no aaa { group | secondary-group }

no aaa
Disables the specified AAA group for the specific APN.

no aaa { group | secondary-group }

• group: Uses the default AAA group.
• secondary-group: Removes the secondary AAA group from the APN’s configuration.

default aaa { group | secondary-group }

Configures the default setting for the specified parameter.
• group: Uses the default AAA group—the one specified at the context level or in the APN template.
• secondary-group: Removes the secondary AAA group from the APN configuration.

aaa_group_name

Specifies the AAA server group for the APN.
aaa_group_name must be an alphanumeric string of 1 through 63 characters.

secondary-group aaa_group_name

Specifies the secondary AAA server group for the APN.
aaa_group_name must be an alphanumeric string of 1 through 63 characters.
Usage

Use this command to configure AAA functionality at the APN level.
Instead of having a single list of servers per context, this feature configures multiple server groups within a
context and applies individual server group for APNs in that context. Each server group consists of a list of
AAA servers for each AAA function (accounting, authentication, charging, etc.).
The AAA secondary server group supports the RADIUS Fire-and-Forget feature in conjunction with GGSN
for secondary accounting (with different RADIUS accounting group configuration) to the RADIUS servers
without expecting acknowledgement from the server, in addition to standard RADIUS accounting. This
secondary accounting will be an exact copy of all the standard RADIUS accounting message (RADIUS Start
/ Interim / Stop) sent to the standard AAA RADIUS server.
If the same AAA group is configured with both the aaa group aaa_group_name and the aaa
secondary-group aaa_group_name commands, then this configuration will have no effect and secondary
accounting will not happen.
The AAA secondary server group configuration takes effect only when used with APN accounting-mode set
to radius-diameter (or) with mediation-acct enabled. The RADIUS accounting triggers for both standard
RADIUS accounting and secondary accounting will be taken from the AAA group configured with the aaa
group aaa_group_name command. On the fly change of this configuration is not supported. Any change to
the configuration will have effect only for new calls.

Example

The following command applies the AAA server group star1 to an APN within the specific context:

    aaa group star1
**access-link**

Configures IP fragmentation processing over the Access-link (PPP, GTP etc.).

**Product**

- GGSN
- P-GW
- SAEGW

**Privilege**

- Security Administrator, Administrator

**Mode**

- Exec > Global Configuration > Context Configuration > APN Configuration
- `configure > context context_name > apn apn_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
access-link ip-fragmentation { normal | df-ignore | df-fragment-and-icmp-notify }

default access-link ip-fragmentation
```

- **normal**
  
  Default: Enabled
  
  Drops the packet and sends an ICMP unreachable message to the source of packet. This is the default behavior.

- **df-ignore**
  
  Default: Disabled
  
  Ignores the DF (Don’t Fragment) bit setting; fragments and forwards the packet over the access link.

- **df-fragment-and-icmp-notify**
  
  Default: Disabled
  
  Partially ignore the DF bit; fragments and forwards the packet, but also returns an ICMP error message to the source of the packet. The number of ICMP errors sent like this is rate-limited to one ICMP error packet per second per session.

**Usage**

If the IP packet to be forwarded is larger than the access-link MTU and if the DF (Don’t Fragment) bit is set for the packet, then the fragmentation behavior configured by this command is applied. Use this command to fragment packets even if they are larger than the access-link MTU.

Fragmentation may also occur for other reasons, regardless of whether or not fragmentation is performed because of one of the above reasons.

Payloads are encapsulated within IP/UDP/GTP before being sent to the SGSN. If that encapsulation causes the packet to exceed 1500 bytes, the inner IP payload is fragmented (even if it's not considered too-large by...
the above tests) into two payloads (if the DF bit is not set). If the DF bit is set (and access-link ip-
fragmentation normal is configured), the system performs IP fragmentation of the entire packet (i.e., IP
fragmentation in the outer IP header) rather than fragmenting the inner IP payload. Either way, the result is
two packets, but in one case the MS would have to perform IP reassembly while in the other case the SGSN
would have to perform reassembly.

Example

Set fragmentation so that the DF bit is ignored and the packet is forwarded anyway by entering the following
command:

\texttt{access-link ip-fragmentation df-ignore}
**accounting-mode**

Configures the protocol to be used for PDP context accounting by this APN.

**Product**

- eWAG
- GGSN
- P-GW
- SAEGW

**Privilege**

- Security Administrator, Administrator

**Mode**

`Exec > Global Configuration > Context Configuration > APN Configuration`

`configure > context context_name > apn apn_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
accounting-mode { gtpp | none | radius-diameter [ no-early-pdus ] [ no-interims ] }
```

**default accounting-mode**

- **default**
  
  Restores the command to its default setting.

- **gtpp**
  
  Configures the APN to use GPRS Tunneling Protocol Prime for accounting purposes. If used, accounting will begin as soon as the PDP context is established. This is the default setting. Default: Enabled

**Important:** The system’s GTPP parameters must be configured prior to using this protocol for accounting. Refer to the `gtpp` commands in the *Context Configuration Mode Commands* chapter.

- **none**
  
  Disables accounting for PDP contexts using this APN.
  
  When accounting mode is set to none, it indicates to the GTP stack at session manager to not generate the regular GTPP accounting triggers. Default: Disabled.

- **radius-diameter**
  
  Configures the APN to use RADIUS protocol for accounting purposes. Default: Disabled
**Important:** The system’s RADIUS accounting parameters must be configured prior to using either of the protocols for accounting. Refer to the `radius` commands in the **Context Configuration Mode Commands** and the **AAA Server Group Configuration Mode Commands** chapters.

### no-early-pdus

Configures the GGSN to discard user traffic once the buffer is full until the RADIUS server has returned a response to the GGSN’s accounting START request per 3GPP standards.

Configures the GGSN to delay PDUs from/to MS until the RADIUS server returns a response to the GGSN’s accounting START request as per 3GPP standards. The GGSN buffers up to two PDUs per call. Additional PDUs disable the queuing. On receiving the Accounting response message, the GGSN forwards all the subsequent PDUs for that call.

**Important:** For StarOS 10.0 and earlier releases, the system buffers up to four PDUs and queues or discards the remaining PDUs.

**Important:** For StarOS 11.0 and later releases, the system is configured so that none of the PDUs are discarded.

### no-interims

Disables the generation of RADIUS interims per APN.

When configured, RADIUS interim updates for this APN will not be sent, regardless of what is configured in the context that is used for RADIUS accounting.

**Important:** Different CLI commands are used to disable RADIUS interims for RADIUS accounting and mediation accounting. To disable RADIUS interims for RADIUS accounting, use the following command: `accounting-mode radius no-interims`. To disable RADIUS interims for mediation accounting, use the following command: `mediation-device context-name context_name no-interims`.

### Usage

This command specifies which protocol, if any, will be used to provide accounting for PDP contexts accessing the APN profile.

When the GTPP protocol is used, accounting messages are sent to the charging gateways (CGs) over the Ga interface. The Ga interface and GTPP functionality are typically configured within the system’s source context. As specified by the standards, a CDR is not generated when a session starts - CDRs are generated according to the interim triggers (configured using the `cc` command in the GGSN service configuration mode) and a CDR is generated when the session ends. For interim accounting, STOP/START pairs are sent based on configured triggers.

GTPP version 2 is always used. However, if version 2 is not supported by the CGF, the system reverts to using GTPP version 1. All subsequent CDRs are always fully-qualified partial CDRs. All CDR fields are R4.

If the `radius` option is used, RADIUS protocol is used as configured in the Context Configuration mode or the AAA Server Group Configuration mode.

If the RADIUS protocol is used, accounting messages can be sent over a AAA interface or the Gi to the RADIUS server. The AAA or Gi interface(s) and RADIUS functionality are typically configured with the system’s destination context along with the APN. RADIUS accounting begins immediately after an IP address is allocated for the MS. Interim accounting can be configured using the `radius accounting`
interim interval. The **radius accounting interim interval** command sends INTERIM-UPDATE messages at specific intervals.

Keywords to this command can be used in combination to each other, depending on configuration requirements.

---

**Important:** If the accounting type in the APN is set to 'none' then G-CDRs will not be generated. If accounting type is left as default “GTPP” and “billing-records” are configured in the ACS Rulebase Configuration Mode, then both G-CDRs and eG-CDRs would be generated.

---

**Example**

The following command configures the APN to use the RADIUSr protocol for accounting:

```
accounting-mode radius
accounting-mode radius no-interims no-early-pdus
accounting-mode radius no-early-pdus no-interims
```
**active-charging bandwidth-policy**

Configures the bandwidth policy to be used for subscribers who use this APN.

**Product**
- ACS
- GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
active-charging bandwidth-policy bandwidth_policy_name

{ default | no } active-charging bandwidth-policy [ fallback-enabled ]
```

- **default**
  Configures the default setting.
  Default: The default bandwidth policy configured in the rulebase is used for subscribers who use this APN.

- **no**
  Disables bandwidth control for the APN.

- **bandwidth-policy bandwidth_policy_name**
  Specifies the bandwidth policy name. `bandwidth_policy_name` must be an alphanumeric string from 1 through 63 characters.

- **fallback-enabled**
  Determines whether policy under rulebase can be applied as a fallback value. Fallback is disabled by default.

**Usage**
Use this command to configure bandwidth policy to be used for subscribers who use this APN.

**Example**
The following command configures a bandwidth policy named `standard` for the APN:

```
active-charging bandwidth-policy standard [ fallback-enabled ]
```
active-charging link-monitor tcp

Enables the TCP link monitoring feature on the Mobile Video Gateway. This command can be configured in either APN Configuration Mode or Subscriber Configuration Mode.

**Product**
MVG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

**Syntax**

```
```

- **default**
  Sets TCP link monitoring to its default value, which is the same as **no**.

- **no**
  Deletes the TCP link monitoring settings and disables TCP link monitoring if previously configured.

**link-monitor tcp**

Enables the TCP link monitoring feature on the Mobile Video Gateway. Note that TCP link monitoring is not enabled by default. Also note that when this command is configured without the `log` option, TCP link monitoring is enabled without logging, and the output from TCP link monitoring is only used by the dynamic translating feature.

```
log [ rtt [ histogram | time-series ] ] [ bitrate [ histogram | time-series ] ]
```

This option enables statistical logging for TCP link monitoring.

The `rtt` option can be used to enable either `histogram` or `time-series` logging for RTT.

Similarly, the `bitrate` option can be used to enable either `histogram` or `time-series` logging for bit rate.

When `rtt` and `bitrate` options are used without additional options, histogram and time-series logging are enabled for RTT and/or bit rate respectively.

- **-noconfirm**
  Specifies that the command must execute without prompting for confirmation.
**Usage**

Use this command to enable TCP link monitoring on the Mobile Video Gateway.

**Examples**

The following command enables TCP link monitoring with statistical logging, with histogram and time-series logging enabled for both RTT and bit rate:

```
active charging link-monitor tcp log
```

The following command enables TCP link monitoring with statistical logging, with histogram and time-series logging enabled for RTT:

```
active charging link-monitor tcp log rtt
```

The following command enables TCP link monitoring with statistical logging, with histogram logging enabled for RTT:

```
active charging link-monitor tcp log rtt histogram
```

The following command enables TCP link monitoring with statistical logging, with histogram logging enabled for RTT and time-series logging enabled for bit rate:

```
active charging link-monitor tcp log rtt histogram bitrate time-series
```
active-charging rulebase

Specifies the name of the Active Charging Service (ACS) rulebase to be used for subscribers who use this APN.

**Product**
ACS
eWAG
GGSN
MVG
P-GW
SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**

configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```bash
active-charging rulebase rulebase_name

no active-charging rulebase
```

**Usage**

Use this command to specify the ACS rulebase to be used for subscribers who use the APN.

**Example**

The following command specifies the ACS rulebase named `rule1` for the APN:

```bash
active-charging rulebase rule1
```
active-charging rulebase-list

Specifies the name of the ACS rulebase list to be used for subscribers who use this APN.

Product
ACS
GGSN
MVG
P-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration
```bash
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:
```
[context_name]host_name(config-apn)#
```

Syntax

```
active-charging rulebase-list rulebase_list_name

no active-charging rulebase-list
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>active-charging</code></td>
<td>Activates the rulebase list for the APN</td>
</tr>
<tr>
<td><code>rulebase_list_name</code></td>
<td>Specifies the name of the ACS rulebase list</td>
</tr>
<tr>
<td><code>no</code></td>
<td>Removes the rulebase list configured in the APN</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to specify the ACS rulebase list to be used for subscribers who use the APN. The rulebase list is created and configured in the ACS Configuration Mode. For more information, see the `rulebase-list` command in the *ACS Configuration Mode Commands* chapter.

**Example**

The following command specifies the ACS rulebase list named `rblist` for the APN:

```
active-charging rulebase-list rblist
```

The following command removes the rulebase list named `rblist` from the APN:

```
no active-charging rulebase-list rblist
```
apn-ambr

Configures the Aggregated Maximum Bit Rate (AMBR) for all PDNs using this APN.

**Product**
- P-GW
- SAEGW
- GGSN

**Privilege**
 Administrator

**Mode**
 Exec > Global Configuration > Context Configuration > APN Configuration

`configure > context context_name > apn apn_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
apn-ambr rate-limit direction { downlink | uplink } [ burst-size { auto-readjust duration seconds | bytes } | violate-action { drop | lower-ip-precedence | shape [ transmit-when-buffer-full ] | transmit } ]
```

[ default | no ] apn-ambr rate-limit direction { downlink | uplink } 

---

**default**

Returns the selected command to it’s default setting of no APN-AMBR.

---

**no**

Disables the selected command.

---

**rate-limit direction { downlink | uplink }**

Specifies that the rate limit is to be applied to either the downlink (network to subscriber) traffic or the uplink (subscriber to network) traffic.

- **downlink**: Applies the AMBR parameters to the downlink direction.
- **uplink**: Applies the AMBR parameters to the uplink direction.

---

**burst-size { auto-readjust duration seconds | bytes }**

This parameter is used by policing and shaping algorithms to permit short bursts of traffic in order to not exceed the allowed data rates. It is the maximum size of the token bucket.

- **auto-readjust duration seconds**: The duration (in seconds) used in this burst size calculation: burst size = peak data rate/8 * auto-readjust duration
  - `seconds` must be an integer value from 1 to 30. Default is 1 second
- **bytes**: Specifies the burst size in bytes allowed by this APN for the associated PDNs. It must be an integer from 1 to 4294967295 (1 byte to 4 GB).
**Important:** In 17.3 and later releases, this option has been deprecated.

```plaintext
violate-action { drop | lower-ip-precedence | shape [ transmit-when-buffer-full ] | transmit }
```

The action that the P-GW will take when the data rate of the bearer context exceeds the AMBR.

- **drop**: Drops violating packets.
- **lower-ip-precedence**: Sets the DSCP value to zero (“best effort”) for violating packets.
- **shape [ transmit-when-buffer-full ]**: Places all violating packets into a buffer and, optionally, transmits the packets when the buffer is full.

**Important:** The **shape** keyword and optional **transmit-when-buffer-full** are only available in StarOS v12.0 and earlier releases. P-GW does not currently support traffic shaping for APN-AMBR.

- **transmit**: Transmits violating packets. This is the default setting.

### Usage

Use this command to enforce the AMBR for the APN on bearers that do not have a Guaranteed Bit Rate (GBR).

### Example

The following command sets the downlink burst rate to use an auto-readjust duration of 2 seconds and lowers the IP precedence of violating packets:

```
apn-ambr rate-limit direction downlink burst-size auto-readjust duration 2 violate-action lower-ip-precedence
```
associate accounting-policy

Associates the APN with specific pre-configured policies configured in the same context.

Product

P-GW
SAEGW

Privilege

Administrator

Mode

Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

[ no ] associate accounting-policy name

no

Removes the selected association from this APN.

name

Associates the P-GW APN with an accounting policy configured in the same context. name must be an existing accounting policy expressed as a string of 1 through 63 characters.

Accounting policies are configured through the policy accounting command in the Context Configuration mode.

Usage

Use this command to associate the P-GW APN with an accounting policy configured in this context.

Example

The following command associates this P-GW APN with an accounting policy called acct1:

associate accounting-policy acct1
associate qci-qos-mapping

Associates a pre-configured QCI-QoS-Mapping table with this APN to support per APN DSCP marking.

Product
P-GW
SAEGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration
configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

[ no ] associate qci-qos-mapping qci_qos_map_table_name

no
Removes the selected association of QCI-QoS-Mapping table from this APN.

qci_qos_map_table_name
Specifies a preconfigured QCI-QoS-Mapping table from global configuration mode to this APN.
qci_qos_map_table_name must be an existing QCI-QoS-mapping table expressed as a string of 1 through 63 characters.
QCI-QoS-Mapping tables are configured in QCI-QoS_Mapping Configuration mode.

Usage
Use this command to associate a preconfigured QCI-QoS-Mapping table with an APN to provide per APN basis DSCP marking.
The GGSN/PGW supports configurable DSCP marking of the outer header of a GTP-U tunnel packet based on a QCI/THP table for the Gn/Gp and S5/S8 interfaces. This feature allows configuring DSCP marking table on a per APN basis.

Important: In order to be backward compatible with old configuration, if a DSCP marking table is associated with GGSN service and not with the APN, then the one in GGSN service will be used. If table is associated in both GGSN service and APN, then the one on APN will take precedence.

Example
The following command associates a preconfigured QCI-QoS-Mapping table dscp_mark_table1 with this APN.

associate qci-qos-mapping dscp_mark_table1
authentication

Configures the APN’s authentication parameters.

Product

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

```
```

default authentication

default

Sets the default authentication type for this APN. By default allow-noauth is the type for authentication for an APN.

msid-auth

Obsolete. Use imsi-auth.

imsi-auth

Default: Disabled.
Configures the APN to attempt to authenticate the subscriber based on their International Mobile Subscriber Identification (IMSI) number.

msisdn-auth

Default: Disabled.
Configures the APN to attempt to authenticate the subscriber based on their Mobile Station International Integrated Services Digital Network (MSISDN) number as described in the Usage section of this command.
username-strip-apn
Default: Disabled.
This keyword if enabled, either with msisdn-auth or imsi-auth strips the APN name from the user name msisdn@apn or imsi@apn received from AAA and makes the user name as msisdn or imsi respectively.

username-append-apn
Default: Disabled.
This keyword if enabled, works only with pap and chap options. If username-append-apn option enabled in authentication CLI, then apn name will be appended to the pco received username and same username will be used across all interfaces.

password-use-pco
Default: Disabled.
This keyword, if enabled, uses the password received through Protocol Configuration Options (PCO) from AAA for authentication.

prefer-chap-pco
Default: Disabled.
If this keyword along with msisdn-auth/imsi-auth is enabled, GGSN performs Challenge Handshake Authentication Protocol (CHAP) authentication, if CHAP parameters are received in Protocol Configuration Options (PCO). However, chap username would be constructed as msisdn@apn / imsi@apn and chap challenge, chap response parameters should be used as it is from CHAP parameters received in the PCO IE. If CHAP parameters are not received in the PCO IE of the CPC Request, GGSN does normal Password Authentication Protocol (PAP) authentication with PAP username as msisdn@apn / imsi@apn (ignoring any PAP username if received).

eap initial-access-request
Default: Enabled
Configures the type of initial access request to be used in Diameter EAP (Extensible Authentication Protocol) request. This feature is applicable to only Diameter-based AAA interface and not applicable to RADIUS or any other type of AAA interface.

authenticate-authorize
Default: Enabled
Configures the “authenticate and authorize” type of initial access request to be used in a Diameter EAP request.

authenticate-only
Default: Disabled
Configures the “authenticate only” type of initial access request to be used in a Diameter EAP request.

allow-noauth
Default: Enabled
Configures the APN to not perform authentication for PDP contexts as described in the Usage section.

pco-username
Default: Disabled
This option is used in conjunction with allow-noauth. It allows session to get established when PCO contains both pap and chap in authentication disabled case.

```
chap preference
```
Default: Disabled
Configures the APN to attempt to use CHAP to authenticate the subscriber as described in the Usage section of this command.
A preference must be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on. It must be an integer from 1 through 1000. The lower the integer, the higher the preference.

```
convert-to-mschap
```
Default: Disabled
If enabled, the CHAP parameters received with the length of 49 bytes, the AAAmgr converts it to MSCHAP.

```
mschap preference
```
Default: Disabled
Configures the APN to attempt to use the Microsoft Challenge Handshake Authentication Protocol (MSCHAP) to authenticate the subscriber as described in the Usage section of this command.
A preference can be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on. It must be an integer from 1 through 1000. The lower the integer, the higher the preference.

```
pap preference
```
Default: Disabled
Configures the APN to attempt to use PAP to authenticate the subscriber as described in the Usage section of this command.
A preference must be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on. It must be an integer from 1 through 1000. The lower the integer, the higher the preference.

**Usage**

Use this command to specify how the APN profile should handle PDP context authentication and what protocols to use (if any). The ability to configure this option is provided to accommodate the fact that not every MS will implement the same authentication protocols.
The authentication process varies depending on whether the PDP context is of type IP or PPP. Table given in this section describes these differences.
For IP PDP contexts, the authentication protocol and values will be passed from the SGSN as Protocol Configuration Options (PCOs) within the create PDP context PDU to the GGSN. The GGSN requires that the authentication protocol is specified by this command (with no regard to priority) and will use this information to authenticate the subscriber.

Table 14. Authentication Process Variances Between PDP Context Type

<table>
<thead>
<tr>
<th>Authentication Mechanism</th>
<th>IP PDP Context Behavior</th>
<th>PPP PDP Context Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Authentication Mechanism</td>
<td>IP PDP Context Behavior</td>
<td>PPP PDP Context Behavior</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>allow-noauth</td>
<td>Allows the session even if the PCOs do not match any of the configured algorithms. If there was no match and the <code>aaa constructed-nai authentication</code> parameter is enabled in the authentication context, the system attempts to determine a subscriber profile (via PAP with no password) using the subscriber’s MSISDN as the username.</td>
<td>Allows the session with no authentication algorithm selected. If the <code>aaa constructed-nai authentication</code> parameter is enabled in the authentication context, the system attempts to determine a subscriber profile (via PAP with no password) using the subscriber’s MSISDN as the username.</td>
</tr>
<tr>
<td>chap</td>
<td>If also specified in the PCOs, this protocol will be used to authenticate the subscriber.</td>
<td>Attempts this protocol according to its configured priority. If accepted by the remote end of the PPP connection, this protocol will be used to provide authentication.</td>
</tr>
<tr>
<td>mschap</td>
<td>If also specified in the PCOs, this protocol will be used to authenticate the subscriber.</td>
<td>Attempts this protocol according to its configured priority. If accepted by the remote end of the PPP connection, this protocol will be used to provide authentication.</td>
</tr>
<tr>
<td>pap</td>
<td>If also specified in the PCOs, this protocol will be used to authenticate the subscriber. If this protocol is used is specified and the <code>allow-noauth</code> parameter is disabled, the system will attempt to use the APN’s default username/password specified by the <code>outbound</code> command for authentication via PAP.</td>
<td>Attempts this protocol according to its configured priority. If accepted by the remote end of the PPP connection, this protocol will be used to provide authentication.</td>
</tr>
<tr>
<td>imsi-auth</td>
<td>Values in the PCOs are ignored. The subscriber’s IMSI is used as the username for PAP authentication. No password is used.</td>
<td>The subscriber’s IMSI is used as the username for PAP authentication. No password is used.</td>
</tr>
<tr>
<td>msisdn-auth</td>
<td>Values in the PCOs are ignored. The subscriber’s MSISDN is used as the username for PAP authentication. No password is used.</td>
<td>Option not available.</td>
</tr>
</tbody>
</table>

**Example**

The following command would configure the system to attempt subscriber authentication first using MSCHAP, then CHAP, and finally PAP. Since the `allow-noauth` command was also issued, if all attempts to authenticate the subscriber using these protocols fail, then the subscriber would be still be allowed access.

```
authentication mschap 1 chap 2 pap 3 allow-noauth
```

To enable `imsi-auth` or `msisdn-auth`, the following command instances must be issued:

```
authentication imsi-auth
authentication msisdn-auth
```
authorize-with-hss

This command enables or disables subscriber session authorization per APN via a Home Subscriber Server (HSS) over an S6b Diameter interface. This feature is required to support the interworking of GGSN with P-GW and HA.

**Product**
P-GW
SAEGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
authorize-with-hss [ egtp [ s2b ] [ s5-s8 ] [ report-ipv6-addr ] ] | lma [ s6b-aaa-group aaa-group-name ] [ report-ipv6-addr ] | report-ipv6-addr ]
```

{ default | no } authorize-with-hss

<table>
<thead>
<tr>
<th>command</th>
<th>description</th>
</tr>

<td>Enables S6b authorization for eGTP only.</td>
</tr>
<tr>
<td>s2b</td>
<td>Enables S6b authorization for eGTP S2b.</td>
</tr>
<tr>
<td>s5-s8</td>
<td>Enables S6b authorization for eGTP S5S8.</td>
</tr>
<tr>
<td>lma</td>
<td>Enables S6b authorization for LMA only.</td>
</tr>
</tbody>
</table>

The keyword `s6b-aaa-group` `aaa-group-name` is used to enable the configuration of AAA group used for S6b authorization in PMIP P-GW. Two AAA groups are defined within APN configuration, one for RADIUS and another one for Diameter. All the parameters required for RADIUS authentication and accounting will go under `radius_group`. Similarly, Diameter authentication parameters will go under `s6b_group`.  

---
Important: If the S6b AAA group is configured under both APN and P-GW service, the APN level configuration takes higher precedence.

report-ipv6-addr

Enables the IPv6 address reporting through Authorization-Authentication-Request (AAR) towards the S6b interface.

Usage

Use this command to enable/disable the authorization support per APN for subscriber over S6b interface, which is used between P-GW and the 3GPP AAA to exchange the information related to charging, GGSN discovery, etc.
bearer-control-mode

Enables or disables the bearer control mode for network controlled QoS (NCQoS) through this APN. It also controls the sending of an IE in GTP messages.

Product
- GGSN
- P-GW
- SAEGW

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

Syntax

```
bearer-control-mode [ mixed | ms-only | none [ prefer-local-value ] ]
```

default bearer-control-mode

```
default
Sets the bearer control mode to default mode of “none”.
```

```
mixed
Default: Disabled.
This keyword indicates that the bearer will be controlled by User Equipment (UE) and network side (from GGSN) as well.
To enable network controlled QoS this option must be enabled.
```

```
ms-only
Default: Disabled.
This keyword indicates that the bearer will be controlled by the UE side.
```

```
one
Default: Enabled.
This keyword indicates that the system will not send any BCM mode information, BCM IE and BCM information in the protocol configuration option (PCO) IE within GTPC messages sent by the GGSN. This option is useful in networks where AGWs or firewalls do not support unknown optional IEs in GTP messages.
```

```
prefer-local-value
Default: Disabled.
```

This keyword indicates that the APN configured with “none” option for bearer control mode will not be overridden by any other interface (e.g. Gx interface towards PCRF). As a result it is ensured that BCM IE is never sent in GTP message.

**Important:** When bearer control mode is set to “none” with the keyword set “prefer-local-value”, even PCRF provided values will not override APN config and therefore sending of BCM mode IE and BCM in PCO IE in CPC Response is suppressed.

Usage

Use this command to enable the QoS through bearer control. This can be done either through the MS side or from both the GGSN and MS. To enable network requested QoS user need to enable “Mixed” mode for bearer control.

With this keyword the operator can control sending of BCM information in GTPC messages from the GGSN. With MS-Only or Mixed options in this mode, the system sends the BCM information element in every Create PDP Context Response and Unknown PDP Context Request and Response message. In some networks AGWs/Firewall drop/reject GTPC messages if there is an Unknown optional IE. To resolve this, the operator can use the “none” option to control sending of BCM IE and BCM information in the PCO IE within GTPC messages from the GGSN.

Example

The following command enables the bearer control from network and MS side for NCQoS.

```
bearer-control-mode mixed
```
**cc-home**

Configures the home subscriber charging characteristics (CC) used by the GGSN when those from the SGSN will not be accepted.

**Product**
GGSN
P-GW
SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
cc-home { behavior bits | profile index }
default cc-home
default
```

Restores the cc-home parameter to its default setting of the following:

- **behavior bits**: 0x00
- **profile index**: 8

**behavior bits**

 Specifies the behavior bit for the home subscriber charging characteristic. *bits* can be configured to any unique bit from 001H to FFFH (0001 to 1111 1111 1111 bin) where the least-significant bit corresponds to B1 and the most-significant bit corresponds to B12.

**profile index**

 Specifies the profile index for the home subscriber charging characteristic. *index* can be configured to any integer value between 0 and 15. Default: 8

![Important](image)

**Important:** 3GPP standards suggest that profile index values of 1, 2, 4, and 8 be used for hot billing, flat rate billing, prepaid billing and normal billing, respectively. A single charging characteristics profile can contain multiple behavior settings.

**Usage**

When the GGSN is configured to reject the charging characteristics sent by the SGSN for “home” subscribers, it uses the profile index specified by this command to determine the appropriate CCs to use.
Multiple behavior bits can be configured for a single profile index by ORing the bit strings together and converting the result to hexadecimal.

The properties of the actual CC profile index are configured as part of the GGSN service using the `cc profile` command. Refer to the *GGSN Service Configuration Mode* chapter of this reference for additional information on this command.

**Example**

The following command configures a behavior bit of 2 (0000 0000 0010) and a profile index of 10 for home subscribers charging characteristics:

```
cc-home behavior 2 profile 10
```

The following command configures the behavior bits 3 (0000 0000 0100) and 5 (0000 0001 0000 bin) and a profile index of 14 for home subscriber charging characteristics:

```
cc-home behavior 14 profile 14
```
### cc-roaming

Configures the roaming subscriber charging characteristics (CC) used by the GGSN when those from the SGSN will not be accepted.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > APN Configuration
- `configure > context context_name > apn apn_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
cc-roaming { behavior bits | profile index }
```

#### default cc-roaming

```
default
```

Restores the cc-roaming parameter to its default setting of the following:

- **behavior bits**: 0x00
- **profile index**: 8

**behavior bits**

Specifies the behavior bit for the roaming subscriber charging characteristic. *bits* can be configured to any unique bit from 001H to FFFH (0001 to 1111 1111 1111 bin) where the least-significant bit corresponds to B1 and the most-significant bit corresponds to B12.

**profile index**

Specifies the profile index for the roaming subscriber charging characteristic. *index* can be configured to any integer value between 0 and 15. Default: 8

**Important:** 3GPP standards suggest that profile index values of 1, 2, 4, and 8 be used for hot billing, flat rate billing, prepaid billing and normal billing, respectively. A single charging characteristics profile can contain multiple behavior settings.

**Usage**

When the GGSN is configured to reject the charging characteristics sent by the SGSN for “roaming” subscribers, it uses the profile index specified by this command to determine the appropriate CCs to use.
Multiple behavior bits can be configured for a single profile index by ORing the bit strings together and convert the result to hexadecimal.

The properties of the actual CC profile index are configured as part of the GGSN service using the cc profile command. Refer to the GGSN Service Configuration Mode chapter of this reference for additional information on this command.

**Example**

The following command configures a behavior bit 10 (0010 0000 0000) and a profile index of 10 for roaming subscriber charging characteristics:

```
cr-roaming behavior 200 profile 10
```

The following command configures the behavior bits 9 (0001 0000 0000) and 6 (0000 0010 0000) and a profile index of 14 for roaming subscriber charging characteristics:

```
cr-roaming behavior 120 profile 14
```
**cc-sgsn**

Specifies the source for charging characteristics (CC) - those configured locally or those received from the SGSN.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator
- Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > APN Configuration
  - `configure > context context_name > apn apn_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
cc-sgsn { gxreturned | homesubscriber-use-GGSN | radiusreturned | roamingsubscriber-use-GGSN | visitingsubscriber-use-GGSN } +

cc-sgsn { use-GGSN behavior bits profile index[ 0...15 ] [ radiusreturned { acceptinvalid | replaceinvalid } ] [ gxreturned { acceptinvalid | replaceinvalid } ] }

default cc-sgsn

no cc-sgsn { [ radiusreturned | homesubscriber-use-GGSN | roamingsubscriber-use-GGSN | visitingsubscriber-use-GGSN ] + | [ use-GGSN ] [ radiusreturned { acceptinvalid | replaceinvalid } ] [ gxreturned { acceptinvalid | replaceinvalid } ] }

default cc-sgsn
```

Restores the cc-sgsn parameter to its default setting of the following:
- `home-subscriber-use-GGSN`: Disabled
- `roaming-subscriber-use-GGSN`: Disabled
- `visiting-subscriber-use-GGSN`: Disabled

**no cc-sgsn**

Causes the GGSN/P-GW to accept CCs from the SGSN(s) when the `no cc-sgsn` command is entered with all applicable keywords. Otherwise, `no cc-sgsn` can be used to turn off one or more of the GGSN/P-GW sources of CC.

- `roaming-subscriber-use-GGSN`
- `home-subscriber-use-GGSN`
- `roaming-subscriber-use-GGSN`
- `visiting-subscriber-use-GGSN`
Before entering `no cc-sgsn`, it is helpful to determine which CC sources have been configured. This can be done with either `show configuration` or `show apn name` in Exec Mode.

**home-subscriber-use-GGSN**

Configures the GGSN/P-GW to use the locally defined charging characteristics for home subscribers, as configured with the APN Configuration Mode `cc-home` command.

**radiusreturned**

Configures the GGSN/P-GW to accept Gx returned charging characteristics for all subscribers for the APN.

**gxreturned**

Configures the GGSN/P-GW to accept charging characteristics returned from the RADIUS server for all subscribers for the APN.

**acceptinvalid**

Configures the GGSN/P-GW to accept charging characteristics returned from PCRF for all subscribers for the APN. It always accepts CC with profile index zero.

**replaceinvalid**

Configures GGSN/P-GW to accept charging characteristics returned from PCRF for all subscribers for the APN, except if CC profile index is zero, it will be replaced with default profile index. Default profile index is 8. This is the default behavior for gxreturned CC.

**roamingsubscriber-use-GGSN**

Configures the GGSN/P-GW to use the locally defined charging characteristics for roaming subscribers, as configured with the APN Configuration Mode `cc-roaming` command.

**use-GGSN [ behavior bits ] profile index [ 0...15 ]**

Configures the GGSN/P-GW to accept charging characteristics for all subscribers in the APN.

*bits* specifies the behavior bit for the charging characteristic. This variable can be configured to any unique bit from 001H to FFFH (0001 to 1111 1111 1111 bin) where the least-significant bit corresponds to B1 and the most-significant bit corresponds to B12.

*index* indicates which profile defined with `cc profile` in GGSN Service Configuration mode, the GGSN will use as a source for CCs. The index can be configured to an integer from 0 to 15.

The `use-GGSN` keyword can be entered alone or in conjunction with the `radiusreturned` keyword. When entered, this keyword overrides the previous configuration using any of the home, roaming, and/or visiting keywords.

**visittingsubscriber-use-GGSN**

Configures the GGSN/P-GW to use the locally defined charging characteristics for visiting subscribers, as configured with the APN Configuration Mode `cc-visiting` command.

More than one of the above keywords can be entered within a single command.
Usage

This command specifies whether or not CCs received from the SGSN will be accepted. If they are not accepted, the GGSN/P-GW will use those that have been configured locally.

The GGSN/P-GW’s behavior can be configured for the following subscriber types:

- **Home**: Subscribers belonging to the same Public Land Mobile Network (PLMN) as the one on which the GGSN/P-GW is located.

- **Roaming**: Subscribers that are serviced by an SGSN belonging to a different PLMN than the one on which the GGSN/P-GW is located.

- **Visiting**: Subscribers belonging to a different PLMN than the one on which the GGSN/P-GW is located.

- **Any subscriber in the APN**.

Example

The following command instructs the GGSN/P-GW to accept CCs for any subscriber in the APN based on local profile configurations of CCs.

\[ \text{cc-sgsn use-GGSN profile x} \]

Assuming the CC source as defined with the previous command, the following command instructs the GGSN/P-GW to accept CCs supplied by the SGSN(s) and disables the acceptance of CCs supplied by the GGSN/P-GW for any subscriber within the APN:

\[ \text{no cc-sgsn use-GGSN} \]

The following command instructs the GGSN/P-GW to accept CCs for any subscriber in the APN based on CC information returned from the RADIUS server. This command can be issued after the previous command to expand the possible sources.

\[ \text{cc-sgsn radius-returned} \]

The following command disables the acceptance of CCs supplied by the GGSN/P-GW for visiting and roaming subscribers:

\[ \text{no cc-sgsn roaming-subscriber-use-GGSN visiting-subscriber-use-GGSN} \]
**cc-visiting**

Configures the visiting subscriber charging characteristics (CC) used by the GGSN when those from the SGSN will not be accepted.

**Product**
GGSN
P-GW
SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```bash
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```bash
cc-visiting behavior bits profile index
```

**default cc-visiting**

```
default
```

Restores the cc-visiting parameter to its default setting of the following:

- **behavior bits**: 0x00
- **profile index**: 8

**behavior bits**

Specifies the behavior bit for the visiting subscriber charging characteristic. *bits* can be configured to any unique bit from 001H to FFFH (0001 to 1111 1111 1111 bin) where the least-significant bit corresponds to B1 and the most-significant bit corresponds to B12.

**profile index**

Specifies the profile index for the visiting subscriber charging characteristic. *index* can be configured to any integer value between 0 and 15. Default: 8

---

**Important:** 3GPP standards suggest that profile index values of 1, 2, 4, and 8 be used for hot billing, flat rate billing, prepaid billing and normal billing, respectively. A single charging characteristics profile can contain multiple behavior settings.

**Usage**

When the GGSN is configured to reject the charging characteristics sent by the SGSN for “visiting” subscribers, it uses the profile index specified by this command to determine the appropriate CCs to use.
Multiple behavior bits can be configured for a single profile index by ORing the bit strings together and convert the result to hexadecimal.

The properties of the actual CC profile index are configured as part of the GGSN service using the cc profile command. Refer to the GGSN Service Configuration Mode chapter of this reference for additional information on this command.

Example

The following command configures a behavior bit 7 (0000 0100 0000) and a profile index of 10 for visiting subscriber charging characteristics:

```
cc-visiting behavior 40 profile 10
```

The following command configures the behavior bits 1 (0000 0000 0001) and 12 (1000 0000 0000) and a profile index of 14 for visiting subscriber charging characteristics:

```
cc-visiting behavior 801 profile 14
```
content-filtering category

Enables or disables the specified pre-configured Category Policy Identifier for Category-based Content Filtering support.

Product
CF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

content-filtering category policy-id cf_policy_id

no content-filtering category policy-id

no

Disables the previously configured category policy identifier for Content Filtering support to the APN. This is the default setting.

policy-id cf_policy_id

Applies the specified content filtering category policy ID, configured in the ACS Configuration Mode, to this APN.

cf_policy_id must be a category policy ID entered as an integer from 1 through 4294967295.

If the specified category policy ID is not configured in the ACS Configuration Mode, all packets will be passed regardless of the categories determined for such packets.

**Important:** Category Policy ID configured through this mode overrides the Category Policy ID configured through content-filtering category policy-id command in the ACS Rulebase Configuration Mode.

Usage

Use this command to enter the Content Filtering Policy Configuration Mode and to enable or disable the Content Filtering Category Policy ID for an APN.

**Important:** If Content Filtering Category Policy ID is not specified here the similar command in the ACS Rulebase Configuration Mode determines the policy.

Example

Up to 64 different policy IDs can be defined.
The following command enters the Content Filtering Policy Configuration Mode and enables the Category Policy ID 101 for Content Filtering support:

```
content-filtering category policy-id 101
```
**credit-control-client**

Configures the credit-control client parameters for subscribers who use this APN.

**Product**
- GGSN
- HA
- IPSG
- PDSN
- P-GW

**Privilege**
Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > APN Configuration
- `configure > context context_name > apn apn_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
credit-control-client { event-based-charging | override session-mode { per-sub-session | per-subscriber } }
no credit-control-client { event-based-charging | override session-mode }
default credit-control-client event-based-charging
```

---

- **no**
  Disables the configured setting.

- **default**
  Resets the command to its default setting of disabled.

- **event-based-charging**
  Enables event-based charging.

- **override session-mode { per-sub-session | per-subscriber }**
  Overrides the session-mode configured through the CLI command “`require ecs credit-control session-mode per-subscriber`” in Global Configuration mode so that different APN can operate in different modes. For example, one APN can be configured to work in per-subscriber mode, while another in per-sub-session mode. This keyword is used to switch between subscriber level Gy and sub-session level Gy.
**Important:** This CLI can be changed on the fly. The modified values will be reflected only in the new subscriber session.

The no command removes the override CLI and makes the APN fall back to the configuration specified through the CLI command “require ecs credit-control session-mode per-subscriber”.

**Usage**

Use this command to configure the credit-control client parameters for this APN. This configuration should be enabled to report UE’s PLMN, timezone and ULI changes through Event-based-Gy session. In the event that both Gy Online charging and Gy event reporting are enabled, the P-GW shall send only CCR-Update requests to the OCS and shall not send CCR-Event requests. With the inclusion of this keyword `override session-mode` ... in 14.1 release, it is possible to seamlessly change the configuration from bearer level to APN level and vice-versa without requiring a system reboot.

**Example**

The following command enables event-based Gy support for the current APN:

```
credit-control-client event-based-charging
```
credit-control-group

Configures the credit control group to be used for subscribers who use this APN.

**Product**
- GGSN
- ACS
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > APN Configuration
- `configure > context context_name > apn apn_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
credit-control-group cc_group_name [ cc-profile cc_profile_index ]

no credit-control-group [ cc_group_name cc-profile cc_profile_index ]
```

- `no`
  - Removes the previously configured credit control group from the APN configuration.

  - **cc_group_name**
    - Specifies name of the credit control group as an alphanumeric string of 1 through 63 characters.

  - **Important**: Release 16.0 onwards, a maximum of up to four credit-control-group - charging-profile configurations are possible within one APN.

  - **cc-profile cc_profile_index**
    - Specifies the charging-characteristic preference for the credit-control-group.
    - For example, 1 for Hot Billing, 2 (Flat Rate), and 8 (Post-Paid)
    - `cc_profile_index` must be an integer from 0 through 15.
    - Note that one charging-characteristic value can be mapped to only one credit-control-group inside one APN.

  - **Important**: The CLI command “cc-sgsn” within APN configuration mode, should be used cautiously as this will cause the charging-chars to be altered/modified.

**Usage**

- Use this command to configure the credit control group for this APN.
Creating different credit control groups enables applying different credit control configurations (DCCA dictionary, failure-handling, session-failover, Diameter endpoint selection, etc.) to different subscribers on the same system.

Without credit control groups, only one credit control configuration is possible on a system. All the subscribers in the system will have to use the same configuration.

In releases prior to 16.0, only one credit-control-group can be specified inside an APN. In 16.0 and later releases, the APN configuration is extended to include the Charging-Characteristic (CC) preference for the credit-control-group. This APN configuration is also extended to allow configuring additional credit-control-groups for each of the CC values. With this enhancement, the OCS selection can be done based on the CC value received via GTP request.

When the local authentication (session-setup-request) is done, the credit-control-group with the matching charging-characteristic will be selected, and used. If there is no matching charging-characteristic configuration found for the credit-control-group selection, then the default credit-control-group for the APN will be selected.

The CC based OCS selection feature is applicable only for the Charging-Chars value received via GTP-Auth-Request, and during the session-establishment. The Charging-Chars value updated via AAA/PCRF after the session setup will not cause any change in already selected "credit-control-group". Once the credit-control-group is selected (after session setup), this feature is not applicable.

APN configuration information is stored in AAA manager. Credit control group information from the APN configuration is filled during the session-authentication time, by AAA manager. So, AAA manager should be informed of the Charging-Characteristic value received at the time of Session-Authentication, so that the desired credit-control-group can be selected.

Thus, the operator has the added flexibility to choose different OCS charging servers based on their business logic. This could help multi-national operators to choose correct OCS servers based on countries for roaming subscribers.

**Example**

The following command configures a credit control group named `testgroup12` for the current APN:

```
credit-control-group testgroup12
```
**daf-pdp-type**

By configuring this command P-GW/GGSN can set different behavior of assigning PDN Type and return cause code when request for ipv4v6 PDN with DAF bit False is received.

**Product**

GGSN

P-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > APN Configuration

`configure > context context_name > apn apn_name`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-apn)#`

**Syntax**

```
daf-pdp-type { ipv4 | ipv6 } cause-code { network-preference | single-address-bearer-only }
```

---

**daf-pdp-type**

Configures PDP type for requested IPv4v6 PDN with Dual Address Flag zero. Default PDP type is IPv6.

**ipv4**

Configures PDP type for this APN to be IPv4.

**ipv6**

Configures PDP type for this APN to be IPv6.

**cause-code**

Configures GTP cause code for requested IPv4v6 PDN with Dual Address Flag zero. Default GTP cause code is single-address-bearer-only.

**network-preference**

New PDP type due to network preference.

**single-address-bearer-only**

New PDP type due to single address bearer only.
**Usage**

By configuring this command P-GW/GGSN can set different behavior of assigning PDN Type and return cause code when request for ipv4v6 PDN with DAF bit False is received. If this command is not configured P-GW/GGSN it uses the default option of assigning ipv6 pdn type with return cause of ‘New PDN Type due to single address bearer only’.

**Example**

The following command configures PDP type and GTP cause code for requested IPv4v6 PDN due to network preference.

```
daf-pdp-type ipv4 cause-code network-preference
```
data-tunnel mtu

Configures the Maximum Transmission Unit (MTU) for data sent on the IPv6 tunnel between the P-GW and the mobile node.

Product
P-GW
SAEGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

data-tunnel mtu bytes

default data-tunnel mtu

default

Returns the command to the default value of 1500.

bytes

Specifies the MTU for the IPv6 tunnel between the P-GW and the mobile node. bytes must be an integer between 1280 and 2000. Default: 1500

Usage

Use this command to set the MTU for data traffic on the IPv6 tunnel between the P-GW and the mobile node.

Example

The following command sets the MTU for IPv6 data traffic to 1400 bytes:

data-tunnel mtu 1400
data-tunneling ignore df-bit

Controls the handling of the DF (Don't Fragment) bit present in the user IPv4/IPv6 packet for tunneling used for the Mobile IP data path.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > APN Configuration
- configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
[ default | no ] data-tunneling ignore df-bit
```

- **default**
  
  Restores the data-tunneling parameter to its default setting of disabled.

- **no**

  Disables this option. The DF bit in the tunneled IP packet header is not ignored during tunneling. This is the default setting.

- **ignore df-bit**

  Ignores the DF bit in the tunneled IP packet header during tunneling. This is the default setting.

**Usage**

Use this command to configure a user so that during Mobile IP tunneling the DF bit is ignored and packets are fragmented. If this feature is enabled, and fragmentation is required for the tunneled user IPv4/IPv6 packet, then the DF bit is ignored and the packet is fragmented. Also the DF bit is not copied to the outer header. In the GGSN, this command also affects the other L3 tunneling options, IP-in-IP and GRE, but does not affect L2TP tunneling.

**Example**

To enable fragmentation of a subscribers packets over a MIP tunnel even when the DF bit is present, enter the following command:

```
data-tunneling ignore df-bit
```
dcca origin endpoint

This command is obsolete. To configure the Diameter Credit Control Origin Endpoint, in the Credit Control Configuration Mode, use the `diameter origin endpoint` command.
dcca peer-select

Specifies the Diameter credit control primary and secondary host for credit control.

Product
GGSN
ACS
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration
configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

dcca peer-select peer host_name [ realm realm_name ] [ secondary-peer host_name ]

no dcca peer-select

no

Removes the previously configured Diameter credit control peer selection.

host_name

Specifies a unique name for the peer as an alphanumeric string of 1 through 63 characters that allows punctuation marks.

realm realm_name

Specifies the ream as an alphanumeric string of from 1 through 127 characters that allows punctuation marks. The realm may typically be a company or service name.

secondary-peer host_name

Specifies a back-up host that is used for fail-over processing as an alphanumeric string of from 1 through 63 characters. When the route-table does not find an AVAILABLE route, the secondary host performs fail-over processing.

Usage

Use this command to select a Diameter credit control peer and realm.
**Caution:** This configuration completely overrides all instances of `diameter peer-select` that have been configured within the Credit Control Configuration Mode for an Active Charging Service.

**Example**

The following command selects a Diameter credit control peer named test and a realm of `companyx`:

```
dcca peer-select test realm companyx
```
description

Sets the descriptive text for the object.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

description text

no description

**no**
Clears the description for the object.

text

Specifies the descriptive text as an alphanumeric string of 1 to 79 characters. If you include spaces between words in the description, you must enclose the text within double quotation marks (" "), for example, “AAA BBBB”.

**Usage**
The description should provide useful information on the object’s primary function, services, endusers, etc.
**dhcp context-name**

Configures the name of the context on the system in which Dynamic Host Control Protocol (DHCP) functionality is configured.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
```
Exec > Global Configuration > Context Configuration > APN Configuration
```
```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:
```
[context_name]host_name(config-apn)#
```

**Syntax**
```
[ no ] dhcp context-name name
```

- **no**
  Removes a previously configured context name.

- **name**
  Specifies the name of a context configured on the system in which one or more DHCP services are configured. *name* is an alphanumeric string of 1 through 79 characters that is case sensitive.

**Usage**
If the APN is to support dynamic address assignment via DHCP (either the proxy or relay mode), this parameter must be configured to point the APN to the name of a pre-configured context on the chassis in which one or more DHCP services are configured. The `configure` command can be used to identify a single DHCP service instance within the specified context to use to facilitate the address assignment.

**Example**
The following command configures the APN to look for DHCP services in a context called `dhcp-ctx`:
```
dhcp context-name dhcp-ctx
```
dhcp lease-expiration-policy

Configures the system’s handling of PDP contexts whose DHCP assigned IP lease has expired.

Product
- GGSN
- P-GW
- SAEGW

Privilege
- Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

Syntax

```
dhcp lease-expiration-policy { auto-renew | disconnect }
default dhcp lease-expiration-policy
```

**default**

Restores the dhcp lease-expiration-policy parameter to its default setting of auto-renew.

- **auto-renew**

Configures the system to automatically renew an IP address’ lease when it is about to expire for PDP contexts facilitated by the APN. Default: Enabled

- **disconnect**

Configures the system to automatically release the PDP context when the lease for the IP address associated with that context expires. Default: Disabled

Usage

Use this command to specify the action the system is to take when leases for IP addresses for PDP contexts that it are currently facilitated by the current APN are about to expire.

Example

The following command causes the system to release PDP contexts associated with the current APN when the lease for their DHCP-assigned IP address expires:

```
dhcp lease-expiration-policy disconnect
```
**dhcp service-name**

Configures the name of a specific DHCP service to use when dynamically assigning IP addresses to PDP contexts using the Dynamic Host Control Protocol.

**Product**

GGSN  
P-GW  
SAEGW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
[ no ] dhcp service-name service_name
```

---

**no**

Removes a previously configured DHCP service name.

---

**service_name**

Configures the name of the DHCP service instance that is to be used by the current APN for the dynamic assignment of IP addresses to PDP contexts. The name can be an alphanumeric string of 1 through 63 characters that is case sensitive.

---

**Usage**

Use this command to specify a pre-configured DHCP service instance that is to be used by the APN for IP address assignment when the Dynamic Host Control Protocol is used. The name of the context in which the desired DHCP service is configured must be specified by the dhcp context-name command.

**Example**

The following command instructs the APN to use a DHCP service called dhcp1:

```
dhcp service-name dhcp1
```
**dhcpv6 context-name**

Configures the name of the context on the system in which DHCPv6 functionality is configured. If a DHCPv6 service is configured in the APN, this DHCPv6 context name is used to get an address.

**Product**
- GGSN
- P-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

`configure > context context_name > apn apn_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
dhcpv6 context-name ctxt_name

[ no ] dhcp context-name
```

---

**no**
Removes a previously configured context name.

---

**ctxt_name**
Specifies the name of a context configured on the system in which one or more DHCPv6 services are configured. `ctxt_name` is an alphanumeric string of 1 through 79 characters that is case sensitive.

---

**Usage**
If the APN is to support dynamic address assignment via DHCPv6, this parameter must be configured to point the APN to the name of a pre-configured context on the chassis in which one or more DHCPv6 services are configured.
The command can be used to identify a single DHCPv6 service instance within the specified context to use to facilitate the address assignment.

**Example**
The following command configures the APN to look for DHCPv6 services in a context called `dhcpv6-ctx`:

```
dhcpv6 context-name dhcpv6-ctx
```
dhcpv6 service-name

Specifies which DHCPv6 service to use, if the alloc-type is configured as dhcpv6-client or dhcpv6-relay.

**Product**

GGSN
P-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
[ no ] dhcpv6 service-name service_name
```

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
</table>

Removes a previously configured DHCPv6 service name.

<table>
<thead>
<tr>
<th>service_name</th>
</tr>
</thead>
</table>

Configures the name of the DHCPv6 service instance that is to be used by the current APN for the dynamic assignment of IPv6 addresses to PDP contexts. The name can be an alphanumeric string of 1 through 63 characters that is case sensitive.

**Usage**

Use this command to specify a pre-configured DHCPv6 service instance that is to be used by the APN for IPv6 address assignment when the Dynamic Host Control Protocol is used. The name of the context in which the desired DHCP service is configured must be specified by the dhcpv6 context-name command.

**Important:** Only one DHCPv6 service can be configured for an APN

**Example**

The following command instructs the APN to use a DHCPv6 service called dhcpv6_svc:

```
dhcp service-name dhcpv6_svc
```
dns

Configures the Domain Name Service (DNS) servers that will be used by the APN for PPP.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration
configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

dns { primary | secondary } { address }

no dns { primary | secondary } { dns_address }

no
Deletes a previously configured DNS server.

primary
Configures the primary DNS server for the APN.

secondary
Configures the secondary DNS server for the APN. Only one secondary DNS server can be configured.

address
Configures the IP address of the DNS server expressed in IPv4 dotted-decimal notation. Default: primary = 0.0.0.0, secondary = 0.0.0.0

dns_address
Specifies the IP address of the DNS server to remove, expressed in IPv4 dotted-decimal notation.

Usage
DNS servers are configured on a per-APN profile basis. This allows each APN profile to use specific servers in processing PDP contexts. The configured DNS IP addresses are relayed to the subscriber within IPCP if the PDP type is PPP, or as PCOs (Protocol Configuration Options) if the PDP type is IP.
The DNS can be specified at the APN level in APN configuration as well as at the Context level in Context configuration mode with `ip name-servers` command, or it can be received from AAA server. When DNS is requested in PCO configuration, the following preference will be followed for DNS value:

1. DNS Values received from LNS have the first preference.
2. DNS values received from RADIUS Server has the second preference.
3. DNS values locally configured with APN has the third preference.
4. DNS values configured at context level with `ip name-servers` command has the last preference.

**Important:** The same preference would be applicable for the NBNS (NetBIOS Name Service) servers to be negotiated via ICPC (Initial Connection Protocol Control) with the LNS (L2TP Network Server).

**Example**

The following commands configure a primary DNS server address of 192.168.100.3 and a secondary DNS server address of 192.168.100.4:

```plaintext
dns primary 192.168.100.3

dns secondary 192.168.100.4
```
egtp

Enables/disables the Overcharging Protection feature on an APN service.

Product
P-GW
SAEGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration
configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

egtp overcharge-protection [ drop-all | transmit-all ]
{ default | no | remove } egtp overcharge-protection

- default
  Disables overcharging protection.

- no
  Disables overcharging protection.

- remove
  Removes overcharging protection configuration.

overcharge-protection [ drop-all | transmit-all ]

- drop-all: Configures overcharging protection to drop all packets received in LORC.
- transmit-all: Configures overcharging protection to send all packets received in LORC mode to S-GW.

Usage

Use this command to enable/disable the Overcharging Protection feature on an APN service.
When Overcharging Protection feature is configured at both P-GW service and APN, configuration at APN takes priority.

Important: Use of Overcharging Protection feature requires that a valid license key be installed. Contact your Cisco account representative for information on how to obtain a license.

Example

The following command configures overcharging protection to drop all packets received in LORC
egtp overcharge-protection drop-all
ehrpd-access

Configures the P-GW to exclude IPv6 traffic from being delivered to UEs, accessing PDNs from the eHRPD network that do not have IPv6 capabilities.

Product
P-GW
SAEGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

[ default | no ] ehrpd-access drop-ipv6-traffic

[ default | no ]
Resets this command to its default setting of disabled.

drop-ipv6-traffic
Excludes IPv6 traffic from being delivered to UEs, accessing PDNs from the eHRPD network that do not have IPv6 capabilities.

Usage
Use this command to exclude IPv6 traffic from being delivered to UEs on the eHRPD network that do not have IPv6 capabilities.
emergency-apn

Configures this APN as an emergency APN for Voice over LTE (VoLTE) based E911 support.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```plaintext
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
[ default | no ] emergency-apn
```

- Resets this command to its default setting of disabled.

**Usage**

Use this command to configure this APN as an emergency APN for VoLTE based E911 support. With this support, a UE is able to connect to an emergency PDN and make Enhanced 911 (E911) calls while providing the required location information to the Public Safety Access Point (PSAP). E911 is a telecommunications-based system that is designed to link people who are experiencing an emergency with the public resources that can help. This feature supports E911-based calls across the LTE and IMS networks. In a voice over LTE scenario, the subscriber attaches to a dedicated packet data network (PDN) called EPDN (Emergency PDN) in order to establish a voice over IP connection to the PSAP. Both signaling and RTP media flow over a dedicated emergency bearer. Additionally, different than normal PDN attachment that relies on AAA and PCRF components for call establishment, the EPDN attributes are configured locally on the P-GW, which eliminates the potential for emergency call failure if either of these systems is not available.
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Usage
Use this command to return to the parent configuration mode.
**firewall policy**

Enables or disables Stateful Firewall support for the APN.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
firewall policy firewall
{ default | no } firewall policy
```

<table>
<thead>
<tr>
<th>no</th>
<th>Disables Stateful Firewall support for this APN.</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Configures the default setting for Stateful Firewall support. Default: Disabled</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to enable or disable Stateful Firewall support for this APN.

**Important:** This command is only available in StarOS 8.0. In StarOS 8.1 and later, this configuration is available in the ACS Rulebase Configuration Mode.

**Important:** Unless Stateful Firewall support for this APN is enabled using this command, firewall processing for this APN is disabled.

**Important:** If firewall is enabled, and the rulebase has no firewall configuration, Stateful Firewall will cause all packets to be discarded.

**Example**

The following command enables Stateful Firewall support for an APN:

```
firewall policy firewall-required
```
The following command disables Stateful Firewall support for an APN:

```
no firewall policy
```
fw-and-nat policy

Specifies the Firewall-and-NAT policy to be used for subscribers who use this APN.

[context_name]host_name(config-apn)#

Syntax

fw-and-nat policy fw_nat_policy

{ default | no } fw-and-nat policy

default

Configures the default setting.

Default: The default Firewall-and-NAT policy configured in the rulebase is used for subscribers who use this APN.

no

Disables Firewall and NAT for the APN.

fw_nat_policy

Specifies the Firewall-and-NAT policy for the APN as an alphanumeric string of 1 through 63 characters. Note that this policy will override the default Firewall-and-NAT policy configured in the ACS rulebase.

Usage

Use this command to configure the Firewall-and-NAT policy for the APN. Note that the policy configured in the subscriber mode will override the default policy configured in the ACS rulebase. If a policy is not configured in the subscriber mode, the default policy configured in the ACS rulebase will be used.

Important: This command is customer-specific and is only available in StarOS 8.1.
Important: This customer-specific command must be used to configure the Policy-based Firewall-and-NAT feature.

Example

The following command configures a Firewall-and-NAT policy named standard for the APN:

```
fw-and-nat policy standard
```
gsm-qos negotiate

Enables negotiation of the QoS Reliability Class attribute based on the configuration provided for Service Data Unit (SDU) Error Ratio and Residual Bit Error Ratio (BER) attributes in the APN.

Product

GGSN
P-GW
SAEGW

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > APN Configuration
configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

```
gsm-qos negotiate sdu-error-ratio sdu-error-ratio-code [ residual-ber residual-ber-code ]

```

no
Disables negotiation of the QoS Reliability Class attribute.

```
sdu-error-ratio sdu-error-ratio-code
```

Enables the negotiation of the QoS Reliability Class attribute based on Service Data Unit (SDU) Error Ratio attributes. `sdu-error-ratio-code` corresponds to distinct SDU Error ratio values within an integer range of 1 to 7.

```
residual-ber residual-ber-code
```

Enables the optional configuration of negotiation of the QoS Reliability Class attribute based on Residual Bit Error Ratio (BER) attributes. `residual-ber-code` corresponds to distinct Residual Bit Error Ratio values within an integer range of 1 to 9.

Usage

This command configures the QoS attribute Reliability Class to be negotiated based on the configuration provided for SDU Error Ratio and Residual BER attributes. The derived Reliability Class and the configured values for SDU Error Ratio and Residual BER are sent back in CPC and UPC response. The mapping for `sdu-error-ratio-code` is as follows:

<table>
<thead>
<tr>
<th>Code</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10-2</td>
</tr>
</tbody>
</table>

Residual BER needs to be specified when SDU Error Ratio is set to codes 1, 2, 3 or 7 (Or, SDU Error Ratio is intended to be set to a value greater than $5\times10^{-4}$), for determining the Reliability Class QoS attribute. Otherwise, the Residual BER value received in the Create PDP context request QoS (or UPC request) would be used. The mapping for `residual-ber-code` is as follows:

<table>
<thead>
<tr>
<th>Code</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>$5\times10^{-2}$</td>
</tr>
<tr>
<td>2</td>
<td>10^{-2}</td>
</tr>
<tr>
<td>3</td>
<td>$5\times10^{-3}$</td>
</tr>
<tr>
<td>4</td>
<td>$4\times10^{-3}$</td>
</tr>
<tr>
<td>5</td>
<td>10^{-3}</td>
</tr>
<tr>
<td>6</td>
<td>10^{-4}</td>
</tr>
<tr>
<td>7</td>
<td>10^{-5}</td>
</tr>
<tr>
<td>8</td>
<td>10^{-6}</td>
</tr>
<tr>
<td>9</td>
<td>$6\times10^{-8}$</td>
</tr>
</tbody>
</table>

**Example**

The following commands configures the negotiation of QoS attribute Reliability Class based on Service Data Unit (SDU) Error Ratio 3 attributes in the APN:

```
gsm-qos negotiate sdu-error-ratio 3
```
gtpp group

Enables a configured GTPP server group to an APN for CGF accounting functionality.

**Important:** In releases prior to 11.0, only one GTPP group is allowed to be configured per APN. Releases 11.0 through 15.0, this CLI can be used to configure up to a maximum of 32 GTPP groups. In 16.0 and later releases, this CLI allows the user to configure only up to six GTPP groups.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)>
```

**Syntax**

```
gtpp group group_name [ accounting-context ac_context_name ]
```

```
default gtpp group
```

```
no gtpp group group_name
```

**no**

Removes all the configured GTPP groups for the specific APN.

```
group_name
```

Specifies the name of server group that is used for authentication/accounting for specific APN. `group_name` must be an alphanumeric string of 1 to 63 characters. It must be identical to the one configured earlier within the same APN context.

**Important:** In Release 11.0 and later, if you have mistakenly configured a GTPP group, you should remove the initially configured group and configure the new desired group. However, in Releases prior to 11.0, there is no need to remove the incorrect configuration; instead you can directly reconfigure the desired GTPP group.

**Important:** If a GTPP group entry is invalid, this GTPP group will be ignored and the next valid GTPP group in the APN will be used. If no valid GTPP group exists, then the default GTPP group in the accounting context specified by the GGSN service will be used.
accounting-context ac_context_name

Specifies the name of an accounting context on the system that processes accounting for PDP contexts handled by this GGSN service for accounting to specific APN.

ac_context_name must be an alphanumeric string of 1 through 79 characters that is case sensitive.

Note that if an accounting context is not specified here, the system uses the GGSN service context or the context configured by the accounting context command in the GGSN Service Configuration mode.

Usage

This feature provides the GTPP server configurables under a GTPP group node. Instead of having a single list of servers per context, this feature configures multiple server groups within a context and applies individual an GTPP server group for subscribers in that context. Each server group consists of a list of CGF (Charging Group Function) accounting servers.

In case no GTPP group is applied for the said APN or default APN template, then the default GTPP server group available at the context level is applicable for accounting of a specific APN.

Important: When multiple GTPP groups are applied to the same APN, the load will be shared across these GTPP groups. Sessions for this APN will use all the configured GTPP groups in a round robin fashion.

Once a GTPP group is selected for a subscriber session, the GTPP group will never change under any circumstances. A request is initially sent to primary CGF server configured in that group. When the primary fails to respond, the request is sent to secondary CGF server.

The process of failover from primary to secondary is per the 3GPP standards. Multiple GTPP groups configuration is actually supported only for load sharing of sessions within an APN and not used for failover.

When all CGFs are down in a GTPP group, the requests are archived either in hard disk or main memory depending on whether or not streaming is enabled.

The AAA proxy allocates a lot of memory on a per GTPP group basis statically regardless of the usage. So if the number of GTPP groups is reduced to around 3 then the issue with the AAA proxy going to warn memory state will not be observed.

In releases prior to 16.0, up to a maximum of 32 GTPP groups were allowed to be configured per APN. In 16.0 and later releases, there is a limit of configuring only up to six GTPP groups per APN. In case customers are using more than six GTPP groups, the AAAProxy will use more memory than is supported and will be in “warn” state of memory. With the reduction in the number of GTPP groups configured, there will no CDR loss due to AAA proxy kill as CDRs are archived in AAA manager when AAA proxy goes to warn state.

Example

The following command applies a previously configured GTPP server group named star1 to an APN within the specific context:

```
gtp group star1
```

The following command disables the applied GTPP server group for the specific APN:

```
no gtp group star1
```
gtpp secondary-group

Enables or associates a preconfigured secondary GTPP server group to an APN for CGF (Charging Group Function) accounting functionality. By default it is disabled.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator
- Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration
```
configure > context context_name > apn apn_name
```
Entering the above command sequence results in the following prompt:
```
[context_name]host_name(config-apn)#
```

**Syntax**
```
gtpp secondary-group group_name [ accounting-context actt_ctxt_name ]
[ default | no ] gtpp secondary-group group_name
```

---

**default**
Default: Enabled
Restores the default mode for secondary GTPP group for APN template.

---

**no**
Disables the configured/associated GTPP secondary group for specific APN.

---

**group_name**
Specifies the name of secondary GTPP server group that is used as an alternate for the primary GTPP group associated with a specific APN for storage of GTPP messages. *group_name* must be an alphanumeric string of 1 through 63 characters. It must be the same name as configured earlier within the same APN context.

---

**accounting-context actt_ctxt_name**
Specifies the name of an accounting context on the system that processes accounting for PDP contexts handled by this GGSN service for accounting to a specific APN. *actt_ctxt_name* specifies the name of the context to be used for accounting as an alphanumeric string of 1 through 79 characters that is case sensitive.
Note that if an accounting context is not specified here, the system uses the GGSN service context or the context configured by the *accounting context* command in the GGSN Service Configuration mode.

**Usage**
Use this feature to provide the secondary GTPP server group support for an APN.
When the secondary GTPP group is configured with this command, the GTPP messages will also be mirrored to the secondary servers. This secondary group configuration is ignored, if the configured `group_name` is the same as the primary group. It will also be ignored, if the configured GTPP `group_name` and/or accounting context `ac_context_name` is invalid. In such cases, the call will be established successfully (unlike the primary group configuration where the call drops).

In the absence of a configured `ac_context_name` context, the GGSN service context is chosen by default. The secondary group messages are low priority and thus are purged when there is no room for the new messages.

For more information on GTPP group, refer the description of the `gtpp group` command.

**Example**

The following command applies a previously configured GTPP server group named `star2` to as secondary GTPP group to an APN within the specific context:

```
gtpp secondary-group star2
```

The following command disables the applied secondary GTPP server group for the specific APN:

```
no gtpp secondary-group star2
```
idle-timeout-activity

Configures a session idle-timeout to be reset with uplink packets only, or with both uplink and downlink packets.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

[ no ] idle-timeout-activity ignore-downlink

default idle-timeout-activity

default
Sets or restores the command to the default setting.

ignore-downlink
Sets the system to ignore the downlink traffic for consideration as activity for idle-timeout.

Usage
If idle-timeout-activity ignore-downlink is configured, the downlink (network to subscriber) traffic will not be used to reset the idle-timeout. Only uplink (subscriber to network) packets will be able to reset the idle-timeout.
By default, ignore-downlink is negated by the no command so downlink traffic is also used to reset the idle-timeout.

Example
The following command causes both uplink and downlink traffic to reset a session idle-timeout:

default idle-timeout-activity

The following command causes the session idle-timeout to be reset with only uplink packets:

idle-timeout-activity ignore-downlink
ignore-alt-config

Configures preference to APN/AAA-defined behavior/parameters. If the parameters are not defined in APN/AAA, they will not be provisioned from any other source/configuration in the system, even if they are available there.

Product
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

[ no ] ignore-alt-config { no-dns | no-s6b }

no
Disables DNS server address preference or S6b authentication on a per-APN level.

no-dns
Gives preference to DNS server address configured in APN. If name server addresses is not found in APN configuration, it will not be provisioned from SGi context, even if it is configured there.

no-s6b
Enables/disables S6b authentication on a per-APN level.
Ignores alternate service-level configuration for S6b authorization when S6b authorization is disabled at APN.

Usage
Use this command to enable/disable DNS server address preference or S6b authentication on a per-APN level.

Important: Configuration in APN will take precedence over configuration in P-GW service configuration.

Example

The following command to give preference to DNS server address configured in APN:

ignore-alt-config no-dns
ikev2 tsr

Configures the Traffic Selector responder (TSr) negotiation behavior during IKEv2 Security Association (SA) establishment.

Product
PDG/TTG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration
configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

[ default ] ikev2 tsr { wildcard | user-specified }

default
Specifies the default behavior, which is wildcard TSr negotiation.

wildcard
Specifies that during TSr negotiation, the PDG/TTG always returns an any-to-any IP address range, an any-to-any port range, and allows any protocol, irrespective of the traffic selector ranges received from the UE. This is the default behavior.

user-specified
Specifies that during TSr negotiation, the PDG/TTG responds to each UE request with the UE-specified IP address ranges. This enables split tunneling on the PDG/TTG, and enables the UE to tunnel only a specified traffic range to the PDG/TTG and send other traffic directly out the WLAN.

Usage
Use this command to specify the TSr negotiation behavior on the PDG/TTG.

Example
The following command enables user-specified TSr negotiation on the PDG/TTG:

ikev2 tsr user-specified
ims-auth-service

Applies an IMS (IP Multimedia Subsystem) authorization service to a subscriber through APN for Gx interface support and functionality.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration
configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

[ no ] ims-auth-service auth_service_name

no
Disables the applied IMS authorization service for a specific APN.

auth_service_name
Specifies the name of the IMS authorization service name that is used for Gx interface authentication for a specific APN. auth_service_name must be a alphanumeric string of 1 through 63 characters preconfigured within the same context as this APN.

Usage

This feature provides the IMS authorization service configuration for Gx interface in IMS service node.

Example

The following command applies a previously configured IMS authorization service named gx_interface1 to an APN within the specific context:

ims-auth-service gx_interface1

The following command disables the applied IMS authorization service gx_interface1 for the specific APN:

no ims-auth-service gx_interface1
ip access-group

Configures an IPv4/IPv6 access group for the current APN profile.

Product
ACS
eWAG
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration
configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

ip access-group acl_group_name [ in | out ] [ fallback-enabled ]
[ no ] ip access-group acl_group_name [ in | out ]

no
Removes a previously configured IPv4/IPv6 access group association.

 acl_group_name
Specifies the name of the IPv4/IPv6 access group. acl_group_name is a previously configured ACL group expressed as an alphanumeric string of 1 to 79 characters.

 in | out
Default: both (in and out)
Specifies the access-group as either inbound or outbound by the keywords in and out, respectively.

Usage
Use this command to apply a single IPv4/IPv6 access control list to multiple subscribers via this APN for inbound or outbound IPv4/IPv6 traffic.
If no traffic direction is specified, the selected access control list will be applied to both directions.

Example
The following command associates the sampleipv4Group access group with the current APN profile for both inbound and outbound access.

 ip access-group sampleipv4Group
The following command removes the outbound access group flag for `sampleipv4Group`.

```bash
no ip access-group sampleipv4Group out
```
**ip address alloc-method**

Configures the method by which this APN will obtain IP addresses for PDP contexts.

**Product**

GGSN
P-GW
SAEGW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
ip address alloc-method { dhcp-proxy [ allow-deferred ] [ prefer-dhcp-options ] | dhcp-relay | local [ allow-deferred ] | no-dynamic [ allow-deferred ] } [ allow-user-specified ]
```

**default ip address allocation-method**

```
__default__
```

Restores the APN ip parameters to the following default settings.

```
__dhcp-proxy__
```

Default: Disabled
Configures the APN to assign an IP address received from a DHCP server.

**Important:** If this option is used, the system’s DHCP parameters must be configured.

```
__dhcp-relay__
```

Configures the APN to forward DHCP packets received from the MS to a DHCP server. Default: Disabled

**Important:** If this option is used, the system’s DHCP parameters must be configured.

```
__local__
```

Configures the APN to allocate IP addresses from a pool configured in the destination context on the system. Default: Enabled
**Important:** If this option is used, the name of the IP address pool from which to allocate addresses must be configured using the `ip address pool-name` command. If no pool name is specified, the system will attempt to allocate an address from any public pool configured in the destination context.

```plaintext
no-dynamic
```

Disables the dynamic assignment of IP addresses to PDP contexts using this APN. Default: Disabled

If a PDP context needing an IP address is received by an APN with this option enabled, it will be rejected with a cause code of 220 (Unknown PDP address or PDP type).

```plaintext
prefer-dhcp-options
```

If this keyword is specified with `dhcp-proxy` for IP address allocation configuration, the GGSN will prefer DHCP-supplied parameters over values provided by AAA server or by local configuration. This keyword controls the following parameters:

- primary and secondary Domain Name Server (DNS) addresses
- primary and secondary NetBIOS Name Server (NBNS) addresses

These values will be sent out in the PCO IE of a GTP Create PDP Response Message whenever the MS Requests them in a Create PDP Request Message.

Default: Disabled

**Important:** This keyword is available only with `dhcp-proxy` ip allocation method as this functionality is implemented only for GGSN acting as DHCP proxy.

By default, this functionality is disabled. Hence, DNS and NBNS values received from a DHCP server will not be considered by the GGSN.

```plaintext
allow-deferred
```

Enables support for P-GW deferred address allocation. Default: Disabled

```plaintext
allow-user-specified
```

Enables support for PDP contexts requesting the use of specific (static) addresses. Default: Enabled

**Important:** If this option is not enabled, PDP contexts requesting the use of a static address will be rejected with a cause code of 220 (Unknown PDP address or PDP type).

**Usage**

Use this command to configure the method by which the APN profile will assign IP addresses to PDP contexts.

When the PDP context is being established and the APN name is determined, the system will examine the APN’s configuration profile. Part of that procedure is determining how to handle IP address allocation. The figure in the Example section below displays the process used by the system to determine how the address should be allocated.

**Example**

The following command configures the APN to dynamically assign an address from a DHCP server and reject PDP sessions with static IP addresses:
ip address alloc-method dhcp-proxy

The following command configures the APN to reject sessions requesting dynamically assigned addresses and only allow those with static addresses:

ip address alloc-method no-dynamic allow-user-specified

The following figure provides the IP address allocation process:
Figure 3. IP Address Allocation Process

1. Start
2. Is a user-specified IP address provided?
   - Yes: Is allow-user-specified option enabled?
     - Yes: Address available in locally configured static pool?
       - Yes: Use IP address specified by user
       - No: System rejects session with cause code 220 (DCH, Unknown PDP address or PDP type)
     - No: Use assigned IP address
   - No: Use IP address from specified pool
3. Is authentication required?
   - Yes: IP address provided by authentication server?
     - Yes: Does IP address exist in a configured static pool?
       - Yes: Use assigned IP address
       - No: Use IP address from specified pool
     - No: Use IP address from specified pool
   - No: IP address pool name provided by authentication server?
4. Is local allocation method enabled?
   - Yes: Is pool name configured for ip address pool name command?
     - Yes: Does pool name match a configured static pool?
       - Yes: Use IP address from specified pool
       - No: System rejects session with cause code ALL_DYNAMIC_PDP_A DDR_OCCUPIED
     - No: Use IP address from specified pool
   - No: Assign IP address from block received from DHCP server
5. Is dhcp-proxy allocation method enabled?
   - Yes: System negotiates IP address of 0.0.0.0 with MG
   - No: System receives DHCP packets from MG and forwards them to DHCP server
6. Is dhcp-relay-agent option enabled?
   - Yes: System rejects session with cause code 220 (DCH, Unknown PDP address or PDP type)
   - No: System rejects session with cause code 220 (DCH, Unknown PDP address or PDP type)
ip address pool

Configures the name of an IP address pool configured on the system from which to assign an address for a PDP context.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

class configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

[ no ] ip address pool name pool_name

- no
  Removes a previously configured pool name.

- pool_name
  Specifies the name of the pool configured on the system from which an IP address will be assigned. The name is expressed as an alphanumeric string of 1 through 31 characters that is case sensitive.

Usage
If the ip address alloc-method command is configured to allow the assignment of IP addresses from a local pool configured on the system. It command instructs the system as to which pool should be used. The pool specified by this command must be a pool configured in the destination context on the system. Please refer to the ip pool command in the Context Configuration Mode Commands chapter for information on configuring IP address pools. Multiple APNs can use the same IP address pool if required. In addition, this command could be issued multiple times to allow a single APN to use different address pools.

⚠️ Caution: From 14.0 onward for configuration of multiple IP pool in an APN, GGSN expects Framed-IP-Address and Framed-Pool from RADIUS.

⚠️ Caution: In pre-release 14.0, the maximum number of IP pools in an APN is 16 for static and dynamic type of pool. From 14.0 onward this limit has been changed for static address allocation to 1 and out of the maximum 16 pools which can be configured under a particular APN, the first IP pool should be a static pool, which is the only working static pool from an APN.

Example

Command Line Interface Reference, StarOS Release 16
The following command configures the system to use a pool named `private_pool1` for address allocation:

```
   ip address pool private_pool1
```
ip address pool-exhaust-action

Configures the behavior to accept/reject a call if the IPv4 address pool is exhausted.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator
- Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
ip address pool-exhaust-action { ipv6-accept | ipv6-reject }
```

- **ipv6-accept**
  GGSN/P-GW will not reject the call; follows the standard behavior of allocating the available IP address.

- **ipv6-reject**
  Enables rejecting a call if GGSN/P-GW cannot allocate the IPv4 address for PDN type IPv4v6.

**Usage**

As per the standard behavior, when a UE sends a Create Request to GGSN/P-GW with PDN type IPv4v6, it should allocate both IPv4 and IPv6 address to the UE. If GGSN/P-GW fails to allocate the IPv4 address due to IP pool exhaustion, then it allocates only IPv6 address and changes the PDN Type to IPv6 and the call continues. In order to control this behavior, this CLI has been introduced; when configured, the following behavioral scenarios will be in place:

- CLI executed with **ipv6-reject** option will reject a call if GGSN/P-GW cannot allocate the IPv4 address for PDN type IPv4v6.
- CLI executed with **ipv6-accept** option will not reject a call and follow the standard behavior.

**Example**

The following command will reject a call if IPv4 type address allocation is not possible by GGSN/P-GW:

```
ip address pool-exhaust-action ipv6-reject
```
ip context-name

Configures the name of the destination context to use for subscribers accessing this APN.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

[ no ] ip context-name ctxt_name

no
Removes a previously configured context name.

ctxt_name

Specifies the name of the context through which subscriber data traffic will be routed. ctxt_name must be an alphanumeric string from 1 to 79 characters.

Usage
Use this command to specify the name of a destination context configured on the system through which to route all subscriber data traffic. This context will be used for subscribers accessing this APN. If no name is specified, the system will use the context in which the APN is configured as the destination context.

When the APN is used to support Mobile IP functionality, this command is used to indicate the context in which the FA (foreign Agent) service is configured. If no name is specified, the context in which the GGSN service facilitating the subscriber PDP context is used.

Example
The following command configures the system to route subscriber traffic for the APN through a context called isp1:

    ip context-name isp1
ip header-compression

Configures IP packet header compression parameters for this APN.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

ip header-compression vj

default ip header-compression

no ip header-compression

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Disables Van-Jacobson header compression.</td>
</tr>
<tr>
<td>no</td>
<td>Disables Van-Jacobson header compression.</td>
</tr>
<tr>
<td>vj</td>
<td>Enables Van-Jacobson header compression for IP packets. Default: Enabled</td>
</tr>
</tbody>
</table>

Usage
IP header compression reduces packet header overhead resulting in more efficient utilization of available bandwidth.

Example
The following command disables packet header compression for the APN:

no ip header-compression
ip hide-service-address

Renders the IP address of the GGSN unreachable from mobile stations (MSs) using this APN. This command is configured on a per-APN basis.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

[ default | no ] ip hide-service-address

default

Does not allow the mobile station to reach the GGSN IP address using this APN.

no

Allows the mobile station to reach the GGSN IP address using this APN.

Usage

This hides the GGSN IP address from the mobile station for security purposes.

Example

The following command allows the GGSN’s IP address to be viewed by the mobile station:

no ip hide-service-address
**ip local-address**

Configures the local-side IP address of the subscriber's point-to-point connection.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
**Exec > Global Configuration > Context Configuration > APN Configuration**

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
ip local-address  ip_address
```

```
no ip local-address
```

- **no**
  Removes a previously configured IP local-address.

```
ip_address
```

Specifies an IP address configured in a destination context on the system through which a packet data network can be accessed. `ip_address` must be expressed in IPv4 dotted-decimal notation.

**Usage**

This parameter specifies the IP address on the system that the MS uses as the remote-end of the PPP connection. If no local address is configured, the system uses an unnumbered scheme for local-side addresses.

**Example**

The following command configures a local address of 192.168.1.23 for the MS:

```
ip local-address 192.168.1.23
```
ip multicast discard

Configures the IP multicast discard packet behavior.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
[ default | no ] ip multicast discard
```

- **default**
  
  Restores the APN IP parameters to the default multicast settings, which is to discard PDUs.

- **no**
  
  Removes a previously configured IP multicast discard.

**Usage**

This command specifies if IP multicast discard is enabled or disabled.

**Example**

The following command enables IP multicast discard for an APN:

```
ip multicast discard
```
ip source-violation

Enables or disables packet source validation for the current APN.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name] host_name(config-apn) #

Syntax

ip source-violation { ignore | check [ drop-limit limit ] } [ exclude-from-accounting ]

default ip source-violation

default
Restores the APN ip parameters to the default settings check enabled, drop-limit 10.

ignore
Default: Disabled
Disables source address checking for the APN.

check [ drop-limit limit ]
Default: Enabled, limit = 10
Enables the checking of source addresses received from subscribers for violations.
A drop-limit can be configured to set a limit on the number of invalid packets that can be received from a subscriber prior to their session being deleted. limit can be configured to any integer value between 0 and 1000000. A value of 0 indicates that all invalid packets will be discarded but the session will never be deleted by the system.

exclude-from-accounting
Default: Disabled
Excludes the packets identified with IP source violation from the statistics generated for accounting records.

Usage
Source validation is useful if packet spoofing is suspected or for verifying packet routing and labeling within the network.
Source validation requires the source address of received packets to match the IP address assigned to the subscriber (either statically or dynamically) during the session.

**Example**

The following command enables source address validation for the APN and configures a drop-limit of 15:

```
   ip source-violation check drop-limit 15
```
**ip user-datagram-tos copy**

Controls the copying of the IP ToS octet value from user IPv4/IPv6 datagrams into the IP header of GTP tunnel encapsulations.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > APN Configuration

```bash
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
[ default | no ] ip user-datagram-tos copy
```

**default**

Sets the default behavior of this command. By default this function is disabled.

**no**

Removes the preconfigured parameter for this command.

**Usage**

This command enables or disables the copying of the ToS byte from the inner IP header to the outer IP header for an RP connection.

When this function is enabled, the SGSN can detect the special ToS marking in the outer IP header of GTP tunnel packets and identify certain packets as control messages.
ipv6 access-group

Configures the IPv6 access group for the current APN profile which applies a single Access Control List (ACL) to multiple subscribers via the APN for IPv6 traffic.

Product
- GGSN
- ACS
- P-GW
- SAEGW

Privilege
Security Administrator, Administrator

Mode
- Exec > Global Configuration > Context Configuration > APN Configuration
- configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

Syntax

```
ipv6 access-group group_name [ in | out ] [ fallback-enabled ]

[ no ] ipv6 access-group group_name [ in | out ]
```

- **no**
  Removes a previously configured IPv6 ACL applied to a particular APN for IPv6 traffic. If at least one of the two `{ in | out }` options is not selected for the ACL that will be removed, the ACL will be removed for both directions.

- **group_name**
  Specifies the name of the IPv6 access group as an alphanumeric string of 1 through 79 characters.

- **in | out**
  Default: both (in and out)
  Specifies the access-group as either inbound or outbound by the keywords `in` and `out`, respectively.
  If no direction is supplied in the base command, the specified IPv6 access control list will be applied to both directions.

Usage
Use this command to apply a single IPv6 access control list to multiple subscribers via an APN for inbound or outbound IPv6 traffic.
If no traffic direction is specified, the selected access control list will be applied to both traffic directions.

Example
The following command associates the `sampleipv6Group` access group with the current APN profile for both inbound and outbound access:

```
ipv6 access-group sampleipv6Group
```

The following removes the outbound access group flag for `sampleipv6Group`:

```
no ipv6 access-group sampleipv6Group out
```
ipv6 address alloc-method

Controls the IPv6 address allocation method for a particular APN.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

ipv6 address alloc-method { dhcpv6-proxy [allow-prefix-delegation] | local | no-dynamic } [ allow-user-specified ]

[ default ] ipv6 address alloc-method

default
Configures the default address allocation method which is “local”.

dhcpv6-proxy
Configures the IPv6 address from DHCP server for the APN.

allow-prefix-delegation
Configures the APN to allow DHCPv6 prefix-delegation.

local
Configures the IPv6 address from the local pool configured.

no-dynamic
Configures the IPv6 address as indicated by the authentication server.

allow-user-specified
When any of the above three options is specified with allow-user-specified, the static IP address provided by UE takes priority and allocated/configured.

Usage

With the support of DHCPv6 and dual PDP IPv4v6, the separate allocation methods are required for IPv4 and IPv6. Earlier the IPv6 address was allocated through local pool or RADIUS Returned, but with the new options: local, no-dynamic, and DHCPv6-proxy, the IPv6 address allocation can be done for a particular
APN. The static address allocation can be enabled by the use of `allow-user-specified` keyword with the above three options. From 15.0 onward the support of prefix delegation for DHSCv6 is added to assign a network address prefix to a user site, configuring the user’s router with the prefix to be used for each interface it is attached to. This is one of the methods for delegating IPv6 address prefixes to an IPv6 subscriber's network.

**Example**

The following command provides an example of allocating the IP address from DHCP server:

```
ipv6 address alloc-method dhcpv6-proxy allow-user-specified
```

The following commands configures the prefix-delegation for DHCPv6 with 52 bit length:

```
ipv6 address alloc-method dhcpv6-proxy allow-prefix-delegation
ipv6 address prefix-delegation-len 52
```
**ipv6 address prefix-delegation-len**

Configures the supported prefix length to 48/52/56 bit length per-APN for DHCPv6 prefix-delegation support.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] ipv6 address prefix-delegation-len { 48 | 52 | 56 }
```

`no`
Removes the configured prefix-delegation length to allow DHCPv6 prefix delegation.

**Usage**
Use this command to configure the length of prefix (48/52/56) to allow with DHCPv6 prefix delegation.

**Example**
The following command sets the allowed prefix length to 52 bit for DHCPv6 prefix delegation support:

```
ipv6 address prefix-delegation-len 52
```
**ipv6 address pool-exhaust-action**

Configures the behavior to accept/reject a call if the IPv6 address pool is exhausted.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```plaintext
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```plaintext
ipv6 address pool-exhaust-action { ipv4-accept | ipv4-reject }
```

**ipv4-accept**

GGSN/P-GW will not reject the call; follows the standard behavior of allocating the available IP address.

**ipv4-reject**

Enables rejecting a call if GGSN/P-GW cannot allocate the IPv6 address for PDN type IPv4v6.

**Usage**

As per the standard behavior, when a UE sends a Create Request to GGSN/P-GW with PDN type IPv4v6, it should allocate both IPv4 and IPv6 address to the UE. If GGSN/P-GW fails to allocate the IPv6 address due to IP pool exhaustion, then it allocates only IPv4 address and changes the PDN Type to IPv4 and the call continues. In order to control this behavior, this CLI has been introduced; when configured, the following behavioral scenarios will be in place:

- CLI executed with **ipv4-reject** option will reject a call if GGSN/P-GW cannot allocate the IPv6 address for PDN type IPv4v6.
- CLI executed with **ipv4-accept** option will not reject a call and follow the standard behavior.

**Example**

The following command will reject a call if IPv6 type address allocation is not possible by GGSN/P-GW:

```plaintext
ipv6 address pool-exhaust-action ipv4-reject
```
ipv6 dns

Configures primary and secondary IPv6 Domain Name Service (DNS) servers.

**Product**
GGSN
P-GW
SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```bash
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```bash
[context_name]host_name(config-apn)#
```

**Syntax**

```bash
[ no ] ipv6 dns { primary | secondary } { ipv6_dns_address }
```

- **no**
  Deletes a previously configured DNS server.

- **primary**
  Configures the IPv6 address of primary DNS server for the APN.

- **secondary**
  Configures IPv6 address of the secondary DNS server for the APN. Only one secondary DNS server can be configured.

- **ipv6_dns_address**
  The IP address of the DNS server entered using IPv6 colon-separated-hexadecimal notation.

**Usage**

DNS servers are configured on a per-APN profile basis. This allows each APN profile to use specific servers in processing PDP contexts.

The DNS can be specified at the APN level in APN configuration as well as at the Context level in Context configuration mode with `ip name-servers` command, or it can be received from AAA server.

When DNS is requested in PCO configuration, the following preference will be followed for DNS value:

1. DNS Values received from LNS have the first preference
2. DNS values received from RADIUS Server has the second preference
3. DNS values locally configured with APN has the third preference
4. DNS values configured at context level with `ip name-servers` command has the last preference.
Important: The same preference would be applicable for the NBNS (NetBIOS Name Service) servers to be negotiated via ICPC (Initial Connection Protocol Control) with the LNS (L2TP Network Server).

Example

The following command provides an example of setting the primary DNS server:

```
ipv6 dns primary fe80::c0a8:a04
```
**ipv6 egress-address-filtering**

Enables or disable IPv6 egress address filtering. This function filters out packets not meant for the mobile interface ID. The GGSN records the source interface ID of all the packets received from the mobile node. When packets sent to the mobile node are received, the destination interface ID is compared against the list of recorded interface IDs and with the local interface-ID assigned to the MS during IPv6CP. If no match is found, the packet is dropped.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > APN Configuration
- `configure > context context_name > apn apn_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
[ no ] ipv6 egress-address-filtering
```

- `no`
  - Disables IPv6 egress address filtering.

**Usage**

Used to filter packets that arrive from the internet to a particular site.

**Example**

The following command provides an example disabling egress address filtering:

```
no ipv6 egress-address-filtering
```
**ipv6 initial-router-advt**

Creates an IPv6 initial router advertisement interval for the current APN.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > APN Configuration

`configure > context context_name > apn apn_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
ipv6 initial-router-advt { interval int_value | num-advts num_value }
[ default ] ipv6 initial-router-advt { interval | num-advts }
```

- `default`
  - Resets interval or num-advts to their default setting.

- `interval int_value`
  - Specifies the time interval (in milliseconds) when the initial IPv6 router advertisement is sent to the mobile node as an integer from 100 through 16000. Default: 3000ms

- `num-advts value num_value`
  - Specifies the number of initial IPv6 router advertisements sent to the mobile node as an integer from 1 through 16. Default: 3

**Usage**

This command is used to set the advertisement interval and the number of advertisements. Using a smaller advertisement interval increases the likelihood of router being discovered more quickly when it first becomes available.

**Example**

The following command specifies the initial ipv6 router interval to be 2000ms:

```
ipv6 initial-router-advt interval 2000
```
I3-to-I2-tunnel address-policy

Configures the address allocation/validation policy, when subscriber L3 (IPv4/IPv6) sessions are tunneled using an L2 tunneling protocol, such as L2TP.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration
configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

l3-to-l2-tunnel address-policy { alloc-only | alloc-validate | no-alloc-validate }
default l3-to-l2-tunnel address-policy

default
Restores the layer 3-to-layer 2 tunnel address policy parameter to the default setting of validation with no allocation.

alloc-only
Specifies that the system locally allocates and validates subscriber addresses. Default: Disabled

alloc-validate
Specifies that the system allocates addresses when IP addresses are dynamically assigned. The system does not validate the address specified by the subscriber. Default: Disabled

no-alloc-validate
Specifies that the system does not allocate or validate subscriber addresses locally for such sessions; it passes the address between remote tunnel terminator to the mobile node. Default: Enabled

Usage
This command can be useful for MIP HA sessions tunneled from the system using L2TP tunnels, or GGSN PDP contexts of type IP tunneled using L2TP to a remote LNS.

Example
The following command configures the system to locally allocate and validate subscriber addresses:

l3-to-l2-tunnel address-policy alloc-only
loadbalance-tunnel-peers

Configures how tunnel-peers are selected for this APN.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration
```
configure > context context_name > apn apn_name
```
Entering the above command sequence results in the following prompt:
```
[context_name]host_name(config-apn)#
```

**Syntax**
```
loadbalance-tunnel-peers { balanced | prioritized | random }
```
```
default loadbalance-tunnel-peers
```

**default**
Restores the loadbalance-tunnel-peers parameter to the default setting of random.

**balanced**
Tunnel-peer selection is made without regard to prioritization, but in a sequential order that balances the load across the total number of peer nodes available. Default: Disabled

**prioritized**
Tunnel-peer selection is made based on the priority configured for the peer. Default: Disabled

**random**
Tunnel-peer selection is random in order. Default: Enabled

**Usage**
Use this command to configure the load-balancing algorithm that defines how the tunnel-peers are selected by the APN when multiple peers are configured in the APN.

**Example**
The following command sets the APN to connect to tunnel-peers in a sequential order:
```
load-balancing balanced
```
long-duration-action detection

Sets the detection of a session that exceeds the long duration timer and sends notification.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

long-duration-action detection

default long-duration-action

default

Restores the long-duration-action parameter to its default setting of detection.

long-duration-action detection

Detects long duration sessions and sends SNMP TRAP and CORBA notification. This is the default behavior. Default: Enabled

Usage
Use this command to detect a session that exceeds the limit set by the long duration timer.
Refer to the timeout idle and timeout long-duration commands for information on setting the long duration timer.

Example
Use the following command to enable detecting the session that exceeds the long duration timer:

long-duration-action detection
long-duration-action disconnection

Specifies what action is taken when the long duration timer expires.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
long-duration-action disconnection [ suppress-notification ] [ dormant-only ] +
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>long-duration-action disconnection</td>
<td>Detects a long duration session and disconnects the session after sending SNMP TRAP and CORBA notification. Default: Disabled</td>
</tr>
<tr>
<td>suppress-notification</td>
<td>Suppress the SNMP TRAP and CORBA notification after detecting and disconnecting a long duration session. Default: Disabled</td>
</tr>
<tr>
<td>dormant only</td>
<td>Disconnects the dormant sessions after long duration timer and inactivity time with idle time-out duration expires. It sends the SNMP TRAP and CORBA notification after disconnecting a long duration session. Default: Disabled</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to determine what action is taken when a session exceeds the limit set by the long duration timer.
Refer to the `timeout idle` and `timeout long-duration` command for information on setting the long duration timer.

**Example**

Use the following command to enable disconnecting sessions that exceed the long duration timer:

```
long-duration-action disconnection
```

Use the following command to disconnect the session that exceed the long duration timer without sending SNMP TRAP and CORBA notification:

```
long-duration-action disconnection suppress-notification
```
Use the following command to disconnect the session that exceed the long duration timer and also inactivity timer for idle time-out duration and send SNMP TRAP and CORBA notification:

```
long-duration-action disconnection dormant-only
```

Use the following command to disconnect the session that exceed the long duration timer and also inactivity timer for idle time-out duration without sending any SNMP TRAP and CORBA notification. If the session is idle and the session-idle-time >= inactivity time the session gets disconnected. Even if session is idle when the long-duration timed-out and session-idle time < inactivity time the timer value is reset to idle-timeout time.

```
long-duration-action disconnection dormant-only suppress-notification
```
mbms bmsc-profile

Applies a configured Broadcast-Multicast Service Center (BM-SC) profile to subscribers through APN for Multimedia Broadcast Multicast Service (MBMS) support and functionality.

Product

GGSN
P-GW
SAEGW

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

mbms bmsc-profile name bmsc_profile_name

[ default | no ] mbms bmsc-profile

default

Applies the default BMSC profile to the subscribers through the APN.

no

Deletes a previously associated BM-SC profile with this APN.

name bmsc_profile_name

Specifies a name for the BM-SC profile already configured in BMSC configuration mode.
bmsc_profile_name is an alphanumeric string of 1 through 79 characters that may contain dots (.) and/or dashes (-).

Usage

Use this command to associate a configured BM-SC profile to use for MBMS contexts with this APN for MBMS feature support.
For more information on BM-SC profile configuration, refer to the BMSC Profile Configuration Mode Commands chapter.
This command also configures the specific BM-SC profile to use for Internet Group Management Protocol (IGMP) JOIN requests received from PDP contexts with this APN.

Example

Following command applies a previously configured BM-SC profile named bm_sc_1 to an APN within the specific context.
mbms bmsc-profile name bm_sc_1
mbms bearer timeout

Configures the session timeout values for the Multimedia Broadcast Multicast Service (MBMS) bearer contexts with this MBMS APN.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration
configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

mbms bearer timeout { absolute | idle } time

[ default | no ] mbms bearer timeout { absolute | idle }

default
Sets the default value for the followed option for MBMS bearer context timeout.

no
Returns the timeout parameter to its default setting. If neither the absolute or idle keywords are used in conjunction with this keyword, both timeout options will be returned to their default settings.

absolute
Configures the absolute maximum time (in seconds) an MBMS bearer context may exist in any state (active or idle). Default: Disabled

idle
Default: Disabled
Configures the maximum amount of time (in seconds) an MBMS bearer context may be idle.

time
time can be any integer value between 0 and 4294967295. A time of 0 disables timeouts for this APN. Default: 0

Usage
Use this command to limit the amount of time that an MBMS bearer context session can remain connected.
Example

The following commands enables an absolute time timeout of 60000 seconds for MBMS bearer context:

```
mbms bearer timeout absolute 60000
```
mbms ue timeout

Configures the session timeout values for the Multimedia Broadcast Multicast Service (MBMS) user equipment (UE) contexts with this MBMS APN.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration
configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:
[context_name]host_name(config-apn)#

Syntax
mbms ue timeout absolute time
[ default | no ] mbms ue timeout absolute

default
Set the default value for the followed option for MBMS UE context timeout.

no
Returns the timeout parameter to its default setting. If neither the absolute or idle keywords are used in conjunction with this keyword, both timeout options will be returned to their default settings.

absolute time
Configures the absolute maximum time (in seconds) an MBMS UE context may exist in any state (active or idle). time can be any integer value between 0 and 4294967295. A time of 0 disables timeouts for this APN. Default: 0

Usage
Use this command to limit the amount of time that an MBMS UE context session can remain connected.

Example
The following commands enables an absolute time timeout of 60000 seconds for MBMS UE context:

mbms bearer timeout absolute 60000
mediation-device

Enables the use of a mediation device and specifies the system context to use for communicating with the device.

Product
- GGSN
- P-GW
- SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

mediation-device [ context-name context_name ] [ delay-GTP-response ] [ no-early-PDUs ] [ no-interims ] +

[ default | no ] mediation-device

Indicates that more than one of the options can be specified with a single execution of the command.

default
Changes the mediation device to no context-name configured and restores the mediation device’s default properties.

no
Deletes the mediation-device configuration.

context-name context_name
Configures the mediation VPN context for this APN as an alphanumeric string of 1 through 79 characters that is case sensitive. If not specified, the mediation context is the same as the destination context of the subscriber. Default: The subscriber’s destination context.

delay-GTP-response
When enabled, delays the CPC response until an Accounting Start response is received from the mediation device. Default: Disabled

no-early-pdus
Specifies that the system delays PDUs from the MS until a response to the GGSN accounting start request is received from the mediation device. The PDUs are queued, not discarded. Default: Disabled
If “no-early-PDUs” is enabled, the chassis does not send uplink/downlink data from/to a MS until it receives the Acct-Rsp Start for the same from the mediation device. On receiving the Acct-Rsp, pending PDUs are forwarded. The chassis buffers up to two PDUs per call. As soon as the third PDU comes, the buffering is disabled and all the PDUs are forwarded for that call.

Configures the system to queue up to two PDUs until the mediation device returns a response to the system's accounting START request per 3GPP standards. On receiving the Accounting response message, the system forwards the subsequent PDUs without discarding any of the packets.

**Important:** For StarOS 10.0 and earlier releases, the system buffers up to four PDUs and queues or discards the remaining PDUs.

**Important:** For StarOS 11.0 and later releases, the system is configured so that none of the PDUs are discarded.

```
no-interims
```

Disables sending interims to the mediation server. Default: Disabled

**Important:** Different commands are used to disable RADIUS interims for RADIUS accounting and mediation accounting. To disable RADIUS interims for mediation accounting, use the following command: `mediation-device context-name context_name no-interims`. To disable RADIUS interims for RADIUS accounting, use the following command: `accounting-mode radius-diameter no-interims`.

**Usage**

This command enables mediation device support for the APN. Mediation devices can be either deep-packet inspection servers or transaction control servers. Keywords to this command can be used in combination to each other, depending on configuration requirements.

**Example**

The following command enables mediation device support for the APN and uses the protocol configuration located in an `system context` called `ggsn1`:

```
mediation-device context-name ggsn1
mediation-device context-name ggsn1 no-interims no-early-pdus
mediation-device no-early-pdus no-interims
mediation-device no-interims no-early-pdus
```

The following command enables mediation device support for the APN and uses the protocol configuration located in the `subscribers destination context`:

```
mediation-device
```
mobile-ip home-agent

Configures the IP address of the home agent (HA) used by the current APN to facilitate subscriber Mobile IP sessions.

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

mobile-ip home-agent ip_address [ alternate ]

no mobile-ip home-agent ip_address alternate

default mobile ip home-agent

default
Restores the APN mobile-ip parameters to the default setting, no HA address defined.

default

no
Removes a previously configured HA address.

ip_address
Specifies the IP address of the HA expressed in IPv4 dotted-decimal notation.

alternate
Designates this Mobile IP HA as the alternate that will be used in the event of a fail-over.

Usage
If the APN is configured to support Mobile IP for all PDP contexts it is facilitating, this command specifies the IP address of the HA that is to be used.

Example
The following command configures an HA IP address of 192.168.1.15:

mobile-ip home-agent 192.168.1.15
mobile-ip min-reg-lifetime-override

Specifies the minimum registration timer to override the platform-wide default on an enterprise basis. This feature is associated with 4G LTE scenarios employing Network Mobility (NEMO) routing.

Product
P-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration
configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

\[context_name]host_name(config-apn)\#

Syntax

```
mobile-ip min-reg-lifetime-override { seconds | infinite }
```

default mobile-ip min-reg-lifetime-override

no mobile-ip min-reg-lifetime-override

default
Sets the minimum registration time to 600 seconds.

no
Deletes the registration interval entered via this command.

```
seconds
```

Specifies the minimum registration interval in seconds as an integer from 1 through 65534. Default = 600

```
infinite
```

Sets the minimum registration interval as “infinite” (forever) for this subscriber.

Usage
Specify the minimum registration timer to override the platform-wide default on an enterprise basis. With this command, NEMO traffic could be re-routed symmetrically to an alternate carrier within the specified number of seconds following a failure on the primary communication path.

Example
The following command sets the minimum registration override interval to 900 seconds:

```
mobile-ip min-reg-lifetime-override 900
```
**mobile-ip mn-aaa-removal-indication**

Configures the system to remove various information elements when relaying Registration Request messages to the HA.

**Product**
- GGSN
- FA
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration
`configure > context context_name > apn apn_name`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-apn)#`

**Syntax**

```
[ default | no ] mobile-ip mn-aaa-removal-indication
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Sets the default setting for mobile IP MN-AAA-Removal-Indication.</td>
</tr>
<tr>
<td>no</td>
<td>Disables this functionality. This is the default setting.</td>
</tr>
</tbody>
</table>

**Usage**

When this functionality is enabled, the MN-FA challenge and MN-AAA authentication extensions are removed when relaying a Registration Request (RRQ) to the HA.
**mobile-ip mn-ha-hash-algorithm**

Designates the encryption algorithm to use for Hash-based Message Authentication Code (HMAC).

**Product**

GGSN
P-GW
SAEGW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > APN Configuration

```

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
mobile-ip mn-ha-hash-algorithm { hmac-md5 | md5 | rfc2002-md5 }
```

```
default mobile-ip mn-ha-hash-algorithm
```

**Usage**

Provides security by encrypting the data.

**Example**

The following command sets encryption for md5:

```
mobile-ip mn-ha-hash-algorithm md5
```
mobile-ip mn-ha-shared-key

Configures the subscriber MobileNode-Home Agent (MN-HA) shared key.

**Product**
GGSN
P-GW
SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration
configure > context context_name > apn apn_name

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
mobile-ip mn-ha-shared-key key

no mobile-ip mn-ha-shared-key
```

*no*
Disables this functionality. This is the default setting.

*key*
Specifies the subscriber MN-HA shared key as either an alphanumeric string or a hexadecimal number sequence beginning with “0x”. The string or sequence consists of 16 to 127 characters.

**Usage**

Configures a shared key for the APN.

**Example**

The following command configures a shared key as the alphanumeric string **sfd23408imi9yn**:

```
mobile-ip mn-ha-shared-key sfd23408imi9yn
```
**mobile-ip mn-ha-spi**

Configures the Mobile IP Security Parameter Index (SPI).

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > APN Configuration

\[\text{configure} \ \text{> context context_name} \ \text{> apn apn_name}\]

Entering the above command sequence results in the following prompt:

\[
\text{[context_name]host_name(config-apn)#}
\]

**Syntax**

\[\text{mobile-ip mn-ha-spi} \ \text{spi_number}\]

\[\text{no mobile-ip mn-ha-spi}\]

- \(\text{no}\)
  - Disables this functionality. This is the default setting.

- \(\text{spi_number}\)
  - Specifies the SPI as an integer from 256 through 4294967295.

**Usage**

Configures an SPI for the APN.

**Example**

The following command configures an SPI of \(15111111111111111111111111111111\):

\[\text{mobile-ip mn-ha-spi} \ 15111111111111111111111111111111\]
**mobile-ip required**

Enables support for Mobile IP functionality for all PDP contexts facilitated by the current APN.

**Product**
- GGSN
- FA
- P-GW
- SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
[ default | no ] mobile-ip required
```

- **default**
  Applies the default setting for mobile-ip for the APN. Default is disabled.

- **no**
  Disables mobile-ip for the APN.

**Usage**

Mobile IP functionality for IP PDP contexts is only supported at the APN-level. This command enables or disables Mobile IP support for the APN.

When Mobile IP is performed, the system authenticates the subscriber and the Mobile IP FA.

If this option is enabled, the system deletes all PDP contexts attempting to access the APN for which a Mobile IP session cannot be established.
mobile-ip reverse-tunnel

Configures the system to support reverse-tunneling for Mobile IP sessions facilitated by the current APN.

Product
- GGSN
- FA
- P-GW
- SAEGW

Privilege
- Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

[ default | no ] mobile-ip reverse-tunnel

default
Designates the default reverse tunnel for the APN. The default is enabled.

no
Disables this functionality.

Usage
Use this command to enable support for Mobile IP reverse tunneling for the APN. Reverse tunneling is enabled by default.
nai-construction

Configures the Network Access Identifier (NAI) construction parameters on a per-APN basis only, rather than by per-aaa-group when constructed NAI authentication is enabled.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

nai-construction { imsi | msisdn } [ override-null-username ] [ encrypted password encrypt_password | use-shared-secret-password | password password ]

no nai-construction

no
Disables the NAI construction at the APN level.

imsi
Enables NAI construction using IMSI for authentication for a user. GGSN constructs NAI using IMSI when no user-name is received. This is the default setting. Default: Enabled

msisdn
Enables NAI construction using Mobile Station International ISDN Number (MSISDN) for authentication for a user. GGSN constructs NAI using MSISDN when no user-name is received.

override-null-username
Enables NAI construction using IMSI/MSISDN for authentication for a user or when empty user name is received.

encrypted password
Specifies an encrypted password is to be used for this NAI-constructed user. string is an alphanumeric string of 0 through 63 characters.
password

Configures the authentication user-password for this NAI-constructed user. password is an alphanumeric string of 0 through 63 characters.

use-shared-secret-password

Specifies use of the RADIUS authentication shared secret password for this NAI-constructed user.

Usage

NAI-construction defines the behavior for construction at the APN level. If defined for a particular APN, this command works independently and overwrites the behavior of aaa constructed-nai defined at the context level for calls involving this APN.

Note that NAI construction using IMSI or MSISDN, where either no user name is received or a blank user name is received for authentication, is applicable only when NAI constructed authentication is enabled using the aaa nai-construction authentication command in Context Configuration Mode.

Example

The following command enables NAI-construction using IMSI as the authentication type with an encrypted password:

    nai-construction imsi encrypted password s1289sf980333jwwdo97342
nbns

Configures and enables use of NetBios Name Service (NBNS) for the APN.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

[ no ] nbns { primary | secondary } IP_address

no
Removes/disables use of a previously configured NetBios Name Service.

primary
Designates primary NBNS server. Must be followed with an IPv4 address in dotted-decimal notation.

secondary
Designates secondary/failover NBNS server. Must be followed with an IPv4 address in dotted-decimal notation.

IP_address
Specifies the IP address in IPv4 dotted-decimal notation.

Usage
This command specifies NBNS parameters. The NBNS option is present for both pdp type IP and pdp type PPP for GGSN.
The system can be configured to use NetBios Name Service for the APN.

Example
The following command configures the APN’s NetBios Name Service to primary IP 192.168.1.15.

nbns primary 192.168.1.15
**network-behind-mobile**

Allows enabling/disabling the Network Behind Mobile Station (NBMS) for the APN.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
network-behind-mobile { max-addresses-behind-mobile max_addrs | max-subnets max_subnets } [ default | no ] network-behind-mobile
```

- **default**
  
  Enables the default settings for this function. It enables NBMS with max-subnets as 10 and max-addresses-behind-mobile as 16,777,214 default values.

- **no**
  
  Disables the network behind mobile station functionality on the APN.

- **max-addresses-behind-mobile max_addrs**

  Configures the maximum number of addresses that are allowed in a single Network/subnet Behind MS. 
  `max_addrs` must be an integer from 1 through 16,777,214.
  Default: 16,777,214

- **max-subnets max_subnets**

  Specifies the maximum number of subnets that can be enabled for a call in the APN. 
  `max_subnets` must be an integer from 1 through 16.
  Default: 10

**Usage**

Use this command to enable or disable NBMS for the APN.

**Example**

The following command enables NBMS and allows a maximum of 16 routes to be installed on the APN wherein maximum 268,435,454 host addresses are allowed in each network:
network-behind-mobile max-subnets 16
nexthop-forwarding-address

Configures the next hop forwarding address for the APN.

Product

GGSN
P-GW
SAEGW

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

nexthop-forwarding-address ip_address

no nexthop-forwarding-address

no

Disables this function. This is the default setting.

ip_address

Specifies the IP address of the nexthop forwarding address in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

Ensure the route is available for this nexthop address and its directly connected host. Use of an arbitrary address can cause a routing loop within the host and lead to dropped packets.

Usage

Use this command to configure the next hop forwarding address for the APN.

Example

The following command configures the next hop forwarding address to 10.1.1.1:

nexthop-forwarding-address 10.1.1.1
npu qos

Configures an NPU QoS priority queue for packets facilitated by the APN.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

npu qos traffic priority { best-effort | bronze | derive-from-packet-dscp | gold | silver }

default npu qos traffic priority

default

Configures the default NPU QoS traffic priority.

traffic priority { best-effort | bronze | derive-from-packet-dscp | gold | silver }

best-effort: Assigns the best-effort queue priority. This is the lowest priority.
brown: Assigns the bronze queue priority. This is the third-highest priority.
derive-from-packet-dscp: Specifies that the priority is to be determined from the DSCP (Differentiated Services Code Point) field in the packet's TOS octet. Default: Enabled
gold: Assigns the gold queue priority. This is the highest priority.
silver: Assigns the silver queue priority. This is the second-highest priority.

Usage

This command is used in conjunction with the Network Processing Unit (NPU) Quality of Service (QoS) functionality.
The system can be configured to determine the priority of a subscriber packet either based on the configuration of the APN, or from the differentiated service (DS) field in the packet's TOS octet (representing the differentiated service code point (DSCP) value).
Refer to the GGSN Administration Guide for additional information on NPU QoS functionality.

Example

The following command configures the APN’s priority queue to be gold:

    npu qos traffic priority gold
outbound

Configures the APN host username and password.

**Product**
GGSN
P-GW
SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
outbound { [ encrypted ] password pwd | username name }
```

**no outbound password | username**

```
no
```

Removes previously configured outbound information for the APN.

**encrypted**

The `encrypted` keyword is intended only for use by the chassis while saving configuration scripts. The system displays the `encrypted` keyword in the configuration file as a flag that the variable following the `password` keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file.

```
password pwd
```

Specifies the password to use for session authentication as an alphanumeric string of 1 through 132 characters that is case sensitive.

```
username name
```

Specifies the username to use for session authentication as an alphanumeric string of 1 to 127 characters that is case sensitive.

**Usage**

This command can be used to provide a username and password for authentication when the subscriber does not supply one in accordance with 3GPP standards. In addition, it can be used to create a PPP session when using L2TP to tunnel IP PDP contexts.

If only a username is specified using this command, the password is determined based on the setting of the `aaa constructed-nai` command in the Context Configuration mode. That command is also used to
determine the password if an outbound username and password are configured for the APN when the imsi-auth keyword is specified for the `authentication` command in this mode.

Example

The following commands configures an APN username of `isp1` and a password of `secRet123`.

```plaintext
outbound username isp1
outbound password secRet123
```
p-cscf

Enables use of locally configured Proxy Call Session Control Function (P-CSCF) addresses or a Fully Qualified Domain Name (FQDN).

Product
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration
configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

In StarOS V14.x and earlier:

```
p-cscf { fqdn fqdn | primary [ ip IPv4_address | ipv6 IPv6_address ] | secondary [ ip IPv4_address | ipv6 IPv6_address ] }
```

```
```

In StarOS V15.0 and later:

```
p-cscf { fqdn fqdn | priority address_priority [ ip IPv4_address | ipv6 IPv6_address ] }
```

```
no p-cscf { fqdn fqdn | priority address_priority [ ip | ipv6 ] }
```

```
no
```

Disables use of previously configured P-CSCF addresses or FQDN.

```
fqdn fqdn
```

Configures the P-CSCF FQDN server name for the APN as an alphanumeric string of 1 through 256 characters.

```
primary [ ipIPv4_address | ipv6 IPv6_address ]
```

Specifies the primary P-CSCF address for the APN.
IPv4_address must be expressed in IPv4 dotted-decimal notation.
IPv6_address must be expressed in IPv6 colon-separated-hexadecimal notation.

```
secondary [ ip IPv4_address | ipv6 IPv6_address ]
```

Specifies the secondary P-CSCF address for the APN.
IPv4_address must be expressed in IPv4 dotted-decimal notation.
IPv6_address must be expressed in IPv6 colon-separated-hexadecimal notation.
priority address_priority [ ip IPv4_address | ipv6 IPv6_address ]

Specifies the priority for P-CSCF address for the APN.
address_priority is an integer from 1 to 3. 1 is the highest priority.
IPv4_address must be expressed in IPv4 dotted-decimal notation.
IPv6_address must be expressed in IPv6 colon-separated-hexadecimal notation.

Usage

Use this command to specify the P-CSCF addresses or FQDN server name associated with this APN.

Example

The following command enables a P-CSCF with the primary IPv4 address 10.2.3.4 for the APN:

   p-cscf primary ip 10.2.3.4

The following command enables a P-CSCF with FQDN server name pcscfalias1.ind.pun.cisco.com for the APN:

   p-cscf fqdn pcscfalias1.ind.pun.cisco.com

The following command enables a P-CSCF with the IPv4 address 10.2.3.4 at the highest priority of 1 for the APN:

   p-cscf priority 1 ip 10.2.3.4
pco-options

This command controls the sending of customized PCO (Protocol Configuration Options) options in the network to MS GTP messages and configures APN to include link MTU in PCO IE.

Product
- P-GW
- GGSN

Privilege
- Security Administrator
- Administrator

Mode
- Exec > Global Configuration > Context Configuration > APN Configuration
  ```
  configure > context context_name > apn apn_name
  ```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

Syntax

```
pco-options { custom1 [ ue-requested ] | link-mtu bytes } 
{ default | no } pco-options [ custom1 | link-mtu ]
```

`custom1`
Enable sending of customized PCO options in the network to MS messages; send customized PCO options to all UEs regardless of support.

`ue-requested`
Enable sending of customized PCO options in the network to MS messages for “UE-Requested” mode; send PCO to only UEs that request customized PCO options.

`link-mtu bytes`
Configures APN to include link MTU in PCO IE, if it is requested by UE. When UE sends IPv4 Link MTU Size PCO request during Initial attach/ Standalone PDN connection, then the S-GW/SGSN/HSGW sends the same transparently in Create Session Request, Create/Update PDP Context Request, or PBU to P-GW, GGSN, or PMIP-PGW. Create Session Response, Create/ Update PDP Context Response/ PBA will be sent with latest configured MTU size PCO value in APN. If UE is in outbound roaming, then default value (1500) will be provided in the MTU size PCO. bytes must be an integer from 1280 to 2000. Default: 1500

`default`
Disable sending of customized PCO options in the network to MS messages and/or sets the link MTU PCO to 1500 bytes.

`no`
Do not send customized PCO options to any UEs and/or sets the link MTU PCO to 1500 bytes.
Usage

Use this command to enable or disable sending of customized PCO options in the network to MS GTP messages and configure link MTU size PCO value.

Important: Configure custom PCO values in `pco-custom1` command in **ACS Charging Action Configuration Mode**.

Example

The following command enables sending customized PCO options to all UEs regardless of support:

```
pco-options custom1
```

The following command disables sending of customized PCO options in the network to MS messages and sets the link MTU PCO to 1500 bytes:

```
default pco-options
```
**pdn-behavior**

Configures specific PDN behavior.

**Product**
P-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
pdn-behavior { custom1 | ims }

[ default | no ] pdn-behavior
```

- **default | no**
  
  Configures APN as “Normal”.

- **custom1**
  
  Configures APN as a Custom1 (well-known) APN. Re-auth Requested reason code returned for PDN disconnect.

- **ims**
  
  Configures APN as an IMS APN. Re-auth Requested reason code returned for PDN disconnect.

**Usage**

Use this command to configure specific PDN behavior.

**Example**

The following command configures APN as an IMS APN which returns reason code Re-auth Requested for PDN disconnect:

```
pdn-behavior ims
```
pdp-type

Configures the type of PDP contexts that are supported by this APN.

Product

SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration
configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

pdp-type { ipv4 [ ipv6 ] | ipv6 [ ipv4 ] | ppp }

default pdp-type

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configures the default PDP type, IPv4, for the APN.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ipv4 [ ipv6 ]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enables support for IPv4 PDP contexts. Also enables support for IPv6 if the IPv6 optional keyword is entered in this command. Default: Enabled</td>
</tr>
</tbody>
</table>

**Important:** Entering both IPv4 and IPv6 in either order enables support for both.

<table>
<thead>
<tr>
<th>ipv6 [ ipv4 ]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enables support for IPv6 PDP contexts. Also enables support for IPv4 if the IPv6 optional keyword is entered in this command. Default: Disabled</td>
</tr>
</tbody>
</table>

**Important:** Entering both IPv4 and IPv6 in either order enables support for both.

<table>
<thead>
<tr>
<th>ppp</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enables support for PPP PDP contexts. Default: Disabled</td>
</tr>
</tbody>
</table>
Usage

IP PDP context types are those in which the MS is communicating with a PDN such as the Internet or an intranet using IP. PPP PDP contexts are those in which PPP or PPP Network Control Protocol (NCP) frames from the MS are either terminated at, or forwarded by the GGSN.

If a session specifies a PDP type that is not supported by the APN, the system rejects the session with a cause code of 220 (DCH, Unknown PDP address or PDP type).

Caution: For the IPv6 calls to work, the destination context must have at least one IPv6 interface configured.

Example

The following command configures the APN to support PPP context types:

```
pdp-type ppp
```
**permission**

Enables or disables the ability to use authorized services for the current APN.

**Product**

P-GW  
SAEGW  
GGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > APN Configuration

\[ configure > context context_name > apn apn_name \]

Entering the above command sequence results in the following prompt:

\[ [context_name]host_name(config-apn)# \]

**Syntax**

\[ [ no ] permission \{ nemo \} \]

**Usage**

Use this command to enable support for NEMO or PMIPv6 functionality on the APN. These options are disabled by default.

**Example**

The following command enables NEMO functionality:

```
permission nemo
```

The following command disables NEMO functionality:

```
no permission nemo
```
policy

Configures the Mobile IPv6 policy to set the action to be taken when IPv4/IPv6 subscriber packets need to be tunneled and the encapsulated packets exceed the tunnel maximum transmission unit (MTU).

Product

P-GW
SAEGW

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)##

Syntax

policy ipv6 tunnel mtu exceed { fragment [ inner ] | notify-sender }

[ default | no ] policy ipv6 tunnel mtu exceed

default
IPv6: System will do a Path MTU (PMTU) discovery and send “ICMPv6 Packet Too Big” to the original sender if the subscriber packet exceeds MTU after encapsulation.
IPv4: System will do an outer IPv6 fragmentation if the packet exceeds MTU after encapsulation.

no
Disables this functionality.

ipv6 tunnel mtu exceed { fragment [ inner ] | notify-sender }

fragment: System will do an outer IPv6 fragmentation if the subscriber packet exceeds MTU after encapsulation.
inner: IPv6: System will do a PMTU discovery and send “ICMPv6 Packet Too Big” to the original sender if the subscriber packet exceeds MTU after encapsulation.
IPv4: If packet will exceed tunnel MTU after encapsulation, based on DF bit and ignore-df config, the original IPv4 packet will be fragmented and then encapsulated so that it will not exceed MTU, or ICMP Error will be sent if IPv4 packet fragmentation is not allowed.
notify-sender: IPv6: System will do a PMTU discovery and send “ICMPv6 Packet Too Big” to the original sender if subscriber packet exceeds MTU after encapsulation.
IPv4: System will do an outer IPv6 fragmentation if packet exceeds MTU after encapsulation.
Usage

This command sets the Mobile IPv6 policy for the action to be taken when IPv4/IPv6 subscriber packets need to be tunneled and the encapsulated packets exceed tunnel MTU size.

Example

The following command causes the system to do outer IPv6 fragmentation if the subscriber packet exceeds MTU after encapsulation:

```
policy ipv6 tunnel mtu exceed fragment
```
ppp

Configures the Point-to-Point Protocol (PPP) options for the current APN.

- Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```bash
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
ppp { data-compression { protocols protocols | mode modes } | keepalive seconds | min-compression-size min_octets | mtu max_octets }
```

default ppp { data-compression protocols | keepalive | min-compression-size | mtu }

no ppp { data-compression protocols | keepalive seconds | mtu }

---

default

Configures the default PPP parameters for the specified APN.

---

no

Resets the option specified to its default setting.

---

data-compression { mode modes | protocols protocols }

Configures the data compression or the compression protocol to use for the APN. Default: all protocols enabled

**mode modes**: Sets the compression mode to one of the following:
- **normal**: Packets are compressed using the packet history for automatic adjustment and for best compression.
- **stateless**: Each packet is compressed individually.

**protocols protocols**: Sets the compression protocol to one of the following:
- **deflate**: DEFLATE algorithm
- **mppc**: Microsoft Point-to-Point Compression
- **stac**: STAC LZS algorithm
**keepalive seconds**

Specifies the frequency of sending the Link Control Protocol (LCP) keep alive messages. `seconds` must be either 0 or an integer from 5 through 14400. The special value 0 disables the keep alive messages entirely. Default: 30

**min-compression-size min_octets**

Specifies the smallest packet to which compression may be applied as an integer from 0 through 2000. Default: 128

**mtu max_octets**

Specifies the maximum transmission unit (MTU) for packets accessing the APN as an integer from 100 through 2000. Default: 1500

**Important:** The MTU refers to the PPP payload which excludes the two PPP octets. Therefore, an MTU of 1500 corresponds to the 3GPP standard MTU of 1502 for GTP packets with PPP payloads.

**Usage**

Adjust packet sizes and compression to improve bandwidth utilization. Each network may have unique characteristics such that determining the best packet size and compression options may require system monitoring over an extended period of time.

**Example**

The following command configures the ppp data-compression mode for the APN to be `stateless`:

```
ppp data-compression mode stateless
```

The following command configures an MTU of `500` for the APN:

```
ppp mtu 500
```
proxy-mip

Configures support for Proxy Mobile IP functionality for the APN.

Product

GGSN
FA
P-GW
SAEGW

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

[ default | no ] proxy-mip { required | null-username static-homeaddr }

default

Configures the default proxy MIP setting for the specified APN

no

Disables this functionality.

required

Default: Disabled.
Enables proxy-mip for all subscribers using this APN.

null-username static-homeaddr

Configures handling of RRQ to enable the acceptance without an NAI extension in this APN. Default: Disabled

Usage

This command requires that Proxy Mobile IP functionality be performed for all PDP contexts facilitated by the APN.
When Proxy Mobile IP is performed, the system performs subscriber authentication but not Mobile IP FA authentication. It can be configured to handling of RRQ without NAI extension in an APN. More information about Proxy Mobile IP support for the GGSN can be found in the GGSN Administration Guide.

Example
The following command causes the system to support Proxy Mobile IP for all PDP contexts facilitated by the APN:

```
proxy-mip required
```

The following command will enable the accepting of RRQ without NAI extensions in this APN.

```
proxy-mip null-username static-homeaddr
```
qci

Specifies the QoS Class Index (QCI) value to be used to mark bearers classified as IMS media for preferential treatment during session recovery and ICSR switchover.

Product

- GGSN
- P-GW
- S-GW
- SAE-GW

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

qci value_bytes ims-media

no qci value_bytes ims-media

no

Disables this IMS QCI feature.

ims-media

Marks bearers classified as IMS media for preferential treatment during session recovery and ICSR switchover.

value_bytes

Specifies the QCI value an integer from 1 through 254.

Usage

Use this command to specify the QCI value to be used to mark bearers classified as IMS media for preferential treatment during session recovery and ICSR switchover.

The following prerequisites apply to the implementation of this feature:

- A dedicated APN must be reserved for VoLTE traffic.
- A call connected to this APN will not be classified as Active VoLTE unless there is a dedicated bearer matching the VoLTE-configured QCI.
- Preferential treatment would be given to only those calls which are active VoLTE.
A GGSN call connected to this APN will not be classified as Active VoLTE unless there is network initiated bearer matching the VoLTE-configured QCI.

VolTE marking is preserved across a Gn-Gp handoff.

When this feature is enabled via a CLI command, the actions are taken:

- During bearer creation
  - New bearer QCI is matched against APN configuration.
  - If the QCI matches an APN configuration, the bearer is marked for preferential treatment.
  - Flow_entries are modified with this information (if this is first VoLTE bearer).
  - Egtpu_session is updated with the VoLTE tag during a rx_setup request.
  - An indication message informs ECS about the VoLTE tagging.

- During bearer deletion
  - Flow_entry is updated with VoLTE information if this is the last VoLTE bearer.
  - ECS is informed of the deletion via an indication message.

Example

The following command enables preferential treatment for IMS bearers with a QCI of 9:

```
qci 9 ims-media
```
**qos negotiate-limit**

Cconfigures the QoS profile to provide the peak and committed data rate limits that the GGSN assigns to the APN. The GGSN sends the QoS profile to the SGSNs in response to GTP Create/Update PDP Context requests for traffic shaping and policing functionality.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > APN Configuration

```bash
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```bash
qos negotiate-limit direction { downlink | uplink } [ qci qci_val ] [ peak-data-rate bps ] [ committed-data-rate bps ] [ committed-data-rate [ peak-data-rate bps ] ]
```

```bash
no qos negotiate-limit direction { downlink | uplink } [ qci qci_val ]
```

**no**

Disables the QoS Profile for the APN.

**direction { downlink | uplink }**

- **downlink**: Apply the specified limits and actions to the downlink (to-Gn direction).
- **uplink**: Apply the specified limits and actions to the uplink (to-Gi direction).

**qci qci_val**

- **qci_val** is the QoS Class Identifier (QCI) for which the negotiate limit is being set. QCI ranges from 1 to 9. If no qci-val is configured, it will be handled as an undefined-qci (same as undefined-qos class).

**committed-data-rate bps**

- **bps** must be an integer from 1 through 16000000 for the downlink direction or 1 through 8640000 for the uplink direction. The value must also correspond to one of the permitted values identified the tables below. If a non-permitted value is entered for this parameter, the system rounds the value to the nearest lower supported value, except in the case where value is less than 1,000 bps. In this case, the system rounds the value to 1,000 bps. In addition, if the configured committed rate is lower than the value configured for the peak-data-rate, the system uses the configured peak rate for this parameter.
**Important:** System measurements for this value exclude the GTP and outer packet headers. In addition, some traffic classes have both a committed rate and a peak rate, while other traffic classes have just a peak rate. If a committed rate is not applicable (such as, the traffic class is **background** or **interactive**), an error occurs if this option is configured. If the committed-rate is applicable (such as, the traffic class is **conversational** or **streaming**), the values supplied by the SGSN are used if this option is not configured.

**peak-data-rate** *bps*

Default: See the Usage section for this command

Specifies the peak data-rate for the subscriber in bps (bits per second).

*bps* must be an integer from 1 through 16000000 for the downlink direction or 1 through 8640000 for the uplink direction. The value must also correspond to one of the permitted values identified in the tables below. If a non-permitted value is entered for this parameter, the system rounds the value to the nearest lower supported value, except in the case where value is less than 1,000 bps. In this case, the system rounds the value to 1,000 bps.

**Usage**

This command configures the APN quality of service (QoS) profile. This feature enables configuring and enforcing bandwidth limitations on individual PDP contexts of a particular traffic class. Traffic classes are defined in 3GPP TS 23.107 and are negotiated during PDP context activation. Bandwidth enforcement is configured and enforced independently for the downlink and the uplink directions.

The profile information is sent to the SGSN(s) in response to GTP Create/Update PDP Context Request messages. If the QoS profile requested by the SGSN is lower than the configured QoS profile configured, the profile requested by the SGSN is used. If the QoS profile requested by the SGSN is higher, the configured rates are used.

Note that the values for the uplink/downlink committed-data-rate and peak-data-rate parameters are exchanged in the GTP messages between the GGSN and the SGSN. Therefore, the values used may be lower than the configured values. When negotiating the rate with the SGSN(s), the system convert this to a value that is permitted by GTP as shown in the tables below.

**Table 15. Permitted Values for Committed and Peak Data Rates in GTP Messages**

<table>
<thead>
<tr>
<th>Value (bps)</th>
<th>Increment Granularity (bps)</th>
</tr>
</thead>
<tbody>
<tr>
<td>From 1000 to 63,000</td>
<td>1,000 (e.g. 1000, 2000, 3000, ... 63000)</td>
</tr>
<tr>
<td>From 64,000 to 568,000</td>
<td>8,000 (e.g. 64000, 72000, 80000, ... 568000)</td>
</tr>
<tr>
<td>From 57,600 to 8,640,000</td>
<td>64,000 (e.g. 576000, 640000, 704000, ... 86400000)</td>
</tr>
<tr>
<td>From 8,700,000 to 16,000,000</td>
<td>100,000 bps (e.g. 8700000, 8800000, 8900000, ... 16000000)</td>
</tr>
</tbody>
</table>

The command can be entered multiple times to specify different combinations of direction and class. If this command is not configured at all, the GGSN does not perform traffic policing or QoS negotiation with the SGSN.

Additional information on the QoS traffic shaping functionality is located in the *System Administration Guide*.

**Example**

The following command sets an uplink peak data rate of 128000 bps for QoS negotiation limit:
qos negotiate-limit direction uplink peak-data-rate 128000
qos rate-limit

Configures the action on a subscriber traffic flow that violates or exceeds the peak/committed data rate under traffic policing functionality.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

no qos rate-limit direction { downlink | uplink } [ qci qci_val ]

no

Disables the QoS data rate limit configuration for the APN.

Important: When no Qos Profile is configured, the system defaults to using the information provided by the SGSN.

qos rate-limit direction { downlink | uplink }

downlink: Apply the specified limits and actions to the downlink (the Gn direction).
uplink: Apply the specified limits and actions to the uplink (the Gi direction).

qci qci_val

qci_val is the QoS Class Identifier (QCI) for which the negotiate limit is being set. QCI ranges from 1 to 9. If no qci-val is configured, it will be handled as an undefined-qci (same as undefined-qos class).

burst-size { bytes | auto-readjust [ duration dur ] }

Default: See Usage section for this command.
The burst size allowed, in bytes for peak data rate and committed data rate.
bytes must be an integer from 1 through 6000000.

**Important:** It is recommended that the minimum value of this parameter be configured to the greater of the following two values: 1) three times greater than packet MTU for the subscriber connection, OR 2) 3 seconds worth of token accumulation within the “bucket” for the configured peak-data-rate. In addition, if the committed-data-rate parameter is specified, the burst-size is applied to both the committed and peak rates.

`auto-readjust [ duration dur ]` keyword provides the option to calculate the Burst size dynamically while configuring the rate-limit. Whenever this keyword is enabled to calculate burst size, the GGSN QoS negotiated rate is enforced for this calculation. Whenever there is a change in the rates (due to a QoS update), the burst sizes will be updated accordingly. This keyword also provides two different burst sizes. One burst size for peak rate and another for committed rate. By default this keyword is disabled.

`duration dur` describes the duration of burst in seconds. If duration is not specified this keyword will use 1 second as default value.

`dur` must be an integer between 1 through 30.

`exceed-action { drop | lower-ip-precedence | transmit }

The action to take on the packets that exceed the committed-data-rate but do not violate the peak-data-rate. The following actions are supported:

- `drop`: Drop the packet.
- `lower-ip-precedence`: Transmit the packet after lowering the ip-precedence.
- `transmit`: Transmit the packet.

`violate-action { drop | lower-ip-precedence | shape [ transmit-when-buffer-full ] | transmit }

The action to take on the packets that exceed both the committed-data-rate and the peak-data-rate. The following actions are supported:

- `drop`: Drop the packet.
- `lower-ip-precedence`: Transmit the packet after lowering the IP precedence.
- `shape [ transmit-when-buffer-full ]`: This keyword is not supported in this release.

**Important:** Traffic Shaping is not supported on the GGSN, P-GW, or SAEGW.

- `transmit`: Transmit the packet.

+ More than one of the above keywords can be entered within a single command.

**Usage**

This command configures APN quality of service (QoS) through traffic policing. This command enables the actions on subscriber flows exceeding or violating the allowed peak/committed data rate.

**Important:** This command is not intended for bearer level policing.
**Important:** If the exceed/violate action is set to “lower-ip-precedence”, this command may override the configuration of the `ip qos-dscp` command in the GGSN Service Configuration mode for packets from the GGSN to the SGSN. In addition, the GGSN service `ip qos-dscp` command configuration can override the APN setting for packets from the GGSN to the Internet. Therefore, it is recommended that this command not be used in conjunction with this action.

The command can be entered multiple times to specify different combinations of direction and class. If this command is not configured at all, the GGSN does not perform traffic policing or QoS negotiation with the SGSN. (It accepts all of the SGSN-provided values for the PDP context.)

To calculate the burst size dynamically, an optional keyword `auto-readjust [ duration dur ]` is provided with the `burst-size` keyword. By default, the burst size is fixed if defined in bytes with this command. Regardless of the rate being enforced, burst-size is fixed as set by the `burst-size bytes` parameter.

The `auto-readjust [ duration dur ]` keyword enables variable burst size depending on the rate being enforced. The system calculates burst size using a per token bucket algorithm calculation as \( T = B / R \), where \( T \) is the time interval, \( B \) is the burst size and \( R \) is the Rate being enforced. It also provides different burst size for Peak and Committed data rate limiting.

If the `auto-readjust` keyword is not used, a fixed burst size must be defined which will be applicable for peak data rate and committed data rate regardless of the rate being enforced.

If the `auto-readjust` keyword is provided without specifying the duration, a default duration of 1 second will be used for burst size calculation.

**Example**

The following command lowers the IP precedence when the committed-data-rate and the peak-data-rate are violated in uplink direction:

```
qos rate-limit direction uplink violate-action lower-ip-precedence
```
qos-renegotiate

This keyword is obsolete.
qos traffic-police

This command is obsolete. This functionality is now supported through qos negotiate-limit and qos rate-limit commands.

Mode

Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#
radius

This command is obsolete.
radius group

This command is obsolete.
radius returned-framed-ip-address

Sets the policy whether or not to reject a call when the RADIUS server supplies 255.255.255.255 as the framed IP address and the MS does not supply an address.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn) #

Syntax

radius returned-framed-ip-address 255.255.255.255-policy { accept-call-when-ms-ip-not-supplied | reject-call-when-ms-ip-not-supplied }

default radius returned-framed-ip-address 255.255.255.255-policy

default
Set the policy to its default of rejecting calls when the RADIUS server does not supply a framed IP address and the MS does not supply an address.

{ accept-call-when-ms-ip-not-supplied | reject-call-when-ms-ip-not-supplied }

accept-call-when-ms-ip-not-supplied: Accept calls when the RADIUS server does not supply a framed IP address and the MS does not supply and address.
reject-call-when-ms-ip-not-supplied: Reject calls when the RADIUS server does not supply a framed IP address and the MS does not supply an address.

Usage
Use this command to set the behavior in the APN when the RADIUS server supplies 255.255.255.255 as the framed IP address and the MS does not supply an address.

Example
Use the following command to set the APN to reject calls when the RADIUS server does not supply a framed IP address and the MS does not supply an address:

radius returned-framed-ip-address 255.255.255.255-policy reject-call-when-ms-ip-not-supplied
radius returned-username

Configures the username that is returned in accounting messages. If the username is not available in the Protocol Configuration Options (PCO), the RADIUS returned username is preferred to the constructed username (imsi@apn, msisdn@apn, or outbound username).

Product
- GGSN
- P-GW
- SAEGW

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration > Context Configuration > APN Configuration
- configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

radius returned-username { override-constructed-username | prefer-constructed-username }

default radius returned-username

default

The default value for the RADIUS returned-username is prefer-constructed-username. The constructed username (imsi@apn, msisdn@apn) will be used.

**Important:** If the username is available in the PCO, that username will be used regardless of the setting for this command (radius returned-username).

override-constructed-username

If the RADIUS server returns a username in the Access-Accept message and that username is not available in the Protocol Configuration Options (PCO), the new username from the RADIUS server will be used.

prefer-constructed-username

If the username is not available in the PCO, a constructed username (imsi@apn, msisdn@apn) will be used regardless of the username from the RADIUS server. This is the default.

Usage

Use this command to configure the username that is returned in accounting messages

Example

Following command sets the default value for the RADIUS returned-username is prefer-constructed-username [constructed username (imsi@apn, msisdn@apn)]:

radius returned-username prefer-constructed-username

default radius returned-username

default

The default value for the RADIUS returned-username is prefer-constructed-username. The constructed username (imsi@apn, msisdn@apn) will be used.

**Important:** If the username is available in the PCO, that username will be used regardless of the setting for this command (radius returned-username).

override-constructed-username

If the RADIUS server returns a username in the Access-Accept message and that username is not available in the Protocol Configuration Options (PCO), the new username from the RADIUS server will be used.

prefer-constructed-username

If the username is not available in the PCO, a constructed username (imsi@apn, msisdn@apn) will be used regardless of the username from the RADIUS server. This is the default.

Usage

Use this command to configure the username that is returned in accounting messages

Example

Following command sets the default value for the RADIUS returned-username is prefer-constructed-username [constructed username (imsi@apn, msisdn@apn)]:

radius returned-username prefer-constructed-username

default radius returned-username

default

The default value for the RADIUS returned-username is prefer-constructed-username. The constructed username (imsi@apn, msisdn@apn) will be used.

**Important:** If the username is available in the PCO, that username will be used regardless of the setting for this command (radius returned-username).

override-constructed-username

If the RADIUS server returns a username in the Access-Accept message and that username is not available in the Protocol Configuration Options (PCO), the new username from the RADIUS server will be used.

prefer-constructed-username

If the username is not available in the PCO, a constructed username (imsi@apn, msisdn@apn) will be used regardless of the username from the RADIUS server. This is the default.
default radius returned-username
**restriction-value**

Configures the level of restriction to ensure controlled co-existence of the Primary PDP Contexts.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)\# 
```

**Syntax**

```
restriction-value value

[ default | no ] restriction-value
```

- **default | no**
  Default: no restriction-value
  Entering either default or no restriction-value sets the internal value to zero (0) so that connection to any APN is allowed.

- **value**
  Specifies a unique number that identifies the type of network supported for primary PDP contexts facilitated by this APN. The following values are supported:
  - 1: Value used for Wireless Application Protocol (WAP) or Multimedia Messaging Service (MMS) type of networks. This corresponds to APN type public-1.
  - 2: Value used for Internet or Packet-Switched Public Data Network (PSPDN) type of networks. This corresponds to APN type public-2.
  - 3: Value used for corporate customers who use MMS. This corresponds to APN type private-1.
  - 4: Value used for corporate who do not use MMS. This corresponds to APN type private-2.

**Usage**

Restricts the ability to have connections to public access and certain private APNs as required by the APN configuration. Also allows co-existence of the Primary PDP Contexts in a controlled manner. It does not restrict the total number of Primary PDP Contexts for the user. It also configures a method for preventing hackers in the public domain from using the UE as a router.

Access is provided based on the following rules:
- If value = 1, then PDP contexts with restriction values of 0, 1, 2, and/or 3 are allowed
• If `value` = 2, then PDP contexts with restriction values of 0, 1 and/or 2 are allowed
• If `value` = 3, then PDP contexts with restriction values of 0 and/or 1 are allowed
• If `value` = 4, then PDP contexts with no restriction values are allowed
• If `default` or `no` syntax is entered, then no PDP contexts have restriction

In the event that a Maximum APN Restriction value is received from the SGSN as part of a PDP Context Create (CPCR) or Update (UPCR) message, the GGSN allows the request based on the following matrix:
• If `maximum` = 0, then allow connection to any APN
• If `maximum` = 1, then allow APN Restriction values of 0, 1, 2, and/or 3
• If `maximum` = 2, then allow APN Restriction values of 0, 1 and/or 2
• If `maximum` = 3, then allow APN Restriction values of 0 and/or 1
• If `maximum` = 4, then always reject
• If `maximum` = anything else, then allow all APN Restriction values (1, 2, 3, and/or 4)

Refer to 3GPP 23.060 version 6.9.0 for more information.

Example

The following command sets the restriction value of the APN to 2:

```
restriction-value 2
```
**secondary ip pool**

This command specifies a secondary IP pool to be used as backup pool for Network Address Translation (NAT).

**Important**: This command is license dependent. For more information please contact your Cisco account representative.

**Product**
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)\$
```

**Syntax**

```
secondary ip pool pool_name

no secondary ip pool
```

**Syntax**

```
no
```

Removes the previous secondary IP pool configuration.

```
pool_name
```

Specifies the secondary IP pool name.

*pool_name* must be an alphanumeric string of 1 through 31 characters.

**Usage**

Use this command to configure a secondary IP pool for NAT subscribers, which is not overwritten by the RADIUS supplied list. The secondary pool configured will be appended to the RADIUS supplied IP pool list / APN provided IP pool list whichever is applicable during call setup.

**Example**

The following command configures a secondary IP pool named *test123*:

```
secondary ip pool test123
```
**selection-mode**

Configures the level of verification that will be used to ensure a mobile station’s subscription to use this APN.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```plaintext
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```plaintext
selection-mode { chosen-by-sgsn | sent-by-ms | subscribed } +
default selection-mode
```

- **default**
  - Sets the default selection mode as “subscribed”.

- **chosen-by-sgsn**
  - Default: Disabled
  - The MS’s subscription will not be verified and the APN will be provided by the SGSN.

- **sent-by-ms**
  - Default: Disabled
  - The MS’s subscription will not be verified and the APN will be provided by the MS.

- **subscribed**
  - Default: Enabled
  - The MS’s subscription will be verified by the SGSN.

- **+**
  - More than one of the above keywords can be entered within a single command.

**Usage**

Use this command to specify the level of verification that will be used to ensure a MS’s subscription to use this APN. This setting must match the corresponding setting on the SGSN. If the two settings are not identical, the GGSN rejects the session with a cause code of 201 (D1H, User authentication failed).
Example

The following command specifies that the MS’s subscription will not be verified and that the APN name will be supplied by the SGSN:

```
selection-mode chosen-by-sgsn
```
timeout

Configures the session timeout values for this APN.

**Product**

- GGSN
- P-GW
- SAEGW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > APN Configuration

```bash
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
timeout { absolute | qos-renegotiate } time

[ default | no ] timeout [ absolute | qos-renegotiate ]
```

- **default**
  
  Set the default value for the followed option.

- **no**
  
  Returns the timeout parameter to its default setting. If neither the absolute or idle keywords are used in conjunction with this keyword, both timeout options will be returned to their default settings.

- **absolute**
  
  Configures the absolute maximum time a session may exist in any state (active or idle).

- **qos-renegotiate**
  
  This keyword is obsolete.

- **time**
  
  Default:
  - absolute = 0 (Disabled)
  - qos-renegotiation = 300

  Measured in seconds, the time can be configured to any integer value between 0 and 4294967295. A time of 0 disables timeouts for this APN.
Usage
Use this command to limit the amount of time that a subscriber session can remain connected or as a QoS renegotiation dampening timer.

Example
The following commands enables an absolute time timeout of 60000 seconds:

```
timeout absolute 60000
```
timeout bearer-inactivity

This command configures the bearer inactivity timer and the threshold value of the traffic through an APN. The bearer inactivity timer can also be configured to exclude default bearer/primary bearer from monitoring bearer inactivity.

Product
- GGSN
- P-GW
- SAEGW
- SGW

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration > Context Configuration > APN Configuration
- configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

In StarOS 15.0 and later releases:

```
timeout bearer-inactivity [gbr | non-gbr] dur_seconds volume-threshold {downlink | total | uplink} bytes
```

```
timeout bearer-inactivity exclude-default-bearer
[default | no] timeout bearer-inactivity [exclude-default-bearer | gbr | non-gbr]
```

In StarOS 14.x and earlier releases:

```
timeout bearer-inactivity dur_seconds volume-threshold total bytes
```

```
[default | no] timeout bearer-inactivity
```

default
Sets the bearer inactivity timer to disabled mode.

no
Removes the configured bearer inactivity timer values and traffic threshold limit.

```
timeout
```

Specifies that a bearer time out value will be configured for this APN.

gbr
Specifies that the GGSN/GW will check for low activity on a GBR bearer.
### non-gbr
Specifies that the GGSN/GW will check for low activity on a non-GBR bearer.

**Important:** P-GW only supports non-GBR bearer type sessions.

### dur_seconds
Specifies the timeout duration in seconds to check inactivity on the bearer.
- In StarOS 16.0 and later releases: `dur_seconds` must be an integer value from 300 to 2592000 (5 minutes to 720 hours). The minimum configurable value of bearer inactivity timer was reduced from 900 seconds to 300 seconds.
- In StarOS 15.0 releases: `dur_seconds` must be an integer value from 900 to 2592000 (15 minutes to 720 hours). The minimum configurable value of bearer inactivity timer was reduced from 3600 seconds to 900 seconds.
- In StarOS 14.x and earlier releases: `dur_seconds` must be an integer value from 3600 through 2592000.

### volume-threshold
This keyword sets the volume threshold in bytes to check the low activity on the bearer.

### downlink
Threshold value of the downlink data traffic in a bearer.

### total
Specifies that the total of both uplink and downlink data will be used as a volume threshold.

### uplink
Threshold value of the uplink data traffic in a bearer.

### bytes
`bytes` must be an integer value from 1 through 4294967295.

### exclude-default-bearer
Ignore bearer inactivity handling for default/primary bearer.

### Usage
Use this command to configure the bearer inactivity timer and the threshold value of the traffic through an APN. This enables the deletion of bearers experiencing less data traffic than the configured threshold value. Bearer inactivity timer is started only when time and volume threshold is configured.

**Important:** Only one threshold is allowed to be configured per APN which is to monitor total, uplink, or downlink traffic.

The bearer inactivity timer can also be configured to exclude default bearer/primary bearer from monitoring bearer inactivity.
Example

The following command enables the inactivity time on the bearer with a timeout duration of 7200 seconds and the total traffic volume of 25600 bytes in uplink and downlink directions as thresholds:

```
timeout bearer-inactivity 7200 volume-threshold total 25600
```
timeout emergency-inactivity

Configures the emergency session inactivity-timeout for this APN. The APN must be configured as an emergency APN for Voice over LTE (VoLTE) E911 support.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

timeout emergency-inactivity seconds

[ default | no ] timeout emergency-inactivity

default | no

Indicates the timeout specified is to be returned to its default behavior. If no specific timeout is specified, then all are set to their default behavior.

seconds

Default: 0 (disabled)
Specifies the timeout duration, in seconds, to check inactivity on the emergency session.
seconds must be an integer value from 1 through 3600.

Usage

Use this command to set the emergency session inactivity-timeout for this APN.
At reception of an IP CAN Session Modification Request triggered by the Policy and Charging Rules Function (PCRF) for an IP-CAN (IP Connectivity Access Network) session serving an IMS emergency session that removes all PCC rules with a QCI other than the default bearer QCI and the QCI used for IMS signalling, the Policy and Charging Enforcement Function (PCEF) shall start a configurable inactivity timer (to enable PSAP Callback session). When the configured period of time expires, the PCEF shall initiate an IP-CAN Session Termination Request for the IP-CAN session serving the IMS Emergency session.
If a PCRF-Initiated IP-CAN Session Modification Request provides new PCC rule(s) with a QCI other than the default bearer QCI and the QCI used for IMS signalling, the PCEF shall cancel the inactivity timer.
Refer to the emergency-apn command in this chapter for additional information.

Example

The following command sets the emergency inactivity timeout duration to 450 seconds.

    timeout emergency-inactivity 450
timeout idle

Configures the idle timeout duration for the long duration timer associated with a subscriber session.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
timeout idle idle_dur
```

```
[ default | no ] timeout idle
```

- **default | no**
  Indicates the timeout specified is to be returned to its default behavior. If no specific timeout is specified, then all are set to their default behavior.

- **idle_dur**
  Default: 0
  Designates the maximum duration of the session (in seconds). After expiry the system considers the session as dormant or idle and terminates the session.

  *idle_dur* must be an integer value in the range from 0 through 4294967295.

  The special value 0 disables the timeout specified.

**Usage**

Use this command to set the idle time duration for subscriber session to determine the dormant session. Refer to the `long-duration-action detection` and `long-duration-action disconnection` command in this chapter for additional information.

**Example**

Following command sets the idle timeout duration to 450 seconds.

```
timeout idle 450
```
timeout idle micro-checkpoint-periodicity

Enables configuration of periodic idle seconds micro checkpoint timer on a per-APN basis.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
timeout idle idle_dur [ micro-checkpoint-periodicity time_in_seconds ]
[ default | no ] timeout idle
```

- **default | no**
  Indicates the timeout specified is to be returned to its default behavior. If no specific timeout is specified, then all are set to their default behavior.

- **idle_dur**
  Designates the maximum duration of the session (in seconds). After expiry, the system considers the session as dormant or idle and terminates the session.
  - **default**
    must be an integer value in the range from 0 through 4294967295.
    Default: 0
  - **no**
    The special value 0 disables the timeout specified.

- **micro-checkpoint-periodicity time_in_seconds**
  Configures periodic idle seconds micro checkpoint timer on a per-APN basis.
  Idle seconds micro checkpoints are sent at the configured regular intervals to the standby chassis; otherwise, they are sent at intervals of 10 seconds, which is the default value.
  - **default**
    must be an integer value in the range from 0 through 4294967295.
    Default: 10

**Important:** Micro-checkpoint-periodicity value should be less than idle timeout value.

**Usage**

Use this command to set the idle time duration and micro-checkpoint-periodicity timer for subscriber session to determine the dormant session.

**Example**
Following command sets the idle timeout duration to 10 seconds and micro-checkpoint-periodicity to 15 seconds.

```
timeout idle 10 micro-checkpoint-periodicity 15
```
timeout long-duration

Configures the long duration timeout and inactivity duration for subscriber sessions.

Product

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

timeout long-duration ldt_timeout [ inactivity-time inact_timeout ]

no timeout long-duration

no
Indicates the timeout specified is to be returned to its default behavior. If no specific timeout is specified then all timeouts are set to their default behavior.

ldt_timeout
Default: 0
Designates the maximum duration of the session (in seconds) before the system automatically reports/terminates the session.
Specifies the maximum amount of time (in seconds) before the specified timeout action is initiated.
ldt_timeout must be an integer value in the range from 0 through 4294967295.
The special value 0 disables the timeout specified.

inactivity-time inact_timeout
Specifies the maximum amount of time (in seconds) before the specified session is marked as dormant.
inact_timeout must be an integer value in the range from 0 through 4294967295.
The special value 0 disables the inactivity time specified.

Usage
Use this command to set the long duration timeout period and inactivity timer for subscriber sessions. Reduce the idle timeout to free session resources faster for use by new requests.
Refer to the long-duration-action detection and long-duration-action disconnection commands in this chapter for additional information.

Example
The following command sets the long duration timeout duration to 300 seconds and the inactivity timer for subscriber session to 45 seconds.
timeout long-duration 300 inactivity-time 45
tpo policy

The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
**tunnel address-policy**

This command specifies the address allocation/validation policy for all tunneled calls (IP-IP, IP-GRE) except L2TP calls. This means that GGSN IP address validation could be disabled for specified incoming calls.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > APN Configuration

```
configure > context context_name > apn apn_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn) #
```

**Syntax**

```
tunnel address-policy { alloc-only | alloc-validate | no-alloc-validate }
```

**default tunnel address-policy**

---

**default**

Resets the tunnel address-policy to alloc-validate.

---

**alloc-only**

IP addresses are allocated locally and no validation is done.

---

**alloc-validate**

Default. The VPN Manager allocates and validates all incoming IP addresses from a static pool of IP addresses.

---

**no-alloc-validate**

No IP address assignment or validation is done for calls arriving via L3 tunnels. Incoming static IP addresses are passed. This allows for the greatest flexibility.

**Usage**

This command supports scalable solutions for Corporate APN deployment as many corporations handle their own IP address assignments. In some cases this is done to relieve the customer or the mobile operators from the necessity of reconfiguring the range of IP addresses for the IP pools at the GGSN. For calls coming through L2TP tunnels, the command `l3-to-l2-tunnel address policy` as defined in the APN Configuration mode, will be in effect.

**Example**
Use the following command to reset the IP address validation policy to validate against a static pool of address:

```
default tunnel address-policy
```

Use the following command to disable all IP address validation for calls coming through tunnels:

```
tunnel address-policy no-alloc-validate
```
**tunnel gre**

Configures Generic Routing Encapsulation (GRE) tunnel parameters between the GGSN and an external gateway for the APN.

**Product**
- GGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > APN Configuration
- `configure > context context_name > apn apn_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
tunnel gre peer-address peer_address local-address local_addr [ preference num ]
```  

```
no tunnel gre peer-address peer_address
```  

**no**

Disables GRE tunneling for the APN.

**peer-address peer_address**

Specifies the IP address of the external gateway terminating the GRE tunnel. `peer_address` must be expressed in dotted decimal notation.

**local-address local_addr**

Specifies the IP address of the interface in the destination context of the GGSN originating the GRE tunnel. `local_addr` must be expressed in IPv4 dotted-decimal notation.

**preference num**

Default: 1

This option can be used to assign a preference to the tunnel. `preference` can be configured to any integer value from 1 to 128.

**Important:** Only one GRE tunnel per APN is supported. Therefore, the preference should always be set to “1”.

**Usage**

Subscriber IP payloads are encapsulated with IP/GRE headers and tunneled by the GGSN to an external gateway.
Example

The following command configures the system to encapsulate subscriber traffic using GRE and tunnel it from a local address of 192.168.1.100 to a gateway with an IP address of 192.168.1.225:

```
tunnel gre peer-address 192.168.1.225 local-address 192.168.1.100 preference 1
```
tunnel ipip

Configures IP-in-IP tunnelling parameters between the GGSN and an external gateway for the APN.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration
configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

```plaintext
tunnel ipip peer-address peer_address local-address local_addr [ preference num ]
no tunnel ipip
```

no
Disables IP-in-IP tunneling for the APN.

**peer-address peer_address**

Specifies the IP address of the external gateway terminating the IP-in-IP tunnel.
`peer_address` must be expressed in IPv4 dotted-decimal notation.

**local-address local_addr**

Specifies the IP address of the interface in the destination context of the GGSN originating the IP-in-IP tunnel.
`local_addr` must be expressed in IPv4 dotted-decimal notation.

**preference num**
Default: 1
If multiple tunnels will be configured, this option can be used to assign a preference to the tunnel.
`preference` can be configured to any integer value from 1 to 128.

Usage
Subscriber IP payloads are encapsulated with IP-in-IP headers and tunneled by the GGSN to an external gateway.

Example
The following command configures the system to encapsulate subscriber traffic using IP-in-IP and tunnel it from a local address of `192.168.1.100` to a gateway with an IP address of `192.168.1.225`:
tunnel i pip peer-address 192.168.1.225 local-address 192.168.1.100 preference 1
**tunnel ipsec**

This command configures sessions for the current APN to use an Internet Protocol Security (IPSec) tunnel based on the IP pool corresponding to the subscribers assigned IP address.

**Product**
- GGSN

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > APN Configuration
  ```
  configure > context context_name > apn apn_name
  ```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-apn)#
```

**Syntax**

```
[ no ] tunnel ipsec use-policy-matching-ip-pool
```

- **no**
  - Disables the use of the IPSec policy that matches the IP pool that the assigned IP address relates to.

**Usage**

Use this command to set the APN to use an IPSec policy that is assigned to the IP pool that the subscribers assigned IP address relates to.

**Example**

The following command enables the use of the policy that matches the IP pool address:

```
tunnel ipsec use-policy-matching-ip-pool
```
tunnel l2tp

Configures Layer 2 Tunnelling Protocol (L2TP) parameters between the GGSN and an external gateway for the APN.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration
configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)\$

Syntax

```plaintext
tunnel l2tp [ peer-address ins-address [ [ encrypted ] secret l2tp_secret ] [ preference num ] [ tunnel-context name ] [ local-address ip-address ] [ crypto-map map_name { [ encrypted ] isakmp-secret crypto_secret } ] [ local-hostname hostname ]

no tunnel [ peer-address ins-address]
```

no

Disables L2TP, or secure L2TP tunneling for the APN if a specific peer-address is not specified, or, if a peer-address is specified, this keyword removes the peer-address configuration from the APN.

**peer-address ins-address**

Specifies the IP address of the LNS node that the LAC service connects to.

*Ins-address must be expressed in IPv4 dotted-decimal notation.*

**Important:** A maximum of four LNS peers can be configured per APN.

**encrypted**

This keyword is intended only for use by the system while saving configuration scripts. The system displays the encrypted keyword in the configuration file as a flag that the variable following the secret keyword is the encrypted version of the plain text secret. Only the encrypted secret is saved as part of the configuration file.

**secret l2tp_secret**

Specifies the shared secret (password) between the L2TP Access Concentrator (LAC) service (configured on the system) and the LNS node.

*l2tp_secret* must be an alphanumeric string of 1 through 127 characters and is case sensitive.
**preference num**

Default: 1
Specifies the preference of the tunnel if the LAC service communicates with multiple LNS nodes.
`preference` can be configured to any integer value from 1 to 128.

**tunnel-context name**

Specifies the name of the destination context on the system in which the LAC service(s) is configured.
`name` must be an alphanumeric string of 1 through 79 characters and is case sensitive.

**Important:** If this option is not configured, the system will attempt to determine the name of the destination context from the `ip context-name` parameter configured for the APN.

**local-address ip-address**

Specifies the IP address of an interface that is bound to a LAC service. This is a mechanism to dictate which LAC service to use to facilitate the subscriber’s L2TP session.
`address` is the IP address of the interface in IPv4 dotted-decimal notation.

**Important:** If the address configured does not exist or is not bound to a LAC service, the system will automatically choose a LAC service to use.

**local-hostname hostname**

This keyword configures LAC-Hostname to be used for the communication with the LNS peer for this APN. When Tunnel parameters are not received from the RADIUS server, Tunnel parameters configured in APN are considered for the LNS peer selection. When APN Configuration is selected, local-hostname configured with the “tunnel l2tp” command in the APN for the LNS peer will be used as a LAC Hostname.

**Important:** For this configuration to take effect allow `aaa-assigned-hostname` command, which is used to configure LAC-Hostname based on the “Tunnel-Client-Auth-ID” attribute received from the RADIUS server, needs to be configured in the LAC Service Configuration mode.

`hostname` is name of the local host for the LNS peer and must be an alphanumeric string of 1 through 127 characters.
When Tunnel parameters are not received from the RADIUS Server, Tunnel parameters configured in APN will be considered for the LNS peer selection. When APN Configuration is selected, the local hostname `hostname` configured with this command in the APN for the LNS peer will be used as a LAC Hostname.

**crypto-map map_name { [ encrypted ] secret crypto_secret }**

Configures the IPSec crypto-map policy that is to be associated with this L2TP tunnel configuration for secure L2TP.
`map_name` is the name of a crypto-map policy configured on the system expressed as an alphanumeric string of 1 through 127 characters and is case sensitive.
`encrypted` is intended only for use by the system while saving configuration scripts. The system displays the encrypted keyword in the configuration file as a flag that the variable following the secret keyword is the encrypted version of the plain text secret. Only the encrypted secret is saved as part of the configuration file.
`secret` specifies the secret associated with the crypto-map policy. `crypto_secret` can be from 0 to 255 bytes.
Usage

This command can be used to configure the GGSN to tunnel subscriber traffic to one or more peer LNSs using L2TP or L2TP with IPSec.

When using L2TP, the system functions as a L2TP access Concentrator (LAC) and tunnels traffic to a peer L2TP Network Server (LNS). LAC functionality is supported through the configuration of LAC Services defined in destination contexts configured on the system.

When using crypt-map policies, the system functions in the same fashion as with L2TP, with the exception that the encapsulated L2TP traffic is further encrypted using IPSec. IPSec functionality is supported through the definition of crypto maps configured in the same destination context as the LAC services.

A maximum of four LNS peers can be configured per APN. If no peer is specified, the system will use the LAC Service(s) configured in the same destination context as the APN.

Example

The following command configures L2TP support for the APN. It configures the APN to tunnel traffic to an LNS with an IP address of 192.168.1.50 through a LAC service bound to an interface with an IP address 192.168.1.201 configured in a destination context on the system called pdn1. The shared secret between the system and the LNS is 5496secRet. This will be the only LNS configured so the default preference of 1 will not be changed.

```
tunnel l2tp peer-address 192.168.1.50 secret 5496secRet tunnel-context pdn1 local-address 192.168.1.201
```
virtual-apn gdcr

Defines which APN (Gn or virtual) is used in charging records.

- SAEGW

Privilege
- Security Administrator
- Administrator

Mode
Exec > Global Configuration > Context Configuration > APN Configuration

configure > context context_name > apn apn_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-apn)#

Syntax

virtual-apn gdcr apn-name-to-be-included { Gn | virtual }

default virtual-apn gdcr apn-name-to-be-included

default

Returns the CDR related parameters to the default values.

gcdr apn-name-to-be-included { gn | virtual }

Defines which APN is to be sent in charging records (CDR):
- Gn: Use the Gn APN name received in the Create PDP Context Request message from SGSN or the S5 APN name received in the PDN Connectivity Request from MME.
- virtual: Use the virtual APN selected by the GGSN/P-GW. This is the default.

Usage

Defines which APN is to be sent in charging records (CDR), either the APN received in the Create PDP Context Request from the SGSN, or the APN received in the PDN Connectivity Request from the MME.

Example

The following command configures the gateway to use the APN supplied by the SGSN or MME.

virtual-apn gdcr apn-name-to-be-included gn
virtual-apn preference

Defines one or more criteria used to redirect a call received on a particular APN to another APN.

[context_name]host_name(config-apn)#

Syntax

virtual-apn preference priority apn apn_name [ access-gw-address { ip_address | ip_address/mask } | bearer-access-service service_name | cc-profile cc_profile_index [ rat-type { eutran | gan | geran | hspa | utran | wlan } ] | domain domain_name | mcc mcc_number mnc mnc_number [ cc-profile cc_profile_index ] | [ msin-range from msin_range_from to msin_range_to ] | [ rat-type { eutran | gan | geran | hspa | utran | wlan } ] | msisdn-range from msisdn_start_range to msisdn_to_range [ rat-type { eutran | gan | geran | hspa | utran | wlan } ] | roaming-mode { home | roaming | visiting } ]

no virtual-apn preference priority

Removes a previously configured “virtual” APN.

preference priority

Specifies the order in which the referenced APNs are compared by the system.
priority specifies the order and can be configured to any integer value from 1 (highest priority) to 1000 (lowest priority).

apn apn_name

Specifies the name of an alternative APN configured on the system that is to be used for PDP contexts or PDN connections with matching properties.
apn_name is the name of the alternative APN expressed as an alphanumeric string of 1 through 62 alphanumeric characters and is case insensitive. It may also contain dots (.) and/or dashes (-).
**access-gw-address**  {  *ip_address*  |  *ip_address/mask*  }

Specifies the Access Gateway (SGSN/SGW/Other) IP address.

*ip_address* must be an IPv4 address in dotted-decimal or an IPv6 address in colon-separated-hexadecimal notation.

*ip_address/mask* must be an IPv4 address in dotted-decimal or an IPv6 address in colon-separated-hexadecimal notation with network-host mask separation.

**bearer-access-service**  *service_name*

Specifies the Bearer Access Service (GGSN/P-GW/Other) name. This service name is unique across the context.

*service_name* must be an alphanumeric string of 1 through 63 characters.

For eWAG and IPSG, this option is not supported in this release.

**cc-profile**  *cc_profile_index*

Specifies the charging characteristics (CC)-profile index.

*cc_profile_index* must be an integer from 1 to 15.

For eWAG and IPSG, this option is not supported in this release.

**domain**  *domain_name*

Specifies the domain name (realm). This is compared with the domain name portion of subscriber’s username (user@domain).

*domain_name* must be an alphanumeric string of 1 through 79 characters, is case sensitive and can contain all special characters.

For eWAG and IPSG, this option is not supported in this release.

**mcc**  *mcc_number*  *mnc*  *mnc_number*

*mcc* : Specifies the mobile country code (MCC) portion of the PLMN’s identifier.

*mcc_number* is the PLMN MCC identifier and can be configured to any 3-digit integer value between 100 and 999.

*mnc* : Specifies the mobile network code (MNC) portion of the PLMN’s identifier.

*mnc_number* is the PLMN MNC identifier and can be configured to any 2- or 3-digit integer value between 00 and 999.

For eWAG and IPSG, this option is not supported in this release.

**msin-range**  *msin_range_from*  to  *msin_range_to*

This option is supported only for the GGSN.

Specifies the IMSI MSIN range.

*msin_range_from* is the start prefix of the IMSI MSIN range and can be configured between 0 and 9999999999.

*msin_range_to* is the end prefix of the IMSI MSIN range and can be configured as a string of size 1 to 10 digits between 0 and 9999999999.

*msin-range* should follow the following rules:

- Start prefix (such as *msin_range_from*) and end prefix (such as *msin_range_from*) must be of the same length.
- Total length of *mcc* + *mnc* + *msin-range* <= 15 digits.
- For a given combination of *mcc* + *mnc* + *msin-range* (start-end prefix), overlapping range is not allowed.
**msisdn-range from msisdn_start_range to msisdn_to_range**

Specifies the MSISDN range.

*msisdn_start_range* is the starting MSISDN number which is a string of size 2 to 15 and its value ranges between 00 and 99999999999999999.

*msisdn_to_range* is the ending MSISDN number which is also a string of size 2 to 15 and its value ranges between 00 and 99999999999999999.

For eWAG, this keyword is not supported in this release.

**rat-type { eutran | gan | geran | hspa | utran | wlan }**

The type of the Radio Access Technology (RAT).

The available options include:

- eutran
- gan
- geran
- hspa
- utran
- wlan

For eWAG, the *rat-type* keyword is not supported in this release.

**roaming-mode { home | roaming | visiting }**

Supports separate PDP context or PDN connection processing for roaming, visiting, and home subscribers.

For eWAG and IPSG, this option is not supported in this release.

---

**Usage**

This command simplifies the configuration process for mobile operators allowing them to provide subscribers with access to a large number of packet data networks, characterized by APN templates, while only having to configure a small number of APNs on the HLR.

Each “virtual” APN is a reference, or a link, to an alternate APN configured on the system. Each reference is configured with a rule that subscriber PDP contexts or PDN connections are compared against and a priority that dictates the comparison order.

**GGSN**

The references works as follows:

1. A Create PDP Context Request message is received by the GGSN. The message specifies an APN configured in the HLR.
2. The GGSN determines whether its own matching APN configuration contains “virtual” APN references.
3. The system determines the priority of the references and compares the associated information pertaining to the PDP context against the configured rules.
4. If the rule matches, the parameters in the APN specified by the reference are applied to the PDP context. If not, the rules in the reference with the next highest priority are compared against the PDP context. This occurs until a match is found. If none of the references match, then the parameters within the current APN are applied to the PDP context.

The GGSN supports a maximum of 1023 Virtual APN mapping configurations in a system. A single Gn APN can be configured with up to 1000 mapping rules. Multiple Gn APNs are supported - each requiring Virtual APN mapping configurations. The limit imposed is that the total virtual APN mappings across all Gn APNs should not exceed 1023.
The functionality provided by this command can also be used to restrict access to particular APNs. To restrict access based on a particular criteria (domain name, mcc/mnc, etc.), the "virtual" APN reference should refer to an APN that is not configured on the system and contains the desired rule. All calls matching the configured rule would then be denied with a reason code of 219 (DBH), Missing or Unknown APN.

**eWAG**

For eWAG, in this release only the **access-gw-address** Virtual APN configuration option is supported. For information on how virtual APN configuration can be used in eWAG deployments, refer to the *Enhanced Wireless Access Gateway Administration Guide*.

**IPSG**

For IPSG, in this release only the following Virtual APN configuration options are supported:

- **access-gw-address** (RADIUS client in the case of IPSG)
- **msisdn-range from msisdn_start_range to msisdn_to_range**
- **rat-type**

All these attributes are sent in access-request in Auth-Proxy mode or Acct-Start in other modes to trigger Virtual APN selection.

The functionality provided by this command can also be used to restrict access to particular APNs. To restrict access based on a particular criteria (domain name, mcc/mnc, etc.), the “virtual” APN reference should refer to an APN that is not configured on the system and contains the desired rule. All calls matching the configured rule would then be denied with a reason code of 219 (DBH), Missing or Unknown APN.

**P-GW/SAEGW**

The Virtual APN feature allows a carrier to use a single APN to configure differentiated services. The APN that is supplied by the MME is evaluated by the P-GW in conjunction with multiple configurable parameters. Then, the P-GW selects an APN configuration based on the supplied APN and those configurable parameters. APN configuration dictates all aspects of a session at the P-GW. Different policies imply different APNs. After basic APN selection, however, internal re-selection can occur based on the following parameters:

- S-GW address: **access-gw-address**
- Service name: **bearer-access-service**
- Call control profile index: **cc-profile**
- Domain name part of username (user@domain): **domain**
- MCC-MNC of IMSI: **mcc mcc_number mnc mnc_number**
- MSISDN range: **msisdn-range from msisdn_start_range to msisdn_to_range**
- Subscriber type: **rat-type**

In StarOS v12.x and earlier, the P-GW supports a maximum of 1024 Virtual APNs in a system. In StarOS v14.0 and later, the P-GW supports a maximum of 2048 Virtual APNs in a system.

The functionality provided by this command can also be used to restrict access to particular APNs. To restrict access based on a particular criteria (domain name, mcc/mnc, etc.), the “virtual” APN reference should refer to an APN that is not configured on the system and contains the desired rule. All PDN connections matching the configured rule would then be denied with a reason code of 219 (DBH), Missing or Unknown APN.

**Example**

The following commands configure two “virtual” APNs, priority 1 references the *bigco* APN with a domain rule of *bigco.com*, priority 2 references the *bigtown* APN with a mobile country code rule of 100 and a mobile network code rule of 50.

```plaintext
virtual-apn preference 1 apn bigco domain bigco.com

virtual-apn preference 2 apn bigtown mcc 100 mnc 50 msin-range from 4000000000 to 4999999999
```
virtual-apn preference 3 apn bigco.com access-gateway-address 192.168.62.2

virtual-apn preference 4 apn bigco.co.kr access-gateway-address 192.168.60.2/24
The APN Profile configuration mode defines a set of parameters controlling the SGSN or MME behavior when a specific APN is received or no APN is received in a Request. An APN profile is a key element in the Operator Policy feature and an APN profile is not used or valid unless it is associated with an APN and this association is specified in an operator policy (see the Operator Policy Configuration Mode Commands).

Essentially, an APN profile is a template that consists of a set of APN-specific commands that may be applicable to one or more APNs. When a subscriber requests an APN that has been identified in a selected operator policy, the set of commands in the associated APN profile will be applied. The same APN profile can be associated with multiple APNs and multiple operator policies.

The SGSN and the MME each support a total of 1,000 APN profile configurations per SGSN/MME; up to 50 APN profiles can be associated with a single operator policy. For additional SGSN limit information, refer to Engineering Rules in the SGSN Administration Guide.

```
Mode
Exec > Global Configuration > APN Profile Configuration
configure > apn-profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(apn-profile-profile_name)#
```

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
accounting context

This command allows you to define the name of the accounting context and associate a GTPP group with this APN profile.

Product
SaMOG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > APN Profile Configuration

configure > apn-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(apn-profile-profile_name)#

Syntax

accounting context context_name gttp group group_name

remove accounting context

remove

Removes the accounting configuration from this profile’s configuration.

column

Specifies the accounting context. context_name must be an alphanumeric string of 1 through 79 characters.

gttp group group_name

Identifies the GTPP group, where the GTPP related parameters have been configured in the GTPP Group Configuration mode, to associate with this SaMOG APN profile. group_name must be an alphanumeric string of 1 through 63 characters.

Usage

Use this command to associate a predefined GTPP server group, including all its associated configuration, with a specific SaMOG APN profile. Even if an accounting context is also specified in a call control profile, the priority is given to the accounting context of the APN profile.

Example

The following command identifies an accounting context called account1 and associates a GTPP server group named roaming with defined charging gateway accounting functionality:

    accounting context account1 gttp group roaming
accounting mode

This command allows you to define the mode of accounting to be performed for this SaMOG APN profile.

Product
SaMOG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > APN Profile Configuration

configure > apn-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(apn-profile-profile_name)#

Syntax

accounting mode { gtpp | none }

{ default | remove } accounting mode

---

default
Resets the accounting mode to GTPP.

---

remove
Removes the accounting mode from this profile’s configuration.

---

gtpp
Specifies that GTPP accounting is performed. This is the default method.

---

none
Specifies that no accounting will be performed for the APN profile.

Usage

Use this command to specify the accounting mode for an SaMOG APN profile to generate bearer-based SaMOG CDRs. Even if an accounting mode is also specified in a call control profile, the priority is given to the accounting mode of the APN profile.

Example

The following command specifies that no accounting will be used for the APN profile:

    accounting mode none
address-resolution-mode

Identifies the address resolution mode for this APN profile. This command is specific to the SGSN. From release 16.2 onwards this command is supported for S4-SGSN.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > APN Profile Configuration
    configure > apn-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(apn-profile-profile_name)#

Syntax

address-resolution-mode { fallback-for-dns | local }

default address-resolution-mode

    default
    Resets the configuration to the default value, that is, fallback-for-dns.

    fallback-for-dns
    Instructs the system to try DNS resolution. If the DNS query fails, the SGSN will use locally configured addresses, if they have been configured. The pgw-address configured under apn-profile will be treated as fallback for dns address and will used only after dns failure.
    Default: enabled

    local
    Instructs the system to only use locally configured addresses and not to use DNS query.
    Default: disabled

Usage

Use this command to specify the DNS query or local address resolution for this APN profile.

Example

The following command sets the address resolution mode to use local addresses only if the DNS query fails:

    address-resolution-mode fallback-for-dns
**apn-resolve-dns-query**

Command enables the SGSN to send Straightforward Name Authority Pointer (SNAPTR) type DNS query for APN resolution on a per APN basis.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > APN Profile Configuration

configure > apn-profile profile_name

Entering the above command sequence results in the following prompt:

```
[local]host_name(apn-profile-profile_name)#
```

**Syntax**

```
apn-resolve-dns-query snaptr [ epc-ue | non-epc-ue ]
remove apn-resolve-dns-query snaptr
```

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>remove apn-resolve-dns-query snaptr</code></td>
<td>Removes the DNS SNAPTR function from the configuration.</td>
</tr>
<tr>
<td><code>epd-ue</code></td>
<td>Configures the S-NAPTR queries to be applicable for EPC-capable UE.</td>
</tr>
<tr>
<td><code>non-epc-ue</code></td>
<td>Configures the S-NAPTR queries to be applicable for non-EPC-capable UE.</td>
</tr>
</tbody>
</table>

**Usage**
SNAPTR filters based on the EPC-capability of the user equipment (UE). Use this command to enable SNAPTR type DNS query for APN resolution for 3G subscribers with EPC subscription. Configuration in this mode promotes control of this feature per APN. If neither of the keywords is included with the configuration, then S-NAPTR query is applicable to all UE, both EPC-capable UE and non-EPC capable UE. By default, this functionality is not enabled.

**Example**
Enable the SGSN to select a PGW during APN resolution:

```
apn-resolve-dns-query snaptr
```
apn-type

Identifies the type of APN as an IMS APN.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > APN Profile Configuration
configure > apn-profile profile_name

Entering the above command sequence results in the following prompt:
[local] host_name(apn-profile-profile_name)#

Syntax

apn-type ims

remove apn-type ims

remove

Erases this identification configuration from the APN profile and resets to the default.

Usage
This command identifies the APN as an IMS APN. This enables the SGSN to delay sending Modify Bearer Request to the S-GW until after receiving the Forward Relocation Complete Ack from the peer during SRNS procedure. By default this identification is disabled.

Example
Identify the APN for this profile as an IMS type APN:

    apn-type ims
**associate accounting-policy**

Associates the APN with specific pre-configured policies configured in the same context for SaMOG charging.

**Product**
SaMOG

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > APN Profile Configuration

`configure > apn-profile profile_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(apn-profile-profile_name)#
```

**Syntax**

```
associate accounting-policy policy_name
remove associate accounting-policy
```

**Syntax**

- `remove`
  - Removes the association of the policy from the APN profile.

- `policy_name`
  - Specified the policy name to associate to the APN profile. `policy_name` must be an existing accounting policy, and must be an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to associate the SaMOG APN profile with an accounting policy configured in this context to provide triggers to generate CDRs. The accounting policy configured under the APN profile takes priority over the accounting policy configured under the call control profile.

**Example**

The following command associates this SaMOG APN with an accounting policy called `acct1`:

```
associate accounting-policy acct1
```
associate qci-qos-mapping

Provides operators with a configuration to associate a Qos Class Identifier (QCI) Qualityof Service (QoS) mapping table with a specified APN profile configuration.

Product
SGW
SAE-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > APN Profile Configuration
configure > apn-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(apn-profile-profile_name)#

Syntax

[remove] associate qci-qos-mapping mapping_table_name

remove
Removes the specified QCI to QoS mapping table association.

associate qci-qos-mapping mapping_table_name
Instructs the application to associate the specified QCI QoS mapping to this APN profile.

Usage
Associates a QCI QoS mapping table with an APN profile.

Example
This example associates a QCI QoS mapping table with the APN Profile ‘QCIQOSMap’.

associate qci-qos-mapping QCIQOSMap
associate quality-of-service-profile

Associates the specified Quality of Service profile with the APN profile.

Product
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration > APN Profile Configuration
configure > apn-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(apn-profile-profile_name)#

Syntax

associate quality-of-service-profile <qos_profile_name> access-type [ gprs | umts ]

remove associate quality-of-service-profile access-type [ gprs | umts ]

remove
Removes the association of the specified Quality of Service profile with the APN profile.

access-type
The access-types listed below are configured through this command:

- gprs
- umts

qos_profile_name
The name of the Quality of Service profile to be associated with the APN profile.

Usage
This command is used to associate the specified Quality of Service profile with the APN profile. The access-type must be configured as either gprs or umts.

Example
Use this command to associate a Quality of Service Profile named test in an UMTS network with the APN profile.

associate quality-of-service-profile test access-type umts
**associate sgw-paging-profile**

This command allows the association of an SGW Paging Profile with an APN profile on the S-GW.

**Product**
S-GW

**Privilege**
Administrator, Security Administrator

**Mode**
Exec > Global Configuration > APN Profile Configuration

```text
configure > apn-profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(apn-profile-profile_name) #
```

**Syntax**

```
[ remove ] associate sgw-paging-profile three-tuple
```

- **remove**
  Removes the S-GW Paging Profile from the APN Profile.

- **associate sgw-paging-profile three-tuple**
  Associates an SGW Paging Profile with an APN profile on the S-GW. S-GW Paging Profiles are configured in Global Configuration Mode with the `sgw-paging-profile three-tuple` command.

**Usage**
Use this command to associate an S-GW paging profile with an APN profile on the S-GW.

**Example**
This example associates an S-GW paging profile with an APN profile on the S-GW.

```text
associate sgw-paging-profile three-tuple
```
**CC**

Configures the charging characteristics (CC) for this APN profile.

**Product**
- SGSN
- S-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**

Exec > Global Configuration > APN Profile Configuration

```bash
configure > apn-profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(apn-profile-profile_name)#
```

**Syntax**

```bash
cc { local-value-for-scdrs behavior bit_value profile index_bit | prefer { hlr-value-for-scdrs | local-value-for-scdrs } }
remove cc { local-value-for-scdrs | prefer }
```

---

**remove**

Removes the charging characteristics configuration from this APN profile.

---

**local-value-for-scdrs behavior bit_value profile index_bit**

Sets the value of the behavior bits and profile index for the charging characteristics for S-CDRs locally, when the Home Location Register (HLR) does not provide these values.

If the HLR provides the charging characteristics with behavior bits and profile index, and the operator wants to ignore what the HLR provides, then specify the `prefer local-value-for-scdrs` keyword with this command.

- `bit_value`: must be a hexadecimal value between 0x0 and 0xFFF.
- `index_bit`: must be an integer from 1 through 15.

Some of the index values are predefined according to 3GPP standard:

- **1** for hot billing
- **2** for flat billing
- **4** for prepaid billing
- **8** for normal billing

Defaults: `bit_value = 0x0`; `index_bit = 8`

---

**prefer { hlr-value-for-scdrs | local-value-for-scdrs }**

Specify what charging characteristic settings the system will use for S-CDRs.
• **hlr-value-for-scdrs**: instructs the system to use charging characteristic settings received from the HLR for S-CDRs.

• **local-value-for-scdrs**: instructs the profile preference to only use locally configured/stored charging characteristic settings for S-CDRs.

Default: **hlr-value-for-scdrs**

### Usage

Use this command to specify the charging characteristic for S-CDRs -- either from the HLR or locally from the SGSN.

These charging characteristics parameters for S-CDRs and M-CDRs are also configurable in the Call-Control Profile configuration mode. When CC parameters are specified in both types of profiles, then:

- For generation of M-CDRs, the parameters configured in the Call-Control Profile configuration mode will take precedence.

- For generation of S-CDRs, the parameters configured in the APN Profile configuration mode will take precedence.

### Example

The following command configures the APN profile to instruct the SGSN not to use charging characteristic settings received from the HLR for S-CDR generation:

```
cr prefer hlr-value-for-scdrs
```
**dedicated-bearers**

Configures the MME to either accept or reject dedicated GBR and Non-GBR bearers.

**Product**
MME

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > APN Profile Configuration

```
configure > apn-profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(apn-profile-profile_name)#
```

**Syntax**

```
dedicated-bearers { gbr { accept | reject } | non-gbr { accept | reject } }
[ remove ] dedicated-bearers { gbr | non-gbr }
```

- **remove**
  Removes the configuration, returning the system to the default setting where the MME accepts GBR or Non-GBR dedicated bearers.

- **gbr { accept | reject }**
  Configures the MME to accept or reject dedicated GBR bearers.

- **non-gbr { accept | reject }**
  Configures the MME to accept or reject dedicated Non-GBR bearers.

**Usage**

The MME differentiates GBR and Non-GBR dedicated bearers as follows: GBR Bearers - QCI value ranges from 1 to 4; Non-GBR bearers - QCI value ranges from 5-9.

In the case of a UE-initiated Bearer Resource Allocation Reject, the ESM cause “EPS QOS not accepted” is used and the corresponding bearer allocation reject MME statistic is incremented.

In the case of a Create Bearer Request Reject, the EGTP cause “Service denied” is used and the corresponding EGTP statistic is incremented.

**Note**: Handling of multiple bearers in a Create Bearer request from S-GW for Partial accept/reject of GBR/Non-GBR dedicated bearers is a current limitation.

**Example**

The following commands configure the MME to reject both GBR and Non-GBR dedicated bearers:

```
dedicated-bearers gbr reject

dedicated-bearers non-gbr reject
```
description

Defines a descriptive string relevant to the specific APN profile.

SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > APN Profile Configuration
configure > apn-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(apn-profile-profile_name)#

Syntax

description description

remove description

remove
Removes the configured description from this APN profile.

description
Specifies a description for this APN profile as an alphanumeric string of 1 through 100 characters. The string may include spaces, punctuation, and case-sensitive letters if the string is enclosed in double quotation marks (").

Usage
Define information that identifies this particular APN profile.

Example
Indicate that APN profile apnprof1 is to be used for customers in Saudi Arabia and that the profile was created on April 10th of 2010:

description “apnprof1 defines APNs for customers in Saudi Arabia (4/10/10).”
direct-tunnel

Defines the permission for direct tunnel establishment by GGSNs. This command is specific to the SGSN.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > APN Profile Configuration

```
configure > apn-profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(apn-profile-profile_name)#
```

**Syntax**

```
direct-tunnel not-permitted-by-ggsn
remove direct-tunnel
```

---

**remove**
Removes the direct tunnel establishment configuration from this APN profile.

**not-permitted-by-ggsn**
Specifies that a direct tunnel is not permitted by the GGSN when resolved by this APN. Default: disabled.

---

**Usage**
Use this command to enable/disable the permission for establishment of direct tunnels between an RNC and a GGSN.

**Example**
The following command instructs the SGSN not to permit establishment of a direct tunnel with a GGSN:

```
direct-tunnel not-permitted-by-ggsn
```
**dns-extn**

Takes an offset group of digits from the MSISDN and appends the digits to the DNS query string to create a new APN intended to assist roaming subscribers to use the local GGSN.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > APN Profile Configuration

```
configure > apn-profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(apn-profile-profile_name)#
```

**Syntax**

```
dns-extn { charg-id { binary | decimal | hexadecimal } | lac-rac | msisdn start-offset start_digits end-offset end-digits | rnc-id [ charg-id { binary | decimal | hexadecimal } ] } 
```

```
remove dns-extn { charg-id | lac-rac | msisdn | rnc-id [ charg-id ] }
```

**charg-id { binary | decimal | hexadecimal }**

Instructs the SGSN to take the profile index value of the charging characteristics, from the PDP subscription record (selected during APN selection) and include the profile index value in the APN name prior to sending out DNS queries. The operator can also specify the format (binary, decimal or hexadecimal) for the CC information to be included.

**lac-rac**

Enables the SGSN to append geographical information to the APN string that is being sent in the DNS query. This information is used during the DNS query process to select the geographically closest GGSN.

**msisdn start-offset start_digits end-offset end-digits**

Defines an offset group of digits from the MSISDN and appends the digits to create a new APN DNS query string that is intended to assist roaming subscribers to use the local GGSN.

- **start_digits** is an integer from 1 through 14 that identifies the position of the first digit in the MSISDN to start the offset.
- **end-digits** is an integer from 2 through 15 that identifies the position of the last digit in the MSISDN to be part of the offset.

**rnc-id [ charg-id { binary | decimal | hexadecimal } ]**

Instructs the SGSN to include the ID of the calling RNC in the APN DNS query string. Optionally, the profile index value of the charging characteristics can be inserted into the APN name prior to sending out DNS queries. As well, the operator can specify the format (binary, decimal or hexadecimal) for the CC information to be included.
Usage

With this command, the APN in the DNS query string, used for querying the GGSN address, can be appended with additional information, such as:

- digits from the MSISDN
- LAC/RAC info
- RNC-ID
- profile index from the charging characteristics information (SCHAR)

This additional information allows some customization of the DNS query string to facilitate selecting a specific (usually local or nearest) GGSN.

For example, roaming subscribers using a specific APN may want to be directed to a specific GGSN. This can be achieved by having an operator policy for roaming subscribers associated with an APN profile that includes a configuration specifying certain digits, from the MSISDN or geographical information from the LAC/RAC, be appended to the APN. This is then used as the DNS query string.

In addition, the operator must configure appropriate DNS entries to enforce the selection of the required GGSN. After appending the MSISDN digits to the DNS query string, the string will have the form:

```
ni.<digits>.mnc*.mcc*.gprs
```

After appending the LAC/RAC information to the DNS query string, the string will have the form:
```
<apn_network_id>.racAAAA.lacBBBB.<apn_operator_id>
```
where the AAAA and BBBB are Hex-coded digits (less than 4 significant digits and one or more zero (“0”) digits will be inserted to the left side of the Hex to fill the 4-digit coding).

After appending the charging characteristic (SCHAR) information, the DNS string will take the following form:
```
<apn_network_id>.<profile_index>.<apn_operator_id>
```
The profile index in the following example has an integer value 10:
```
quicknet.com.uk.1010.mnc234.mcc027.gprs
```

If the RNC-ID information is configured to be a part of the APN name, and if inclusion of the profile index of the charging characteristics information is also enabled before the DNS query is sent, the profile index is included after the included RNC-ID and the DNS APN name will appear in the following form:
```
<apn_network_id>.<rnc_id>.<profile_index>.<apn_operator_id>
```

Once the DNS extension is defined, the selected extension is applicable when either the wildcard APN feature or the default APN feature are configured and used.

The information is appended to the DNS query and the actual APN string sent to the GGSN will not be modified in any way.

Example

A sample MSISDN is ‘11223345566778’ and a sample APN NI (network identifier) is ‘wap98.testnetz.ca’. The following command instructs the SGSN to create a new APN with digits pulled from the MSISDN and appended to the APN:
```
msisdn start-offset 3 end-offset 9
```
The resulting APN DNS query string would have appended 7 digits (2233445) to the APN NI so that it would appear something like
```
wap98.testnetz.ca.2233445.mnc009.mcc262.gprs
```
Enable inclusion of geographical information in the APN string used for the DNS query to locate the closest GGSN:
```
lac-rac
```
In the following example, the DNS query for a subscriber using RNC 0321 with the profile index of value 8 would appear as:
```
quicknet.com.uk.0321.1000.mnc234.mcc027.gprs
```
end

Exits the current configuration mode and returns to the Exec mode.

configure > apn-profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(apn-profile-profile_name)#
```

**Syntax**

```
[ remove ] gn-gtp-version v1-only
```

- **remove**
  
  Used with the command, this filter erases the previous GTPv1 configuration and returns the SGSN configuration to the default value of both GTPv1 and GTPv0.

- **v1-only**
  
  This extension must be included to complete the command. This extension disables GTPv0 fallback.

**Usage**

During activation, the SGSN sends GTPv1 PDP Requests a GGSN and if no response is available from the GGSN after the maximum number of retransmissions and timeout, then before trying an alternate GGSN, the SGSN attempts to create GTPv0 PDP Requests and retries are carried out. Only after GTPv0 retransmissions and timeout would the SGSN try activation with the next available GGSN.

The SGSN supported GTPv0 fallback. After exhausting all configured retry attempts for GTPv1, the SGSN would retry the GTP-C Request using GTPv0. This fallback is conditional and is done only when the GTP version of a GGSN is unknown during the first attempt at activating a PDP context with the GGSN.

This command allows the operator to disable the GTPv0 fallback for GTP-C Requests to GGSNs corresponding to a specific APN, thus reducing unnecessary signalling if all known GGSN support GTPv1 only. Hence, if more than one GGSN address is returned by the DNS server during activation, then the SGSN more immediately attempts activation with the next GGSN after exhausting all the GTPv1 retry attempts. If only one GGSN address is returned, then the SGSN rejects the activation after exhausting all the configured GTPv1 retries.

**Example**

The following command disables GTPv0 fallback:

```
 gn-gtp-version v1-only
```
The following command deletes the previous configuration and re-enables the default so the SGSN will attempt activation via both GTPv1 and if needed GTPv0:

```
remove gn-gtp-version v1-only
```
**gateway-address**

Configures the IPv4 or IPv6 address of the GGSN supporting the APN associated with this APN profile. Also, use this command to create a secondary pool of GGSNs. This command is specific to the SGSN.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > APN Profile Configuration

```
configure > apn-profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(apn-profile-profile_name)#
```

**Syntax**

```
gateway-address ip_address { priority priority | weight weight [ secondary-pool ] }  
no gateway-address  ip_address
```

- **no**
  Disables the GGSN address configured in this APN profile.

- **ip_address**
  Specifies the IP address for the GGSN in IPv4 dotted-decimal or IPv6 colon-separated notation.

- **priority priority**
  Specifies the priority, for the configured GGSN address, to be considered during address selection. If the highest priority GGSN fails to respond, the next priority level GGSN is selected. **priority** is an integer from 1 through 100. Note that the lower integer has the higher priority, so that 1 is the highest priority.

- **weight weight [ secondary-pool ]**
  Specifies the weight (preference) assigned to a GGSN to facilitate load balancing. **weight** is an integer from 1 to 100 where 1 is the least preferred and 100 is the most preferred. If a weight is assigned to an address, then load balancing (of primary CPC requests) depends on the weight value. For example:

  GGSN1 172.16.130.1 weight 30 and GGSN2 172.16.130.3 weight 70

  With this configuration, 30% of the activation requests for this APN will go to GGSN1 and 70% of the requests will go to GGSN2. Also note that the sum of the weights does not need to be 100. The calculation of weight percentiles is carried out proportionately, so the following configuration will also yield the same 30% - 70% results:

  GGSN1 172.16.130.1 weight 6 and GGSN2 172.16.130.3 weight 14
**secondary-pool**

This optional keyword allows the operator to enable multiple GGSN pools by assigning the GGSN to a secondary pool of GGSNs. The selection algorithm for GGSNs in a secondary pool is weight-based.

**Usage**

Use this command to define priority or load balancing to be applied during GGSN selection. A maximum of 16 GGSN address can be configured for this APN profile. Also use this command to setup GGSN pools - primary and secondary pools with up to 16 GGSNs in each pool. By default, GGSNs will always be selected from the primary pool. However, working in tandem with the `ggsn-fail-retry-timer` command configuration (SGTP service configuration mode) which enables the local DNS feature, some of the primary GGSNs can be temporarily blacklisted if they become unavailable or overburdened.

**Example**

Set a GGSN address with a secondary priority level:

```
gateway-address 123.123.123.2 priority 2
```

Add a GGSN to the secondary GGSN pool and define selection weighting of 7th:

```
gateway-address 198.168.138.8 weight 7 secondary-pool
```

**gtp**

Enables or disables the GTPC private extension for the Overcharging Protection feature. This command is specific to the SGSN.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > APN Profile Configuration

`configure > apn-profile profile_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(apn-profile-profile_name)#
```

**Syntax**

```
[ remove ] gtp private-extension loss-of-radio-coverage send-to-ggsn [ send-to-peer-sgsn ]
```

<table>
<thead>
<tr>
<th>remove</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disables the inclusion of the GTPC private extension, thereby disabling the Overcharging Protection feature.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>private-extension loss-of-radio-coverage send-to-ggsn</th>
</tr>
</thead>
<tbody>
<tr>
<td>Instructs the SGSN to set a proprietary GTPC private extension (in the LORC Intimation IEs) in the event of loss of radio coverage (LORC). These private extensions are only understood by a GGSN with an Overcharging Protection license. The mandatory <code>loss-of-radio-coverage send-to-ggsn</code> keyword set instructs the SGSN to forward the private extension flag to the GGSN in the event of a loss of radio coverage (LORC).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>send-to-peer-sgsn</th>
</tr>
</thead>
<tbody>
<tr>
<td>This optional keyword instructs the SGSN to also forward the LORC private extension to the peer SGSN.</td>
</tr>
</tbody>
</table>

**Usage**

`gtp private-extension` is one of the two commands required to enable the Overcharging Protection feature. The second command sets the RANAP cause code in the Iu Release to enable the SGSN to detect the LORC state of the MS/UE. This second command is configured in the IuPS service and is explained in the `IuPS Service Configuration Mode` chapter.

When there is a loss of coverage and the Overcharging Protection feature is enabled with the `gtp private-extension` command, the SGSN includes the proprietary private extension in the GTP LORC Intimation IE messages. This LORC IE is also included in UPCQ, DPCQ, and SGSN Context Response GTP messages. Refer to the `SGSN Administration Guide` for additional information regarding the Overcharging Protection feature.

**Example**

Use the following command to have the SGSN send the GGSN the GTPC private extension in the LORC Intimation IE:
gtp private-extension loss-of-radio-coverage send-to-ggsn
**idle-mode-acl**

Configures a group of access control lists (ACLs) that define rules to apply to downlink data destined for UEs in an idle mode.

**Product**

S-GW  
SAEGW  

**Privilege**

Administrator  

**Mode**

Exec > Global Configuration > APN Profile Configuration  

```bash  
configure > apn-profile profile_name  
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(apn-profile-profile_name)#  
```

**Syntax**

```
[ remove ] idle-mode-acl { ipv4 | ipv6 } access-group acl_name  
```

<table>
<thead>
<tr>
<th>remove</th>
<th>Removes the specified ACL name from the access group.</th>
</tr>
</thead>
</table>
| { ipv4 | ipv6 } access-group acl_name | Specifies the ACL type to add to the access group.  
  - *ipv4*: Specifies that an IPv4 ACL is being added to the access group.  
  - *ipv6*: Specifies that an IPv6 ACL is being added to the access group.  

access-group acl_name specifies the name of the ACL being added to the access group as an existing IPv4 or IPv6 ACL name expressed as an alphanumeric string of 1 through 47 characters.

**Usage**

Use this command to create a group of ACLs that contain rules to apply to data sent to UEs that are currently in idle mode.  
IPv4 ACLs are configured through the Context Configuration Mode using the `ip access-list` command.  
IPv6 ACLs are configured through the Context Configuration Mode using the `ipv6 access-list` command.

**Example**

The following command configures the APN profile to use an IPv4 ACL named `acl-3-permit` to apply rules to downlink data sent to UEs that are currently in idle mode:

```
idle-mode-acl ipv4 access-group acl-3-permit  
```
ip

Defines the IP parameters for this APN profile.

Product

SGSN

Privilege

Administrator

Mode

Exec > Global Configuration > APN Profile Configuration

configure > apn-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(apn-profile-profile_name)#

Syntax

no ip qos-dscp { downlink | uplink } { background | conversational | interactive | streaming } +

Important: All parameters not specifically configured will be included in the configuration with default values.

default

Resets the configuration to the default values.

no

Disables the specified IP QoS-DSCP mapping.

qos-dscp

Configures the Differentiated Services Code Point (DCSP) marking to be used for sending packets of a particular 3GPP QoS class.

downlink | uplink

Configures the packets for either downlink (network to subscriber) or uplink (subscriber to network) direction. downlink and uplink configuration must include one or more of the following:

- background - Configures the DSCP marking to be used for packets of sessions subscribed to 3GPP background class. Must be followed by a DSCP marking
• **conversational** - Configures the DSCP marking to be used for packets of sessions subscribed to 3GPP conversational class. Must be followed by a DSCP marking.

• **interactive** - Configures the DSCP marking to be used for packets of sessions subscribed to different traffic priorities in the 3GPP interactive class. Must be followed by a traffic handling priority (THP): 1, 2, or 3.

• **streaming** - Configures the DSCP marking to be used for packets of sessions subscribed to 3GPP streaming class. Must be followed by a DSCP marking.

**DSCP marking options**

Downlink and uplink must include a DSCP forwarding marking; supported options include:

- af11 - Designates use of Assured Forwarding 11 PHB
- af12 - Designates use of Assured Forwarding 12 PHB
- af13 - Designates use of Assured Forwarding 13 PHB
- af21 - Designates use of Assured Forwarding 21 PHB
- af22 - Designates use of Assured Forwarding 22 PHB
- af23 - Designates use of Assured Forwarding 23 PHB
- af31 - Designates use of Assured Forwarding 31 PHB
- af32 - Designates use of Assured Forwarding 32 PHB
- af33 - Designates use of Assured Forwarding 33 PHB
- af41 - Designates use of Assured Forwarding 41 PHB
- af42 - Designates use of Assured Forwarding 42 PHB
- af43 - Designates use of Assured Forwarding 43 PHB
- be - Designates use of Best Effort forwarding PHB
- ef - Designates use of Expedited Forwarding PHB

Forwarding defaults for both uplink and downlink are:

- conversational - ef;
- streaming - af11;
- interactive 1 - ef;
- interactive 2 - af21;
- interactive 3 - af21;
- background - be

**source-violation**

Configures settings related to IP source-violation detection with one of the following criteria:

- **deactivate** - deactivate the PDP context with one of the following conditions:
  - all-pdp - deactivates all PDP context of the MS/UE. Default is to deactivate errant PDP contexts.
  - exclude-from-accounting - excludes packets having an invalid source IP address from the statistics used in the accounting records.
• **linked-pdp** - deactivate all associated pdp contexts (primary and secondary). Default is to deactivate errant pdp context.

• **tolerance-limit** - Configures maximum number of allowed IP source violations before the session is deactivated.

• **discard** - discard errant packets, can include the following option:
  • **exclude-from-accounting** - excludes packets having an invalid source IP address from the statistics used in the accounting records.

• **ignore** - ignore checking of packets for MS/UE IP source violation.

---

**Usage**

This command configures a range of IP functions to be associated with the APN profile; such as:

• SGSN/S-GW action in response to detected IP source violations,

• DSCP marking for downlink and uplink configuration per traffic class,

• QoS class diffserv code.

**Example**

The following command configures the APN profile to instruct the SGSN or S-GW not to check incoming packets for IP source violation information:

```
ip source-violation ignore
```
isr-sequential-paging

Enables or disables the Intelligent Paging for ISR feature.

Product
S-GW
SAEGW

Privilege
Administrator

Mode
Exec > Global Configuration > APN Profile Configuration
configure > apn-profile profile_name
Entering the above command sequence results in the following prompt:

[local]host_name(apn-profile-profile_name)#

Syntax

[ remove ] isr-sequential-paging

remove

Disables Intelligent Paging for ISR.

Usage

This command initiates the Intelligent Paging for ISR feature for the specified APN Profile, where paging occurs first towards the last known RAT, then towards the other RAT.
The Intelligent Paging for ISR feature is license dependant. Contact your Cisco account representative for more information.
**local-offload**

Enables or disables the SaMOG Local Breakout (LBO) Enhanced feature.

**Product**
SaMOG

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > APN Profile Configuration

`configure > apn-profile profile_name`

Entering the above command sequence results in the following prompt:

```plaintext
[local]host_name(apn-profile-profile_name)#
```

**Syntax**

```
llocal-offload
```

```
no llocal-offload
```

Disables Local Breakout for this APN profile.

**Usage**

Use this command to enable or disable the SaMOG LBO Enhanced feature. When enabled, LBO will be allowed for the UE connecting to the specified SSID, through which this APN profile is reached.
location-reporting

Configure location change reporting via ULI IE per APN for an S4-SGSN.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > APN Profile Configuration
configure > apn-profile profile_name

Entering the above command sequence results in the following prompt:
[local]host_name(apn-profile-profile_name)#

Syntax

location-reporting access-type { gprs | umts }
remove location-reporting access-type { gprs | umts }

Syntax
disable

Disables the location change reporting definition in the APN profile configuration.

disable

access-type { gprs | umts }

Allows the operator to select location change reporting for the 2G and / or the 3G subscribers. Both access types can be identified in a single command or the command can be issued twice. Either way, two separate entries are created, one for each access type.

Usage
As with all APN profiles, to enable location change reporting, this APN profile must be associated with a call control profile.
Location change reporting for a Gn-SGSN is enabled with the location reporting command in the Call Control Profile configuration mode. That command can be used to configure the location change reporting function for the S4-SGSN, however that configuration would be over-ridden by an APN profile configuration. As well, using this APN profile location reporting command gives the operator greater control to apply location change reporting per APN.

Example
Enable location change reporting for 2G subscribers:

    location-reporting access-type gprs
**mobility-protocol**

This command allows you to configure the default mobility protocol type to be used for setting up a call when the AAA server forwards an IP address directly.

**Product**
SaMOG

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > APN Profile Configuration
configure > apn-profile *profile_name*

Entering the above command sequence results in the following prompt:

```
[local]host_name(apn-profile-profile_name)#
```

**Syntax**

```
 mobility-protocol { gtpv1 | gtpv2 }
```

```
no mobility-protocol
```

**Usage**

Use this command to configure the default mobility protocol type to be used for setting up a call when the AAA server forwards an IP address directly. If mobility protocol is also configured under the Call Control Profile Configuration Mode, the value configured here will override the configured value in the Call Control profile.

By default, all APN profiles will use the mobility protocol configured under the Call Control Profile Configuration Mode. To configure different mobility protocol values for different APN profiles, use the `mobility-protocol` command in this configuration mode.

**Example**

The following command configures mobility protocol to GTPv2:

```
 mobility-protocol GTPv2
```
This command configures QCI and ARP in the apn-profile for Network Triggered Service Restoration (NTSR).

Product

S-GW

Privilege

Administrator, Security Administrator

Mode

Exec > Global Configuration > APN Profile Configuration

configure > apn-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(apn-profile-profile_name)#

Syntax

ntsr { all | qci number arp-priority-watermark number }

no ntsr all

no ntsr qci number arp-priority-watermark number

no

Removes the specified configuration parameters.

ntsr

Enables the network triggered service restoration configuration.

all

Specifies that the NTSR configuration is enabled for all bearers with any qci or arp for MME restoration.

qci

Specifies the Quality of Class Identifier for this NTSR configuration. Must be an integer from 1 to 255.

arp-priority-watermark

Specifies the ARP’s priority level watermark value. Must be an integer from 1 to 15.

Usage

This command configures qci and arp in the apn-profile for NTSR. The S-GW will decide to retain or release the bearer based on the configured qci/arp, after path failure is detected on ingress side of S-GW. The S-GW can configure a maximum of 2 qci and arp-priority-watermark per apn-profile. The apn-profile can also be configured to retain all bearers from that PDN.

Example

This example configures the apn-profile to retain all bearers from the PDN.
ntsr all
**overcharge-protection**

Enables overcharge protection for APNs controlled by this APN profile. Each overcharging protection option is a standalone configuration and it does not override the previous option set, if any.

**Product**
S-GW
P-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > APN Profile Configuration
`configure > apn-profile profile_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(apn-profile-profile_name)#
```

**Syntax**

```
overcharge-protection { abnormal-s1-release | ddn-failure | drop-limit drop_limit_value { packets | bytes } }

[ remove ] overcharge-protection { abnormal-s1-release | ddn-failure | drop-limit }
```

- **remove**
  Removes the specified configuration.

- **abnormal-s1-release**
  (for future use) If overcharging protection is enabled for abnormal-s1-release, S-GW would send MBR to pause charging at P-GW if Abnormal Release of Radio Link signal occurs from MME.

**Important:** Though the command is available in this release, this scenario is not possible.

- **ddn-failure**
  If overcharging protection is enabled for ddn-failure message, MBR would be sent to P-GW to pause charging upon receiving DDN failure from MME/S4-SGSN.

- **drop-limit drop_limit_value { packets | bytes }**
  Send MBR to pause charging at P-GW if specified number of packets/bytes is dropped for a PDN connection. `drop_limit_value` is an integer from 1 through 99999.

  - **packets:** Configures drop-limit in packets.
  - **bytes:** Configures drop-limit in bytes.
Usage
Use this command to specify P-GW to pause charging on abnormal-s1-release, DDN failure notification, or if the number of packets or bytes dropped exceeds the configured limit.

Example
Use the following command to signal P-GW to pause charging when the number of packets dropped exceeds 1000:

```
overcharge-protection drop-limit 1000 packets
```
pdp-data-inactivity

Configures the APN profile regarding PDP data inactivity. This command is specific to the SGSN.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > APN Profile Configuration

configure > apn-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(apn-profile-profile_name)#

**Syntax**

```
pdp-data-inactivity { action { deactivate [ all-pdp | linked-pdp ] | detach-when { all-pdp-inactive | any-pdp-inactive } } | timeout minutes minutes }

default pdp-data-inactivity { action | timeout }

no pdp-data-inactivity timeout
```

**default**
Resets the APN Profile configuration to the default values for PDP data-inactivity.

**no**
Disables the timeout feature of the PDP data-inactivity configuration for this APN profile.

**action**
Defines the action to be taken if PDP data-inactivity occurs:

- **deactivate** - defines which PDP context should be deactivated:
  - **all-pdp** - deactivates all PDP contexts.
  - **linked-pdp** - deactivates only linked PDP contexts.
- **detach-when** - defines the condition that warrants a detach:
  - **all-pdp-inactive** - detach when all PDP contexts are inactive.
  - **any-pdp-inactive** - detach when any PDP context is inactive.

**timeout minutes minutes**

Specifies the inactivity timeout in minutes. *minutes*: is an integer from 1 through 1440. Note that even though the timeout is set for minutes, the configuration displays in seconds.
Usage

Use this command to define how the SGSN will handle a situation where the PDP is not fully active. Repeat the command, as needed, to configure more than one keyword-controlled function.

Example

Use the following command to have the SGSN deactivate all PDP contexts associated with the APN when it detects the PDP is inactive:

```
pdp-data-inactivity action deactivate all-pdp
```

Use the following command to have the SGSN wait 2 minutes after detecting PDP data inactivity:

```
pdp-data-inactivity timeout minutes 2
```
pdp-type-ipv4v6-override

Configure the PDP type to use, per APN, if dual PDP type addressing is not supported by the network and the MS/UE requests the IPv4v6 PDP type.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > APN Profile Configuration

```
configure > apn-profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(apn-profile-profile_name)#
```

**Syntax**

```
pdp-type-ipv4v6-override { ipv4 | ipv6 }
remove pdp-type-ipv4v6-override
```

**remove**

Deletes the override configuration and reverts to the default behavior so the SGSN ignores the IPv4v6 request and sends IPv4 to the GGSN.

**ipv4**

Configures IPv4 as the PDP type to send towards the GGSN when overriding the dual PDP type addressing requested by the MS/UE.

**ipv6**

Configures IPv6 as the PDP type to send towards the GGSN when overriding the dual PDP type addressing requested by the MS/UE.

**Usage**

This command configures the SGSN to send either IPv4 or IPv6 towards the GGSN when the MS/UE requests PDP type as IPv4v6 but either the SGSN or the RNC is not configured to support dual PDP type.

**Example**

Use this command to configure the SGSN to always send IPv6, for the PDP type, to the GGSN when overriding a dual PDP type address request from the MS/UE:

```
pdp-type-ipv4v6-override ipv6
```
pgw-address

Configures the IPv4 or IPv6 address of the P-GW supporting the APN associated with this APN profile.

Product
- ePDG
- MME
- SGSN

Privilege
- Administrator

Mode
- Exec > Global Configuration > APN Profile Configuration
  - configure > apn-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(apn-profile-profile_name)#

Syntax

```
pgw-address ip_address [ s5-s8-protocol pmip ] [ weight weight ]
```

```
no pgw-address ip_address
```

- **no**
  - Disables the P-GW address configured in this APN profile.

- **ip_address**
  - Specifies the IP address for the P-GW in IPv4 dotted-decimal or IPv6 colon-separated notation.

- **s5-s8-protocol pmip**
  - *MME only.* Configures the S5-S8 protocol for the gateway.

- **weight weight**
  - Specifies the weight (preference) assigned to the addressed P-GW for load balancing. weight is an integer from 1 through 100 where 1 is the least preferred and 100 is the most preferred. If no weight is specified, the P-GW address is assigned a default weight of 1.
  - If a weight is assigned to an address, the weights of the P-GW(s) (that are operational) are totaled, and then a weighted round-robin selection is used to distribute new primary PDP contexts (for MME) or primary CPC requests (for SGSN) or new PDN connections (for ePDG) among the P-GW(s) according to their weights. As with all weighted round-robin algorithms, the distribution does not look at the current distribution, but simply uses the weights to distribute new requests. For example, two P-GWs assigned weights of 70 and 30 would distribute 70% of calls to one, and 30% to the other. The sum of all weights do not need to total 100.

**Usage**

Use this command to define load balancing to be applied during P-GW selection. A maximum of 16 P-GW addresses can be configured for this APN profile.
On the S4-SGSN, use this command to configure a local P-GW address for operators wishing to bypass DNS resolution of APN FQDN.

Example

The following command configures the P-GW IP address for this APN profile as 10.2.3.4:

```
pgw-address 10.2.3.4
```
qos allow-upgrade

Configure this command to allow upgrade of QoS from GGSN. The “Upgrade QoS Supported” flag is now set in “Create PDP Context” and “Update PDP Context” messages sent by SGSN. The SGSN signals the availability of this functionality by use of the “Upgrade QoS Supported” bit within the Common Flags IE. The SGSN sets the “Upgrade QoS Supported” bit within the Common Flags IE to “1” within the “Create PDP Context” and “Update PDP Context” procedures.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > APN Profile Configuration
`configure > apn-profile profile_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(apn-profile-profile_name)#
```

**Syntax**

```
qos allow-upgrade access-type { gprs | umts } [ prefer-as-cap-subscription ]

remove qos allow-upgrade access-type { gprs | umts }
```

**remove**
Removes the support for QoS upgrade from the configuration for this APN profile.

**access-type { gprs | umts }**
Allows the operator to choose the access type as either “gprs” or “umts” based on whether it is 2G or 3G network scenario.

**prefer-as-cap-subscription**
Enable this optional keyword to configure capping of QoS with Subscribed QoS (local/HLR). If this keyword is enabled, SGSN accepts a higher QoS in the Create/Update PDP Context Response than sent in Create/Update PDP Context Request, but negotiates and restricts the value within HLR/local subscribed QoS. If this keyword is disabled, the SGSN accepts the QoS in Create PDP Context Response and Update PDP Context Response as the Negotiated QoS (this QoS may be downgraded by the RNC in case of UMTS access).

**Usage**

This command enables the QoS upgrade support feature. On configuring this command, the SGSN sets the “Upgrade QoS Supported” flag within the common flags IE in Tunnel management messages, Create PDP Context Request and Update PDP Context Request messages. The SGSN accepts the QoS from GGSN in Create PDP Context Response, Update PDP Context Request/Response messages as the Negotiated QoS for the PDP session.

**Example**

Command Line Interface Reference, StarOS Release 16

---

**1491**
Use the following command to configure QoS upgrade support in a UMTS scenario:

```
qos allow-upgrade access-type umts prefer-as-cap-subscription
```
**qos apn-ambr**

Configures the APN-AMBR (aggregate maximum bit rate) that will be stored in the Home Subscriber Server (HSS).

**Product**
- MME
- SGSN

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > APN Profile Configuration
  - `configure > apn-profile profile_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(apn-profile-profile_name)#
```

**Syntax**

```
qos apn-ambr max-ul mbr-up max-dl mbr-dwn
remove qos apn-ambr
```

**Usage**

- `remove` Removes the APN-AMBR changes from the configuration for this APN profile.

```
max-ul mbr-up max-dl mbr-dwn
```

- Defines the maximum bit rates for uplink (subscriber to network) and downlink (network to subscriber) traffic.
  - `mbr-up` is an integer from 0 through 1410065408.
  - `mbr-dwn` is an integer from 0 through 1410065408.

**Example**

```
qos apn-ambr max-ul 24234222 max-dl 23423423
```
qos class

Configures local values for the traffic class (TC) parameters for the quality of service (QoS) configured for this APN profile.

**Important:** To enable any of the values/features configured with this command, the qos prefer-as-cap configuration (also in the APN profile configuration mode) must be set to either local or both-hlr-and-local.

### Product
SGSN

### Privilege
Security Administrator, Administrator

### Mode
Exec > Global Configuration > APN Profile Configuration

`configure > apn-profile profile_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(apn-profile-profile_name)#
```

### Syntax

```
qos class { background | conversational | interactive | streaming } [ qualif_option ]
remove qos class { background | conversational | interactive | streaming } [ qualif_option ]
```

- **remove**

  Removes previously defined values for the specified option or for an entire class if a qualifying option is not included in the command.

#### background

Selects the background traffic class. This ‘best-effort’ class manages traffic that is handled as a background function, like email, where time to delivery is not a key factor. The selection of background traffic class can be refined with the addition of one of the following qualifying options:

- `all-values`
- `arp`
- `mbr-down`
- `mbr-map-down`
- `mbr-map-up`
- `mbr-up`
- `residual-bit-error-rate`
- `sdu`
All qualifying options are explained below.

**conversational**
Selects the ‘real-time’ conversational traffic class of service, which has the most stringent time requirements of the four classes and is typically reserved for voice traffic. The section of the conversational traffic class can be refined with the addition of one of the following qualifying options:

- all-values
- arp
- gbr-down
- gbr-up
- mbr-down
- mbr-map-down
- mbr-map-up
- mbr-up
- min-transfer-delay
- residual-bit-error-rate
- sdu

All qualifying options are explained below.

**interactive**
Selects interactive traffic class of service. This class is characterized by a request/response pattern (someone sends data and then waits for a response) which requires the preservation of the data but delivers on a ‘best-effort’ model. The section of the interactive traffic class can be refined with the addition of one of the following qualifying options:

- all-values
- arp
- mbr-down
- mbr-map-down
- mbr-map-up
- mbr-up
- residual-bit-error-rate
- sdu
- thp

All qualifying options are explained below.
streaming

Selects the streaming traffic class of service, which handles one-way, real-time data transmission - such as streaming video or audio. The section of the interactive traffic class can be refined with the addition of one of the following qualifying options:

- all-values
- arp
- gbr-down
- gbr-up
- mbr-down
- mbr-map-down
- mbr-map-up
- mbr-up
- min-transfer-delay
- residual-bit-error-rate
- sdu

All qualifying options are explained below.

qualif_option

Qualifying options are the QoS parameters and they include:
- all-values - This option will change the configuration to predefined values for all the relevant QoS parameters for the class. This keyword is not used if other options are to be defined. The predefined values are:

1. Predefined QoS Parameters

**QoS Parameter** | **Predefined Value**  
---|---  
SDU Error Ratio | 7 (1 * 10^-3)  
Residual Bit Error Rate | 1 (5 * 10^-2)  

- **arp** - Sets the allocation/retention priority. Enter an integer from 1 to 3.
- **gbr-down** - Guaranteed Kbps rate for the downlink direction. Enter an integer from the range 1 to 256000.
- **gbr-up** - Guaranteed Kbps rate for the uplink direction. Enter an integer from 1 to 256000.
- **mbr-down** - Maximum Kbps rate for the downlink direction. Enter an integer from the range 1 to 256000.
- **mbr-map-down from from_kbps to to_kbps** - Map received HLR MBR (from value) to a locally configured downlink MBR value (to value):
  - **from_kbps** - Enter an integer from 1 to 25600.
  - **to_kbps** - Enter an integer from 1 to 25600.
- **mbr-map-up from from_kbps to to_kbps** - Map received HLR MBR (from value) to a locally configured uplink MBR value (to value):
  - **from_kbps** - Enter an integer from 1 to 25600.
  - **to_kbps** - Enter an integer from 1 to 25600.
- **mbr-up** - Maximum Kbps rate for the uplink direction. Enter an integer from 1 to 256000.
- **min-transfer-delay** - Minimum transfer delay in milliseconds. Enter an integer from 80 to 4000.
- **residual-bit-error-rate** -
  - Background TC residual-bit-error-rate range is from 4*10^-4 to 6*10^-8. Enter one of the following integers, where:
    - 4: represents 4*10^-3
    - 7: represents 10^-5
    - 9: represents 6*10^-8
  - Conversational TC residual-bit-error-rate range is from 5*10^-2 to 10^-6. Enter one of the following integers, where:
    - 1: represents 5*10^-2
    - 2: represents 10^-2
    - 3: represents 5*10^-3
    - 5: represents 10^-3
    - 6: represents 10^-4
    - 7: represents 10^-5
    - 8: represents 10^-6
  - Interactive TC residual-bit-error-rate range is from 4*10^-4 to 6*10^-8. Enter one of the following integers, where:
**qos class**

- **4**: represents $4 \times 10^{-3}$
- **7**: represents $10^{-5}$
- **9**: represents $6 \times 10^{-8}$

- Streaming TC residual-bit-error-rate range is from $5 \times 10^{-2}$ to $10^{-6}$. Enter one of the following integers, where:
  - **1**: represents $5 \times 10^{-2}$
  - **2**: represents $10^{-2}$
  - **3**: represents $5 \times 10^{-3}$
  - **5**: represents $10^{-3}$
  - **6**: represents $10^{-4}$
  - **7**: represents $10^{-5}$
  - **8**: represents $10^{-6}$

- **sdu** - Signalling data unit keyword, must include one of the following options:
  - **delivery-order**- Enter one of the two following options:
    - **no**- Without delivery order
    - **yes**- With delivery order
  - **erroneous**- Enter one of the two following options:
    - **no**- Erroneous SDUs will not be delivered
    - **no-detect**- Erroneous SDUs are not detected ('-')
    - **yes**- Erroneous SDUs will be delivered
  - **error-ratio**- The SDU error-ratio range is from $10^{-3}$ to $10^{-6}$. Enter an integer from 1 to 6, where:
    - **3**: Represents $10^{-3}$
    - **4**: Represents $10^{-4}$
    - **6**: Represents $10^{-6}$
  - **max-size**- Defines the maximum number of octets (size) of the SDU. Enter an integer from 10 to 1502.
  - **thp** - Sets the traffic handling priority. Enter an integer from 1 to 3.

**Usage**

This command defines the qualifying options (parameters) for each QoS traffic class defined for this APN profile.

**Important:** Typically this command is only used to define QoS parameters when the APN record does not exist in the subscription record.
Repeat the command as often as needed with different options to define all required QoS criteria. For example, to configure the maximum bit rate (MBR) for the downlink and uplink directions for a traffic class, this command must be used twice, specifying `mbr-down` once and `mbr-up` once.
