The following command sets the intercept watch timeout setting to 15 seconds:

```
firewall tcp-syn-flood-intercept watch-timeout 15
```
**firewall tcp-syn-with-ecn-cwr**

This command configures Stateful Firewall action on TCP SYN packets with either ECN or CWR flag set.

**Product**

PSF

**Privileges**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Firewall-and-NAT Policy Configuration

```
active-charging service service_name > fw-and-nat policy policy_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-fw-and-nat-policy)#
```

**Syntax**

```
firewall tcp-syn-with-ecn-cwr { drop | permit }
```

```
default firewall tcp-syn-with-ecn-cwr
```

- **default**
  
  Configures the default setting.
  
  Default: **permit**

- **drop**
  
  Drops TCP SYN packets with either ECN or CWR flag set.

- **permit**
  
  Permits TCP SYN packets with either ECN or CWR flag set.

**Usage**

Use this command to configure Stateful Firewall action on receiving a TCP SYN packet with either ECN or CWR flag set.

**Example**

The following command configures Stateful Firewall to drop TCP SYN packets with ECN / CWR flag set:

```
firewall tcp-syn-with-ecn-cwr drop
```
firewall udp-checksum-error

This command configures Stateful Firewall action on packets with UDP Checksum error.

Product
PSF

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Firewall-and-NAT Policy Configuration

active-charging service service_name > fw-and-nat policy policy_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-fw-and-nat-policy)#

Syntax

firewall udp-checksum-error { drop | permit }

default firewall udp-checksum-error

default

Configures the default setting.
Default: drop

drop

Drops packets with UDP Checksum error.

permit

Permits packets with UDP Checksum error.

Usage

Use this command to configure Stateful Firewall action on packets with UDP Checksum error. For NAT-only calls, packets with UDP Checksum error are permitted.

Example

The following command specifies to drop packets with UDP Checksum error:

firewall udp-checksum-error drop
firewall validate-ip-options

This command enables / disables the Stateful Firewall validation of IP options for errors.

Product
PSF

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Firewall-and-NAT Policy Configuration

active-charging service service_name > fw-and-nat policy policy_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-fw-and-nat-policy)#

Syntax

[ default | no ] firewall validate-ip-options

- default
  Configures the default setting.
  Default: Disabled. Same as no firewall validate-ip-options

- no
  Disables validation of IP options.

Usage
Use this command to enable / disable Stateful Firewall validation of IP options. When enabled, Stateful Firewall will drop packets with IP option errors.
For NAT calls, validation of IP Options is disabled.

Example
The following command enables validation of IP options:

firewall validate-ip-options
nat binding-record

This command configures the generation of NAT Binding Records.

Product  
NAT

Privilege  
Security Administrator, Administrator

Mode  
Exec > ACS Configuration > Firewall-and-NAT Policy Configuration

active-charging service service_name > fw-and-nat policy policy_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-fw-and-nat-policy) #

Syntax

nat binding-record edr-format edr_format [ port-chunk-allocation ] [ port-chunk-release ]

{ default | no } nat binding-record

default

Configures the default setting.  
Default: port-chunk-release

no

Disables generating NAT Binding Records.

edr-format edr_format

Specifies the Event Data Record (EDR) format name.  
edr_format must be an alphanumeric string of 1 through 63 characters.

port-chunk-allocation

Specifies generating NAT Binding Records when a port-chunk is allocated.

port-chunk-release

Specifies generating NAT Binding Record when a port-chunk is released.

Usage

Use this command to configure the generation of NAT Binding Records.

Example

The following command configures an EDR format named test123 and specifies generating NAT Binding Records when a port-chunk is allocated:

    nat binding-record edr-format test123 port-chunk-allocation
nat check-point-info

This command enables or disables the checkpointing of basic NAT, H323 and SIP ALG recovery. ICSR recovery can also be enabled or disabled for basic NAT and SIP flows.

Product
PSF
NAT

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Firewall-and-NAT Policy Configuration

active-charging service service_name > fw-and-nat policy policy_name

Entering the above command sequence results in the following prompt:
[local]host_name(config-fw-and-nat-policy)#

Syntax

[ default | no ] nat check-point-info { basic [ icsr-also | limit-flows limit ] | h323-alg | sip-alg [ icsr-also ] }

default
Configures this command with its default setting.
Default: Disabled

no
Disables the basic NAT recovery and stand-alone H323 ALG and SIP ALG recovery. Also disables ICSR recovery for SIP ALG.

basic [ icsr-also | limit-flows limit ]
Configures the basic flow checkpointing information.
  • icsr-also: Enables checkpointing for ICSR.
  • limit-flows: Limits the specified flows for basic NAT checkpointing. limit must be an integer from 1 through 100.
    Default: 100

h323-alg
Enables checkpointing of H323 ALG.

sip-alg [ icsr-also ]
Enables checkpointing of SIP ALG.
  • icsr-also: Enables checkpointing for ICSR.
Usage

Use this command to enable or disable the checkpointing of basic NAT, standalone H323 and SIP ALG recovery. ICSR recovery can also be enabled or disabled for basic NAT and SIP flows. The maximum basic flows that can be checkpointed is also configured. By default, 100 flows can be recovered in a standalone chassis and ICSR setup.

Example

The following command enables basic NAT recovery and ICSR recovery with flows limited to 10:

```
nat check-point info basic limit-flows 10 icsr-also
```
**nat icsr-flow-recovery**

This command enables/disables the NAT ICSR Flow checkpointing support for subscribers in a Firewall-and-NAT policy. This command is deprecated in StarOS 14.0 and later releases, and is replaced by the `nat check-point-info` command.

**Product**
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Firewall-and-NAT Policy Configuration

```shell
active-charging service service_name > fw-and-nat policy policy_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-fw-and-nat-policy)#
```

**Syntax**

```
[ default | no ] nat icsr-flow-recovery
```

- **default**
  - Configures the default setting.
  - Default: Disabled. Same as `no icsr-flow-recovery`.

- **no**
  - Disables the NAT ICSR Flow checkpointing.

**Usage**

Use this command to enable/disable all NAT ICSR Flow checkpointing for subscribers using this policy.

**Example**

The following command enables NAT ICSR Flow checkpointing:

```
nat icsr-flow-recovery
```
**nat policy**

This command enables/disables Network Address Translation (NAT) support in a Firewall-and-NAT policy.

**Important:** In release 8.3, this configuration is available in the ACS Rulebase Configuration Mode.

**Product**
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Firewall-and-NAT Policy Configuration

```
active-charging service service_name > fw-and-nat policy policy_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-fw-and-nat-policy)#
```

**Syntax**

In 12.1 and earlier releases:

```
nat policy nat-required [ default-nat-realm nat_realm_name [ fw-and-nat-action action_name ] ]
```

```
no nat policy
```

In 12.2 and later releases:

```
nat policy [ ipv4-and-ipv6 | ipv4-only | ipv6-only ] [ default-nat-realm nat_realm_name [ fw-and-nat-action action_name ] ]
```

```
no nat policy
```

**no**

Disables both NAT44 and NAT64 support in the Firewall-and-NAT policy.

**nat-required**

Enables NAT support in the Firewall-and-NAT policy.

**Important:** This keyword is available only in 12.1 and earlier releases, and is supported in release 12.2 for backward compatibility. The `nat policy nat-required` command enables only NAT44.

**ipv4-and-ipv6**

Enables NAT processing for both IPv4 and IPv6 in the Firewall-and-NAT policy.

**ipv4-only**

Enables NAT processing for IPv4 in the Firewall-and-NAT policy.
### nat policy

**ipv6-only**

Enables NAT processing for IPv6 in the Firewall-and-NAT policy.

**default-nat-realm nat_realm_name**

Specifies the default NAT realm for the Firewall-and-NAT policy. `nat_realm_name` must be the name of an existing NAT realm, and must be an alphanumeric string of 1 through 31 characters.

**fw-and-nat-action action_name**

Specifies the Firewall-and-NAT action name. `action_name` must be an alphanumeric string of 1 through 63 characters.

### Usage

Use this command to enable/disable IPv4 and/or IPv6 NAT support for all subscribers using a Firewall-and-NAT policy.

In release 8.1, to enable NAT support for a subscriber, Stateful Firewall must also be enabled for that subscriber. See the `firewall policy` CLI command.

Once NAT is enabled for a subscriber, the NAT IP address to be used is chosen from the NAT realms specified in the rules. See the `access-rule` CLI command.

You can enable/disable NAT at any time, however the changed NAT status will not be applied to active calls. The new NAT status will only be applied to new calls.

### Example

The following command enables NAT support in a Firewall-and-NAT policy:

```
   nat policy nat-required
```

The following command disables NAT support in a Firewall-and-NAT policy:

```
   no nat policy
```

The following command enables IPv4 and IPv6 NAT support in a Firewall-and-NAT policy:

```
   nat policy ipv4-and-ipv6
```
nat private-ip-flow-timeout

This command configures the Private IP NPU flow timeout setting.

**Product**
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Firewall-and-NAT Policy Configuration

```
active-charging service service_name > fw-and-nat policy policy_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-fw-and-nat-policy)#
```

**Syntax**

```
nat private-ip-flow-timeout timeout
{ default | no } nat private-ip-flow-timeout
```

---

**default**

Configures the default setting.
Default: 180 seconds

---

**no**

Disables the Private IP NPU flow timeout configuration.
When disabled, the flow is installed at call setup and will be removed only when the subscriber disconnects.

---

**timeout**

Specifies the Private IP NPU flow timeout period in seconds.

*timeout* must be an integer from 180 through 86400.

---

**Usage**

Use this command to configure the Private IP NPU flow timeout setting.
For NAT-enabled calls, by default, the downlink private IP NPU flow will not be installed at call setup for a subscriber session. The flow will only be installed on demand. When there is no traffic on the private flow, the private IP flow will be removed after the configurable timeout period.

---

**Example**

The following command configures the Private IP NPU flow timeout setting to 36000 seconds:

```
nat private-ip-flow-timeout 36000
```
nat suppress-aaa-update

This command suppresses sending NAT Bind Update (NBU) to the AAA server when PPP disconnect happens.

**Important:** This command is customer-specific. For more information please contact your local service representative.

**Product**
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Firewall-and-NAT Policy Configuration

```
active-charging service service_name > fw-and-nat policy policy_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-fw-and-nat-policy)#
```

**Syntax**

```
nat suppress-aaa-update call-termination

default nat suppress-aaa-update
```

```
default
```

Configures the default setting.
Default: No suppression of AAA updates.

**Usage**
Use this command to suppress sending of NBU to the AAA server when PPP disconnect happens, as these NBUs would be cleared at the AAA after receiving the accounting-stop. This enables to minimize the number of messages between the chassis and AAA server. When not configured, NBU are sent to the AAA server whenever a port chunk is allocated, de-allocated, or the call is cleared (PPP disconnect).

**Example**
The following command suppresses the sending of NBU to the AAA server:

```
nat suppress-aaa-update call-termination
```
Chapter 137
Firewall-and-NAT Access Ruledef Configuration Mode Commands

The Firewall-and-NAT Access Ruledef Configuration Mode is used to configure and manage Access rule definitions used by the Stateful Firewall (FW) and Network Address Translation (NAT) in-line services.

Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration

active-charging service service_name > access-ruledef access_ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-fw-ruledef)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
bearer 3gpp apn

This command configures an access ruledef to analyze user traffic based on APN bearer.

Product
PSF
NAT

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration

active-charging service service_name > access-ruledef access_ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-fw-ruledef)#

Syntax

[ no ] bearer 3gpp apn [ case-sensitive ] operator value

no
Removes previously configured bearer ruledef.

case-sensitive
This keyword makes the rule case sensitive.
By default, ruledefs are not case sensitive.
Default: Disabled

operator

Specifies how to logically match the APN name.
operator must be one of the following:
  • !=: Does not equal
  • !contains: Does not contain
  • !ends-with: Does not end with
  • !starts-with: Does not start with
  • =: Equals
  • contains: Contains
  • ends-with: Ends with
  • starts-with: Starts with

value

The APN name to match in bearer flow.
value must be an alphanumerical string of 1 through 63 characters that can include punctuation characters.
Usage
Use this command to specify an access ruledef to analyze user traffic based on APN name.

Example
The following command creates an access ruledef for analyzing user traffic for an APN named `apn12`:

```
bearer 3gpp apn = apn12
```
bearer 3gpp imsi

This command configures an access ruledef to analyze user traffic based on International Mobile Station Identification (IMSI) number in bearer flow.

Product
PSF
NAT

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration

active-charging service service_name > access-ruledef access_ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-fw-ruledef)#

Syntax

[ no ] bearer 3gpp imsi { operator msid | { !range | range } imsi_pool imsi_pool }

no
Removes previously configured bearer ruledef.

operator
Specifies how to logically match the MSID.
operator must be one of the following:
  • !=: Does not equal
  • ==: Equals

msid
Specifies the Mobile Station Identifier.

{ !range | range } imsi_pool imsi_pool
{ !range | range }: Specifies the range criteria:
  • !range: Not in the range of
  • range: In the range of

imsi_pool imsi_pool: Specifies the IMSI pool name. imsi_pool must be an alphanumeric string of 1 through 63 characters.

Usage
Use this command to specify an access ruledef to analyze user traffic based on IMSI number of mobile station.

Example
The following command creates an access ruledef to analyze user traffic for the IMSI number 9198838330912:

```
bearer 3gpp imsi = 9198838330912
```

**bearer username**

This command configures an access ruledef to analyze user traffic based on user name of the bearer flow.

**Product**

PSF

NAT

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration

```
active-charging service service_name > access-ruledef access_ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-fw-ruledef)#
```

**Syntax**

```
[ no ] bearer username [ case-sensitive ] operator value
```

- **no**
  - Removes previously configured bearer ruledef.

- **case-sensitive**
  - This keyword makes the rule case sensitive.
  - By default, ruledefs are not case sensitive.
  - Default: Disabled

- **operator**
  - Specifies how to logically match the MSID.
  - `operator` must be one of the following:
    - `!=`: Does not equal
    - `!=contains`: Does not contain
    - `!=ends-with`: Does not end with
    - `!=starts-with`: Does not start with
    - `=`: Equals
    - `contains`: Contains
    - `ends-with`: Ends with
    - `starts-with`: Starts with

- **value**
  - Specifies the user name.
  - `value` must be an alphanumeric string of 1 through 127 characters.
Usage

Use this command to specify a access ruledef to analyze user traffic based on user name of the bearer flow.

Example

The following command creates an access ruledef for analyzing user traffic for the user name user12:

```
bearer username = user12
```
create-log-record

This command enables/disables access ruledef logging.

Product
PSF

- All

**Privilege**
- Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
### icmp any-match

This command configures an access ruledef to match any ICMPv4 traffic for the user.

**Product**
PSF
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration

```plaintext
active-charging service service_name > access-ruledef access_ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-fw-ruledef)#
```

**Syntax**

```
[ no ] icmp any-match operator condition
```

- **no**
  - Removes previously configured ICMPv4 any-match ruledef.

- **operator**
  - Specifies how to logically match the analyzed state.
  - `!`: Does not equal
  - `=`: Equals

- **condition**
  - Specifies the condition to be matched for the user traffic.
  - `FALSE`: Specified condition is FALSE.
  - `TRUE`: Specified condition is TRUE.

**Usage**
Use this command to specify an access ruledef to match any ICMPv4 traffic of the user.

**Example**
The following command creates an access ruledef to match any non-ICMPv4 traffic of the user:

```
icmp any-match = FALSE
```
**icmp code**

This command configures an access ruledef to analyze user traffic based on ICMPv4 code.

**Product**

PSF

```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-acs-fw-ruledef)#
```

**Syntax**

```
[ no ] icmp code operator code
```

- **no**
  - Removes previously configured ICMPv4 code ruledef.

- **operator**
  - Specifies how to logically match the ICMPv4 code.
  - **operator** must be one of the following:
    - !=: Does not equal
    - <=: Less than or equals
    - ==: Equals
    - >=: Greater than or equals

- **code**
  - Specifies the ICMPv4 code.
  - **code** must be an integer from 0 through 255.

**Usage**

Use this command to define an access ruledef to analyze user traffic based on the ICMPv4 code.

**Example**

The following command creates an access ruledef for analyzing user traffic using the ICMPv4 code as 23:

```
icmp code = 23
```
icmp type

This command configures an access ruledef to analyze user traffic based on ICMPv4 type.

Product
PSF
NAT

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration
active-charging service service_name > access-ruledef access_ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-fw-ruledef)#

Syntax

[ no ] icmp type operator type

no
Removes previously configured ICMPv4 type ruledef.

operator
Specifies how to logically match the ICMPv4 type.
operator must be one of the following:
• !=: Does not equal
• <=: Less than or equals
• ==: Equals
• >=: Greater than or equals

type
Specifies the ICMPv4 type.
type must be an integer from 0 through 255.
For example, 0 for ECHO Reply, 3 for Dest. Unreachable, and 5 for Redirect.

Usage
Use this command to define an access ruledef to analyze user traffic based on the ICMPv4 type.

Example
The following command creates an access ruledef for analyzing user traffic using an ICMPv4 type as 123:

icmp type = 123
icmpv6 any-match

This command configures an access ruledef to match any ICMPv6 traffic for the user.

**Product**

  Specifies how to logically match the packet flow direction.
  *operator* must be one of the following:
  - `!=`: Does not equal
  - `==`: Equals

- **condition**
  Specifies the condition to match.
  *condition* must be one of the following:
  - `TRUE`: Analyzed
  - `FALSE`: Not analyzed

**Usage**

Use this command to define an access ruledef to analyze user traffic based on the IP packet flow direction as downlink.

**Example**

The following command creates access ruledef for analyzing user traffic using an IP packet direction to downlink (to subscriber):

```
ip downlink = TRUE
```
ip dst-address

This command configures an access ruledef to analyze user traffic based on IP destination address.

Product
- PSF
- NAT

Privilege
Security Administrator, Administrator

Mode
- Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration
- \texttt{active-charging service service\_name > access\_ruledef access\_ruledef\_name}

Entering the above command sequence results in the following prompt:

```
[local]host\_name(config-acs-fw-ruledef)#
```

Syntax

```
[ no ] ip dst-address { operator { ipv4/ipv6\_address | ipv4/ipv6\_address/mask } | { !range | range } host\_pool host\_pool }
```

- **no**
  - Removes previously configured IP destination address ruledef.

- **operator**
  - Specifies how to logically match the IP destination address.
  - **operator** must be one of the following:
    - !=: Does not equal
    - <=: Less than or equals
    - =: Equals
    - >=: Greater than or equals

- **ipv4/ipv6\_address**
  - Specifies the IP address of destination node for outgoing traffic.

- **ipv4/ipv6\_address/mask**
  - Specifies the IP address of destination node for outgoing traffic.

- **!range | range**
  - Specifies the range criteria:
    - !range: Not in the range of
    - range: In the range of

- **host\_pool host\_pool**
  - Specifies the host pool name. **host\_pool** must be an alphanumeric string of 1 through 63 characters.
**Usage**

Use this command to specify an access ruledef to analyze user traffic based on the IP destination address.

**Example**

The following command creates an IP ruledef for analyzing user traffic using an IP destination address of 10.1.1.1:

```
ip dst-address = 10.1.1.1
```
ip protocol

This command configures an access ruledef to analyze user traffic based on the protocol being transported by IP packets.

Product
PSF
NAT

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration

active-charging service service_name > access-ruledef access_ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-fw-ruledef)#

Syntax

```
[ no ] ip protocol { { operator { protocol | protocol_assignment } } | { operator protocol_assignment } }
```

- **no**
  Removes previously configured IP protocol address ruledef.

- **operator { protocol | protocol_assignment }**
  - **operator:** Specifies how to logically match the IP protocol.
  - **operator** must be one of the following:
    - !=: Does not equal
    - ==: Equals
  - **protocol:** Specifies the protocol by name.
  - **protocol** must be one of the following:
    - ah
    - esp
    - gre
    - icmp
    - tcp
    - udp
  - **protocol_assignment:** Specifies the protocol by assignment number. **protocol_assignment** must be an integer from 0 through 255 (for example, 1 for ICMP, 6 for TCP, and 17 for UDP).

- **operator protocol_assignment**
  - **operator:** Specifies how to logically match the IP protocol.
  - **operator** must be one of the following:
ip protocol

- <=: Less than or equals
- >=: Greater than or equals

protocol_assignment: Specifies the protocol by assignment number.
protocol_assignment must be an integer from 0 through 255 (for example, 1 for ICMP, 6 for TCP, and 17 for UDP).

Usage

Use this command to specify an access ruledef to analyze user traffic based on the IP protocol.

Example

The following command creates IP ruledef for analyzing user traffic using a protocol assignment of 1:

```
ip protocol = 1
```
**ip server-ip-address**

This command configures an access ruledef to analyze user traffic based on IP server address.

**Product**
PSF
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration

```plaintext
active-charging service service_name > access-ruledef access_ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-fw-ruledef)#
```

**Syntax**

```
[ no ] ip server-ip-address { operator { ipv4/ipv6_address | ipv4/ipv6_address/mask } | { !range | range } host-pool host_pool_name }
```

- **no**
  Removes previously configured IP server address.

- **operator { ipv4/ipv6_address | ipv4/ipv6_address/mask }**
  Specifies how to logically match the IP server address.
  **operator** must be one of the following:
  - !=: Does not equal
  - <=: Less than or equals
  - =: Equals
  - >=: Greater than or equals

- **ipv4/ipv6_address**: Specifies the server IP address. For uplink packets (subscriber to network), this field matches the destination IP address in the IP header. For downlink packets (network to subscriber), this field matches the source IP address in the IP header. `ipv4/ipv6_address` must be an IP address in IPv4-dotted decimal notation or IPv6 colon-separated hexadecimal notation.

- **ipv4/ipv6_address/mask**: Specifies the server IP address with subnet mask bit. For uplink packets (subscriber to network), this field matches the destination IP address in the IP header. For downlink packets (network to subscriber), this field matches the source IP address in the IP header. `ipv4/ipv6_address/mask` must be an IP address in IPv4 dotted-decimal notation or IPv6 colon-separated hexadecimal notation with subnet mask bit. The mask bit is a numeric value which is the number of bits in the subnet mask.

- **{ !range | range } host-pool host_pool_name**
  Specifies the range criteria.
  - !range: Not in the range of
  - range: In the range of
**Usage**

Use this command to specify an access ruledef to analyze user traffic based on IPv4 or IPv6 server address. For uplink packets, this field matches the destination IP address in the IP header. For downlink packets, this field matches the source IP address in the IP header.

**Example**

The following command creates an IP ruledef for analyzing user traffic using IPv4 server address 10.1.1.1:

```
ip server-ip-address = 10.1.1.1
```
ip server-ipv6-network-prefix

This command configures an access ruledef to analyze user traffic based on IPv6 server prefix.

Product
PSF
NAT

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration

active-charging service service_name > access-ruledef access_ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-fw-ruledef)#

Syntax

[ no ] ip server-ipv6-network-prefix operator ipv6_prefix/prefix_length

no
Removes previously configured IPv6 server prefix.

operator ipv6_prefix/prefix_length

operator: Specifies how to logically match the IPv6 server prefix.
operator must be one of the following:
  • !=: Does not equal
  • =: Equals

ipv6_prefix/prefix_length: Specifies the server’s IPv6 address with subnet mask bit.
ipv6_prefix/prefix_length must be in IPv6 colon-separated-hexadecimal notation with subnet mask bit. The prefix_length is the number of bits to match. The configurable prefix length values are 32, 40, 48, 56, 64 and 96.

Usage
Use this command to specify an access ruledef to analyze user traffic based on IPv6 server prefix. When a first packet for a flow is received, it is matched against a set of rules configured in the Firewall-and-NAT policy. If the incoming IPv6 packet matches a ruledef and configured prefix, then it indicates that NAT64 needs to be applied on the packet. If the packet did not match the prefix configured, then NAT64 will not be applied on the packet. If there is no rule matching the packet or if there is no rule configured, then the incoming IPv6 packet is matched against the well-known prefix. If the well-known prefix matches, then NAT64 is applied on the packet.

Example
The following command creates an IP ruledef to analyze user traffic using the IPv6 server prefix abcd:dcba with 32 bits of the server IPv6 address:

ip server-ipv6-network-prefix = abcd:dcba::/32
ip src-address

This command configures an access ruledef to analyze user traffic based on IP source address.

Product

Mode
Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration
active-charging service service_name > access-ruledef access_ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-accs-fw-ruledef)#

Syntax

[ no ] ip src-address { operator { ipv4/ipv6_address | ipv4/ipv6_address/mask } | { !range | range } host-pool host_pool }

no

Removes previously configured IP destination address ruledef.

---

operator { ipv4/ipv6_address | ipv4/ipv6_address/mask }

operator: Specifies how to logically match the IP source address.
operator must be one of the following:
- !=: Does not equal
- <=: Less than or equals
- =: Equals
- >=: Greater than or equals

ipv4/ipv6_address: Specifies the IP address using IPv4 dotted-decimal notation or IPv6 colon-separated-hexadecimal notation.
ipv4/ipv6_address/mask: Specifies the IP address using IPv4 dotted-decimal notation or IPv6 colon-separated-hexadecimal notation with subnet mask bit. The mask bit is a numeric value which is the number of bits in the subnet mask.

{ !range | range } host-pool host_pool

!range | range: Specifies the range criteria:
- !range: Not in the range of
- range: In the range of

host-pool host_pool: Specifies the host pool name. host_pool must be an alphanumeric string of 1 through 63 characters.
Usage

Use this command to specify an access ruledef to analyze user traffic based on the IP source address.

Example

The following command creates IP ruledef for analyzing user traffic using an IP source address of 10.1.1.1:

```
   ip src-address = 10.1.1.1
```
ip uplink

This command configures an access ruledef to analyze user traffic based on IP packet flow in the uplink direction (from subscriber).

Product
PSF
NAT

Privilege
Security Administrator, Administrator

Mode
Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration

Syntax
[ no ] ip uplink operator condition

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
<tbody>
<tr>
<td>Removes previously configured IP uplink match ruledef.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>operator</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies how to logically match the IP packet flow direction.</td>
</tr>
<tr>
<td>operator must be one of the following:</td>
</tr>
<tr>
<td>• !=: Does not equal</td>
</tr>
<tr>
<td>• ==: Equals</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the condition to match.</td>
</tr>
<tr>
<td>condition must be one of the following:</td>
</tr>
<tr>
<td>• TRUE: Not analyzed</td>
</tr>
<tr>
<td>• FALSE: Analyzed</td>
</tr>
</tbody>
</table>

Usage
Use this command to define an access ruledef to analyze user traffic based on the IP packet flow direction as uplink.

Example
The following command creates access ruledef for analyzing user traffic using an IP packet direction to uplink (from subscriber):

    ip uplink = TRUE
**ip version**

This command defines rule expressions to match version number in IP header.

**Product**  
PSF  
NAT

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration

active-charging service service_name > access-ruledef access_ruledef_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-acs-fw-ruledef) #

**Syntax**

```
[ no ] ip version = { ipv4 | ipv6 }
```

- **no**  
  Deletes the specified rule expression.

- **ipv4**  
  Specifies the rule expression for IP version 4.

- **ipv6**  
  Specifies the rule expression for IP version 6.

**Usage**

Use this command to define rule expressions to match IPv4/IPv6 version number in IP header.

**Example**

The following command defines a rule expression to match user traffic for the IP version `ipv6`:

```
ip version = ipv6
```
**tcp any-match**

This command configures an access ruledef to match any TCP traffic for the user.

**Product**
PSF
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration

active-charging service service_name > access-ruledef access_ruledef_name

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-fw-ruledef)#
```

**Syntax**

```
[ no ] tcp any-match operator condition
```

- **no**
  Removes previously configured TCP any-match ruledef.

- **operator**
  Specifies how to logically match the analyzed state.
  *operator* must be one of the following:
  - !=: Does not equal
  - ==: Equals

- **condition**
  Specifies the condition to be matched for the user traffic.
  *condition* must be one of the following:
  - **FALSE**: Specified condition is FALSE.
  - **TRUE**: Specified condition is TRUE.

**Usage**

Use this command to specify an access ruledef to match any TCP traffic of the user.

**Example**

The following command creates an access ruledef to match any non-TCP traffic of the user:

```
tcp any-match = FALSE
```
**tcp dst-port**

This command configures an access ruledef to analyze user traffic based on destination TCP port.

**Product**
PSF
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration

```
active-charging service service_name > access-ruledef access_ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-fw-ruledef)#
```

**Syntax**

```
[ no ] tcp dst-port { operator port_number | { !range | range } { start_range to end_range | port-map port_map } }
```

- **no**
  Removes the previously configured destination TCP port ruledef.

- **operator**
  Specifies how to logically match the port number.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `<=`: Less than or equals
  - `=`: Equals
  - `>=`: Greater than or equals

- **port_number**
  Specifies the port number to match.
  `port_number` must be an integer from 1 through 65535.

- **range | !range**
  Specifies the range criteria:
  - `!range`: Not in the range
  - `range`: In the range

- **start_range to end_range**
  Specifies the starting and ending port numbers for the range of destination TCP ports.
  `start_range` must be an integer from 1 through 65535.
  `end_range` must be an integer from 1 through 65535 that is greater than `start_range`.
### port-map port_map

Specifies name of the port-map for the port range.

*port_map* must be an alphanumeric string of 1 through 63 characters.

---

#### Usage

Use this command to specify an access ruledef to analyze user traffic based on destination TCP port.

#### Example

The following command creates an access ruledef for analyzing user traffic matching destination port for TCP as 10:

```
tcp dst-port = 10
```
**tcp either-port**

This command configures an access ruledef to analyze user traffic based on either (destination or source) TCP ports.

**Product**
- PSF
- NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration

```
active-charging service service_name > access-ruledef access_ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-fw-ruledef)#
```

**Syntax**
```
[ no ] tcp either-port { operator port_number | { !range | range } { start_range to end_range | port-map port_map } }
```

- **no**
  Removes previously configured TCP either-port (destination or source) ruledef.

- **operator**
  Specifies how to logically match the port number.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `<=`: Less than or equals
  - `==`: Equals
  - `>=`: Greater than or equals

- **port_number**
  Specifies the port number to match.
  `port_number` must be an integer from 1 through 65535.

- **range | !range**
  Specifies the range criteria:
  - `!range`: Not in the range
  - `range`: In the range

- **start_range to end_range**
  Specifies the starting and ending port numbers for the port range.
  `start_range` must be an integer from 1 through 65535.
  `end_range` must be an integer from 1 through 65535 that is greater than `start_range.`
Firewall-and-NAT Access Ruledef Configuration Mode Commands

```
tcp either-port

port-map port_map

Specifies name of the port-map for the port range.
port_map must be an alphanumeric string of 1 through 63 characters.
```

**Usage**

Use this command to specify an access ruledef to analyze user traffic based on either TCP port.

**Example**

The following command creates an access ruledef for analyzing user traffic matching destination or source port for TCP as 10:

```
tcp either-port = 10
```
**tcp src-port**

This command configures an access ruledef to analyze user traffic based on source TCP port.

**Product**
- PSF
- NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration

```
active-charging service service_name > access-ruledef access_ruledef_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-fw-ruledef)#
```

**Syntax**

```
[ no ] tcp src-port { operator port_number | { !range | range } { start_range to end_range | port-map port_map } }
```

- **no**
  Removes previously configured source TCP port ruledef.

- **operator**
  Specifies how to logically match the port number.
  `operator` must be one of the following:
  - `!=`: Does not equal
  - `<=`: Less than or equals
  - `==`: Equals
  - `>=`: Greater than or equals

- **port_number**
  Specifies the port number to match.
  `port_number` must be an integer from 1 to 65535.

- **range | !range**
  Specifies the range criteria:
  - `!range`: Not in the range
  - `range`: In the range

- **start_range to end_range**
  Specifies the starting and ending port numbers for the port range.
  `start_range` must be an integer from 1 through 65535.
  `end_range` must be an integer from 1 through 65535 that is greater than `start_range`. 
port-map port_map

Specifies name of the port-map for the port range.
port_map must be an alphanumeric string of 1 through 63 characters.

Usage
Use this command to specify an access ruledef to analyze user traffic based on source TCP port.

Example
The following command creates an access ruledef for analyzing user traffic matching source port for TCP as 10:

```
tcp src-port = 10
```
udp any-match

This command configures an access ruledef to match any UDP traffic for the user.

**Product**
- PSF
- NAT

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > ACS Configuration > Firewall-and-NAT Access Ruledef Configuration

active-charging service service_name > access-ruledef access_ruledef_name

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-acs-fw-ruledef)#
```

**Syntax**

```
[ no ] udp any-match operator condition
```

- **no**
  - Removes previously configured UDP any-match ruledef.

- **operator**
  - Specifies how to logically match the analyzed state.
  - `operator` must be one of the following:
    - `!=`: does not equal
    - `=`: equals

- **condition**
  - Specifies the condition to be matched for the user traffic.
  - `condition` must be one of the following:
    - `FALSE`: Specified condition is FALSE.
    - `TRUE`: Specified condition is TRUE.

**Usage**

Use this command to specify an access ruledef to match any UDP traffic of the user.

**Example**

The following command creates an access ruledef to match any UDP traffic of the user:

```
udp any-match = TRUE
```
udp dst-port

This command configures an access ruledef to analyze user traffic based on destination UDP port.

[local]host_name(config-acs-fw-ruledef)#

Syntax

[ no ] udp src-port { operator port_number | { !range | range } { start_range to end_range | port-map port_map } }

no

Removes previously configured source UDP port ruledef.

operator

Specifies how to logically match the port number.
operator must be one of the following:
  • !=: Does not equal
  • <=: Less than or equals
  • =: Equals
  • >=: Greater than or equals

port_number

Specifies the port number to match.
port_number must be an integer from 1 through 65535.

!range | range

Specifies the range criteria.
  • !range: Not in the range
  • range: In the range

start_range to end_range

Specifies the starting and ending port numbers for the port range.
start_range must be an integer from 1 through 65535.
end_range must be an integer from 1 through 65535 that is greater than start_range.
port-map port_map

Specifies name of the port-map for the port range.
port_map must be an alphanumeric string of 1 through 63 characters.

Usage

Use this command to specify an access ruledef to analyze user traffic based on source UDP port.

Example

The following command creates an access ruledef for analyzing user traffic matching source port for UDP as 10:

    udp src-port = 10
Chapter 138
FNG Service Configuration Mode Commands

The FNG Service Configuration Mode is used to configure the properties required for the Femto Network Gateway (FNG) to interface with the Femto Access Points (FAPs) in the network.

Mode

Exec > Global Configuration > Context Configuration > FNG Service Configuration

configure > context context_name > fng-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-fng-service)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
aaa aggregation

Sets the system attributes for A12 aggregation for the FNG service.

**Product**
FNG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > FNG Service Configuration

'configure > context context_name > fng-service service_name'

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-fng-service)#
```

**Syntax**

```
aaa aggregation { interface type a12| destination address ipv4_address | a12-group { context name [ aaa-group name ] | aaa-group name [ context name ] } }

no aaa aggregation interface type a12

no a12 destination address ipv4_address

no aaa aggregation a12-group { context name [ aaa-group name ] | aaa-group name [ context name ] }
```

---

**aaa aggregation interface type a12**

Enables A12 aggregation functionality for the FNG service.

---

**aaa aggregation interface a12 destination address ipv4_address**

Adds a destination address for an AN-AAA server for A12 aggregation. A maximum of ten destination addresses can be configured.

---

**aaa aggregation a12-group { context name [ aaa-group name ] | aaa-group [ context name ] }**

Defines the AAA context and AAA group to be used for A12 aggregation.

If the context name and AAA group are not specified, the FNG defaults to the FNG service context and the default AAA group in that context. If the AAA group is specified but the context is not specified, the FNG uses the FNG service context and the AAA group in that context. If the AAA group is not specified and the context is specified, the FNG uses the default AAA group in that context.

---

**no aaa aggregation interface type a12**

Disables A12 aggregation functionality for the FNG service.

---

**no aaa aggregation a12-destination address ipv4_address**

Deletes the specified destination address for an AN-AAA server.
no aaa aggregation a12-group { context name [ aaa-group name ] | aaa-group [ context name ] }

Deletes the specified AAA context and AAA group to be used for A12 aggregation.

### Usage

Sets the system attributes for AAA aggregation in the FNG service.

### Example

The following command enables the A12 functionality for the FNG service:

```
aggregation interface type a12
```
aaa authentication

Specifies the AAA group to use for FAP authentication.

**Product**
FNG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > FNG Service Configuration
configure > context context_name > fng-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-fng-service)#

**Syntax**

```
aaa authentication { context-name name aaa-group name | context-name name aaa-group name }
```

```no aaa authentication```

Removes any existing authentication configuration.

```
context-name name aaa-group name
```

Specifies the context name and the AAA group name configured in the context for FAP authentication.

- **context-name name**: Specifies the context where the AAA server group is defined as an alphanumeric string of 1 through 79 characters.
- **aaa-group name**: Specifies the name of the AAA group to be used for authentication as an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to specify that during IPSec session establishment using IKEv2 setup, the FNG will use Radius AAA for FAP authentication.

**Example**

Use the following to configure device authentication for an AAA group named *aaa-10* in the FNG context named *fng1*:

```
aaa authentication context-name fng1 aaa-group aaa-10
```
bind

bind

Binds the FNG service IP address to a crypto template and specifies the maximum number of sessions the FNG service supports.

Product
FNG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > FNG Service Configuration

configure > context context_name > fng-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-fng-service)#

Syntax

bind address ipv4_address { crypto-template string }[ max-sessions number ]

no bind

no bind

Removes a previously configured binding.

address ipv4_address

Specifies the IPv4 address of the FNG service.

crypto-template string

Specifies the name of the crypto template to be bound to the FNG service.

string is any value from 0 - 127 alpha and/or numeric characters.

max-sessions number

Specifies the maximum number of sessions to be supported by the FNG service as an integer from 0 through 1000000. Default: 1000000

If the max-sessions value is changed on an existing system, the new value takes effect immediately if it is higher than the current value. If the new value is lower than the current value, existing sessions remain established, but no new sessions are permitted until usage falls below the newly-configured value.

Usage

Binds the IP address used as the connection point for establishing the IKEv2 sessions to a crypto template. It can also define the maximum number of sessions the FNG can support.

Example

The following command binds an FNG service with an IP address of 10.2.3.4 to the crypto template named T1 and sets the maximum number of sessions to 500000:

bind address 10.2.3.4 crypto-template T1 max-sessions 500000
default

Sets or restores the default condition for the selected parameter.

**Product**
FNG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > FNG Service Configuration

```
configure > context context_name > fng-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-fng-service)#
```

**Syntax**

```
default { { aaa attribute 3gpp2-service-option } | duplicate-session-detection | ip source-violation { drop-limit | period } | setup-timeout | subscriber name }
```

---

**aaa attribute 3gpp2-service-option**

Sets or restores the default value of 4095.

---

**duplicate-session-detection**

Sets or restores the default option for duplicate session detection to be fapid-based.

---

**ip source-violation { drop-limit | period }**

Sets or restores the IP source violation detection defaults, as follows:

- **drop-limit**: Sets or restores the maximum number of IP source violations within the detection period before dropping the call to the default value of 10.
- **period**: Sets or restores the detection period for IP source violations to the default value of 120 seconds.

---

**setup-timeout**

Sets or restores the maximum time allowed for session setup to the default value of 60 seconds.

---

**subscriber name**

Sets or restores the name of the default subscriber.

The name is a string of 1-127 characters.

---

**username mac-address-stripping**

The default behavior is to disable stripping the MAC address from the username.

---

**Usage**

Configures the default settings for a given parameter.

---

**Example**

Configures the default settings for a given parameter.
Use the following command to set the maximum time allowed for session setup to the default value of 60 seconds:

```
default setup-timeout
```
**duplicate-session-detection**

Configures the FNG to detect duplicate call sessions based on Femtocell Access Point (FAP) ID and to clear old call information.
This feature is disabled by default.

**Product**
FNG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > FNG Service Configuration

configure > context context_name > fng-service service_name

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-fng-service)#`

**Syntax**

```plaintext
duplicate-session-detection { fapid-based }
no duplicate-session-detection
default duplicate-session-detection
```

- **fapid-based**
  Sets the FNG to detect duplicate call sessions based on the FAP ID.

- **no duplicate-session-detection**
  Disables duplicate session detection.

- **default duplicate-session-detection**
  Sets or restores the default option for duplicate session detection to be fapid-based.

**Usage**

By default, duplicate session detection is disabled. Use this command to enable this feature. It applies only to calls established after the feature has been enabled.

The following command enables duplicate session detection based on FAP ID:

```plaintext
duplicate-session-detection fapid-based
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
end
```

**Usage**

Use this command to return to the Exec mode.
**exit**

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
exit

**Usage**
Use this command to return to the parent configuration mode.
ip source-violation

Sets the parameters for IP source validation. Source validation is useful if packet spoofing is suspected or for verifying packet routing and labeling within the network.

Source validation requires the source address of received packets to match the IP address assigned to the subscriber (either statically or dynamically) during the session.

Product
FNG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > FNG Service Configuration
configure > context context_name > fng-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-fng-service)#

Syntax

ip source-violation { clear-on-valid-packet | drop-limit num | period secs }

no ip source-violation clear-on-valid-packet

clear-on-valid-packet

Configures the service to reset the drop-limit counters upon receipt of a properly addressed packet. Default: disabled

drop-limit num

Sets the maximum number of allowed IP source violations within the detection period before dropping a call as an integer from 1 through 1000000. Default: 10

period secs

Sets the detection period (in seconds) for IP source violations as an integer from 1 through 1000000. Default: 120

Usage

This function allows the operator to configure the network to prevent problems such as when a user gets handed back and forth between two gateways a number of times during a handoff scenario. When a subscriber packet is received with a source IP address violation, the system increments the IP source violation drop-limit counter and starts the timer for the IP source violation period. Every subsequent packet received with a bad source address during the IP source violation period causes the drop-limit counter to increment. For example, if the drop-limit is set to 10, after 10 source violations, the call is dropped. The detection period timer continues to count throughout this process.

Example
The following command sets the drop limit to 15 and leaves the other values at their default values:

   ip source-violation drop-limit 15
**setup-timeout**

Specifies the maximum time allowed to set up a session in seconds.

**Product**
FNG

**Privilege**
Security-Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > FNG Service Configuration
`configure > context context_name > fng-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-fng-service)#
```

**Syntax**

```
setup-timeout integer

default setup-timeout
```

- `setup-timeout integer`
  Sets the session setup timer (in seconds) as an integer from 2 through 300. Default: 60

- `default`
  Sets or restores the default session setup timer value to 60 seconds.

**Usage**

The FNG clears both the user session and tunnels if a call does not initiate successfully before the session setup timer expires.

**Example**

The following command sets the session setup timeout value to the default value of 60 seconds:

```
default setup-timeout
```
Chapter 139
FTP Configuration Mode Commands

The FTP Configuration Mode is used to manage the FTP server options for the current context.

Mode

Exec > Global Configuration > Context Configuration > FTP Configuration

configure > context context_name > server ftpd

Entering the above command sequence results in the following prompt:

[local]host_name(config-ftpd)#

⚠️ **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Use this command to return to the parent configuration mode.
max servers

Configures the maximum number of FTP servers that can be started within any 60 second interval. If this limit is reached, the system waits two minutes before trying to start any more servers.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > FTP Configuration

configure > context context_name > server ftpd

Entering the above command sequence results in the following prompt:

[local]host_name(config-ftp)d#

Syntax

max servers count

count

Default: 40
Specifies the maximum number of servers that can be spawned in any 60-second interval. count must be an integer from 1 through 100.

Usage
Set the number of servers to tune the system response as a heavily loaded system may need more servers to support the incoming requests.
The converse would be true as well in that a system can benefit by reducing the number of servers such that FTP services do not cause excessive system impact to other services.

Example

max servers 50
timeout

Configures the client idle timeout before an FTP session is automatically closed.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > FTP Configuration

```
configure > context context_name > server ftpd
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ftp)
```

**Syntax**

```
timeout seconds
```

- **seconds**
  - Default: 900
  - Specifies the number of seconds of inactivity before an FTP session is automatically closed. `seconds` must be an integer from 10 through 86400.

**Usage**

Adjust the session timeout to fine tune the system. FTP session resources can be released sooner to support additional requests by adjusting the timeout to a smaller value.

**Example**

```
timeout 300
```
Chapter 140
GGSN Service Configuration Mode Commands

The Gateway GPRS Support Node (GGSN) Configuration Mode is used to create and manage GGSN services within the current context.

Mode

Exec > Global Configuration > Context Configuration > GGSN Service Configuration

classic > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ggsn-service)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
accounting

Configures the name of the context configured on the system that processes accounting for PDP contexts handled by this GGSN service.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ggsn-service)#

Syntax

accounting context context_name

no accounting context

no

Removes a previously configured accounting context.

context_name

Specifies the name of the context to be used for accounting. context_name must be an alphanumeric string of 1 through 79 characters that is case sensitive.

Usage

By default, the system attempts to use the same context as the one in which the GGSN service is configured for accounting purposes. This command can be used to either change the system’s default behavior, or allow GPRS Tunneling Protocol Prime (GTPP) accounting to a charging gateway (CG).

By default when GTPP accounting is used, accounting records will be sent to the accounting servers configured in whichever context the GGSN service is configured. This command may be used to override that default.

Example

The following command configures the GGSN service’s accounting context to be plmn1:

accounting context plmn1
**associate gtpu-service**

This command associates a previously configured GTP-U service to bind the GGSN service with a peer. A GTP-U service must be configured in Context Configuration mode before using this configuration.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

`configure > context context_name > ggsn-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ggsn-service)#
```

**Syntax**

```
associate gtpu-service svc_name
noassociate gtpu-service
```

**no**

Removes the associated GTP-U service from this GGSN service configuration.

```
svc_name
```

Identifies the name of the GTP-U service preconfigured in Context Configuration mode to associate with a GGSN service. *svc_name* is an alphanumeric string from 1 through 63 characters.

**Usage**

Use this command to configure GTP-U data plan between GGSN service and peer node. The service defined for GTP-U can be configured in Context configuration mode.

**Example**

Following command associates GTP-U service named *gtpu-hnb1* with specific GGSN service.

```
associate gtpu-service gtpu-hnb1
```
associate peer-map

This command associates a previously configured GGSN peer-map in LTE Policy Configuration mode with GGSN service. A peer-map must be configured before using this configuration.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ggsn-service)#

Syntax

associate peer-map peer_map_name

no associate peer-map

no

Removes the associated Peer-Map from this GGSN service configuration.

peer_map_name

Identifies the name of the Peer Map preconfigured in LTE-Policy Configuration mode to associate with a GGSN service. peer_map_name is an alphanumeric string from 1 through 63 characters.

Usage

Use this command to associate Peer Map with GGSN service. The peer-profile associated with peer map can be configured in GGSN Peer-Profile configuration mode.

Important: When there is no association of peer-map in any of the service, then “default” peer profile of the corresponding service-interface type shall be applied except for GTP-C parameters. Also GTP-C parameters configuration shall be applied from GG service level configuration for GGSN. A maximum of 1024 peer map rules can be configured on one system.

Example

Following command associates Peer Map named ggsn_peer_map1 with specific GGSN service.

associate ggsn_peer_map1
associate pgw-service

This command enables a previously configured P-GW service to which handover will be done by the GGSN service. The P-GW service must be configured in Context Configuration mode before using this configuration.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

execute > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ggsn-service)#

Syntax

associate pgw-service svc_name

no associate pgw-service

no

Removes the associated P-GW service from this GGSN service configuration.

svc_name

Identifies the name of the P-GW service preconfigured in Context Configuration mode to which handover will be done.
The svc_name must be an alphanumeric string from 1 through 63 characters.

Usage

Use this command to allow enabling/disabling bearer handover from GGSN to a P-GW service. The service defined for P-GW can be configured in Context configuration mode.
The P-GW’s eGTP service should have the same bind address as GGSN service and P-GW and GGSN should share same GTP-U, otherwise handover will fail.

Example

Following command enables P-GW service named pgw-test handover with specific GGSN service.

associate pgw-service pgw-test
**authorize-with-hss**

This command enables or disables subscriber session authorization via a Home Subscriber Server (HSS) over an S6b Diameter interface. This feature is required to support the interworking of GGSN with P-GW and HA.

**Product**

GGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > GGSN Service Configuration

`configure > context context_name > ggsn-service service_name`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-ggsn-service)#`

**Syntax**

`authorize-with-hss [ report-ipv6-addr ]`

`[ default | no ] authorize-with-hss`

- **no**
  
  Disables the default authorization of subscriber over S6b interface. Resets the command to the default setting of “authorize locally” from an internal APN authorization configuration.

- **report-ipv6-addr**
  
  Enables the IPv6 address reporting through Authorization-Authentication-Request (AAR) towards the S6b interface.

**Usage**

Use this command to enable/disable the authorization support for subscriber over S6b interface, which is used between GGSN and the 3GPP AAA to exchange the information related to charging, P-CSCF discovery, etc. By use of this feature allows the GGSN service to interact with HSS over S6b interface through Diameter configuration which is already configured on the system.

**Important:** Diameter configuration must be available before enabling this command. For more information of Diameter interface configuration, refer Diameter Endpoint Configuration Mode Commands chapter.

**Important:** This command is a license-enabled feature.

**Example**

The following command enables the subscriber authorization via an HSS over an S6b Diameter interface to provide session interoperability between GGSN and PGW and HA in this GGSN service:

`authorize-with-hss`
bind

bind the GGSN service to a logical IP interface serving as the Gn interface. Specifies the maximum number of subscribers that can access this service over the interface.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name] host_name(config-ggsn-service)#

Syntax

bind address ip_address

no bind address ip_address

no

Removes a previously configured binding for the GGSN service.

ip_address

Specifies the IP address (address) of the interface configured as the Gn interface. ip_address is specified in IPv4 dotted-decimal notation.

Usage

Used to associate or tie the GGSN service to a specific logical IP address. The logical IP address or interface takes on the characteristics of a Gn interface. Only one interface can be bound to a service. The interface should be configured prior to issuing this command.

Example

The following command would bind the logical IP interface with the address of 192.168.3.1 to the GGSN service:

bind address 192.168.3.1

The following command disables a binding that was previously configured:

no bind address
cc behavior

Configures the 3GPP behavior bits associated with the GGSN’s charging characteristics (CC).

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ggsn-service)#

Syntax

cc behavior | no-records nr_value

{ default | no } cc behavior

no-records nr_value

Default: 0 (disabled)

Specifies the behavior bit upon which the GGSN ceases sending accounting records to a server.

nr_value can be configured to an integer from 1 through 12 corresponding to the 12 behavior bits – B1 through B12.

Usage

3GPP standards after 3GPP R98 included 12 behavior bits as part of GGSN charging characteristics. Like the charging characteristics profile index, the behavior bits are sent by the SGSN to the GGSN in the Create PDP Context request message.

This command configures the behavior bits for each of the conditions described.

Example

The following command configures a behavior bit of 10 for no-records:

cc behavior no-records 10
**cc profile**

Configures the charging characteristic (CC) profile index properties.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

`configure > context context_name > ggsn-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ggsn-service) camouflage
```

**Syntax**

```
cc profile index [ buckets number | interval time [ downlink down octets uplink up_octets | total total_octets ] | prepaid [ prohibited | use-rulebase-configuration ] | sgsns num_changes | tariff time1 mins hours [ time2 mins hours [ time3 mins hours [ time4 mins hours [ time5 mins hours [ time6 mins hours ] ] ] ] ] ] | volume [ downlink vol_down_octets uplink vol_up_octets | total total_octets ] ]
```

```
no cc profile index { buckets | interval | prepaid | sgsns | tariff | volume }
```

```
default cc profile index
```

```
no
```

Removes a previously configured profile index.

```
default
```

Returns the specified cc profile to the original default system settings.

```
index
```

Configures a profile index for the parameter to be specified. index can be configured to an integer from 0 through 15.

**Important:** 3GPP standards suggest that profile index values of 1, 2, 4, and 8 be used for hot billing, flat rate billing, prepaid billing and normal billing, respectively. A single charging characteristics profile can contain multiple behavior settings.

```
buckets number
```

Default: 4

 Specifies the number of statistics container changes due to QoS changes or tariff time that can occur before an accounting record should be closed.

`number` can be configured to an integer from 1 through 4.
```
interval time [downlink down_octets uplink up_octets | total total_octets ]
```

Specifies the normal time duration that must elapse before closing an accounting record provided that any or all of the following conditions occur:

- Downlink traffic volume is reached within the time interval
- Uplink traffic volume is reached within the time interval
- Total traffic volume (up and downlink) is reached within the time interval

`time` is measured in seconds and can be configured to an integer from 60 through 40000000.
`down_octets` is the downlink traffic volume measured in octets and can be configured to an integer from 0 through 1000000.
`up_octets` is the uplink traffic volume measured in octets and can be configured to an integer from 0 through 1000000.
`total_octets` is the total traffic volume measured in octets and can be configured to an integer from 0 through 1000000.

```
prepaid { prohibited | use-rulebase-configuration }
```

This command enables or disables prepaid for the specified profile index.
Default: N/A

- `prohibited`: Disable prepaid for the specified profile index.
- `use-rulebase-configuration`: Use the prepaid configuration in the rulebase.

```
sgsns num_changes
```

Default: 4

Specifies the number of SGSN changes (such as, inter-SGSN switchovers) resulting in a new RAI (Routing Area Identity) that can occur before closing an accounting record.
`num_changes` can be configured to an integer from 1 through 15.

```
tariff time1 mins hours time2 mins hours time3 mins hours time4 mins hours time5 mins hours time6 mins hours
```

Specifies time-of-day time values to close the current statistics container (but not necessarily the accounting record). Six different tariff times may be specified. If less than six times are required, the same time can be specified multiple times.

**Important:** The system assumes that the billing system uses the day/date to determine if the statistics container represents an actual tariff period.

For each of the different tariff times, the following parameters must be configured:

- `mins`: The minutes of the hour, an integer value from 0 to 59.
- `hours`: The hour of the day, an integer value from 0 to 23.

```
volume {downlink vol_down_octets uplink vol_up_octets | total total_octets }
```

Specifies the downlink, uplink, and total volumes that must be met before closing an accounting record.
`vol_down_octets` is measured in octets and can be configured to an integer from 100000 to 4000000000.
`vol_up_octets` is measured in octets and can be configured to an integer from 100000 to 4000000000.
`total_octets` is the total traffic volume (up and downlink) measured in octets and can be configured to an integer from 100000 to 4000000000.
Usage
Charging characteristics consist of a profile index and behavior settings. This command configures profile indexes for the GGSN’s charging characteristics. The GGSN supports up to 16 profile indexes. This command works in conjunction with the `cc-sgsn` command located in the APN Configuration Mode that dictates which CCs should be used for subscriber PDP contexts.

Example
The following command configures a profile index of 10 for tariff times of 7:00 AM and 7:30 PM:

```
cc profile 10 tariff time1 0 7 time2 30 19 time3 0 7 time4 30 19
```
**default**

Sets/restores the default value assigned for the specified parameter.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

```
configure > context context_name > ggsn-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ggsn-service)#
```

**Syntax**

```
[ default ] { cc { behavior | profile index } | echo-interval | gtpu echo-interval | gtpu reorder { context | sequence-numbers | timeout } | guard-interval | ip { local-port gtpc-v1 | qos-dscp } | max-retransmissions | plmn { unlisted-sgsn } | setup-timeout | timeout }

cc { behavior | profile index }  
Restores the GGSN’s charging characteristics parameters to the following default settings:
  • **behavior**: Restores all behavior parameters to their default values of 0 (disabled).
  • **profile**: For the specified index, the following defaults are applied:
    • buckets: 4
    • interval: Disabled
    • volume: Disabled
    • sgsns: 4
    • tariff-time: Disabled

echo-interval  
Restores the GTP echo-interval parameter to its default setting of 60.

gtpu echo-interval  
Restores the GTPU echo-interval parameter to its default setting of 60.

gtpu reorder { context | sequence-numbers | timeout }  
Restores the gtpu reordering parameters to the following default settings:
  • gtpu reorder context: Disabled
  • gtpu reorder sequence-numbers: Disabled
  • gtpu reorder timeout: 100 milliseconds
**gtpu udp-checksum insert**
Restores the GGSN gtpu udp-checksum parameter to its default setting of enabled.

**guard-interval**
Restores the GGSN guard-interval parameter to its default setting of 100.

**ip {local-port gtpc-v1 | qos-dscp }**
Restores the GGSN ip parameters to the following default setting:
- **local-port gtpc-v1**: 2123
- **qos-dscp**: conversational ef streaming af11 interactive af21 background be

**max-retransmissions**
Restores the GGSN max-retransmissions parameter to its default setting of 4.

**plmn { unlisted-sgsn }**
Restores the GGSN plmn unlisted-ggsn parameter to its default setting of reject.

**setup-timeout**
Restores the GGSN setup-timeout parameter to its default setting of 60.

**timeout**
Restores the GGSN timeout parameter to its default setting of 5.

**Usage**
After the system has been modified from its default values, this command is used to set/restore specific parameters to their default values.

**Example**
The following command restores the GGSN service’s guard interval parameter to its default setting:

```
default guard-interval```

**GGSN Service Configuration Mode Commands**

**dns-client**

This command defines the context name where a DNS client is configured. It associates an existing DNS client configuration with the GGSN to perform a DNS query for P-CSCF, if a P-CSCF query request in an AAA message is received from the Diameter node.

**Product**  
GGSN

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > Global Configuration > Context Configuration > GGSN Service Configuration  
`configure > context context_name > ggsn-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ggsn-service)#
```

**Syntax**

```
dns-client context dns_ctxt_name
{ no | default } dns-client context
```

- **no**  
  Removes the association of DNS context which was configured to perform DSN query in this GGSN service.

- **default**  
  Sets the default context for the DNS client.

- **dns_ctxt_name**  
  Specifies the name of the context in which a DNS client configuration is present. Typically this should be the same context in which this GGSN service is configured.  
  `dns_ctxt_name` is a context name and must be alphanumeric string of 1 through 79 characters.

**Usage**

Use this command to associate a DNS client configuration to perform DNS query used for the resolution of P-CSCF query received in AAA message from Diameter peer, on the basis of DNS client parameters configured in a context.  
A DNS client configuration must be present in the same context as GGSN service before enabling this command to perform DNS query for P-CSCF.

**Important:** This command is a license-enabled feature.

**Example**

The following command associates a DNS client configuration to perform DNS query for P-CSCF with this GGSN service which is configured in same context as GGSN service:
default dns-client context
echo-interval

Configures the rate at which GPRS Tunneling Protocol (GTP) v1-C Echo packets are sent from the GGSN service to the SGSN.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

Configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name] host_name(config-ggsn-service)#

Syntax

echo-interval seconds [ dynamic [ smooth-factor multiplier ] ]

{ default | no } echo-interval

default

Configures the default value (60 seconds) for echo interval.

no

Disables the sending of GTPv1-C Echo packets.

seconds

Default: 60

Specifies the frequency at which the GGSN service sends GTPv1-C Echo packets to the SGSN(s) it is configured to communicate with.

seconds is measured in seconds and can be configured to an integer from 60 through 3600.

dynamic [ smooth-factor multiplier ]

Enables the dynamic echo timer for the GTP-U service.

smooth-factor multiplier: Introduces a multiplier into the dynamic echo timer as an integer from 1 through 5. Default: 2

Usage

Use this command to adjust the rate at which the GGSN sends these packets. GTPv1-C Echo packets are used to detect whether SGSNs that the GGSN service is communicating with, has become unresponsive or has rebooted.

The system initiates this protocol for each of the following scenarios:

- Upon system boot
Upon the configuration of a new SGSN on the system using the `sgsn address` command as described in this chapter.

Upon the execution of the path failure detection policy as described in `path-failure` command of this chapter.

The echo-interval command is used in conjunction with the `max-retransmissions` and `retransmission-timeout` commands as described in this chapter. In addition to receiving an echo response for this echo protocol, if GGSN receives a Node Alive Request message or a Echo Request message from a presumed dead SGSN, it will immediately assume the SGSN is active again.

If the GGSN discovers that an SGSN has become unresponsive, it will terminate all PDP contexts that had been established with the SGSN.

**Example**

The following command configures the GGSN service to send GTP Echo packets every 120 seconds:

```
echo-interval 120
```
**echo-retransmission-timeout**

Configures the timeout for GTPv1 echo message retransmissions for this service.

**Product**
GGSN

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

```bash
configure > context context_name > ggsn-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ggsn-service)#
```

**Syntax**

```
echo-retransmission-timeout seconds
```

**default echo-retransmission-timeout**

```
default
Returns the command to its default setting of 3.
```

```
seconds
Default: 5
Configures the echo retransmission timeout, in seconds, for the GTPv1 service as an integer ranging from 1 to 20.
```

**Usage**

Use this command to configure the amount of time, in seconds, before the GTPv1 service transmits another echo request message. The value set in this command is used, as is, for the default echo. If dynamic echo is enabled (`echo-interval dynamic`) the value set in this command serves as the dynamic minimum (if the RTT multiplied by the smooth factor is less than the value set in this command, the service uses this value).

**Example**

The following command sets the retransmission timeout for echo messages to 2 seconds:

```
echo-retransmission-timeout 2
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

   end

Usage
Use this command to return to the Exec mode.
**exit**

Exits the current mode and returns to the parent configuration mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

`exit`

**Usage**

Use this command to return to the parent configuration mode.
fqdn

This command defines Fully Qualified Domain Name (FQDN) which would be used for authorization over S6b interface between GGSN and 3GPP AAA/HSS.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ggsn-service)#

Syntax

fqdn host host_name realm realm_id

{ no | default } fqdn

---

no

Removes the configured FQDN host name and realm ID from the GGSN service.

---

default

Sets the system to default mode for this command and configures the host and realm ID value to NULL.

---

host host_name

Specifies the name of the host to be used for authorization over an S6b interface to a 3GPP AAA server/HSS from the GGSN service. host_name is a unique node name for authorization over the S6b interface from this GGSN service. host_name must be an alphanumeric string of 1 through 127 characters. Punctuation marks are allowed.

---

realm realm_id

Specifies the realm as an FQDN to be used for authorization over S6b interface with 3GPP AAA server/HSS from GGSN service. The realm may typically be a company or service name. realm_id is a unique identifier configured for the authorization over S6b interface from this GGSN service, expressed as an alphanumeric string of 1 through 127 characters. Punctuation marks are allowed.

host_name

Usage

Use this command to define host and realm as the FQDN for a 3GPP AAA server/HSS that would be used for authorization over an S6b interface with the GGSN. The realm specified as an FQDN may typically be a company or service name.

By default the FQDN host and realm will be NULL.
Important: This command is a license-enabled feature.

Example

The following configures the hss1 as host name and xyz.com as realm to support authorization over an S6b from this GGSN service:

```
fqdn host hss1 realm xyz.com
```
gtpc allow-on-congestion

This command enables the prioritized handling for VoLTE/Emergency calls for the current GGSN service. This is a license-controlled feature under the license introduced for VoLTE.

Product
GGSN

Privilege
Administrator, Config Administrator

Mode
Exec > Global Configuration > Context Configuration > GGSN Service Configuration
configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ggsn-service)#

Syntax

[ no ] gtpc allow-on-congestion { apn-name [ apn_name ] | arp [ priority ] | rel99arp [ priority ] }

no
Removes the default configuration.

apn-name
Configures the GW to allow calls for this APN even under congestion. apn_name is the access point name to be prioritized. It is a string of size 1 to 64.

arp priority
Configures the GW to allow calls for this ARP even under congestion. priority is the ARP Priority Level, ranging integer 1..15

rel99arp priority
Configures the GW to allow calls for the Rel99 ARP under congestion. Rel99arp is ignored in case EARp is received. priority is the REL99ARP priority, ranging from integer 1..3

Usage

For VoLTE and Emergency calls there are certain scenarios where-in prioritized handling is needed as compared to non-VoLTE calls
When CLI is enabled:

- Under congestion scenarios, emergency calls are given priority and are accepted as much as possible
- Only 3 or less APN and ARP values can be configured for prioritized handling in congestion situation.
- On CPCReq calls having the Release 99 bearer parameter ARP(not EARp) are allowed under congestion.
Example

The following command ignores the congestion situation for apn name “intershat”:

    gtpc allow-on-congestion apn intershat
**gtpc decode-as-hex**

This command configures the GGSN to decode the MCC-MNC parameters from the User Location Information (ULI) to hexadecimal digits.

**Product**
GGSN

**Privilege**
Administrator, Config Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GGSN Service Configuration
configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ggsn-service)#
```

**Syntax**

```
[ default | no ] gtpc decode-as-hex
```

- **default**
  This CLI is disabled by default. The received MCC-MNC parameters of ULI are decoded assuming that, it contains decimal digits only.

- **no**
  Removes the default configuration.

**Usage**
The GTP parameter ULI contains encoded MCC-MNC digits. This new CLI configures GGSN to decode this MCC-MNC into hexadecimal digits. When CLI is disabled, current behavior is in effect - The received MCC-MNC is decoded assuming that, it contains decimal digits only.

When CLI is enabled and if the received MCC-MNC is valid, it is decoded into decimal digits. If the received MCC-MNC is invalid, all digits are decoded into hexadecimal digits, including filler digits, if any. Hexadecimal digits are represented using Upper Case ASCII characters (A, B, C, D, E, F).

**Example**
The following command decodes MCC-MNC as hexadecimal:

```
gtpc decode-as-hex
```
gtpc map-mbr-ambr

This command maps the Maximum Bit Rate AVP received in Update PDP Context QoS message from SGSN to Aggregate Maximum Bit Rate attribute value (AMBR), if AMBR is not received in Update PDP Context QoS message from SGSN. This command is applicable for Gn-Gp GGSN mode only and not applicable to standalone GGSN. By default this command is disabled.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ggsn-service)#

**Syntax**

```
[ default | no ] gtpc map-mbr-ambr
```

**default**
Sets the default mode to map the Maximum Bit Rate AVP received in Update PDP Context QoS message from SGSN to Aggregate Maximum Bit Rate attribute value (AMBR), if AMBR is not received in Update PDP Context QoS message from SGSN.

**no**
Removes the configured mapping of the MBR AVP received in Update PDP Context message from SGSN to AMBR attribute value.

**Usage**

Use this command to map the Maximum Bit Rate AVP received in Update PDP Context QoS message from SGSN to Aggregate Maximum Bit Rate attribute value (AMBR), if AMBR is not received in Update PDP Context QoS message from SGSN.

**Important:** To use this command event trigger for QoS-Change for session must be provisioned on PCRF.

**Example**

The following command configures the GGSN service to map the MBR received in Update PDP Context QoS message from SGSN to Aggregate Maximum Bit Rate attribute value (AMBR):

```
gtpc map-mbr-ambr
```
**gtpc nsapi-in-create-pdp-response**

This command excludes or includes the optional information element (IE) Network Service Access Point Identifier (NSAPI) within “Create PDP Context Response” messages in GTP-C.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

`configure > context context_name > ggsn-service service_name`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-ggsn-service)#`

**Syntax**

```
[ default | no ] gtpc nsapi-in-create-pdp-response
```

**default**
Sets the default mode for GTP-C messages not to include the NSAPI IE in “Create PDP Context Response” messages.

**no**
Removes the preconfigured mode for GTP-C messages; the GTP-C message will not include the NSAPI IE in “Create PDP Context Response” messages. By default it is disabled.

**Usage**
Use this command to exclude or include the NSAPI IE in “Create PDP Context Response” GTP-C messages received from the SGSN.

**Example**
The following command configures the GGSN service to include the optional NSAPI IE in “Create PDP Context Response” messages:

```
gtpc nsapi-in-create-pdp-response
```
**operator-del-cause**

This CLI will enable or disable the Cause-IE feature for Delete PDP Context Request in GGSN.

---

**Important:** This command is license dependent. For more information please contact your Cisco account representative.

---

**Product**

GGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > GGSN Service Configuration

```
    configure > context context_name > ggsn-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ggsn-service)#
```

**Syntax**

```
gtpc operator-del-cause

default gtpc operator-del-cause

no gtpc operator-del-cause
```

---

**operator-del-cause**

Enables or Disables Operator Cause-IE Behavior Feature for Delete PDP Context Request sent to delete the last PDP Context of the PDN connection. This CLI is disabled by default.

---

**default**

Sets the default mode for Operator Cause-IE Behavior Feature. By default, it is disabled.

---

**no**

Disables Operator Cause-IE Behavior Feature.

---

**Usage**

This CLI enables or disables the Cause-IE feature for Delete PDP Context Request in GGSN. The Cause-IE configuration for Delete PDP Context Request is given in the APN configuration and is also available in `clear subscribers` CLI. When this new CLI is enabled, the feature will be applied to GGSN based on the APN configuration or the `clear subscribers` CLI. This new CLI will be disabled by default.

---

**Example**

The following command enables the Cause-IE feature.

```
gtpc operator-del-cause
```
gtpc private-extension

This command includes customer-specific private extensions in GTP-C messages.

**Product**  
GGSN

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

`configure > context context_name > ggsn-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ggsn-service) #
```

**Syntax**

```
gtpc private-extension { { { focs | odb } access-list acl_name in disconnect-on-violation } | ggsn-preservation-mode | loss-of-radio-coverage | none }

default gtpc private-extension

no gtpc private-extension [ focs | ggsn-preservation-mode | loss-of-radio-coverage ]
```

---

**default**

Sets the default mode for GTP-C messages. By default it is disabled.

---

**no**

Disables the configured private extensions for GTP-C messages.

---

**{focs | odb} access-list acl_name in disconnect-on-violation**

Configures the Free-Of-Charge-Service (FOCS) and Operator Determined Barring (ODB) extensions for all packet-oriented services as defined by operators.

- **focs**: Enables or disables Free of Charge Services for the subscriber who has no credit, and also takes the access-list `acl_name` to be applied for FOCS.
- **odb**: Enables or disables “all packet oriented service barred” for the subscriber, and also takes the access-list `acl_name` to be applied for ODB.

- `acl_name` is the name of a configured access control list (ACL) for this service.

---

**Important:** These are the customer-specific keywords and need customer-specific license to use them.

---

**ggsn-preservation-mode**

Enables the processing of customer-specific private extension in Update PDP Context requests. This extension indicates whether the subscriber is active or idle, and whether RAN resources have been released. It also indicates the desired “type” of preservation mode behavior.

When `ggsn-preservation-mode` is configured, different types of accounting records are generated based on the “type” of mode. To enable the generation of different accounting records, the trigger for preservation...
mode must be configured for RADIUS or GTPP for that accounting protocol. If that trigger is not configured, there will be no change in the generation of accounting records.

**Important:** This is a customer-specific keyword and needs customer-specific license to use this feature.

**loss-of-radio-coverage**

Enables the protection against overcharging a subscriber due to loss of radio coverage (LORC) in a GGSN service. It also enables the system to understand the private extension for LORC) in GTP-C Update PDP Context messages from the SGSN.

**Important:** This is a license enabled keyword and need feature-specific license to use it.

**none**

Removes the private extensions from record which are from GTP-C messages received from the SGSN.

**Usage**

Use this command to configure the processing of private extensions within GTP-C messages received from the SGSN. It also configures the customer specific features, such as preservation mode for GGSN service. Overcharging protection (LORC) is a solution which provides the ability to accurately bill customers. This implementation is based on Cisco-specific private extension to GTP messages and/or any co-relation of G-CDRs and S-CDRs. It also does not modify any RANAP messages.

**Important:** This is a license enabled command that requires installation of feature-specific licenses to use this command.

**Example**

The following command configures the GGSN service to record the private extension for protecting the subscribers from overcharging during loss of radio coverage:

```
gtpc private-extension loss-of-radio-coverage
```
gtpc ran-procedure-ready-delay

This command configures the GGSN to enable the RAN Procedure Ready feature for the particular GGSN service and specify the timeout period for the RAN procedure timer in the GGSN. This timer starts on arrival of every secondary Create PDP Context request.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ggsn-service)#

Syntax

```
gtpc ran-procedure-ready-delay [ timeout dur ]
{ default | no } gtpc ran-procedure-ready-delay
```

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Sets the default mode of RAN Procedure Ready feature for this GGSN service. By default it is disabled.</td>
</tr>
<tr>
<td>no</td>
<td>Disables the RAN Procedure Ready feature for this GGSN service. By default it is disabled.</td>
</tr>
<tr>
<td>timeout dur</td>
<td>Specifies the timeout duration (in seconds) for the RAN procedure timer. This timer starts on the arrival of every secondary “Create PDP Context Request” message. This is an optional keyword. If no timeout period is specified, the default value is 10 seconds. dur must be an integer from 1 through 40.</td>
</tr>
</tbody>
</table>

Usage

Use this command to enable the RAN Procedure Ready feature for this GGSN service and specify the timeout period for the RAN procedure timer. This timer starts on the arrival of every secondary “Create PDP Context Request” message. The GGSN waits until the Radio Access Bearer setup is completed and “Update PDP Context Request” is sent by the SGSN. If any downlink data is received before arrival of the “Update PDP Context Request” or before timer expiry, the downlink packets will be queued or buffered. If the buffer becomes full (total buffer limit is of 1024 packets), all newly arriving packets are dropped. The RAN Procedure Ready feature supports the following scenarios when RAB setup timer starts at the GGSN.
• If the GGSN receives the “Update PDP Context Request” before timer expiry, the GGSN stops the timer, sends all the queued/buffered packets in ‘first-in first-out’ manner and disables buffering of subsequent downlink data.

• If the GGSN receives the “Update PDP Context Request” before the timer expires, it processes the “Update PDP Context Request” as usual, but does not disable the buffering of downlink data. It then waits for another “Update PDP Context Request” to come with the RAN Procedure Ready set, or waits for timer to expire.

• If the GGSN does not receive the “Update PDP Context Request” with RAN Procedure Ready set before timer expiry, the timer is fired and the GGSN starts sending all queued packets and disables buffering of subsequent downlink data (assuming that the corresponding SGSN does not support this feature).

• If the timer has expired and the GGSN receives an “Update PDP Context Request” for a secondary PDP context with or without RAN Procedure Ready bit set, the UPC will be processed normally without buffering the packets.

**Important:** This feature does not affect the Enhanced Charging Service or deep packet inspection (DPI) since the buffering of downlink data is done before sending it to an ACSMgr.

**Important:** During an SGSN handoff scenario all packets are processed normally and the downlink packets are buffered until the timer expires.

**Example**

The following command configures the GGSN service to enable the RAN Procedure Ready feature and specify the timeout period as 20 seconds for the RAN Procedure timer in GGSN:

```plaintext
gtpc ran-procedure-ready-delay timeout 20
```
**gtpc support-earp**

Enables Evolved ARP (e-ARP) support for GGSN service on Gn-Gp interface.

**Product**
GGSN

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

**Syntax**

```
[ default | no ] gtpc support-earp
```

- **no**
  Ignores E-ARP IE received in CPC/UPC Messages.

- **default**
  Sets the E-ARP support behavior to default, or disables the support.

**Usage**

NRUPC initiated by GGSN/PGW is not responded to by the SGSNs of some vendors where behavior of SGSN is not compliant to standards. To accommodate SGSN non-compliance, the GGSN/PGW software has been enhanced with CLI-controlled behavior to suppress sending of the GGSN/PGW-initiated UPC only if SGSN requested values are less than PCRF authorized bit rates and if the values of the “No QoS Negotiation” and “Upgrade QoS Supported” flags received in the SGSN-initiated Update Request does not allow change/upgrade in QoS values in Update Response. By default, this behavior is disabled and it should be enabled if interoperability issues are seen with the SGSN. When SGSN informs GGSN that, for a transaction either for Create PDP context Request or Update PDP Context Request, it(SGSN) does not support QoS-Upgrade and/or QoS-Negotiation, and if GGSN has to modify(either upgrade or degrade), QoS, then GGSN sends SGSN a response with unchanged QoS. Followed by the response, GGSN initiates a NRUPC with modified QoS. This is NRUPC for QoS-Change. To honor common flags suppress NRUPC clis are introduced. This command suppress NRUPC (for qos-change) sent from GGSN to SGSN under following condition:

- **When SGSN sends Create PDP Context Request with UQS=0.** If Upgrade QoS Supported bit of the Common Flags IE is set to 0 or the Common Flags IE is absent then the SGSN does not support QoS upgrade in Response message functionality.
- **When SGSN sends Update PDP Context Request with NQN flag = 1.**
- **When SGSN sends Update PDP Context Request QoS Update Support flag = 0**

This suppression feature works with a limited functionality as follows:

- **It works only on MBR and def-eps-qos.**
- **It holds if MBR in CPC/ UPC Request < AMBR authorized by (PCRF/MME).**
- **AMBR is not related to common flags hence no suppression on modification of AMBR.**
It doesn’t hold if MBR in CPC/ UPC Request > AMBR authorized by (PCRF/MME). NRUPC will be generated to equalize the value of MBR to AMBR.

This command enables Evolved ARP support for GGSN service on Gn-Gp interface. Changing E-ARP support for GGSN service can impact existing bearers. By default E-ARP support is disabled.

⚠️ **Caution:** Changing the E-ARP support status from ‘disable’ (default) to ‘enable’ will have less or no impact on existing calls whereas changing the E-ARP support status from ‘enable’ to ‘disable’ will have more impact on existing calls.

**Example**

The following example disables the e-ARP support:

```bash
default gtpc support-earp
```
gtpc suppress-nrupc

This command helps enabling as well as disabling the NRU PC suppression.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ggsn-service)#

Syntax

[ no ] gtpc suppress-nrupc { cpc | upc } { qos-change }

  no
  Disables the NRU PC suppression.

Usage
This command is used to enable or disable the NRU PC suppression caused by QoS change.

Example
The following example disables the NRU PC suppression using “upc” as GTP procedure:

no gtpc suppress-nrupc upc qos-change
gtpu echo-interval

This command is obsolete and now available for configuration in GTP-U service configuration mode.
guard-interval

Configures the time period after which a redundant PDP context request received from an SGSN is treated as a new request rather than a re-send of a previous request.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GGSN Service Configuration
configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ggsn-service)#

Syntax

guard-interval guard_time

{ default | no } guard-interval

default
Configures the default value for guard-interval function for the GGSN service.

no
Disables the guard-interval function for the GGSN service.

guard_time
Default: 100
Specifies the amount of time that must pass before a GGSN service treats a redundant PDP context request as a new request instead of a re-send of a previous request.
guard_time is measured in seconds and can be configured to an integer from 10 through 3600.

Usage
The guard interval is used to protect against replay attacks. Without a guard interval configured, information from a valid PDP context request could be used to gain unauthorized network access.
If the GGSN service receives a PDP context request in which the International Mobile Subscriber Identity (IMSI), the Network Service Access Point Identifier (NSAPI), the end user IP address, and the GTP sequence number are identical to those received in a previous request, the GGSN treats the new request as a re-send of the original. Therefore, information from a valid PDP context request could be collected and re-sent at a later time by an un-authorized user to gain network access.
Configuring a guard interval limits the amount of time that the information contained within a PDP context request remains valid.

Example
The following command configures the GGSN service with a guard interval of 60 seconds:
guard-interval 60
**ip local-port**

Configures the local User Datagram Protocol (UDP) port for the Gn interfaces’ GTP-C socket for GTPv1.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GGSN Service Configuration
configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ggsn-service)#
```

**Syntax**

```
ip local-port gtpc-v1 port#
default ip local-port gtpc-v1
```

**default**
`ip local-port gtpc-v1 port#`

**Usage**

By default, the GGSN service attempts to use GTPv1 when communicating with SGSNs. This parameter configures the UDP port over which the GTP control (GTP-C) sockets are sent.

If an SGSN only supports GTPv0, the GGSN service automatically switches to GTPv0 when communicating with this SGSN. In the scenario, the GGSN service communicates with the SGSN on UDP port 3386 and does not have a GTP-C socket.

**Important**: The UDP port setting on the SGSN must match the local-port setting for the GGSN service on the system in order for the two devices to communicate.

**Example**

The following command configures the GGSN service to use UDP port 2500 for exchanging GTPC sockets with SGSNs when using GTPv1:

```
ip local port 2500
```
ip qos-dscp

Configures the quality of service (QOS) differentiated service code point (DSCP) used when sending data packets over the Gn interface.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ggsn-service)#
```

**Syntax**

```
ip qos-dscp { qci { 1 { dscp } | 2 { dscp } | 3 { dscp } | 4 { dscp } | 5 { dscp } | allocation-retention-priority } | 6 { dscp | allocation-retention-priority } | 7 { dscp | allocation-retention-priority } | 8 { dscp | allocation-retention-priority } | 9 { dscp } } | gtpc } +
```

```
no ip qos-dscp { qci { 1 | 2 | 3 | 4 | 5 { allocation-retention-priority | dscp } | 6 { allocation-retention-priority | dscp } | 7 { allocation-retention-priority | dscp } | 8 { allocation-retention-priority | dscp } | 9 } | gtpc } +
```

**allocation-retention-priority**

Specifies the DSCP for interactive class if the allocation priority is present in the QOS profile.

- allocation-retention-priority can be the integer 1, 2, or 3.
- DSCP values use the following matrix to map based on traffic handling priority and Alloc/Retention priority if the allocation priority is present in the QOS profile.
- The following table shows the DSCP value matrix for allocation-retention-priority.

**Table 27. Default DSCP Value Matrix**

<table>
<thead>
<tr>
<th>Allocation Priority</th>

</tbody>
</table>
qci
Configures the QoS Class Identifier (QCI) attribute of QoS. Here the qci_val is the QCI for which the negotiate limit is being set; it ranges from 1 to 9.

dscp
Default QCI:

- 1: ef
- 2: ef
- 3: af11
- 4: af11
- 5: ef
- 6: ef
- 7: af21
- 8: af21
- 9: be

Specifies the DSCP for the specified traffic pattern. dscp can be configured to any one of the following:

<table>
<thead>
<tr>
<th>af11: Assured Forwarding 11 per-hop-behavior (PHB)</th>
<th>af32: Assured Forwarding 32 PHB</th>
</tr>
</thead>
<tbody>
<tr>
<td>af12: Assured Forwarding 12 PHB</td>
<td>af33: Assured Forwarding 33 PHB</td>
</tr>
<tr>
<td>af13: Assured Forwarding 13 PHB</td>

</tr>
<tr>
<td>af22: Assured Forwarding 22 PHB</td>
<td>af43: Assured Forwarding 43 PHB</td>
</tr>
<tr>
<td>af23: Assured Forwarding 23 PHB</td>
<td>be: Best effort forwarding PHB</td>
</tr>
<tr>
<td>af31: Assured Forwarding 31 PHB</td>
<td>ef: Expedited forwarding PHB</td>
</tr>
</tbody>
</table>

More than one of the above keywords can be entered within a single command.

Usage
DSCP levels can be assigned to specific traffic patterns in order to ensure that data packets are delivered according to the precedence with which they are tagged. The diffserv markings are applied to the outer IP header of every GTP data packet. The diffserv marking of the inner IP header is not modified. The traffic patterns are defined by QCI (1 to 9). Data packets falling under the category of each of the traffic patterns are tagged with a DSCP that further indicate their precedence as shown in the following tables:
Table 28. Class structure for assured forwarding (af) levels

The DSCP level can be configured for multiple traffic patterns within a single instance of this command. The no ip qos command can be issued to remove a QOS setting and return it to it’s default setting.

Example

The following command configures the DSCP level for QCI to be Expedited Forwarding, ef:

```
ip qos-dscp qci 1 ef
```
**max-contexts**

Configures the maximum Primary, Secondary per Primary, and PPP context limits for the GGSN service.

**Product**

GGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > GGSN Service Configuration

```bash
configure > context context_name > ggsn-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ggsn-service)#
```

**Syntax**

```
max-contexts { max-primary max_pri_number | max-sec-per-primary max_sec_number | ppp-pdp-contexts context_number }
```

```bash
default max-contexts
default
```

Configures the default value for maximum contexts for the GGSN service.

```bash
max-primary max_pri_number
```

Configures maximum primary PDP context allowed for this service. This includes PPP contexts also. `max_pri_number` can be configured to an integer from 0 through 4000000.

```bash
max-sec-per-primary max_sec_number
```

Default: 10

Indicates the maximum number of times that GTP control packets are retransmitted. `max_sec_number` can be configured to an integer from 0 through 10.

```bash
ppp-pdp-contexts context_number
```

Configures maximum PPP pdp context allowed for this service. `context_number` can be configured to an integer from 0 through 4000000.

**Usage**

This command is used to limit the number of primary contexts including PPP contexts, number of secondary contexts per primary context, and PPP contexts per GGSN service.

**Example**

The following command configures the limits for primary, secondary contexts per primary, as well as the PPP contexts for a GGSN service:

```
max-contexts max-primary 4000000 max-sec-per-primary 10 ppp-pdp-contexts 250000
```
max-retransmissions

Configures the maximum number of times that GTP control packets are retransmitted to an SGSN before it marks it unreachable.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ggsn-service)#

Syntax

max-retransmissions max_number

default max-retransmissions

default

Configures the default value for maximum retries for GTP control packets for the GGSN service.

max_number

Default: 4
Indicates the maximum number of times that GTP control packets are retransmitted.

max_number can be configured to an integer from 0 through 15.

Usage

This command is used in conjunction with the timeout command to control the retransmission of GTP control packets when no response is received from an SGSN. It is equivalent to the N3-REQUESTS parameter discussed in 3GPP TS 29.060.
If no response is received from the SGSN prior to the expiration of the timeout value, the GTP control packets are re-sent by the GGSN. This process occurs as many times as allowed by the configuration of this command.
If the max-retransmissions value is exceeded, the GGSN records a “Path Failure” for that SGSN and releases all PDP contexts associated with it.

Example

The following command configures the maximum number of retransmissions to 8:

max-retransmissions 8
mbms policy

This command enables/disables the Multimedia Broadcast Multicast Services (MBMS) user service support for multicast and/or broadcast mode. It also specifies the policy for MBMS user service mode.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ggsn-service)#

Syntax

mbms policy { multicast broadcast | none }

{ no | default } mbms policy

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
<tbody>
<tr>
<td>Removes or disables the configured MBMS support for multicast and/or broadcast mode in this GGSN service.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restores the default mode of MBMS support in this GGSN service.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>multicast broadcast</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enables the MBMS support and configures the policy for multicast and broadcast of user service.</td>
</tr>
</tbody>
</table>

Usage

Use this command to enable/disable the MBMS user service support for Multicast and/or Broadcast mode. It also specifies the policy for MBMS user service mode.

Example

The following command enables MBMS support in this GGSN service:

    mbms policy multicast broadcast
**newcall**

This command enables or disables the new call related behavior of this GGSN service when duplicate sessions with the same IP address request are received. This feature is required to support interworking with P-GW and HA.

**Product**

GGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > GGSN Service Configuration

```
configure > context context_name > ggsn-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ggsn-service)#
```

**Syntax**

```
newcall duplicate-subscriber-requested-address { accept | reject }

default newcall duplicate-subscriber-requested-address
```

**default**

Restores the default mode for new call session with the same address request received in this GGSN service. It rejects calls with duplicate address requests.

**accept**

Sets the system to "accept" another session using the same IP address for a new call. The new session will be created and the old session will be torn down.

Default: Disabled

**reject**

Rejects new calls with duplicate address requests. This is the default behavior.

Default: Enabled

**Usage**

Use this command to enable or disable new call connections when the UE is not able to gracefully disconnect from the Enterprise PDN before attempting to reconnect via another access method. When enabled this command tears down the old session in order to accept the new connection with the same IP address assignment.

This feature also allows the GGSN to accept a request for a static subscriber address, even if the address is already used by another session. If this feature is not enabled, a new request with the same IP address for another session will be rejected.

**Important:** This command is a license-enabled feature.
Example

The following command allows the GGSN to accept the duplicate call session request with the same IP address:

```
newcall duplicate-subscriber-requested-address accept
```
path-failure

Determines the GTP path-failure behavior on echo/non-echo messages.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GGSN Service Configuration
configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ggsn-service)#

Syntax

path-failure detection-policy gtp { echo [ non-echo ] | non-echo [ echo ] }

{ no | default } path-failure detection-policy

| no |
| No defined detection policy means path-failures are not detected. |

| default |
| Sets the path-failure detection-policy to GTP in echo mode. |

| detection-policy gtp {echo [ non-echo ] | non-echo [ echo ] } |
| Detection-policy is the policy to be used when path-failure is in active state. GTP messages are either gtp(u) (user) or gtp(c) (control) type, and the gtp keyword takes either echo or non-echo as message type. |
| echo: gtp(u) or gtp(c) message. |
| non-echo: a message type other than gtp(u) or gtp(c). |

Usage
Under current circumstances, a GGSN shuts down the GTP tunnel if the associated SGSN does not respond to multiple retries of an echo or non-echo message from the GGSN. In this way, a single call failure could be responsible for the loss of all active calls in the tunnel.
This is also an issue when echo is disabled, or when there is very little traffic on the SGSN and the GGSN is configured with large echo intervals.
This behavior adversely impacts the user experience because the customer has to reconnect every time this happens with their SGSN.

Example
The following example detects path failures when the SGSN fails to respond to multiple echo message retries:

path-failure detection-policy gtp echo
The following example turns off path-failure detection. On timeout of gtp(c) message retries, the particular context will be purged:

```bash
no path-failure detection-policy
```
plmn id

Configures the GGSN’s public land mobile network (PLMN) identifiers. Up to five PLMN IDs can be configured for each GGSN service.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ggsn-service)#

Syntax

plmn id mcc mcc_value [ primary ]

no plmn id mcc [ mnc mnc_value ]

no

Removes a previously configured PLMN identifier for the GGSN service.

mcc mcc_value

Specifies the mobile country code (MCC) portion of the PLMN’s identifier.
mcc_number is the PLMN MCC identifier and can be configured to an integer between 100 and 999.

mnc mnc_value

Specifies the mobile network code (MNC) portion of the PLMN’s identifier. This option is optional.
mnc_number is the PLMN MNC identifier and can be configured to any 2- or 3-digit integer from 00 through 999.

primary

When multiple PLMN IDs are configured, the primary keyword can be used to designate one of the PLMN IDs to be used for the AAA attribute (3GPP-GGSN-MCC-MNC).

Usage

The PLMN identifier is used by the GGSN service to determine whether or not a mobile station is visiting, roaming, or home. Multiple GGSN services can be configured with the same PLMN identifier. Up to five PLMN IDs can be configured for each GGSN Service.

Example

The following command configures the PLMN identifier with an MCC of 462 and MNC of 2:

plmn id mcc 462 mnc 02
plmn unlisted-sgsn

Configures the GGSN’s policy for handling communications from SGSNs with which it is not configured to communicate.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GGSN Service Configuration
configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ggsn-service)#
```

**Syntax**

```
default plmn unlisted-sgsn

plmn unlisted-sgsn [[ foreign [ disable-gtpc-echo | rat-type { GAN | GERAN | HSPA | UTRAN | WLAN } ] | reject-foreign-subscriber ] | home [ disable-gtpc-echo | rat-type { GAN | GERAN | HSPA | UTRAN | WLAN } ] | mcc mcc_value mnc mnc_value [ disable-gtpc-echo | reject-foreign-subscriber ]][ rat-type { GAN | GERAN | HSPA | UTRAN | WLAN } ] | reject ] ]
```

---

**default**

Resets configured parameters to their default settings.

---

**foreign**

Default: Disabled
Specifies that the GGSN service accepts messages from SGSNs that are not configured within the service using the `sgsn address` command.
This keyword also dictates that unlisted SGSNs are treated as if they belong to a foreign PLMN. Therefore, PDP contexts originating from them are treated as visiting or roaming.

---

**mcc** mcc_value

Specifies the mobile country code (MCC) portion of the PLMN’s identifier.
mcc_value is the PLMN MCC identifier and can be configured to an integer from 100 through 999.

---

**mnc** mnc_value

Specifies the mobile network code (MNC) portion of the PLMN’s identifier.
mnc_value is the PLMN MNC identifier and can be configured to a 2- or 3-digit integer from 00 through 999.

---

**disable-gtpc-echo**

Default: Send GTPC Echo messages to unlisted SGSNs.
When this keyword is specified, GTPC echo messages are not sent to unlisted SGSNs.

**reject-foreign-subscriber**

Default: Disabled

Specifies that incoming calls from foreign subscribers are rejected.

**home**

Default: Disabled

Specifies that the GGSN service accepts messages from SGSNs that are not configured within the service using the `sgsn address` command.

This keyword also dictates that unlisted SGSNs are treated as if they belong to the GGSN service's home PLMN.

**rat-type { GAN | GERAN | HSPA | UTRAN | WLAN }**

This keyword configures the type of radio access technology.

- **GAN**: Specifies the Generic Access Network type of Radio Access Technology (RAT).
- **GERAN**: Specifies the GSM EDGE Radio Access Network type of RAT.
- **HSPA**: Specifies the High Speed Packet Access type of RAT.
- **UTRAN**: Specifies the UMTS Terrestrial Radio Access Network type of RAT.
- **WLAN**: Specifies the Wireless Local Access Network type of RAT.

**reject**

Default: Enabled

Specifies that the GGSN service rejects messages from SGSNs that are not configured within the service using the `sgsn address` command.

When the GGSN service rejects the message(s), it returns a cause code of No Resources 199 (C7H, No resources available).

**Usage**

This command works in conjunction with the `sgsn` command that configures the GGSN service to communicate with specific SGSNs. Any messages received from SGSNs not configured in that list are subject to the rules dictated by the `unlisted-sgsn` policy.

**Example**

The following command configures the GGSN service to accept messages from unlisted SGSNs and treat the SGSN as if it is on the GGSN's home network:

```
plmn unlisted-sgsn accept home
```
policy

Specifies the reject code to be used in the “Create PDP Context” response message when a RADIUS server timeouts.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ggsn-service)#

Syntax

policy { accounting-server-timeout use-reject-code { system-failure | no-resources } | authentication-server-timeout use-reject-code { system-failure | user-authentication-failure } }

default policy { authentication-server-timeout | accounting-server-timeout }

default
Restores the specified parameter to its default setting.

accounting-server-timeout use-reject-code { system-failure | no-resources }
Default: no-resources
Specifies the reject code used by the GGSN if communication with an accounting server times out. The possible reject codes are:
- system-failure (204 (CCH))
- no-resources (199 (C7H))

authentication-server-timeout use-reject-code {system-failure | user-authentication-failure }
Default: user-authentication-failure
Specifies the reject code used by the GGSN if communication with an authentication server times out. The possible reject codes are:
- system-failure (204 (CCH))
- user-authentication-failure (209 (D1H))

Usage

This command is used to configure the cause code used by the GGSN if communication with either a RADIUS authentication or accounting server times out. When this parameter is used in conjunction with Radius accounting servers, the response is only set if a flag is configured in the APN Delay GTP Response, only after getting a response to the Accounting Start.
Example

The following command configures the GGSN response to a RADIUS authentication server timeout to be `system-failure`:

```
policy authentication-server-timeout use-reject-code system-failure
```
retransmission-timeout

Configures the timeout period in between retransmissions of GTP control packets. This timeout configuration is not applicable on Echo Request retransmission.

**Important:** In 17.3 and later releases, this command has been deprecated.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

```bash
configure > context context_name > ggsn-service service_name
```

Entering the above command sequence results in the following prompt:

```bash
[context_name]host_name(config-ggsn-service)#
```

**Syntax**

```
retransmission-timeout retransmit_time
```

**default**

```
default retransmission-timeout
```

**default**

Configures the default time interval that must pass without an SGSN response before the GGSN service retransmits GTP control packets.

**retransmit_time**

Default: 5

Specifies the amount of time that must pass without an SGSN response before the GGSN service retransmits GTP control packets.

`retransmit_time` is measured in seconds and can be configured to an integer from 1 through 20.

**Usage**

This command is used in conjunction with the `max-retransmissions` command to control the retransmission of GTP control packets when no response is received from an SGSN.

If no response is received from the SGSN prior to the expiration of the timeout value, the GTP control packets are re-sent by the GGSN. This process occurs as many times as allowed by the configuration of the `max-retransmissions` command.

If the `max-retransmissions` value is exceeded within the `retransmission-timeout` period, the GGSN records a “Path Failure” for that SGSN and releases all PDP contexts associated with it.

**Important:** This retransmission timeout configuration in not applicable for Echo Requests message retransmission. Echo are sent/retransmitted every echo interval, which can be configured separately.
Example

The following command configures a timeout value of 20 seconds:

```
retransmission-timeout 20
```
setup-timeout

Configures the maximum amount of time the GGSN service allows for the setting up of PDP contexts.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

```plaintext
configure > context context_name > ggsn-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ggsn-service)##
```

**Syntax**

```plaintext
setup-timeout setup_time

default setup-timeout
```

**default**

Configures the default maximum amount of time the GGSN service allows for the setting up of PDP contexts.

**setup-time**

Default: 60

Specifies the maximum amount of time the GGSN service allows for the setting up of PDP contexts. 

*setup-time* is measured in seconds and can be configured to an integer from 1 through 6000.

**Usage**

Use this command to limit the amount of time allowed for setting up PDP contexts. If the PDP context is not setup within the configured time frame, the GGSN service rejects the PDP context with a cause code of 199 (C7H, No resources available).

**Example**

The following command allows a maximum of 120 seconds for the setting up of PDP contexts:

```plaintext
setup-timeout 120
```
sgsn address

Configures the SGSNs that this GGSN service is allowed to communicate with.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

```
configure > context context_name > ggsn-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ggsn-service)#
```

**Syntax**

```
sgsn address { { ip_address [ subnetmask netmask ] } | ip_address/netmask } [ plmn-
foreign [ reject-foreign-subscriber ] ] [ mcc mcc_code mnc mnc_code [ reject-foreign-
subscriber ] ] [ rat-type { GAN | GERAN | HSPA | UTRAN | WLAN } ] [ description
description ] [ disable-gtpc-echo ]
```

```
no sgn { address ip_address [ subnetmask netmask ] }
```

**no**
Removes a specific SGSN from the list or all configured SGSNs.

**address**
Configures the IP address of the SGSN.
*ip_address* must be expressed in IPv4 dotted-decimal notation.

**subnetmask**
Configures the subnet mask of the SGSN.
*netmask* must be expressed in IPv4 dotted-decimal notation.

**disable-gtpc-echo**
Default: Send GTPC Echo messages to unlisted SGSNs.
When this keyword is specified, GTPC echo messages are not sent to unlisted SGSNs.

**plmn-foreign**
Indicates whether or not the SGSN belongs to a foreign public land mobile network (PLMN).

**reject-foreign-subscriber**
Default: Disabled
Specifies that incoming calls from foreign subscribers are rejected.
mcc mcc_code

Specifies the mobile country code (MCC) portion of the PLMN’s identifier. 
mcc_code is the PLMN MCC identifier and configured as an integer from 100 through 999.

mnc mnc_code

Specifies the mobile network code (MNC) portion of the PLMN’s identifier. 
mnc_code is the PLMN MNC identifier and configured as a 2- or 3-digit integer from 00 through 999.

rat-type {GAN | GERAN | HSPA | UTRAN | WLAN }

This keyword configures the type of radio access technology. 
GERAN: Specifies the GSM EDGE Radio Access Network type of RAT. 
HSPA: Specifies the High Speed Packet Access type of RAT. 
UTRAN: Specifies the UMTS Terrestrial Radio Access Network type of RAT. 
WLAN: Specifies the Wireless Local Access Network type of RAT.

description description

Add description field to the SGSN entry in GGSN service. 
description is an alphanumeric string of 1 through 63 characters.

Usage

Use this command to configure a list of SGSNs that the GGSN service is to communicate with. This command can be entered multiple times to configure multiple SGSNs.

Important: The GGSN only communicates with the SGSNs configured using this command unless a plmn-policy is enabled to allow communication with unconfigured SGSNs. PLMN policies are configured using the plmn unlisted-sgsn command.

Example

The following command configures the GGSN to communicate with an SGSN on a foreign PLMN with an IP address of 192.168.1.100 and subnet mask of 255.255.255.0:

```
sgsn address 192.168.1.100 subnetmask 255.255.255.0 plmn-foreign
```
sgsn define-multiple-address-group

This command defines an SGSN Multiple Address Group and enters SGSN Multiple Address Group Configuration mode. Whenever there is a change in the control address in a GTPC UPC message, it is treated as an inter-SGSN handoff because an SGSN is usually identified uniquely by a single IP-address. This command supports a multiple address group feature which allows you to specify a set of addresses that specify a single SGSN. When a UPC handoff is received from any address in the group, it is treated as an intra-SGSN handoff.

Product

GGSN

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > GGSN Service Configuration
configure > context context_name > ggsn-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ggsn-service)#

Syntax

sgsn define-multiple-address-group grp_name [ -noconfirm ]

no sgsn define-multiple-address-group grp_name

no

Removes a specific SGSN Multiple Address Group from the list GGSN service configuration.

 grp_name

Specifies the name of an SGSN multiple address group to create or configure.
 grp_name is an alphanumeric string from 1 through 63 characters.

- noconfirm

Specifies that the command must execute without any additional prompt and confirmation from the user.

Usage

Use this command to create or configure an SGSN Multiple Address Group that the GGSN service is to communicate with. This command can be entered multiple times to configure multiple SGSN Multiple Address Groups.

Example

The following command creates an SGSN Multiple Address Group named sgsngrpl and enters SGSN Multiple Address Group Configuration mode:

sgsn define-multiple-address-group sgsngrpl
**sgsn multiple-address-group**

Configures the SGSN multiple address groups that this GGSN service is allowed to communicate with.

**Product**

GGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > GGSN Service Configuration

```plaintext

```

Entering the above command sequence results in the following prompt:

```plaintext
[context_name]host_name(config-ggsn-service)#
```

**Syntax**

```plaintext
sgsn multiple-address-group grp_name [ disable-gtpc-echo ] [ mcc mcc_code mnc mnc_code [ reject-foreign-subscriber ] ] [ plmn-foreign [ reject-foreign-subscriber ] [ rat-type { GAN | GERAN | HSPA | UTRAN | WLAN } ] [ description description ]
```

```plaintext
no sgsn multiple-address-group grp_name
```

---

**no**

Removes a specific SGSN multiple address group from the list of configured SGSN multiple address groups.

**grp_name**

Specifies the name of a configured SGSN multiple address group to use.

**disable-gtpc-echo**

Default: Send GTPC Echo messages to unlisted SGSNs. When this keyword is specified, GTPC echo messages are not sent to unlisted SGSNs.

**plmn-foreign**

Indicates whether or not the SGSN multiple address group belongs to a foreign public land mobile network (PLMN).

**reject-foreign-subscriber**

Default: Disabled
Specifies that incoming calls from foreign subscribers are rejected.

**mcc mcc_code**

Specifies the mobile country code (MCC) portion of the PLMN’s identifier. `mcc_code` is the PLMN MCC identifier and can be configured to an integer from 100 through 999.
mnc mnc_code

Specifies the mobile network code (MNC) portion of the PLMN’s identifier.

*mnc_code* is the PLMN MNC identifier configured as a 2- or 3-digit integer from 00 through 999.

rat-type { GAN | GERAN | HSPA | UTRAN | WLAN }

This keyword configures the type of radio access technology.

GERAN: Specifies the GSM EDGE Radio Access Network type of RAT.
HSPA: Specifies the High Speed Packet Access type of RAT.
UTRAN: Specifies the UMTS Terrestrial Radio Access Network type of RAT.
WLAN: Specifies the Wireless Local Access Network type of RAT.

description description

Add a description field to the SGSN multiple address group entry in the GGSN service configuration.

*description* must be an alphameric string of 1 through 63 characters.

Usage

Use this command to configure a list of SGSN multiple address groups with which the GGSN service is to communicate. This command can be entered multiple times to configure multiple SGSN multiple address groups.

**Important:** The GGSN only communicates with the SGSN multiple address groups configured using this command unless a plmn-policy is enabled to allow communication with unconfigured SGSNs. PLMN policies are configured using the `plmn unlisted-sgsn` command.

Example

The following command configures the GGSN to communicate with an SGSN with multiple address that is defined by an SGSN multiple address group named `sgsngrl` that is on a foreign PLMN:

```
sgsn multiple-address-group sgsngrl plmn-foreign
```
sgsn mcc-mnc

This command configures sgsn mcc-mnc for this GGSN service.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

```
configure > context context_name > ggsn-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ggsn-service)#
```

**Syntax**

```
sgsn mcc-mnc { prefer-rai | prefer-uli }
default sgsn mcc-mnc
```

- **default**
  
  Configures the default option for sgsn mcc-mnc. Default is ‘prefer-uli’.

- **prefer-rai**
  
  Configures sgsn mcc-mnc using rai.

- **prefer-uli**
  
  Configures sgsn mcc-mnc using uli.

**Usage**

Use this command to configure the sgsn mcc-mnc.

**Example**

The following command configures the sgsn mcc-mnc to ‘prefer-rai’:

```
sgsn mcc-mnc prefer-rai
```
trace-collection-entity

This command configures the trace collection entity IP address. Trace collection entity is the destination node to which trace files are transferred and stored.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GGSN Service Configuration

```
configure > context context_name > ggsn-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ggsn-service)#
```

**Syntax**

```
trace-collection-entity IPv4_addr

no trace-collection-entity
```

**no**

Removes the configured IPv4 address for trace collection in this GGSN service.

**IPv4_addr**

Specifies the IP address in IPv4 dotted-decimal notation.

**Usage**

Use this command to configure the trace collection entity IP address. This configuration is required because during signaling session trace activation, CPC REQ and UPC REQ do not provide the IP address for the trace collection entity.

**Example**

The following command configures the trace collection entity IP address with this GGSN service:

```
trace-collection-entity 192.36.56.56
```
Chapter 141
Global Configuration Mode Commands (A-K)

This section includes the commands `aaa accounting-overload-protection` through `imei-profile`. The Global Configuration Mode is used to configure basic system-wide parameters.

Mode

`Exec > Global Configuration`  
`configure`  
Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
aaa accounting-overload-protection

This command configures Overload Protection Policy for accounting requests.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```configure
```
Entering the above command sequence results in the following prompt:

```local host_name(config)#```

**Syntax**

```aaa accounting-overload-protection prioritize-gtpp
{ default | no } aaa accounting-overload-protection```

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Configures the default setting. Default: no priority assigned</td>
</tr>
<tr>
<td>no</td>
<td>Disables the Overload Protection configuration.</td>
</tr>
<tr>
<td>prioritize-gtpp</td>
<td>Gives higher priority to GTPP requests among the other outstanding requests. So while purging the lower priority requests will be selected first.</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to configure Overload Protection Policy for accounting requests.

**Example**

The following command prioritizes GTPP requests among the other outstanding requests:

```aaa accounting-overload-protection prioritize-gtpp```
aaa default-domain

Configure global accounting and authentication default domain for subscriber and context-level administrative user sessions.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
aaa default-domain { administrator | subscriber } domain_name

no aaa default-domain { administrator | subscriber }
```

**no**

Removes all or only the specified configured domain.

**administrator | subscriber**

**administrator**: Configures the default domain for context-level administrative users.

**subscriber**: Configures the default domain for subscribers.

**domain_name**

Sets the default context.

**domain_name** must be an alphanumeric string of 1 through 79 characters.

**Usage**

This command configures the default domain which is used when accounting and authentication services are required for context-level administrative user and subscriber sessions whose user name does not include a domain.

**Example**

The following commands configure the default domains for context-level administrative users and subscribers, respectively:

```
aaa default-domain administrator sampleAdministratorDomain

aaa default-domain subscriber sampleSubscriberDomain
```
aaa domain-matching ignore-case

This command disables case sensitivity when performing domain matching. When this command is enabled, the system disregard case when matching domains.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**

```
[ no ] aaa domain-matching ignore-case

default aaa domain-matching
```

**Usage**
Use this command to configure the system to ignore case when matching domains.

**Example**
The following command configures the system to ignore case when matching domains:

```
aaa domain-matching ignore-case
```
aaa domain-matching imsi-prefix

Enables domain lookup for session based on the International Mobile Subscriber Identity (IMSI) prefix length. Default: Disabled

Important: This command is only available in 8.3 and later releases.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

aaa domain-matching imsi-prefix prefix-length prefix_length
no aaa domain-matching imsi-prefix

default aaa domain-matching

no

Specifies the system must not consider imsi-prefix domain matching method.

prefix-length

Specifies the IMSI length to be matched with the domain.
prefix_length must be an integer from 1 through 15.

Usage

Use this command to configure the IMSI-prefix method of domain matching. This command enables domain lookup for the session based on the IMSI prefix length. If there is a domain configured with the matching IMSI prefix, the associated configuration is used.
This feature does not support partial matches.

Example

The following command configures the IMSI prefix method for domain matching setting the prefix length to 10.

aaa domain-matching imsi-prefix prefix-length 10
aaa large-configuration

This command enables or disables the system to accept a large number of RADIUS configurations to be defined and stored.

**Important:** For this command to take affect, after entering the command the configuration must be saved and reloaded.

When aaa large-configuration is disabled, the following restrictions are in place:

- Only one (1) NAS IP address can be defined per context with the `radius attribute` command.
- The RADIUS attribute `nas-ip-address` can only be configured if the RADIUS group is `default`.
- Only 320 RADIUS servers can be configured system-wide.
- Only 64 RADIUS groups can be configured system-wide.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
[ no ] aaa large-configuration
```

`no`

Disables AAA large configuration support.

**Usage**

When aaa large-configuration is enabled, the system provides the ability to configure multiple NAS IP addresses in a single context to used with different radius groups. As well, the command allows support for up to 1,600 RADIUS server configurations and for a PDSN a maximum of 400 or for a GGSN a maximum of 800 RADIUS server group configurations system-wide.

**Example**

To enable the definition of a large number of RADIUS configurations, enter the following commands in the following order:

In APN Configuration mode, enter:

```
default aaa group
```

In Global Configuration mode, enter:
aaa large-configuration

In Exec mode, use the `save configuration` command and then the `reload` command.
aaa last-resort

Configure global accounting and authentication last resort domain for subscriber and context-level administrative user sessions.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

aaa last-resort context { administrator | subscriber context_name }  
no aaa last-resort context { administrator | subscriber }

no

Removes all or only the specified previously configured authentication last resort domain name.

administrator | subscriber

administrator: Configures the last resort domain for context-level administrative.
subscriber: Configures the last resort domain for the subscribers.

context_name

Specifies the context which is to be set as the last resort. context_name must be an alphanumeric string of 1 to 79 characters.

Usage

Set the last resort context which is used when there is no applicable default domain (context) and there is no domain provided with the subscriber’s or context-level administrative user’s name for use in the AAA functions.

Example

The following commands configure the last resort domains for context-level administrative user and subscribers, respectively:

aaa last-resort administrator sampleAdministratorDomain  
aaa last-resort subscriber sampleSubscriberDomain

The following command removes the previously configured domain called sampleAdministratorDomain:
no aaa last-resort administrator sampleAdministratorDomain
aaa tacacs+

This command enables or disables system-wide TACACS+ AAA (authentication, authorization and accounting) services for administrative users. This command is valid only if TACACS+ servers and related services have been configured in TACACS Configuration Mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration  
`configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
[ no ] aaa tacacs+
```

**Usage**
Enables or disables the use of TACACS+ AAA services for administrative users.

**Example**

```
aaa tacacs+
no aaa tacacs+
```
aaa username-format

Configure global accounting and authentication user name formats for AAA (authentication, authorization and accounting) functions. Up to six formats may be configured.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

[ no ] aaa username-format { domain | username } separator
default aaa username-format

no

Removing the specified user name format from the configuration.

domain | username
Default: username @
domain: indicates the left side of the string from the separator character is a domain name and the right side is the user name.
username: indicates the left side of the string from the separator character is a user name and the right side is the domain name.

Important: The user name string is always searched from right to left for the first occurrence of the separator character.

separator

Specifies the character to use to delimit the domain from the user name for global AAA functions. Permitted characters include: @, %, - , #, or /. To specify a back slash (\) as the separator, you must enter a double back slash (\") on the command line.

Usage

Define the formats for user name delimiting if certain domains or groups of users are to be authenticated based upon their user name versus domain name.

Example

aaa username-format domain @
aaa username-format username %

no aaa username-format username %
active-charging service

This command allows you to create/configure/delete the Active Charging Service (ACS)/Enhanced Charging Service (ECS).

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
active-charging service  acs_service_name [ -noconfirm ]
```

```
no active-charging service  acs_service_name
```

---

**Usage**

Use this command to create/configure/delete an Active Charging Service in the system. Note that, in this release, only one Active Charging Service can be created in the system.

Use this command after enabling ACS using the **require active-charging** command. This command allows administrative users to configure the ACS functionality.

On entering this command, the CLI prompt changes to:

```
[context_name]hostname(config-acs)#
```

**Example**

The following command creates an ACS service named test:

```
active-charging service test
```
alarm

Enables or disables alarming options for the SPIO card or the SSC internal alarms and the central-office external alarms. To verify the state of the alarms, refer to the show alarm command.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]\host_name(config)#

**Syntax**

```
alarm { audible | central-office }

no alarm { audible | central-office }
```

- **no**
  Disables the option specified.

- **audible | central-office**
  - **audible**: indicates the internal audible alarm on the SPIO cards or SSCs are to be enabled.
  - **central-office**: indicates the central office alarms are to be enabled.

**Usage**

Disable CO and audible alarms when an existing device provides such capability.

**Example**

The following commands enable the SPIO card or SSC internal alarms and disable the central office alarms, respectively.

```
alarm audible

no alarm central-office
```
apn-profile

Creates an instance of an Access Point Name (APN) profile.

**Product**
MME
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
[ no ] apn-profile apn_profile_name
```

- **no**
  Deletes the APN profile instance from the configuration.

- **apn_profile_name**
  Specifies the name of the APN profile. Enter an alphanumeric string of 1 through 64 characters.

**Usage**

Use this command to create an instance of an APN profile and to enter the APN profile configuration mode. An APN profile is a template which groups a set of APN-specific commands that may be applicable to one or more APNs. See the *APN Profile Configuration Mode Commands* chapter for information regarding the definition of the rules contained within the profile and the use of the profile.

**Important:** An APN profile is a key element of the Operator Policy feature and is only valid when associated with at least one operator policy.

To see what APN profiles have already been created, return to the Exec mode and enter the `show apn-profile all` command.

**Example**

The following command creates a configuration instance of an APN profile:

```
apn-profile apnprof27
```
apn-remap-table

Creates an instance of an Access Point Name (APN) remap table.

Product
- MME
- SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

[ no ] apn-remap-table apn_remap_table_name

- no
  Deletes the APN remap table instance from the configuration.
- apn_remap_table_name
  Specifies the name of the APN remap table. Enter an alphanumeric string of 1 through 65 characters.

Usage

Use this command to create an instance of an APN remap table and to enter the APN remap table configuration mode. An APN remap table includes entries that define how an incoming APN, or the lack on one, will be handled. See the APN Remap Table Configuration Mode Commands chapter for information regarding the definition of the entries contained within the table and the use of the table.

Important: An APN remap table is a key element of the Operator Policy feature and is only valid when associated with at least one operator policy.

To see what APN remap tables have already been created, return to the Exec mode and enter the show apn-remap-table all command.

Example

The following command creates a configuration instance of an APN remap table:

apn-remap-table pnremap-USorigins-table1
arp

Configures a system-wide time interval for performing Address Resolution Protocol (ARP) refresh.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure
Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

arp base-reachable-time time

default arp base-reachable-time

  default
  Restores the parameter to its default setting.

  time
  Default: 30
  Specifies the ARP refresh interval (in seconds) as an integer from 30 through 86400.

Usage

Use this command to configure a system-wide ARP refresh interval. Once a neighbor is found, the entry is considered valid for at least a random value between the time/2 and the time*1.5.

Example

The following command configures an ARP refresh interval of 1 hour:

    arp base-reachable-time 3600
autoconfirm

This command disables or enables confirmation for certain commands. This command affects all future CLI sessions.

**Important:** To change the behavior for the current CLI session only, use the `autoconfirm` command in the Exec Mode.

**Product**
All

**Privilege**
Security Administrator, Administrator, Operator

**Mode**
Exec > Global Configuration

**Syntax**

```
autoconfirm

no autoconfirm
```

**Usage**

When autoconfirm is enabled, certain commands ask you to answer yes or no to confirm that you want to execute the command. When autoconfirm is disabled the confirmation questions never appear. Disabling autoconfirm disables command confirmation for all future CLI sessions. By default `autoconfirm` is enabled.

**Example**

The following command enables command confirmation for all future CLI sessions;

```
    autoconfirm
```

The following command disables command confirmation for all future CLI sessions;

```
    no autoconfirm
```
autoless

This command is obsolete. It is included in the CLI for backward compatibility with older configuration files. When executed, this command issues a warning and performs no function.
banner

Configures the CLI banner which is displayed upon the start of a CLI session.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
banner { charging-service | lawful-intercept | motd | pre-login } string
no banner { charging-service | lawful-intercept | motd | pre-login }
```

- **no**
  Removes the banner message by setting it to be a string of zero length.

- **charging-service**
  Specifies the Active Charging Service banner message. The banner is displayed upon initialization of an SSH CLI session with ACS-admin privileges (whenever anyone with the CLI privilege bit for ACS logs on).

- **lawful-intercept**
  Refer to the *Lawful Intercept Configuration Guide* for a description of this parameter.

- **motd**
  Configures the CLI banner message of the day which is displayed upon the initialization of any CLI session.

- **pre-login**
  Configures the CLI banner displayed before a CLI user logs in.

**Important:** This banner is displayed only for serial port and telnet log ins. It is not supported in ssh and, therefore, will not be displayed before ssh log ins.

- **string**
  Specifies the banner or message to be displayed at session initialization. *string* may be an alphanumeric string of 0 through 2048 characters. The string must be enclosed in double quotation marks if the banner or message is to include spaces.
Usage
Set the message of the day banner when an important system wide message is needed. For example, in preparation for removing a chassis from service, set the banner 1 or more days in advance to notify administrative users of the pending maintenance.

Example

`banner motd "Have a nice day."`

`banner motd No_News_Today`

`no banner motd`
**boot delay**

Configures the delay period, in seconds, before attempting to boot the system from a software image file residing on an external network server.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```bash
configure
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
boot delay time

no boot delay
```

- **no**
  - Deletes the setting for the boot delay. The boot process executes immediately.

- **time**
  - Specifies the amount of time (in seconds) to delay prior to requesting the software image from the external network server as an integer from 1 through 300.

**Usage**

Useful when booting from the network when connection delays may cause timeouts. Such as when the Spanning Tree Protocol is used on network equipment.

**Important:** The settings for this command are stored immediately in the boot.sys file. No changes are made to the system configuration file.

**Example**

The following sets the boot delay to 10 seconds:

```
boot delay 10
```
boot interface

Configures Ethernet network interfaces for obtaining a system software image during the system boot process.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

Releases prior to 12.2:

\[ boot interface \{ spio-eth1 | spio-eth2 \} \{ medium \{ auto | speed medium_speed \} \{ duplex medium_duplex \} \{ media medium_media \} \} \]

Releases after 12.2:

\[ boot interface \{ local-eth1 | local-eth2 \} \{ medium \{ auto | speed medium_speed \} \{ duplex medium_duplex \} \{ media medium_media \} \}

no

Removes the boot interface configuration from the boot.sys file. Only files from the local file system can be loaded.

spio-eth1 | spio-eth2

Specifies the network interface to be configured where spio-eth1 is the primary interface on the SPIO (slot 24 interface 1 or slot 25 interface 1) and spio-eth2 is the secondary interface on the SPIO (slot 24 interface 2 or slot 25 interface 2). The interfaces are either RJ-45 ifor speeds of 10, 100, or 1000 megabits per second (Mbps), or SFP for the optical Gigabit (1000 Mbps).

local-eth1 | local-eth2

Specifies the network interface to be configured where local-eth1 is the primary ethernet interface and local-eth2 is the secondary ethernet interface.

For the ASR 5000, the primary is interface 1 on the SPIO and the secondary is interface 2 on the SPIO. The interfaces are either RJ-45 ifor speeds of 10, 100, or 1000 megabits per second (Mbps), or SFP for optical Gigabit (1000 Mbps).

For the ASR 5500, the primary is port 1 (1000Base-T) on the MIO and the secondary interface is port 2 (1000Base-T) on the MIO.
Global Configuration Mode Commands (A-K)

**boot interface**

```
medium { auto | speed medium_speed duplex medium_duplex }
```

Default: auto

**auto:** configures the interface to auto-negotiate the interface speed and duplex.

**speed medium_speed duplex medium_duplex:** specifies the speed to use at all times where

- `medium_speed` must be one of:
  - 10
  - 100
  - 1000

The keyword `duplex` is used to set the communication mode of the interface where `medium_duplex` must be one of:

- full
- half

```
media medium_media
```

Default: rj45

Optionally sets the physical interface where `medium_media` must be either rj45 or sfp.

**Usage**

Modify the boot interface settings to ensure the system is able to obtain a software image from an external network server.

---

**Important:** The settings for this command are stored immediately in the boot.sys file. No changes are made to the system configuration file.

**Example**

The following configures the primary interface to auto-negotiate the speed.

```
boot interface spio-eth1 medium auto

boot interface local-eth1 medium auto
```

The following command configures the secondary interface to a fixed gigabit speed at full duplex using RJ45 connectors for the physical interface.

```
boot interface spio-eth2 medium speed 1000 duplex full media rj45

boot interface local-eth2 medium speed 1000 duplex full media rj45
```

The following restores the defaults for the boot interface.

```
no boot interface
```
**boot nameserver**

Configures the IP address of the DNS (Domain Name Service) server to use when looking up hostnames in URLs for network booting.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
boot nameserver ip_address

no boot nameserver
```

- **no**
  Removes the network boot nameserver information from the boot.sys file.

- **ip_address**
  IPv4 dotted-decimal address of the DNS server the system uses to lookup hostnames in URLs for a software image from the network during the system boot process.

**Usage**

Use this command to identify the DNS server to use to lookup hostnames in a software image URL.

**Important:** The settings for this command are stored immediately in the boot.sys file. No changes are made to the system configuration file.

**Example**

The following configures the system to communicate with a DNS nameserver with the IP address of 10.2.3.4:

```
boot nameserver 10.2.3.4
```
**boot networkconfig**

Configures the networking parameters for the Switch Processor I/O card network interfaces to use when obtaining a software image from an external network server during the system boot process.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```plaintext
boot networkconfig { dhcp | { { dhcp-static-fallback | static } ip address spio24 ip_address [ spio25 ip_address ] netmask ip_mask [ gateway gw_address ] } } }
no boot networkconfig
```

**no**

Removes the network configuration information from the boot.sys file.

**dhcp**

Indicates that a Dynamic Host Control Protocol (DHCP) server is used for communicating with the external network server.

**dhcp-static-fallback | static**

**dhcp-static-fallback**: provides static IP address fallback network option when a DHCP server is unavailable.

**static**: specifies a fixed network IP address for the external network server that hosts the software image.

```plaintext
spio24 ip_address [ spio25 ip_address ] netmask ip_mask [ gateway gw_address ]
spio24 ip_address [ spio25 ip_address ]: the IP address to use for the SPIO in slot 24 and optionally the SPIO in slot 25 for network booting. ip_address must be specified using IPv4 dotted-decimal notation.
netmask ip_mask: the network mask to use in conjunction with the IP address(es) specified for network booting. ip_mask must be specified using IPv4 dotted-decimal notation.
gateway gw_address: the IP address of a network gateway to use in conjunction with the IP address(es) specified for network booting. gw_address must be entered using IPv4 dotted-decimal notation.
```

**Important**: If gw_address is not specified, the network server must be on the same LAN as the system. Since both SPIOs must be in the same network, the netmask and gateway settings are shared.
Usage
Configure the network parameters for the ports on the SPIO cards to use to communicate with an external network server that hosts software images.

**Important:** The settings for this command are stored immediately in the boot.sys file. No changes are made to the system configuration file.

**Important:** When configuring static addresses both SPIOs must have different IP addresses. Neither address can be the same as the local context IP address.

Example
The following configures the system to communicate with the external network server via DHCP with a fallback to IP address 192.168.100.10, respectively.

```
boot networkconfig dhcp-static-fallback ip address spio24 192.168.100.10 netmask 255.255.255.0
```

The following command configures the system to communicate with an external network server using the fixed (static) IP address 192.168.100.10 with a network mask of 255.255.255.0.

```
boot networkconfig static ip address spio24 192.168.100.10 netmask 255.255.255.0
```

The following restores the system default for the network boot configuration options.

```
no boot networkconfig
```
boot system priority

Specifies the priority of a boot stack entry to use when the system first initializes or restarts. Up to 10 boot system priorities (entries in the boot.sys file located in the /flash device in the SPC, SMC or MIO) can be configured.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

boot system priority number image image_url config config_path

no boot system priority number

no

Remove a boot stack entry at the priority specified from the boot stack when it is no longer used.

priority number

Specifies the priority for the file group (consisting of an image (.bin) and its corresponding configuration (.cfg) file) specified in the boot stack. The value must be in the range from 1 through 100 where a priority of 1 is the highest. Up to 10 boot system priorities (boot stack entries) can be configured.

**Important:** When performing a software upgrade it is important that the new file group have the highest priority (lowest value) configured.

**Important:** To ensure that higher priority numbers remain open, use an “N-1” priority numbering methodology, where “N” is the first priority in the current boot stack.

image image_url

Specifies the location of a image file to use for system startup. The URL may refer to a local or a remote file. The URL must be formatted according to the following format:
For the ASR 5000:
•[ file: ]{ /flash | /pcmcia1 | /hd }[ /directory ]/filename
•[ http: | tftp: ]//host[ :port ][ /directory ]/filename
For the ASR 5500:
•[ file: ]{ /flash | /usb1 | /hd }[ /directory ]/filename
boot system priority

- `[http: | tftp:]//host[ :port ][/directory ]/filename

**Important:** Use of the SMC hard drive is not supported in this release.

**Important:** Do not use the following characters when entering a string for the field names below: “/” (forward slash), “:” (colon) or “@” (at sign).

- directory is the directory name.
- filename is the actual file of interest.
- host is the IP address or host name of the server.
- port# is the logical port number that the communication protocol is to use.

**Important:** A file intended for use on an ASR 5000 uses the convention xxxx.asr5000.bin, where xxxx is the software build number.

**Important:** A file intended for use on an ASR 5500 uses the convention xxxx.asr5500.bin, where xxxx is the software build number.

**Important:** When using the TFTP, it is advisable to use a server that supports large blocks, per RFC 2348. This can be implemented by using the “block size option” to ensure that the TFTP service does not restrict the file size of the transfer to 32MB.

 configuring  config_path

Specifies the location of a configuration file to use for system startup. This must be formatted according to the following format:

For the ASR 5000:

- `[file: ]{ /flash | /pcmcial | /hd }[ /path ]/filename

For the ASR 5500:

- `[file: ]{ /flash | /usb1 | /hd }[ /path ]/filename

**Important:** Use of the SMC hard drive is not supported in this release.

Where path is the directory structure to the file of interest, and filename is the name of the configuration file. This file typically has a .cfg extension.

**Usage**

This command is useful in prioritizing boot stack entries in the boot.sys file, typically located on the /flash device of the Active SPC, SMC, or MIO, for automatic recovery in case of a failure of a primary boot file group.
**Important:** The configuration file must reside on the SPC’s, SMC’s, or MIO’s local filesystem, stored on one of its local devices (/flash, or /pcmcia1, or /hd-raid/pcmcia1, or /pcmcia2, or /usb1, or /hd-raid). Attempts to load the configuration file from an external network server will result in a failure to load that image and configuration file group, causing the system to load the image and configuration file group with the next highest priority in the boot stack.

**Important:** Configuration changes do not take effect until the system is reloaded.

**Important:** The settings for this command are stored immediately in the boot.sys file. No changes are made to the system configuration file.

**Example**

The following commands set up two locations to obtain a boot file group from.

```plaintext
boot system priority 1 image tftp: //remoteABC/pub/2012jan.bin config /flash/pub/data/2012feb.cfg
boot system priority 2 image /flash /pub/data/2002jun.bin config /pcmcia1/pub/data/2012feb.cfg
```

The following removes the current priority 1 boot entry from the boot.sys file.

```plaintext
no boot system priority 1
```
bulkstats

Enables the collection of bulk statistics and/or enters the bulk statistic configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

- **configure**
  Entering the above command sequence results in the following prompt:
  ```
  [local]host_name(config)#
  ```

**Syntax**

```
bulkstats { collection | historical | mode }
```

```
no bulkstats collection
```

- **collection**
  Enables the statistics collection process. Collects a periodic snapshot of activity and performance data.

- **historical collection**
  Enables the collection of historical bulk statistics. If enabled, StarOS keeps track of activities that require the storing of more data, such as “the highest value that’s been seen over the last 24 hours”.

- **mode**
  Enters the bulk statistics configuration mode. The resulting command-line prompt will look similar to:
  ```
  [[<context-name>]]asr5000(config-bulkstats)#
  ```

- **no**
  Disables the collection of bulk statistics.

**Usage**

The Bulk Statistics Configuration mode consists of commands for configuring bulk statistic properties, such as the periodicity of collection. Detailed command descriptions appear in the *Bulk Statistics Configuration Mode Commands* chapter.

The collected bulk statistics are sent to a collection server (called a receiver). Bulk statistics are statistics that are collected in a group or schema, for example, system statistics, port statistics, RADIUS statistics. Once the receiver, schema, and collection properties are configured, this `bulkstats` command enables or disables the collection of the data.

To collect a sample that will provide an average, for example, an average of CPU counters, the “historical” features must be enabled with the `bulkstats historical collection` command.
Since bulk statistics are collected at regular, user-defined intervals, the **bulkstats force** command in the Exec Mode can be used to manually initiate the immediate collection of statistics.

### Example

```plaintext
bulkstats collection
bulkstats mode
no bulkstats collection
```
**ca-certificate**

Configures and selects an X.509 CA certificate to enable a security gateway or SCM to perform certificate-based peer (client) authentication. The system supports a maximum of 16 certificates and 16 CA root certificates. A maximum of four CA root certificates can be bound to a crypto or ssl template.

**Product**
All IPSec-related products

**Privilege**
Administrator, Security Administrator, Operator

**Mode**
Exec > Global Configuration

**Syntax**
```
ca-certificate name name { der url url | pem { data pemdata | url url [ cert-enc ] [ cert-hash-url url url ] } }

no ca-certificate name name
```

**no**
Disables ca-certificate.

<table>
<thead>
<tr>
<th>name name</th>
</tr>

<table>
<thead>
<tr>
<th>data pemdata</th>
</tr>
</thead>
<tbody>
<tr>
<td>CA certificate data in PEM format. <em>pemdata</em> must be an alphanumeric string of 1 through 4095 characters.</td>
</tr>
</tbody>
</table>
url url

URL of the file containing CA certificate in PEM. url must be an existing URL expressed in one of the following formats:

- `[file://]{/flash | /pcmcia | /hd-raid}/[directory]/<filename`
- `tftp://<host>[:<port>]/[directory]/<filename`
- `ftp://[<username>[:<password>@]<host>[:<port>]/[directory]/<filename`
- `sftp://[<username>[:<password>@]<host>[:<port>]/[directory]/<filename`
- `http://[<username>[:<password>@]<host>[:<port>]/[directory]/<filename`

When read via a file, note that show configuration will not contain the URL reference, but will instead output the data via data pemdata, such that the configuration file is self-contained.

[ cert-enc ] [ cert-hash-url url url

- `cert-enc`: Certificate encoding type other than default encoding type.

no

Removes the named CA certificate.

Usage

Use this command to configure and select an X.509 CA certificate to enable a security gateway or SCM to perform certificate-based peer (client) authentication.

Example

Use the following command to remove a certificate named *fap1*:

```
no ca-certificate data fap1
```
ca-crl

Configures the name and URL path of a Certificate Authority-Certificate Revocation List (CA-CRL).

**Product**
All IPSec-related products

**Privilege**
Operator

**Mode**
Exec > Global Configuration

**Syntax**

```
ca-crl name name { der | pem } { url url }
no ca-crl name name
```

- **no**
  Removes the named CA-CRL.

- **name**
  Provides a name of the CA-CRL. *name* must be an alphanumeric string of 1 through 128 characters.

- **der**
  Specifies that Distinguished Encoding Rules (DER) format is to be used for the source format.

- **pem**
  Specifies that Privacy-enhanced Electronic Mail (PEM) format is to be used for the source format.

- **url**
  Specifies the URL where the CA-CRL is to be fetched. *url* must be an existing URL expressed as an alphanumeric string of 1 through 1023 characters in one of the following formats:
  - [file:][/flash | /pcmcia1 | /hd-raid[/directory]/<filename
  - tftp://<host>[:<port>]/*<directory>*/<filename
  - ftp://[<username>[:<password>]@[<host>[:<port>]/*<directory>*/<filename
  - sftp://[<username>[:<password>]@[<host>[:<port>]/*<directory>*/<filename
  - http://[<username>[:<password>]@[<host>[:<port>]/*<directory>*/<filename
  - ldap://[<host>[:<port>]/*<dn>*/[?[<attributes>]*[<scope>]*[<filter>]*[<extensions>]]
```
Usage

Use this command to name and fetch a CA-CRL from a specified location. Without additional information from the CA, an issued certificate remains valid to any verifier until it expires. To revoke certificates, the CA publishes a CRL periodically to provide an updated list of certificates revoked, but not yet expired. Like a certificate, a CRL is a digital document signed by the CA. In addition to a list of serial numbers of revoked certificates, the CRL includes attributes such as issuer name (same as the issuer name in the certificate), signature (signed by the issuer using the same key that signs certificates), last update (the time this CRL was issued), and next update (the time next CRL will be available).

Example

The following command fetches a CA-CRL named list1.pem from a `host.com/CRLs` location and names the list `CRL5`:

```
ca-crl name CRL5 pem url http://host.com/CRLs/list1.pem
```
call-control-profile

Creates an instance of a call-control profile.

Product
MME
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

[ no ] call-control-profile cc_profile_name

no

Deletes the Call-Control Profile instance from the configuration.

cc_profile_name

Specifies the name of the call-control profile. Enter an alphanumeric string of 1 through 64 characters.

Usage

Use this command to create an instance of a call-control profile and to enter the call-control profile configuration mode. A call-control profile is a template which groups a set of call-handling instructions that may be applicable to one or more incoming calls. See the Call-Control Profile Configuration Mode Commands chapter for information regarding the definition of the rules contained within the profile and the use of the profile.

Important: A call-control profile is a key element of the Operator Policy feature and is only valid when associated with at least one operator policy.

To see what call-control profiles have already been created, return to the Exec mode and enter the show call-control-profile all command.

Example

The following command creates a configuration instance of an call-control profile:

call-control-profile ccprofi
card

Enters the Card Configuration mode for the specified card. (ASR 5x00 only)

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
card slot_number
```

<table>
<thead>
<tr>
<th>slot_number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the slot number of the card for which the card configuration mode is to be entered. slot_number must be an integer from 1 through 48 (on the ASR 5000) or 1 through 20 (on the ASR 5500).</td>
</tr>
</tbody>
</table>

**Usage**

Enter the configuration mode for a specific card when changes are required.

**Important:** This command is not supported on virtual platforms.

**Example**

```
card 8
```
card-standby-priority

Configures the redundancy priorities for packet processing cards by specifying the slot number search order for a standby card when needed.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

card-standby-priority slot_num [ slot_num ] [ slot_num ] ...

**Usage**
Set the standby order of the redundant cards when multiple standby cards are available. Questionable hardware should be placed lower in the priority list.

**Important:** This command replaces the pac-standby-priority command.

**Important:** This command is not supported on all platforms.

**Example**
The following command configures the redundancy priority to use the standby cards in slots 16, 14, and 12 in that order:

```
card-standby-priority 16 14 12
```

The following command configures the redundancy priority to use the standby cards in slots 10, 9, and 7 in that order:

```
card-standby-priority 10 9 7
```
**cdr-multi-mode**

This command enables multiple instances of CDRMOD, one per packet processing card.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
[ default ] cdr-multi-mode
```

- **default**
  Configures this command with its default setting.
  Default: Single-CDRMODE mode

**Usage**

Use this command to enable the multi-CDRMODE mode, wherein there will be one instance of CDRMOD per packet processing card. All the SessMgr instances that are running on a packet processing card will send the records to the CDRMOD instance running on that card.

By default, CDRMOD runs in single mode, wherein there will be only one instance of CDRMOD running for the entire chassis. All the SessMgr instances that are running on a packet processing card will send the records to the CDRMOD instance.

**Important:** For changes to this command to take effect, save the configuration and reboot the system.

**Important:** In multi-CDRMODE mode, you should enable hard-disk usage.
certificate

Configures and selects an X.509 Trusted Author certificate.

Product
All IPSec-related products

Privilege
Administrator, Security Administrator, Operator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
certificate name name { der url url | pem { data pemdata | url url } private-key pem { [ encrypted ] data pemdata | url url [cert-enc] [cert-hash-url url url ] } }
```

no certificate name name

no

Disables certificate.

**name name**

Names the certificate. name must be from 1 to 128 alphanumeric characters.

**der url**

 Specifies that the der format is to be used. url is the url of the file containing certificate in der format. url must be an existing URL expressed in one of the following formats:

- `[file:]//flash | /pcmcia | /hd-raid]//[directory]//<filename
- tftp://<host>[:<port>]/[<directory>]//<filename
- ftp://[<username>[:<password>]@]<host>[:<port>]/[<directory>]//<filename
- sftp://[<username>[:<password>]@]<host>[:<port>]/[<directory>]//<filename
- http://[<username>[:<password>]@]<host>[:<port>]/[<directory>]//<filename

**pem**

Specifies that the Privacy-enhanced Electronic Mail (PEM) format is to be used.

**data pemdata**

Certificate/private key data in PEM format. pemdata must be an alphanumeric string of 1 through 4095 (if private key is not implemented) or 1 through 8191 (if private key is implemented) characters.
url url

URL of the file containing certificate/private key in PEM. url must be an existing URL expressed in one of the following formats:
- ![file://]{/flash | /pcmcia1 | /hd-raid}[/directory]/<filename
- tftp://<host>[:<port>]/<directory>/<filename
- ftp://[<username>[:<password>]]@<host>[:<port>]/<directory>/<filename
- sftp://[<username>[:<password>]]@<host>[:<port>]/<directory>/<filename
- http://[<username>[:<password>]]@<host>[:<port>]/<directory>/<filename

When read via a file, show configuration will not contain the URL reference, but instead outputs the data via data pemdata, such that the configuration file is self-contained.

[ cert-enc ] [ cert-hash-url url url

\textbf{cert-enc}: Certificate encoding type other than default encoding type.

\textbf{cert-hash-url}: Hash & URL of X.509 Certificate.

\begin{verbatim}
private-key
Private key data.
\end{verbatim}

\begin{verbatim}
encrypted
Encrypted private key data.
\end{verbatim}

\begin{verbatim}
no
Removes the named certificate.
\end{verbatim}

\textbf{Usage}

Use this command to Configures and selects an X.509 Trusted Author certificate.

\textbf{Example}

Use the following command to remove a certificate named box1:

\begin{verbatim}
no certificate data box1
\end{verbatim}
cli

Configures global Command Line Interface (CLI) parameters.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

cli { access { monitor-protocol | monitor-subscriber | show-configuration } { administrator | operator } } | configuration-monitor | hidden | login-failure-delay
number | max-sessions number | operator clear-subscriber-one-only | test-commands
[encrypted] password password | trap config-mode }

no cli { configuration-monitor | hidden | login-failure-delay number | max-sessions | operator clear-subscriber-one-only | trap config-mode }

default cli { access { monitor-protocol | monitor-subscriber | show-configuration } | configuration-monitor | login-failure-delay | max-sessions | operator clear-subscriber-one-only | trap config-mode }

no
Removes the specified option.

default
Resets the keywords to their default values.

access { monitor-protocol | monitor-subscriber | show-configuration } { operator | administrator }

Sets access privileges on the monitor protocol and monitor subscriber commands:
monitor-protocol: Selects privileges for the monitor protocol command.
monitor-subscriber: Selects privileges for the monitor subscriber command.
show-configuration: Selects privileges for the show-configuration command. However the default access level for this command is the user with operator privileges.
operator: Sets the privileges for the selected command to allow use by users with operator privileges.
administrator: Restricts use of the selected command to administrators only.

configuration-monitor

When this keyword is enabled, the system executes a show configuration checksum command every 15-minutes. The resulting checksum is compared with the previous checksum.
When a configuration change is detected, a log message and SNMP notification are generated. The SNMP notification only indicates that a change has occurred without identifying what change had been made. The 15-minute interval is fixed and cannot be configured. By default configuration monitoring is disabled.

**hidden**

Enables access to the hidden cli test-commands command. The no cli hidden command disables access to the cli test-commands command. This is the default mode. Refer to the description of the test-commands keyword below for additional information.

**login-failure-delay number**

Specifies the time to wait before a login failure is returned and another login may be attempted. Default is five seconds.

**max-sessions number**

Sets the number of allowed simultaneous CLI sessions on the system. If this value is set to a number below the current number of open CLI sessions, the open sessions will continue until closed. number must be an integer from 2 through 100.

**Caution:** Use caution when setting this command. Limiting simultaneous CLI sessions prevents authorized users from accessing the system if the maximum number allowed has been reached. The system already limits CLI sessions based on available resources. Additional limitation could have adverse effects.

**operator clear-subscriber-one-only**

Restricts Operator to clearing only one subscriber session at a time.

**test-commands [encrypted] password password_string**

Enables access to the cli test-commands mode. The commands and keywords made available under this mode are for internal testing and debugging.

**Caution:** CLI test-commands are intended for diagnostic use only. Access to these commands is not required during normal system operation. These command are intended for use only by Cisco TAC personnel. Some of these commands can slow system performance, drop subscribers, and/or render the system inoperable.

**Important:** An SNMP trap is generated when a user enables cli test-commands (starTestModeEntered). Refer to the SNMP MIB Reference for additional information.

**encrypted**

Specifies that the system will save the password in an encrypted format in the configuration file. The system displays the encrypted keyword in the configuration file as a flag indicating that the variable following the password keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file.

**password password_string**

Prompts for the password required to access cli test-commands. This password must have been previously configured by a Security Administrator via the tech-support test-commands password command. The password is an alphanumeric string of 1 through 64 characters (plain text password) or 1 through 524 characters (encrypted password). If the password keyword is not entered, the user is prompted (no-echo) to enter the password. If tech-support test-commands password has not been enabled, you will be unable to execute cli test-commands.
Once this test mode is entered under Global Configuration mode, **cli test-commands** become part of the current configuration. Therefore, any generated configuration will contain the **cli test-commands** command as the first configuration command.

⚠️ **Caution:** Use of CLI test-commands may cause significant service interruption. Contact Cisco TAC before executing any commands while in this mode.

The **no cli test-commands** command disables access to the CLI test-commands mode.

**trap config-mode**

Enables sending an SNMP trap (**starCLIConfigMode**) when a CLI user enters the configuration mode.

**Usage**

This command sets access parameters and enables several operational parameters for the system’s command line interface.

**Example**

The following command sets the number of allowed simultaneous CLI sessions to 5.

```
cli max-sessions 5
```

The following command sets the command **monitor protocol** to administrator-only

```
cli access monitor-protocol administrator
```
cli-encrypt-algorithm

Specifies the type of encryption algorithm to be used for passwords and secrets.

Product
All

Privilege
Security Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

cli-encrypt-algorithm { A | B }

default cli-encrypt-algorithm

default

Resets the encryption algorithm to “A”.

{ A | B }

Specifies the type of encryption algorithm:

- A – MD5-based cipher (default)
- B – AES-CBC-128 for encryption and HMAC-SHA1 for authentication

Usage

Specify MD5-based cipher (“A”) or AES-CBC-128 for encryption and HMAC-SHA1 for authentication (“B”) when encrypting passwords and secrets.

Example

cli-encrypt-algorithm B
**clock**

Configures system clock timezone and what local time zone to use.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
clock timezone tz [ local ]
no clock timezone
```

- **no**
  Resets the system timezone to the system default UTC.

- **tz**
  Specifies the system time zone to use as one of:
  - `america-buenos-aires` (GMT-3:00; Buenos Aires)
  - `america-caracas` (GMT-4:00) Caracas
  - `america-guatemala` (GMT-6:00; Guatemala, Guatemala)
  - `america-la_paz` (GMT-4:00; La Paz)
  - `america-lima` (GMT-5:00; Lima, Peru)
  - `america-puerto-rico` (GMT-4:00; Puerto Rico)
  - `america-sao-paulo` (GMT -3:00; Brazil)

- us-hawaii (GMT-10:00; Hawaii)
Global Configuration Mode Commands (A-K)

clock ▀

Command Line Interface Reference, StarOS Release 16 ▄ 5181

- **us-indiana** (GMT-6:00; Indiana)
- **us-mountain** (GMT-7:00; Cheyenne, Denver, Las Vegas)
- **us-pacific** (GMT-8:00) San Francisco, LA, Seattle
- **utc** (GMT; Universal Time Coordinated: London, Dublin, Edinburgh, Lisbon, Reykjavik, Casablanca)

**local**

Indicates the timezone specified by `tz` is to be considered the local time zone for local time display and conversion.

**Usage**

Clock and timezone management is necessary for proper accounting records. The chassis may be set to display a different local time than that of the system clock which allows accounting records to use the system time but to display the proper local time for users.

**Example**

```plaintext
   clock timezone utc
   clock timezone us-indiana local
   no clock timezone
```
cmp auto-fetch

Use this command to add a fetch configuration for each certificate for which automatic update is required. This is a Certificate Management Protocol v2 command.

Product
All products supporting IPSec CMPv2 features

**Important:** This command appears in the CLI for this release. However, it has not been qualified for use with any current Cisco StarOS gateway products.

Privilege
Security Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

Syntax

```
cmp auto-fetch current-name cert_name ca-root ca_name time days
no auto-fetch current-name cert_name
```

**no**
Removes auto-fetch configuration for a certificate.

**current-name cert_name**
Specifies a valid security gateway certificate as an alphanumeric string of 1 through 129 characters.

**ca-root ca_name**
Specifies the root certificate of the CA server. `ca_name` is an alphanumeric string of 1 through 129 characters.

**time days**
Specifies the number of days before the certificate expires as the time when the auto fetch should be triggered. `days` is specified as an integer from 1 through 256.

Usage
Use this command to specify when a current certificate should be automatically fetched.

Example
The following command automatically fetches the current certificate 10 days before it is to expire:

```
cmp fetch current-name aqaw12345 ca-root ca001 time 10
```
cmp cert-store location

Use this command to add a file location on /flash disk where the certificates and private keys will be stored. This is a Certificate Management Protocol v2 command.

**Product**

All products supporting IPSec CMPv2 features

**Important:** This command appears in the CLI for this release. However, it has not been qualified for use with any current Cisco StarOS gateway products.

**Privilege**

Security Administrator

**Mode**

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```plaintext
cmp cert-store location pathname [key reuse]
default cmp cert-store
no cmp cert-store
```

- **no**
  
  Removes the certificate storage location configuration.

- **location pathname**
  
  Specifies the storage location of the certificates and key files in the following formats:

  ```plaintext
  *[file:]{ /flash | /usb1 | /hd-raid }[/<directory>]/<filename>
  *tftp://<host>[:<port>]/<directory>/<filename>
  *ftp://[<username>[:<password>]]@<host>[:<port>]/<directory>/<filename>
  *sftp://[<username>[:<password>]]@<host>[:<port>]/<directory>/<filename>
  *http://[<username>[:<password>]]@<host>[:<port>]/<directory>/<filename>
  ```

**Usage**

Use this command to specify where certificates and key files should be stored.

**Example**

The following command stores certificates and key files in a location different from the default location:

```
cmp cert-store location file://certificates
```
**cmp cert-trap time**

Defines when an SNMP MIB certificate expiry trap should be sent as the number of hours before expiration.

**Product**

All products supporting IPSec CMPv2 features

**Important**: This command appears in the CLI for this release. However, it has not been qualified for use with any current Cisco StarOS gateway products.

**Privilege**

Security Administrator

**Mode**

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```plaintext
cmp cert-trap time hours

no cmp cert-trap time

do

no

Removes the certificate expiry MIB trap notification.

time hours

Specifies the number of hours before certificate expiry when a MIB trap should be sent. `hours` is an integer from 1 through 1024.
```

**Usage**

Use this command to set when an SNMP MIB certificate expiry trap should be sent.

**Example**

The following command specifies that an SNMP MIB certificate expiry trap should be sent 48 hours prior to expiration:

```plaintext
cmp cert-trap time 48
```
commandguard

When enabled this command causes the configure and autoconfirm CLI commands to prompt for confirmation (Y/N). When commandguard is disabled, these commands will not prompt for confirmation. If autoconfirm is enabled, commandguard has no affect.

Product
All products

Privilege
Security Administrator, Administrator, Operator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

[ no ] commandguard

Usage
Use this command to prevent users from accidentally entering Configuration mode via the CLI or file replay (most commonly caused by a cut and paste error in the configuration file). By default this command is disabled. The status of commandguard is output in show configuration commands.

Example

The following command enables confirmation prompting for configure and autoconfirm CLI commands:

commandguard
congestion-control

This command enables and disables the congestion control functionality on the system.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

[ default | no ] congestion-control

default
Sets the congestion control to its default value.

no
Disables the congestion control functionality from the system. It is actually the default behavior.

Usage
Congestion control on the system is used to monitor the system for conditions that could potentially degrade performance when the system is under heavy load. Typically, these conditions are temporary (i.e. high CPU or memory utilization) and are quickly resolved. However, continuous or large numbers of these conditions within a specific time interval may impact the system’s ability to service subscriber sessions. The purpose of congestion control is to aid in the identification of such conditions and invoke policies for addressing the situation.

Congestion control operation is based on the configuration of the following:

- **Call disconnections on overload**: With this functionality, the system enables and disables the policy for disconnecting passive calls (chassis-wide) during an overload situation. It also configures and fine-tunes the overload-disconnect congestion control policy for an entire chassis.

- **Congestion condition thresholds**: Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). These thresholds function in a similar fashion to the operation thresholds that can be configured for the system (as described in later in this chapter). The primary difference is that when these thresholds are reached, not only is an SNMP trap generated (starCongestion), but a service congestion policy is invoked as well.

  A threshold tolerance is configured to dictate the percentage under the configured threshold that must be reached in order for the condition to be considered “cleared”. An SNMP trap (starCongestionClear) is then triggered.
**Service congestion policies:** Congestion policies are configurable for each service (e.g., PDSN, GGSN, P-GW, SGSN, etc.). These policies dictate how services respond should the system detect that a congestion condition threshold has been crossed.

Since the congestion control functionality on the system is disabled by default, this command should be executed once congestion-control thresholds and policies have been configured. (Refer to the other congestion-control related commands for more information.)

**Example**

The following command enables the congestion control functionality on the system.

```
congestion-control
```
congestion-control overload-disconnect

This command enables and disables the policy for disconnecting passive calls (chassis-wide) during an overload situation. It also configures and fine-tunes the overload-disconnect congestion control policy for an entire chassis.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

congestion-control overload-disconnect [ iterations-per-stage integer | percent percentage_value | threshold { license-utilization percentage_value | max-sessions-per-service-utilization percentage_value | tolerance number } ]

default congestion-control overload-disconnect [ iterations-per-stage | percent | threshold { license-utilization | max-sessions-per-service-utilization | tolerance } ]

no congestion-control overload-disconnect

---

**default**

When “default” and one of the keywords is added to the command, the policy remains in its current state and the value for the specified keyword is reset to its default value.

When “default” and the command are entered without keywords, the overload-disconnect policy for congestion control is disabled.

---

**no**

Disables the overload-disconnect policy for congestion control.

---

**iterations-per-stage integer**

Specifies the number of calls to be disconnected during the defined number of seconds. *integer* is a value from 2 through 8. The default value is 8.

---

**percent percentage_value**

Specifies the percentage of calls to be disconnected, in stages, during an overload situation. *percentage_value* is an integer from 1 through 100. The default value is 5.
threshold

license-utilization: Specifies the license-utilization percentage threshold for overload situations. If candidates are available, passive calls are disconnected when this threshold is exceeded.

percentage_value is an integer from 1 through 100. The default value is 80.

max-sessions-per-service-utilization: Specifies a percentage of the maximum sessions per service. If candidates are available, passive calls are disconnected when this threshold is exceeded.

percentage_value is an integer from 1 through 100. The default value is 80.

tolerance: Specifies the percentage of calls the system disconnects below the values set for the other two thresholds. In either case, a Clear Traps message is sent after the number of calls goes below the corresponding threshold value. number is an integer from 1 through 25. The default value is 10.

Usage

Use this command to set the policy for call disconnects when the chassis experiences call overload.

To verify the congestion-control configuration use show congestion-control configuration from the Exec mode.

To set overload-disconnect policies for individual subscribers, see overload-disconnect in Subscriber Configuration Mode Commands.

Example

The following command sets an overload-disconnect policy for the chassis in which 5 calls would be disconnected very 5 seconds during an overload situation.

congestion-control overload-disconnect iterations-per-stage 5

Both of the following commands disable the overload-disconnect policy without changing the policy configuration.

default congestion-control overload-disconnect

or

no congestion-control overload-disconnect

To instruct the system to stop call disconnects when the number of calls goes down 85% of the total allowed calls for that service, enter both of the following commands to set the max-sessions-per-service-utilization value to 90% and the tolerance value to 5%:

congestion-control overload-disconnect threshold max-sessions-per-service-utilization 90

congestion-control overload-disconnect threshold tolerance 5
congestion-control policy

Configures congestion control policies.

Product

[local]host_name(config)#

Syntax

congestion-control policy { asngw-service | asnpc-service | cscf-service | fng-service | ggsn-service | ha-service | hnbgw-service | hsgw-service | ipsg-service | lma-service | lns-service | mipv6ha-service | pcc-af-service | pcc-policy-service | pdg-service | pdif-service | pdsn-service | pdsclosedrp-service | pgw-service | phsgw-service | phspc-service | saegw-service | sgsn-service | sgw-service | wsg-service } action { drop | none | redirect | reject }

congestion-control policy { epdg-service | samog-service } action { drop | none | reject }

congestion-control policy mme-service action { drop | none | reject | report-overload { permit-emergency-sessions | reject-new-sessions | reject-non-emergency-sessions } enodeb-percentage percentage }

congestion-control policy { critical mme-service action-profile action_profile_name | major mme-service action-profile action_profile_name | minor mme-service action-profile action_profile_name }

default congestion-control policy { asngw-service | asnpc-service | cscf-service | epdg-service | fng-service | ggsn-service | ha-service | hnbgw-service | hsgw-service | ipsg-service | lma-service | lns-service | mipv6ha-service | mme-service | pcc-af-service | pcc-policy-service | pdg-service | pdif-service | pdsn-service | pdsclosedrp-service | pgw-service | phsgw-service | phspc-service | saegw-service | sgsn-service | sgw-service | wsg-service }

default

Specifies the Congestion Control policy action for the selected service to its default value.

asngw-service

Specifies the Congestion Control policy action for the ASN-GW service.
asnpcc-service
Specifies the Congestion Control policy action for the ASN PC-LR service.

critical
For MME (starting with Release 14.0), this keyword associates the action-profile to be used for critical congestion thresholds for the MME service.

cscf-service
Specifies the Congestion Control policy action for the P-CSCF/A-BG service. Supported policy actions are:
* drop: Specifies that the system should drop incoming packets containing new session requests.
* none: Specifies that the system should take no action.
* redirect: Specifies that the system should redirect new session requests to an alternate device.

**Important:** If this option is used, the IP address of the alternate device must be configured using the policy overload redirect command that is part of the CSCF policy rules configuration.

* reject: Specifies that the system processes new session request messages and responds with a reject message.

epdg-service action
Specifies the Congestion Control policy action for the ePDG service. Supported policy actions are:
* drop: Specifies that the system should drop incoming packets containing new session requests.
* none: Specifies that the system should take no action.
* reject: Specifies that the system processes new session request messages and responds with a reject message.

For ePDG type of session/calls, redirect action is not supported.

fng-service
Specifies the Congestion Control policy action for the FNG service.

ggsn-service
Specifies the Congestion Control policy action for the GGSN service.

ha-service
Specifies the Congestion Control policy action for the HA service.

hnbgw-service
Specifies the Congestion Control policy action for the HNB-GW service. Supported policy actions are:
* drop: Specifies that the system should drop incoming packets containing new session requests.
* none: Specifies that the system should take no action.
Global Configuration Mode Commands (A-K)

congestion-control policy

• reject: Specifies that the system processes new session request messages and responds with a reject message.

hsgw-service

Specifies the Congestion Control policy action for the HSGW service.
Supported policy actions are:
• drop: Specifies that the system should drop incoming packets containing new session requests.
• none: Specifies that the system should take no action.
• redirect: Specifies that the system should redirect new session requests to an alternate device.

Important: If this option is used, the IP address of the alternate device must be configured using the policy overload redirect command that is part of the HSGW service configuration.

• reject: Specifies that the system processes new session request messages and responds with a reject message.

ipsg-service

Specifies the Congestion Control Policy action for the IPSG service. The policy specifies how the IPSG service will respond when the system detects that a congestion condition threshold has been crossed.
Supported policy actions are:
• drop: Specifies that the system should drop incoming packets containing new session requests.
• none: Specifies that the system should take no action.

Default: none

lma-service

Specifies the Congestion Control policy action for the LMA service

lns-service

Specifies the Congestion Control policy action for the LNS service.

mipv6ha-service

Specifies the Congestion Control policy action for the MIPv6-HA service.

major

For MME (starting with Release 14.0), this keyword associates the action-profile to be used for major congestion thresholds for the MME service.

minor

For MME (starting with Release 14.0), this keyword associates the action-profile to be used for minor congestion thresholds for the MME service.

mme-service

Sets the congestion control policy for action to take when subscriber sessions exceeds the defined threshold limit.
For MME type of session/calls, **redirect** action is not supported.

**Important:** The `mme-service` keyword option is available only in releases prior to 14.0. In 14.0 and higher, you must first select either the critical, major or minor policy level first. Refer to the `congestion-action-profile` command in the LTE Policy Configuration mode to create action-profiles which in turn define the actions to be taken when thresholds are exceeded in Release 14.0 and higher for MME.

---

### pcc-af-service

Specifies the Congestion Control policy action for the PCC Application Function (AF) service. Supported policy actions are:

- **drop**: Specifies that the system should drop incoming packets containing new session requests.
- **none**: Specifies that the system should take no action.
- **reject**: Specifies that the system processes new session request messages and responds with a reject message.

### pcc-policy-service

Specifies the Congestion Control policy action for the PCC Policy service. Supported policy actions are:

- **drop**: Specifies that the system should drop incoming packets containing new session requests.
- **none**: Specifies that the system should take no action.
- **reject**: Specifies that the system processes new session request messages and responds with a reject message.

### pdg-service

Specifies the Congestion Control policy action for the PDG service.

### pdif-service

Specifies the Congestion Control policy action for the PDIF service.

### pdsn-service

Specifies the Congestion Control policy action for the PDSN service.

### pgw-service

Specifies the Congestion Control policy action for the P-GW service. Supported policy actions are:

- **drop**: Specifies that the system should drop incoming packets containing new session requests.
- **none**: Specifies that the system should take no action.
- **reject**: Specifies that the system processes new session request messages and responds with a reject message.

For P-GW sessions/calls, **redirect** action is not supported.

### saegw-service

Specifies the Congestion Control policy action for the SAEGW service. Supported policy actions are:
congestion-control policy

- **drop**: Specifies that the system should drop incoming packets containing new session requests.
- **none**: Specifies that the system should take no action.
- **reject**: Specifies that the system processes new session request messages and responds with a reject message.

For SAEGW sessions/calls, **redirect** action is not supported.

---

**samog-service**

Specifies the Congestion Control policy action for the SaMOG service.

Supported policy actions are:

- **drop**: Specifies that the system should drop incoming packets containing new session requests.
- **none**: Specifies that the system should take no action.
- **reject**: Specifies that the system processes new session request messages and responds with a reject message.

---

**sgsn-service**

Specifies the Congestion Control policy - the congestion response actions for the SGSN service.

Prior to Release 17.0, the supported policy actions in this command are:

- **drop**: Specifies that the system should drop incoming packets containing new session requests.
- **none**: Specifies that the system should take no action.
- **reject**: Specifies that the system processes new session request messages and responds with a reject message.

---

**sgw-service**

Specifies the Congestion Control policy action for the S-GW service.

Supported policy actions are:

- **drop**: Specifies that the system should drop incoming packets containing new session requests.
- **none**: Specifies that the system should take no action.
- **reject**: Specifies that the system processes new session request messages and responds with a reject message.

For S-GW sessions/calls, **redirect** action is not supported.

---

**wsg-service**

Specifies the Congestion Control policy action for the WSG service.

Supported policy actions are:

- **drop**: Specifies that the system should drop incoming packets containing new session requests.
- **none**: Specifies that the system should take no action.
- **reject**: Specifies that the system processes new session request messages and responds with a reject message.

---

**action { drop | none | redirect | reject }**

Specifies the policy action:

- **drop**: Specifies that the system should drop incoming packets containing new session requests.
Global Configuration Mode Commands (A-K)

congestion-control policy

- **none**: Specifies that the system should take no action. This is the default for PDIF-service.
- **redirect**: Specifies that the system should redirect new session requests to an alternate device. (CSCF, HA, HSGW, and PDSN only)

**Important**: If this option is used, the IP address of the alternate device must be configured using the `policy overload redirect` command that is part of the service configuration. Note that this option can not be used in conjunction with GGSN, MME, P-GW, SAEGW, or S-GW services.

- **reject**: Specifies that the system processes new session request messages and responds with a reject message.
  (For PDSN and HA, the reply code is 130, “insufficient resources”. For the GGSN, the reply code is 199, “no resources available”.)

```
report-overload { permit-emergency-sessions | reject-new-sessions | reject-non-emergency-sessions } enodeb-percentage percentage
```

**Important**: This set of keywords is supported only by the MME.

Enables the MME to report overload conditions to eNodeBs and take additional action to alleviate congestion situations.
- `permit-emergency-sessions`: Specifies that only emergency sessions are allowed to access the MME during the overload period.
- `reject-new-sessions`: Specifies that all new sessions destined for the MME will be rejected during the overload period.
- `reject-non-emergency-sessions`: Specifies that all non-emergency sessions will be rejected during the overload period.
- `enodeb-percentage percentage`: Configures the percentage of known eNodeBs that will receive the overload report. `percentage` must be an integer from 1 to 100.

**Usage**

Congestion policies can be configured for each service. When congestion control functionality is enabled, these policies dictate how services respond should the system detect that a congestion condition threshold has been crossed.

**Example**

The following command configures a congestion control policy of reject for PDSN services:

```
congestion-control policy pdsn-service action reject
```

The following command configures a congestion control policy of reject for MME services:

```
congestion-control policy mme-service action reject
```
congestion-control threshold

Configures the congestion control threshold values that are to be monitored.

Product
All

Privilege

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

congestion-control threshold { license-utilization percent | max-sessions-per-service-utilization percent | message-queue-utilization percent | message-queue-wait-time time | port-rx-utilization percent | port-specific { slot/port | all } [ tx-utilization percent ] [ rx-utilization percent ] port-specific-rx-utilization critical | port-specific-tx-utilization critical | port-tx-utilization percent | service-control-cpu-utilization percent | system-cpu-utilization percent | system-memory-utilization percent | tolerance percent }

no congestion-control threshold port-specific { slot/port | all }

no congestion-control threshold port-specific { slot/port | all } [ rx-utilization percent ] [ tx-utilization percent ]

no congestion-control threshold port-specific-rx-utilization critical

no congestion-control threshold port-specific-tx-utilization critical

no congestion-control threshold { message-queue-utilization | message-queue-wait-time | port-rx-utilization percent | port-tx-utilization percent | service-control-cpu-utilization | system-cpu-utilization | system-memory-utilization }

default congestion-control threshold keyword

Sets the threshold keyword to its default value.

no congestion-control threshold port-specific { slot/port | all }

This command disables port specific threshold monitoring on the specified port or on all ports.

slot/port: Specifies the port for which port specific threshold monitoring is being configured. The slot and port must refer to an installed card and port.
**Global Configuration Mode Commands (A-K)**

**congestion-control threshold**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>all: Set port specific threshold monitoring for all ports on all cards.</td>
<td></td>
</tr>
<tr>

Global Configuration Mode Commands (A-K)

**congestion-control threshold**

- **all**: Set port specific threshold monitoring for all ports on all cards.
- **rx-utilization percent**: Default 80%. The average percent utilization of port resources for the specified port by received data as measured in 5-minute intervals. `percent` must be an integer from 0 through 100.
- **tx-utilization percent**: Default 80%. The average percent utilization of port resources for the specified port by transmitted data as measured in 5-minute intervals. `percent` must be an integer from 0 through 100.

```plaintext
[ no ] port-tx-utilization percent
```
Default: 80
The average percent utilization of port resources for all ports by transmitted data as measured in 5-minute intervals.
`percent` can be an integer from 0 through 100.

**service-control-cpu-utilization percent**
Default: 80
The average percent utilization of CPUs on which a Demux Manager software task instance is running as measured in 10-second intervals.
`percent` can be an integer from 0 through 100.

**system-cpu-utilization percent**
Default: 80
The average percent utilization for all PSC/PSC2 CPUs available to the system as measured in 10-second intervals.
`percent` can be an integer from 0 through 100.
This threshold setting can be disabled with `no congestion-control threshold system-cpu-utilization` command. In case later you want to enable the same threshold setting `congestion-control threshold system-cpu-utilization` command will enable the CPU utilization threshold to preconfigured level.

**system-memory-utilization percent**
Default: 80
The average percent utilization of all CPU memory available to the system as measured in 10-second intervals.
`percent` can be an integer from 0 through 100.

**tolerance percent**
Default: 10
The percentage under a configured threshold that dictates the point at which the condition is cleared.
`percent` can be an integer from 0 through 100.

**Usage**
Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). These thresholds function in a similar fashion to the operation thresholds that can be configured for the system (as described in later in this chapter). The primary difference is that when these thresholds are reached, not only is an SNMP trap generated (starCongestion), but a service congestion policy is invoked as well.
The tolerance parameter establishes the threshold at which the condition is cleared. An SNMP trap (starCongestionClear) is generated for the clear condition, as well.
Important: The MME (version 14.0 and higher) supports three levels of thresholds – critical, major and minor – for each condition. Refer to the congestion-control threshold commands immediately following this command for information specific to the MME.

Example

The following command configures a system CPU utilization threshold of 75%.

```
congestion-control threshold system-cpu-utilization 75
```

This setting will remain in configuration unless you specify another threshold value in place of 75. This threshold setting can be disabled with `no congestion-control threshold system-cpu-utilization` command but cannot be removed from configuration. Later if you want to enable the previously configured threshold value of 75 percent, you only need to enter the `congestion-control threshold system-cpu-utilization` command without specifying any threshold value. It will enable the CPU utilization threshold to preconfigured level of 75 percent.

For example, `no congestion-control threshold system-cpu-utilization` disables the configured threshold setting and `congestion-control threshold system-cpu-utilization` again enables the threshold setting of 75%.

The following command configures a threshold tolerance of 5%:

```
congestion-control threshold license-utilization tolerance 5
```

In the above examples, the starCongestion trap gets triggered if the license utilization goes above 75% and the starCongestionClear trap gets triggered if it reaches or goes below 70%.
congestion-control threshold license-utilization

Configures the congestion threshold levels for license utilization on the system.

**Important:** This command applies to MME (version 14.0 and higher) and ePDG (version 14.1 and higher).

**Product**
- MME
- ePDG

**Privilege**
- Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
congestion-control threshold license-utilization { critical percent | major percent | minor percent }
```

```
default congestion-control threshold license-utilization
```

Sets all license-utilization thresholds to the default values.

**Critical percent**

Default: 100
The critical threshold value for percent utilization of licensed session capacity, measured in 10-second intervals.
`percent` can be configured to any integer value from 0 to 100.

**Major percent**

Default: 0
The major threshold value for percent utilization of licensed session capacity, measured in 10-second intervals.
`percent` can be configured to any integer value from 0 to 100.

**Minor percent**

Default: 0
The minor threshold value for percent utilization of licensed session capacity, measured in 10-second intervals.
`percent` can be configured to any integer value from 0 to 100.
Usage

Use this command to set the critical, major and minor threshold levels of licensed session capacity as a percentage as measured in 10-second intervals. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well. This command requires a valid product license.

Example

The following command configures a minor threshold level for license utilization of 25%.

```
congestion-control threshold license-utilization minor 25
```

This setting will remain in configuration unless you specify another minor threshold level in place of 25. The following command returns the critical, major, and minor thresholds levels to their default values:

```
default congestion-control threshold license-utilization
```
congestion-control threshold max-sessions-per-service-utilization

Configures the congestion thresholds for the maximum sessions allowed per service.

Important: This command applies to MME (version 14.0 and higher) and ePDG (version 14.1 and higher).

Product
MME
ePDG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

congestion-control threshold max-sessions-per-service-utilization { critical percent | major percent | minor percent }

default congestion-control threshold max-sessions-per-service-utilization

default congestion-control threshold max-sessions-per-service-utilization

Sets all max-sessions-per-service-utilization thresholds to the default values.

critical percent

Default: 80
The critical threshold value for percent utilization of the maximum sessions allowed per service.
percent can be configured to any integer value from 0 to 100.

major percent

Default: 0
The major threshold value for percent utilization of the maximum sessions allowed per service.
percent can be configured to any integer value from 0 to 100.

minor percent

Default: 0
The minor threshold value for percent utilization of the maximum sessions allowed per service.
percent can be configured to any integer value from 0 to 100.
Usage

Use this command to set the critical, major and minor threshold levels of maximum sessions per service as a percentage measured in real-time. This threshold is based on the maximum number of sessions or PDP contexts configured for the a particular service. (Refer to the `bind` command for the PDSN, GGSN, SGSN, or HA services.)

Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well.

This command requires a valid product license.

Example

The following command configures a minor threshold level of 25%.

```bash
congestion-control threshold max-sessions-per-service-utilization minor 25
```

This setting will remain in configuration unless you specify another minor threshold level in place of 25.

The following command returns the critical, major, and minor thresholds levels to their default values:

```bash
default congestion-control threshold max-sessions-per-service-utilization
```
congestion-control threshold message-queue-utilization

Configures the congestion thresholds for the percent utilization of the Demux Manager software task’s message queue.

**Important:** This command applies to ePDG (version 14.1 and higher).

**Product**
ePDG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
congestion-control threshold message-queue-utilization { critical percent | major percent | minor percent }
```

**default congestion-control threshold message-queue-utilization**

Sets all max-sessions-per-service-utilization thresholds to the default values.

**critical percent**

Default: 80

The critical threshold value for percent utilization of the Demux Manager software task’s message queue as measured in 10-second intervals.

*percent* can be configured to any integer value from 0 to 100.

**major percent**

Default: 0

The major threshold value for percent utilization of the Demux Manager software task’s message queue as measured in 10-second intervals.

*percent* can be configured to any integer value from 0 to 100.

**minor percent**

Default: 0

The minor threshold value for percent utilization of the Demux Manager software task’s message queue as measured in 10-second intervals.

*percent* can be configured to any integer value from 0 to 100.
Usage

Use this command to set the critical, major and minor threshold levels of percent utilization of the Demux Manager software task’s message queue as measured in 10-second intervals. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well. This command requires a valid product license.

Example

The following command configures a minor threshold level of 25%.

```
congestion-control threshold message-queue-utilization minor 25
```

This setting will remain in configuration unless you specify another minor threshold level in place of 25. The following command returns the critical, major, and minor thresholds levels to their default values:

```
default congestion-control threshold message-queue-utilization
```
congestion-control threshold message-queue-wait-time

Configures the congestion thresholds for the maximum time (in seconds) messages can be held in queue as measured by packet time stamps.

**Important:** This command applies to ePDG (version 14.1 and higher).

**Product**
ePDG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
congestion-control threshold message-queue-wait-time { critical time | major time | minor time }
```

`default congestion-control threshold message-queue-wait-time`

Sets all max-queue-wait-time thresholds to the default values.

**critical time**

Default: 5

The critical threshold value for the maximum time (in seconds) that messages can be held in queue as measured by packet time stamps.

*time* is measured in seconds and can be an integer from 1 through 30.

**major time**

Default: 0

The major threshold value for the maximum time (in seconds) that messages can be held in queue as measured by packet time stamps.

*time* is measured in seconds and can be an integer from 1 through 30.

**minor time**

Default: 0

The minor threshold value for the maximum time (in seconds) that messages can be held in queue as measured by packet time stamps.

*time* is measured in seconds and can be an integer from 1 through 30.
Usage
Use this command to set the critical, major and minor threshold levels for the maximum time (in seconds) messages can be held in queue. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed a congestion action-profile is invoked, if configured. This command requires a valid product license.

Example
The following command configures a major threshold level of 4 seconds.

```bash
congestion-control threshold message-queue-wait-time major 4
```
This setting will remain in configuration unless you specify another minor threshold level in place of 4. The following command returns the critical, major, and minor thresholds levels to their default values:

```bash
default congestion-control threshold message-queue-wait-time
```
congestion-control threshold port-rx-utilization

Configures the congestion thresholds for average percent utilization of port resources for all ports by received data as measured in 5-minute intervals.

Important: This command applies to ePDG (version 14.1 and higher).

Product
ePDG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

congestion-control threshold port-rx-utilization { critical percent | major percent | minor percent }

default congestion-control threshold port-rx-utilization

default congestion-control threshold port-rx-utilization
Sets all port-rx-utilization thresholds to the default values.

critical percent

Default: 80
The critical threshold value for average percent utilization of port resources for all ports by received data as measured in 5-minute intervals.
percent can be configured to any integer value from 0 to 100.

major percent

Default: 0
The major threshold value for average percent utilization of port resources for all ports by received data as measured in 5-minute intervals.
percent can be configured to any integer value from 0 to 100.

minor percent

Default: 0
The minor threshold value for average percent utilization of port resources for all ports by received data as measured in 5-minute intervals.
percent can be configured to any integer value from 0 to 100.
Usage
Use this command to set the critical, major and minor threshold levels of average percent utilization of port resources for all ports by received data as measured in 5-minute intervals. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well. This command requires a valid product license.

Example
The following command configures a minor threshold level of 25%.

```
congestion-control threshold port-rx-utilization minor 25
```

This setting will remain in configuration unless you specify another minor threshold level in place of 25. The following command returns the critical, major, and minor thresholds levels to their default values:

```
default congestion-control threshold port-rx-utilization
```
congestion-control threshold port-specific

Configures the congestion thresholds for specific port utilization.

**Important:** This command applies to ePDG (version 14.1 and higher).

**Product**
ePDG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
congestion-control threshold port-specific { slot/port [ tx-utilization { critical percent | major percent | minor percent } ] [ rx-utilization { critical percent | major percent | minor percent } ] | all { critical percent | major percent | minor percent } }

no congestion-control threshold port-specific { slot/port { critical | major | minor } | all { critical | major | minor } }
```

Sets all port-specific utilization thresholds to the default values.

**slot/port**

Default: Disabled

Specifies the port for which port specific threshold monitoring is being configured. The slot and port must refer to an installed card and port. If you set port-specific thresholds, when any individual port-specific threshold is reached, congestion control is applied system-wide.

**all**

Set threshold monitoring for all ports on all cards.

**rx-utilization**

Set threshold monitoring for received data only.

**tx-utilization**

Set threshold monitoring for transmitted data only.
**critical percent**

Default: 80
The critical threshold value for average percent utilization of the specified port resources as measured in 5-minute intervals.

*percent* can be configured to any integer value from 0 to 100.

**major percent**

Default: 0
The major threshold value for average percent utilization of the specified port resources as measured in 5-minute intervals.

*percent* can be configured to any integer value from 0 to 100.

**minor percent**

Default: 0
The minor threshold value for average percent utilization of the specified port resources as measured in 5-minute intervals.

*percent* can be configured to any integer value from 0 to 100.

**Usage**

Use this command to set the critical, major and minor threshold levels of average percent utilization of specified resources for all ports by transmitted data as measured in 5-minute intervals. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well.

This command requires a valid product license.

**Example**

The following command configures a minor threshold level of 5% for received data on port 1 of the card in slot 17.

```
congestion-control threshold port-specific 17/1 rx-utilization minor 5
```

This setting will remain in configuration unless you specify another minor threshold level in place of 5.
congestion-control threshold port-rx-utilization

Configures the congestion thresholds for average percent utilization of port resources for all ports by received data as measured in 5-minute intervals.

Important: This command applies to ePDG (version 14.1 and higher).

Product

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

congestion-control threshold port-rx-utilization { critical percent | major percent | minor percent }  

default congestion-control threshold port-rx-utilization

Sets all port-rx-utilization thresholds to the default values.

critical percent

Default: 80
The critical threshold value for average percent utilization of port resources for all ports by received data as measured in 5-minute intervals. percent can be configured to any integer value from 0 to 100.

major percent

Default: 0
The major threshold value for average percent utilization of port resources for all ports by received data as measured in 5-minute intervals. percent can be configured to any integer value from 0 to 100.

minor percent

Default: 0
The minor threshold value for average percent utilization of port resources for all ports by received data as measured in 5-minute intervals. percent can be configured to any integer value from 0 to 100.
Usage

Use this command to set the critical, major and minor threshold levels of average percent utilization of port resources for all ports by received data as measured in 5-minute intervals. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well.

This command requires a valid product license.

Example

The following command configures a minor threshold level of 25%.

```plaintext
congestion-control threshold port-rx-utilization minor 25
```

This setting will remain in configuration unless you specify another minor threshold level in place of 25. The following command returns the critical, major, and minor thresholds levels to their default values:

```plaintext
default congestion-control threshold port-rx-utilization
```
congestion-control threshold port-tx-utilization

Configures the congestion thresholds for average percent utilization of port resources for all ports by transmitted data as measured in 5-minute intervals.

**Important:** This command applies to ePDG (version 14.1 and higher).

**Product**
ePDG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**

`congestion-control threshold port-tx-utilization { critical percent | major percent | minor percent }`

`default congestion-control threshold port-tx-utilization`

Sets all port-tx-utilization thresholds to the default values.

**Critical percent**

Default: 80
The critical threshold value for average percent utilization of port resources for all ports by transmitted data as measured in 5-minute intervals. `percent` can be configured to any integer value from 0 to 100.

**Major percent**

Default: 0
The major threshold value for average percent utilization of port resources for all ports by transmitted data as measured in 5-minute intervals. `percent` can be configured to any integer value from 0 to 100.

**Minor percent**

Default: 0
The minor threshold value for average percent utilization of port resources for all ports by transmitted data as measured in 5-minute intervals. `percent` can be configured to any integer value from 0 to 100.
Usage

Use this command to set the critical, major and minor threshold levels of average percent utilization of port resources for all ports by transmitted data as measured in 5-minute intervals. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well. This command requires a valid product license.

Example

The following command configures a minor threshold level of 25%.

```
congestion-control threshold port-tx-utilization minor 25
```

This setting will remain in configuration unless you specify another minor threshold level in place of 25.

The following command returns the critical, major, and minor thresholds levels to their default values:

```
default congestion-control threshold port-tx-utilization
```
congestion-control threshold service-control-cpu-utilization

Configures the congestion thresholds for average percent utilization of CPUs on which a Demux Manager software task instance is running as measured in 10-second intervals.

Important: This command applies to MME (version 14.0 and higher) and ePDG (version 14.1 and higher).

**Product**

MME

ePDG

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
congestion-control threshold service-control-cpu-utilization { critical percent | major percent | minor percent }
```

**default congestion-control threshold service-control-cpu-utilization**

Sets all service-control-cpu-utilization thresholds to the default values.

**critical percent**

Default: 80

The critical threshold value for average percent utilization of CPUs on which a Demux Manager software task instance is running as measured in 10-second intervals.

*percent* can be configured to any integer value from 0 to 100.

**major percent**

Default: 0

The major threshold value for average percent utilization of CPUs on which a Demux Manager software task instance is running as measured in 10-second intervals.

*percent* can be configured to any integer value from 0 to 100.

**minor percent**

Default: 0

The minor threshold value for average percent utilization of CPUs on which a Demux Manager software task instance is running as measured in 10-second intervals.

*percent* can be configured to any integer value from 0 to 100.
Usage

Use this command to set the critical, major and minor threshold levels of average percent utilization of CPUs on which a Demux Manager software task instance is running as measured in 10-second intervals. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well.

When the service-control-cpu-utilization critical threshold setting is exceeded, ipsecmgrs running in the congested CPU are notified of the congestion. The ipsecmgrs raise traps for service-congestion exceeded and update the NPU so that no new calls are sent to those ipsecmgrs. The NPU does not send any new calls to the congested ipsecmgrs. However, if all ipsecmgrs are congested the action is always drop regardless of the setting for congestion policy action. The packet drops are silently done by the NPU.

When ipsecmgrs are congested and an NPU receives a packet whose Security Parameter Index, Initiator (SPIi) in IKE_SA_INIT matches that of a currently established session, the packet is classified as belonging to the existing session. Since congestion action is applied only on new sessions, such IKE_SA_INIT packets are allowed to create sessions. If the IKE_SA_INIT uses an SPIi which does not match any of the existing sessions, it is processed according to the congestion policy action.

This command requires a valid product license.

Example

The following command configures a minor threshold level of 25%.

```
congestion-control threshold service-control-cpu-utilization minor 25
```

This setting will remain in configuration unless you specify another minor threshold level in place of 25. The following command returns the critical, major, and minor thresholds levels to their default values:

```
default congestion-control threshold service-control-cpu-utilization
```
congestion-control threshold system-cpu-utilization

Configures the congestion thresholds for average percent CPU utilization of all packet processing cards available to the system as measured in 10-second intervals.

Important: This command applies to MME (version 14.0 and higher) and ePDG (version 14.1 and higher).

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

congestion-control threshold system-cpu-utilization { critical percent | major percent | minor percent }

default congestion-control threshold system-cpu-utilization

Sets all system-cpu-utilization thresholds to the default values.

critical percent

Default: 80
The critical threshold value for average percent CPU utilization of all packet processing cards available to the system.
percent can be configured to any integer value from 0 to 100.

major percent

Default: 0
The major threshold value for average percent CPU utilization of all packet processing cards available to the system.
percent can be configured to any integer value from 0 to 100.

minor percent

Default: 0
The minor threshold value for average percent CPU utilization of all packet processing cards available to the system.
percent can be configured to any integer value from 0 to 100.
Usage

Use this command to set the critical, major and minor threshold levels of average percent CPU utilization of all packet processing cards available to the system as measured in 10-second intervals. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well. This command requires a valid product license.

Example

The following command configures a minor threshold level of 25%.

    congestion-control threshold system-cpu-utilization minor 25

This setting will remain in configuration unless you specify another minor threshold level in place of 25. The following command returns the critical, major, and minor thresholds levels to their default values:

    default congestion-control threshold system-cpu-utilization
congestion-control threshold system-memory-utilization

Configures the congestion thresholds for the average percent utilization of all CPU memory available to the system as measured in 10-second intervals.

Important: This command applies to MME (version 14.0 and higher) and ePDG (version 14.1 and higher).

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config)#

Syntax

congestion-control threshold system-memory-utilization { critical percent | major percent | minor percent }

default congestion-control threshold system-memory-utilization

default congestion-control threshold system-memory-utilization

Sets all system-memory-utilization thresholds to the default values.

critical percent

Default: 80
The critical threshold value for the average percent utilization of all CPU memory available to the system as measured in 10-second intervals. percent can be configured to any integer value from 0 to 100.

major percent

Default: 0
The major threshold value for the average percent utilization of all CPU memory available to the system as measured in 10-second intervals. percent can be configured to any integer value from 0 to 100.

minor percent

Default: 0
The minor threshold value for the average percent utilization of all CPU memory available to the system as measured in 10-second intervals. percent can be configured to any integer value from 0 to 100.
Usage

Use this command to set the critical, major and minor threshold levels of average percent utilization of all CPU memory available to the system as measured in 10-second intervals. Thresholds dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the system (congested or clear). When these thresholds are crossed, an SNMP trap is generated (starCongestion) and, if configured, a congestion action-profile is invoked as well. This command requires a valid product license.

Example

The following command configures a minor threshold level of 25%.

    congestion-control threshold system-memory-utilitization minor 25

This setting will remain in configuration unless you specify another minor threshold level in place of 25. The following command returns the critical, major, and minor thresholds levels to their default values:

    default congestion-control threshold system-memory-utilization
congestion-control threshold tolerance

Configures the percentage under a configured threshold value that dictates the point at which the condition is cleared.

**Important:** This command applies to MME (version 14.0 and higher) and ePDG (version 14.1 and higher).

**Product**
- MME
- ePDG

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
- configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
congestion-control threshold tolerance { critical percent | major percent | minor percent }

default congestion-control threshold tolerance system-cpu-utilization
```

**default congestion-control threshold tolerance**

Sets all threshold tolerances to the default values.

**critical percent**

Default: 10
The tolerance percentage for critical thresholds. When a critical threshold drops below this level, the condition is cleared.
`percent` can be configured to any integer value from 0 to 100.

**major percent**

Default: 0
The tolerance percentage for major thresholds. When a major threshold drops below this level, the condition is cleared.
`percent` can be configured to any integer value from 0 to 100.

**minor percent**

Default: 0
The tolerance percentage for minor thresholds. When a minor threshold drops below this level, the condition is cleared.
`percent` can be configured to any integer value from 0 to 100.
Usage
Use this command to set the tolerance limits for critical, major and minor thresholds. The tolerance parameter establishes the threshold at which the condition is cleared. An SNMP trap (starCongestionClear) is generated for the clear condition. This command requires a valid product license.

Example
The following command configures the tolerance level of 5% for minor thresholds.

```
congestion-control threshold tolerance minor 5
```

This setting will remain in configuration unless you specify another tolerance for minor thresholds in place of 5.

The following command returns the critical, major, and minor threshold tolerance levels to their default values:

```
default congestion-control threshold tolerance
```
connectedapps

Enables the configuration of Connected Apps (CA) client communication with the IOS-XR CA server on an ASR 9000. This command sends you to the Connected Apps Configuration mode.

**Product**
SecGW (WSG)

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**
connectedapps

**Usage**
Use this command to go to the Connected Apps Configuration mode. In this mode you can set CA client session parameters and ASR 9000 VSM High Availability (HA) chassis and network modes.

**Example**
The following command sends you to the Connected Apps Configuration mode:

connectedapps
content-filtering category database directory

This command configures the base directory to be used for storing all content-rating databases that are required for Category-based Content Filtering application.

**Product**

CF

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

content-filtering category database directory path directory_path

default content-filtering category database directory path

default

Specifies the default base directory and directory path for Category-based Content Filtering application.

directory_path

Default: /pcmcia1/cf

Specifies the base directory and its path to store all of the full or incremental content rating databases for the Category-based Content Filtering application.
directory_path must be an alphanumeric string of 1 through 255 characters.

**Usage**

Use this command to specify the directory and its path to download all full or incremental category-rating databases to be used for the Category-based Content Filtering application.

Merging of incremental database can be done as part of the database upgrade process performed with upgrade content-filtering category database command in the Executive Mode.

**Example**

The following command configures the /flash/cf_temp/DB as the base directory to download all full and incremental content-rating databases for content filtering application.

content-filtering category database directory path /flash/cf_temp/DB
content-filtering category database max-versions

This command configures the number of full content-rating databases to maintain/archive in the base directory for category-based content filtering application.

**Product**
CF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
content-filtering category database max-versions num_archive

default content-filtering category database max-versions
```

**Usage**

Set the default number of full databases for specified directory path/location.

```
default
```

**num_archive**

Default: 2

Specifies the maximum number of database to be archived or maintained in the specific location.

```
num_archive must be an integer from 1 through 3.
```

**Example**

The following command configures the system to maintain 3 full content-rating databases for category-based content filtering application.

```
content-filtering category database max-versions 3
```
content-filtering category database override

This command specifies the name of a file to be used by the category-rating database load process for category-based content filtering application.

Product: CF

Privilege: Security Administrator, Administrator

Mode: Exec > Global Configuration configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

content-filtering category database override file file_name.extension

default content-filtering category database override file

default

Sets the default content rating database file name; for example, optcmd.bin.

file file_name.extension

Specifies the header of the file in the database directory path location to determine the newest full database. file_name must be an alphanumeric string of up to 10 characters with an extension of 3 characters after a period (.) as extension.

Usage

Use this command to configure the category-rating database file name to determine the newest version of full database. A process called “LOAD_DATABASE” invokes during the system startup or the database upgrade process by upgrade content-filtering category database command in Executive Mode. This process examines the header of each of the files in the database folder specified by content-filtering category directory path command in this mode.

Note that by default system examines the header of those files only which begins with the string “OPTCMDDB” and having extension “.bin”.

Example

The following command configures the system to examine the header of files that begins with CF_sta.DB only for content filtering application.

content-filtering category database override file CF_sta.DB
context

Enters the Context Configuration mode or is used to add or remove a specified context.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
context name [ -noconfirm ]
no context name
```

- **no**
  - Removes the specified context from the configuration.

- **name**
  - Specifies the name of a context to enter, add, or remove. When creating a new context, the context name must be unique.

**Important:** When creating a new context, the `context name` specified must not conflict with the name of any existing context or domain names.

- **-noconfirm**
  - Indicates that the command is to execute without any additional prompt and confirmation from the user.

**Usage**

Configure contexts or remove obsolete contexts.

**Important:** A maximum of 64 contexts may be created.

**Example**

```
context sampleContext

no context sampleContext
```
**crash enable**

Enables or disables the copying of crash data to a specified location.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```configure```
Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
crash enable [ encrypted ] url crash_url [ filename-pattern pattern ] [ restrict mbyte ]
```

```no crash enable```

```
no
```

Removes the specified context from the configuration.

**Important:** System crash information is generated and stored in the crash list even when the `no` keyword is specified. The information maintained in the crash lists is minimal crash information when the `no` keyword has been specified.

- `encrypted`
  Indicates that the URL encrypted for security reasons.

- `filename-pattern pattern`
  The `filename-pattern` is an an alphanumeric string containing any or all of the following variables:
  - `%hostname%` - The system hostname.
  - `%ip%` - A SPIO IP address
  - `%cpu%` - CPU number
  - `%card%` - Card number
  - `%time%` - POSIX timestamp in hexadecimal notation
  - `%filename%` - Alias for `crash-%card%-%cpu%-%time-core%`
  - `%` - A single `%` sign

If no pattern is specified, the result is the same as the pattern `filename`. Use `/` characters in the filename pattern part to store crashes in per-system subdirectories.
url crash_url

Specifies the location to store crash files. `crash_url` may refer to a local or a remote file. `crash_url` must be entered using the following format:

For the ASR 5000:

- `[ file: ]{/flash|/pcmcia1|/hd}[/directory]/
- `tftp://{host[:port#]}/[/directory]/
- `ftp: | sftp: //[/username[:password]@]{host}[/port#]/[/directory]/`

For the ASR 5500:

- `[ file: ]{/flash|/usb1|/hd}[/directory]/
- `tftp://{host[:port#]}/[/directory]/
- `ftp: | sftp: //[/username[:password]@]{host}[/port#]/[/directory]/`

**Important:** Use of the SMC hard drive is not supported in this release.

**Important:** Do not use the following characters when entering a string for the field names below: “/” (forward slash), “:” (colon) or “@” (at sign).

- *directory* is the directory name.
- *filename* is the actual file of interest.
- *username* is the user to be authenticated.
- *password* is the password to use for authentication.
- *host* is the IP address or host name of the server.
- *port#* is the logical port number that the communication protocol is to use.

**restrict mbyte**

Specifies a maximum amount of memory (in megabytes) to use for storing crash files as an integer from 1 through 128. Default: 128

The `restrict` keyword is only applicable to local URLs.

**Usage**

Enable crashes if there are systems that are not stable and the crash information will be useful for trouble shooting. The remote storage of the crash file reduces the memory utilized on the chassis.

**Example**

```
crash enable ftp://remoteABC/pub/crash.dmp
```

```
crash enable /flash/pub/data/crash.dmp restrict 64
```

```
no crash enable
```
**crypto blacklist file**

Configures a blacklist (access denied) file to be used by a Wireless Security Gateway (WSG).

**Product**

All products supporting IPSec blacklisting

**Important:** This command appears in the CLI for this release. However, it has not been qualified for use with any current Cisco StarOS gateway products.

**Privilege**

Security Administrator

**Mode**

Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
crypto blacklist file pathname

no crypto blacklist file
```

**no**

Removes the blacklist file from the system.

**pathname**

Specifies the location of the blacklist file as:

- `[ file: ][/flash]/[usb1]/[hd-raid]/[directory]/<filename>`
- `tftp://[host:[port]][:directory]/<filename>`
- `[ ftp: | sftp: ]//[username:[password]@[host]:port]/[directory]/<filename>`
- `http://[username:[<password>]@]<host>[:<port>]/<directory>/<filename>`

**Usage**

Use this command to configure the location of the blacklist file to be used by a WSG.

A blacklist is a list or register of entities that are being denied a particular privilege, service, mobility, access or recognition. With blacklisting, any peer is allowed to connect as long as it does not appear in the list.

Each entry in the blacklist file should contain the ID type so that the validation is performed for that ID type. In every entry, the ID type and ID value should be separated by a space. Only DOS and UNIX file formatting are supported. For additional information, refer to the *System Administration Guide*. 
**Important:** Either a blacklist, a whitelist or none is configured. Both listing techniques cannot be used simultaneously on the system.

**Example**

```plaintext
crypto blacklist file ftp://remoteABC/pub/blacklist.txt

crypto blacklist file /flash/pub/data/blacklist.txt
```
crypto peer-list

Enables an SecGW to initiate an IKEv2 session setup request when the peer does not initiate a setup request within a specified time interval. Executing this command moves you to the Peer List Configuration mode. This functionality is only applicable for site-to-site (S2S) based tunnels within a WSG service. For remote access tunnels the peer is always the initiator. (VPC-VSM only)

Product
SecGW (WSG)

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:
[local]host_name(config)#

Syntax

crypto peer-list { ipv4 | ipv6 } peer_list_name

no crypto peer-list { ipv4 | ipv6 } peer_list_name

no

Disables the specified crypto peer list.

peer_list_name

Specifies the name of the peer list as an alphanumeric string of one through 32 characters.

Usage

Use this command to enable an SecGW to initiate an IKEv2 session setup request when the peer does not initiate a setup request within a specified time interval. Executing this command moves you to the Peer List Configuration mode. This functionality is only applicable for site-to-site (S2S) based tunnels within a WSG service. For remote access tunnels the peer is always the initiator. (VPC-VSM only)

The following restrictions apply when configuring an SecGW as an Initiator:

- The peer-list peer_list_name command is only executed if the deployment mode for WSG service is site-to-site, and the bind address type matches with the peer list address type (IPv4 or IPv6).
- You cannot change the WSG service deployment-mode if peer-list peer_list_name is enabled under the service. You will be prompted to remove the peer list before changing the mode.
- A maximum of 1,000 peer IP addresses can be added to the peer list via the Peer List Configuration mode address command.
- WSG service address binding is not allowed if a peer list is configured and both address types do not match. An error message is generated if they do not match.
An IPv4 or IPv6 peer list cannot be modified if `peer-list peer_list_name` is enabled under the WSG service.

When a peer list has been configured in the WSG service, the initiator and responder mode timer intervals each default to 10 seconds. The SecGW will wait for 10 seconds in the responder mode for a peer session initiation request before switching to the initiator mode and waiting 10 seconds for a peer response. You can change the default settings for the initiator and/or responder mode intervals using the WSG Service Configuration mode `initiator-mode-duration` and `responder-mode-duration` commands.

For additional information, refer to the Peer List Configuration Mode Commands and WSG Service Configuration Mode Commands chapters of this guide. Also see the Security Gateway as Initiator chapter in the IPSec Reference.

Example

The following command enables SecGW as an Initiator functionality and creates an IPv4 peer list named `peer1`.

```
crypto peer-list ipv4 peer1
```
crypto remote-secret-list

Specifies the remote secret list for storing remote secrets based on the ID type. This command sends you to the Remote Secret List Configuration mode. Only one active remote-secret-list is supported per system.

Product
All products supporting IPSec remote secrets

Important: This command appears in the CLI for this release. However, it has not been qualified for use with any current Cisco StarOS gateway products.

Privilege
Security Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

crypto remote-secret-list listname

no crypto remote-secret-list listname

no

Deletes the remote-secret-list file from the system.

Important: You must unbind the remote-secret-list from any crypto maps or templates before it can be deleted.

listname

Usage

Use this command to specify the remote secret list for storing remote secrets based on the ID type. Only one remote-secret-list can be configured per system. Executing this command places you in the Remote Secret List Configuration mode.

This list of remote pre-shared keys is based on the remote ID type. The remote secret list can contain up to 1000 entries.

For additional information, refer to the Remote Secret List Configuration Commands chapter and the System Administration Guide.

Example

The following command creates a remote-secret-list named rs-list:

crypto remote-secret-list rs-list
crypto whitelist file

Configures a whitelist (access permitted) file to be used by a Wireless Security Gateway (WSG).

**Product**
All products supporting IPSec whitelisting

**Important:** This command appears in the CLI for this release. However, it has not been qualified for use with any current Cisco StarOS gateway products.

**Privilege**
Security Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
crypto whitelist file pathname [ -noconfirm ]
```

```
o crypto whitelist file
```

**no**
Removes the black list file from the system.

```
pathname
```

Specifies the location of the whitelist file as:

- `file:`
  ```
  [/flash|/usb1|/hd-raid]/[directory]/<filename>
  ```

- `tftp://<host>[:port#]/[directory]/<filename>
```

- `ftp: | sftp: //<username>[:password]@[host][:port#]/[directory]/<filename>
```

- `http://<username>[:<password>@@]<host>[:<port>]/[<directory>]/<filename>
```

**Usage**

Use this command to configure the location of the white list file to be used by a WSG.

A whitelist is a list or register of entities that are being provided a particular privilege, service, mobility, access or recognition. With whitelisting, no peer is allowed to connect unless it appears in the list.

Each entry in the whitelist file should contain the ID type so that the validation is performed for that ID type. In every entry, the ID type and ID value should be separated by a space. Only DOS and UNIX file formatting are supported. For additional information, refer to the *System Administration Guide*. 
Important: Usually either a blacklist, a whitelist or none is configured. Both listing techniques cannot be used simultaneously on the system.

Example

crypto whitelist file ftp://remoteABC/pub/whitelist.txt

crypto whitelist file /flash/pub/data/whitelist.txt
**cs-network**

This command creates/removes an HNB-CS network configuration instance for Famed UMTS access over Iu-CS/Iu-Flex interface between Home NodeB Gateway (HNB-GW) service and CS networks elements; i.e. MSC/VLR. This command also configures an existing HNB-CS network instance and enters the HNB-CS Network Configuration mode on a system.

**Product**

HNB-GW

**Privilege**

Administrator

**Mode**

Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

\[
\text{cs-network} \ cs\_instance \ [ \ -\text{noconfirm} \ ] \\
\text{no} \ cs\_network \ cs\_instance
\]

**no**

Removes the specified HNB-CS network instance from the system.

⚠️ **Caution:** Removing the HNB-CS network instance is a disruptive operation and it will affect all UEs accessing MSC(s) configured in specific CS core network through the HNB-GW service.

⚠️ **Caution:** If any HNB-CS Network instance is removed from system all parameters configured in that mode will be deleted and Iu-CS/Iu-Flex interface will be disabled.

**cs_instance**

Specifies the name of the Circuit Switched Core Networks instance which needs to be associated with the HNB Radio Network PLMN via the HNB RN-PLMN Configuration mode. If `cs_instance` does not refer to an existing HNB-PS network instance, the new HNB-CS network instance is created.

`cs_instance` must be an alphanumeric string of 1 through 63 characters.

**-noconfirm**

Indicates that the command is to execute without any additional prompt and confirmation from the user.

**Usage**

Use this command to enter the HNB-CS Network Configuration mode for an existing CS network instance or for a newly defined HNB-CS network instance. This command is also used to remove an existing HNB-CS network instance.
This configuration enables/disables the Iu-CS/Iu-Flex interface on HNB-GW service with CS core network elements; i.e. MSC/VLR.
A maximum of one HNB-CS network instance per HNB-GW service instance which is further limited to a maximum of 256 services (regardless of type) can be configured per system.

⚠️ **Caution:** This is a critical configuration. The HNBs cannot access MSC(s) in CS core network without this configuration. Any change to this configuration would lead to disruption in HNB access to CS core network.

Entering this command results in the following prompt:

```
[context_name]hostname(config-cs-network)#
```

The various parameters available for configuration of an HNB-CS network instance are defined in the *HNB-CS Network Configuration Mode Commands* chapter.

**Example**

The following command enters the existing HNB-CS Network configuration mode (or creates it if it does not already exist) for the instance named *hnb-cs1*:

```
 cs-network hnb-cs1
```

The following command will remove HNB-CS network instance *hnb-cs1* from the system without any warning to operator:

```
 no cs-network hnb-cs1
```
css acsmgr-selection-attempts

This is a restricted command. In 9.0 and later releases this command is obsolete.
css delivery-sequence

This is a restricted command. In 9.0 and later releases this command is obsolete.
css service

This is a restricted command. In 9.0 and later releases this command is obsolete.
**default**

Restores the system default values for the specified parameters.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

**Syntax**

```
default { aaa { accounting-overload-protection domain-matching | usname-format } | arp
cache-reachable-time | autoconfirm | banner [ lawful-intercept | motd | pre-login ] | boot
[ delay | interface | nameserver | networkconfig ] | bulkstats historical collection |
card-standby-priority | cdr-multi-mode | clock timezone | cli max-sessions | congestion-
control [ overload-disconnect | policy | threshold ] | diameter-proxy ramdisk | enforce |
{ imsi-min equivalence | ip optimize-ipid-assignment } | gtp { compression-processes |
rmdisk-limit } | high-availability fault-detection speed | local-user { allow-aaa-
authentication | lockout-time | max-failed-logins } | logging { display | filter runtime |
| network-overload-protection | operational-mode | pac-standby-priority | qos npu
interface-subscriber traffic { bandwidth | priority [ assigned-to dscp { af11 | af12 | af13 |
a21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | ef } ] } | require { cipher ssl resource-percentage | demux card | session recovery } | reveal disabled
commands | snmp { engine-id | heartbeat | history heartbeat | notif-threshold } | system
{ contact | description | hostname | location | serial-number } | system-mac | system-
priority | task { facility sessmgr start | resource cpu-memory-low } | terminal { all |
databits | flowcontrol | parity | speed | stopbits } | threshold { value } | timestamps |
upgrade limit [ time ] [ usage ] }
```

```
| aaa { accounting-overload-protection domain-matching | usname-format } |
|-------------------------|
Restores the aaa behavior to its default of disabled for the following options:

* accounting-overload-protection: Disables OverLoad Protection Policy for Accounting
  Requests.

* domain-matching: Restores the default domain matching method.

* usname-format: Restores the use of the default username format for global AAA services

<table>
<thead>
<tr>
<th>arp base-reachable-time</th>
</tr>
</thead>
</table>
Restores ARP base-reachable-time to 30 seconds.

<table>
<thead>
<tr>
<th>autoconfirm</th>
</tr>
</thead>
</table>
Restores the autoconfirm behavior to its default of disabled.
banner

**lawful-intercept** - Restores the system default message of the day for SSH CLI sessions.

**motd** - Restores the system default message of the day banner.

**pre-login** - Restores the CLI login banner to the system default.

---

**boot [ delay | interface | nameserver | networkconfig ]**

**interface** | **networkconfig** - Restores the default boot interface and network configuration options. The keywords **interface** and **networkconfig** are used to restore the default option settings for the interface and network configuration options, respectively. Defaulting the network configuration boot option removes the network boot option from the boot.sys file. It does not remove the network config options from the configuration file which is managed separately from the boot.sys file.

**delay** - Removes the boot delay setting (if any). The default for boot delay is “no boot delay”.

**nameserver** - Removes the nameserver IP address.

---

**card-standby-priority**

Resets the standby priority of the Packet Services Cards.

---

**cdr-multi-mode**

Restores the default value of this command to Single-CDRMODE mode.

---

**cli max-sessions**

Restores the default value of this command to **no cli max-sessions** which removes the limit on the number of allowed simultaneous CLI sessions on the system.

---

**clock-timezone**

Restores the system’s clock timezone to UTC.

---

**congestion-control [ overload-disconnect | policy | threshold ]**

Restores the system’s congestion-control functionality to its default setting of disabled. You can selectively restore other components to their default values.

---

**diameter-proxy ram-disk**

Restores the ram-disk size to 32MB.

---

**enforce { imsi-min equivalence | ip optimize-ipid-assignment }**

Disables the enforcement of either option.

---

**gtpp { compression-process | ram-disk-limit }**

Restores number of compression processes allowed to 1.
Restores the RAM disk size to 32MB.

---

**high-availability fault-detection speed**

Restores speed to Normal.
### Global Configuration Mode Commands (A-K)

- **local-user** { allow-aaa-authentication | lockout-time | max-failed-logins }
  
  Enables aaa-authentication.
  Restores lock-time to 60 minutes.
  Restores max-failed-logins to 5.

- **logging** {display | filter runtime}

  - **display**: sets the default level of detail to display for trace log information to the system default.
  - **filter runtime**: resets the filtering of logged information to log in real time.

- **network-overload-protection**
  
  For SGSN, disables this attach rate throttle feature that provides network overload protection.

- **operational-mode**
  
  Sets the operational mode of the chassis to the system default.

- **pac-standby-priority**
  
  This parameter has been replaced by the **card-standby-priority** keyword.

- **qos npu inter-subscriber traffic** {bandwidth | priority [ assigned-to dscp { af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | ef } ] }
  
  Restores the following NPU QoS parameters to their default values:
  
  - **bandwidth**:
    - gold: 10%
    - silver: 20%
    - bronze: 30%
    - best-effort: 40%
  
  - **priority**: All DSCP values are mapped to the best-effort priority queue but are not configured.

- **require** { cipher ssl resource-percentage | demux card | session recovery }
  
  Resets the cipher ssl resource-percentage to 0.
  Disables the demux capabilities on the demux card.
  Disables the session recovery feature.

- **snmp** { engine-id | heartbeat | history heartbeat |notif-threshold }

  - **engine-id**: Restores the SNMP engine ID to the system default.
  - **heartbeat**: Restores the SNMP heartbeat interval to 60 minutes.
  - **history heartbeat**: Reenables the recording of heartbeat notifications in SNMP history.
  - **notif-threshold**: Restores the SNMP notification thresholds to the system defaults.

- **system** { contact | description | hostname | location | serial-number }
  
  Sets the following system parameters to their default values:
  
  - **contact**: Resets to none specified.
  - **description**: Resets to none specified.
• **hostname**: Resets to “asr5000” or asr5500”.
• **location**: Resets to none specified.
• **serial-number**: Resets to factory default.

**system-mac hostname**
Resets the system MAC address to the factory default value.

**system-priority hostname**
Resets the system priority to its default value.

**task { facility sessmgr start | resource cpu-memory-low }**

- **facility sessmgr start**: Restores the default session manager start policy to Normal.
- **resource cpu-memory-low**: Resets the system so that when a CPU runs very low on memory (below 12MB) the most over-limit task is killed.

**terminal { all | databits | flowcontrol | parity | speed | stopbits }**

- **all**: Restores all terminal parameters to their default values.
- **databits**: Resets to 8 data bits.
- **flowcontrol**: Resets to none.
- **parity**: Resets to none.
- **speed**: Resets 9600 bits/second.
- **stopbits**: Resets to one stop bit.

**threshold { value }**
Restores thresholding values to their default setting. The possible values are:
• **10sec-cpu-utilization**: CPU utilization using a 10 sec average.
• **aaa-acct-archive-queue-size<1..3>**: AAA accounting archive queue threshold settings.
• **aaa-acct-archive-size**: AAA accounting archive size.
• **aaa-acct-failure**: AAA accounting failure threshold settings
• **aaa-acct-failure-rate**: AAA accounting failure rate threshold settings
• **aaa-auth-failure**: AAA authentication failure threshold settings
• **aaa-auth-failure-rate**: AAA authentication failure rate threshold settings
• **aaa-retry-rate**: AAA retry rate threshold settings
• **aaamgr-request-queue**: AAA manager internal request queue threshold settings
• **asngw-auth-failure**: ASN-GW Auth Failure related threshold
• **asngw-handoff-denial**: ASN-GW handoff denial threshold
• **asngw-max-eap-retry**: ASN-GW maximum EAP retry threshold
• **asngw-network-entry-denial**: ASN-GW Network entry denial threshold
• **asngw-session-setup-timeout**: ASN-GW session setup timeout threshold
• **asngw-session-timeout**: ASN-GW session timeout threshold
• **asnpc-idle-mode-timeout**: ASN-PC idle mode timeout threshold
• **asnpc-im-entry-denial**: ASN-PC IM entry denial threshold
• **asnpc-lu-denial**: ASN-PC lu denial threshold
• **asnpc-session-setup-timeout**: ASN-PC session setup timeout threshold
• **bgp-routes**: bgp routes threshold
• **call-reject-no-resource**: Calls rejected due to no resources threshold settings
• **call-setup**: Calls setup threshold settings
• **call-setup-failure**: Call setup failure threshold settings
• **card-temperature-near-power-off-limit**: Threshold for the gap between the current card temperature and the power off limit
• **cdr-file-space**: CDR file space threshold
• **contfilt-block**: Content Filtering Blocks threshold settings
• **contfilt-rating**: Content Filtering Ratings threshold settings
• **cpu-available-memory**: CPU available memory threshold settings
• **cpu-load**: PSC/PSC2 CPU load (5-minute average)
• **cpu-memory-usage**: Percentage of total CPU memory usage
• **cpu-orbs-critical**: ORBs process CPU usage critical level
• **cpu-orbs-warn**: PORBs process CPU usage warning level
• **cpu-session-throughput**: CPU session throughput threshold settings
• **cpu-utilization**: CPU utilization threshold settings
• **dcca-bad-answers**: Diameter Bad Answers threshold settings
• **dcca-protocol-error**: Diameter Protocol Error threshold settings
• **dcca-rating-failed**: Diameter Rating Failed threshold settings
• **dcca-unknown-rating-group**: Diameter Unknown Rating Group threshold settings
• **diameter**: Diameter threshold settings
• **dns-learnt-ip-max-entries**: DNS IP maximum entries threshold
• **dns-lookup-failure**: DNS Lookup Failure threshold
• **edr-file-space**: EDR file space threshold
• **edr-udr-dropped-flow-control**: EDR-UDRs Dropped due to flow control
• **epdg-current-sessions**: Current EPDG sessions threshold
• **fng-current-active-sessions**: Femto Network Gateway (FNG) current active sessions threshold
• **fng-current-sessions**: FNG current sessions threshold
• **fw-deny-rule**: Stateful Firewall Deny Rule threshold
• **fw-dos-attack**: Stateful Firewall Dos-Attacks threshold
• **fw-drop-packet**: Stateful Firewall Drop Packets threshold
• **fw-no-rule**: Stateful Firewall No-Rule threshold
• **license**: Session license threshold settings
• **mgmt-cpu-memory-usage**: Management (SMC) CPU memory usage threshold
- `mgmt-cpu-utilization`: Management (SMC) CPU utilization threshold (most recent 5-minute average)
- `mme-attach-failure`: MME Attach Failure related threshold
- `mme-auth-failure`: MME Auth Failure related threshold
- `model`: Thresholding model settings
- `monitoring`: Threshold monitoring configuration settings
- `nat-port-chunks-usage`: Port chunk utilization threshold
- `npu-utilization`: NPU utilization threshold (most recent 5-minute average)
- `packets-filtered-dropped`: Filtered/dropped packet threshold settings
- `packets-forwarded-to-cpu`: Forwarded packet threshold settings
- `pdg-current-active-sessions`: PDG current active sessions threshold
- `pdg-current-sessions`: PDG current sessions threshold
- `pdif-current-active-sessions`: Threshold monitoring for only the currently-active PDIF sessions.
- `pdif-current-sessions`: Threshold monitoring for all current PDIF sessions.
- `per-service-asngw-sessions`: The number of sessions per ASN-GW service
- `per-service-ggsn-sessions`: The number of GGSN sessions per GGSN service
- `per-service-gprs-pdp-sessions`: The number of PDP contexts per GPRS service
- `per-service-gprs-sessions`: The number of GPRS sessions per GPRS service
- `per-service-ha-sessions`: The number of HA sessions per HA service
- `per-service-lns-sessions`: The number of LNS sessions per LNS service
- `per-service-pdsn-sessions`: The number of PDSN sessions per PDSN service
- `per-service-samog-sessions`: The number of SaMOG sessions per SaMOG service
- `per-service-sgsn-pdp-sessions`: The number of PDP contexts per SGSN service
- `per-service-sgsn-sessions`: The number of SGSN sessions per SGSN service
- `phsgw-eapol-auth-failure`: Personal Handy Phone Gateway (PHSGW) EAPOL authentication failure threshold
- `phsgw-handoff-denial`: PHSGW handoff denial threshold
- `phsgw-max-eap-retry`: PHSGW maximum EAP retry threshold
- `phsgw-max-eapol-retry`: PHSGW max EAPOL retry threshold
- `phsgw-network-entry-denial`: PHSGW Network entry denial threshold
- `phsgw-session-setup-timeout`: PHSGW session setup timeout threshold
- `phsgw-session-timeout`: PHSGW session timeout threshold
- `phspc-session-setup-timeout`: PHSPC session setup timeout threshold
- `phspc-sleep-mode-timeout`: PHSPC sleep mode timeout threshold
- `phspc-sm-entry-denial`: PHSPC sm entry denial threshold
- `poll`: Threshold polling interval configuration settings
- `ppp-setup-fail-rate`: PPP setup failure rate threshold
Global Configuration Mode Commands (A-K)

- **rp-setup-fail-rate**: RP setup failure rate threshold
- **storage-utilization**: Mass storage (flash memory) utilization
- **subscriber**: subscriber related thresholds
- **system-capacity**: Percentage usage of system resources
- **total-asngw-sessions**: Total ASN-GW sessions threshold
- **total-ggsn-sessions**: Total GGSN sessions for all GGSN services in the system
- **total-gprs-pdp-sessions**: Total PDP contexts for all GPRS services in the system
- **total-gprs-sessions**: Total GPRS sessions per for all GPRS services in the system
- **total-ha-sessions**: Total HA sessions for all HA services in the system
- **total-hnbgw-hnb-sessions**: Total 3G Home NodeB Gateway (HNBGW) HNB sessions for all HNB services in the system
- **total-hnbgw-iu-sessions**: Total HNBGW Iu sessions in the system
- **total-hnbgw-ue-sessions**: Total HNBGW UE sessions in the system
- **total-hsgw-sessions**: Total HRPD Serving Gateway (HSGW) sessions for all HSGW services in the system
- **total-lma-sessions**: Total Local Mobility Anchor (LMA) sessions for all LMA services in the system
- **total-Ins-sessions**: Total L2TP Network Server (LNS) sessions for all LNS services in the system
- **total-mme-sessions**: Total Mobility Management Entity (MME) sessions for all MME services in the system
- **total-pdsn-sessions**: Total PDSN sessions for all PDSN services in the system
- **total-pgw-sessions**: Total Packet Data Network Gateway (PGW) sessions for all PGW services in the system
- **total-saegw-sessions**: Total PDP contexts for all SAEGW services in the system
- **total-sgsn-pdp-sessions**: Total PDP contexts for all SGSN services in the system
- **total-sgsn-sessions**: Total SGSN sessions for all SGSN services in the system
- **total-sgw-sessions**: Total Serving gateway (SGW) sessions for all SGW services in the system

**timestamps**

Resets the inclusion of timestamps in command.

**upgrade limit [ time ] [ usage ]**

Sets upgrade limit values to the defaults. If the optional keywords are not specified all values are reset to their defaults.

- **time**: Resets the maximum time a session may exist during a software upgrade to the default of 120.
- **usage**: Resets the minimum number of sessions before closing the sessions during a software upgrade to the system default of 100.

**Usage**

Restore system defaults to aid in trouble shooting or just prior to modifying additional configuration options.

**Example**

Command Line Interface Reference, StarOS Release 16
default banner motd

default boot

default logging display

default system hostname

default upgrade limit time
diameter dynamic-dictionary

This command allows configuring a Diameter dictionary dynamically at run time, and then loading the dynamic dictionary in to the system.

**Important:** The maximum number of dynamic dictionaries that can be loaded in to the system is 10.

**Product**
- GGSN
- HA
- HSGW
- IPSG
- PDSN
- P-GW
- SAEGW
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration

**Syntax**

```
diameter dynamic-dictionary name url

no diameter dynamic-dictionary name
```

- **no**
  Unloads the specified dynamic Diameter dictionary from the system.

- **name**
  Specifies the name of the dynamic Diameter dictionary as an alphanumeric string of 1 through 15 characters.

- **url**
  Specifies the URL of the Diameter dictionary to be loaded in to the system. The input must be an alphanumeric string of 1 through 127 characters.
Usage

This command is used to define a new Diameter dictionary on the fly, and load the dynamic dictionary into the system.
To perform this configuration, you should first create a text file in ABNF format and configure all the required Diameter AVPs and command codes in the file. Then, save the file in flash or some URL that will be accessible by the system.
Now, configure a dynamic dictionary with an unique name and map it to the URL of the file to be loaded dynamically into the system at the global configuration level.
When the names of the dynamic dictionaries and their URLs are configured, the corresponding files at the respective URLs are parsed and populated in all SessMgr and AAAMgr facilities as new dictionaries and kept available to be used when these dictionary names are configured under any Diameter application level or AAA group.
When a dynamic dictionary name is configured under an application such as IMS authorization service or in a AAA group, the corresponding dictionary (which is already loaded in SessMgrs and AAAMgrs) entry will be used.
There will be only one instance of a dynamic dictionary loaded into a task for one dynamic dictionary name even if the same dictionary name is configured in multiple AAA groups or multiple application configurations. That is, even if the same dictionary name is configured in several applications or several AAA groups, all these applications and AAA groups will refer to the same dynamic dictionary instance.

Example

The following command configures a Diameter dictionary named dyn1 and loads this dictionary to /flash/diameter_custom1.sndd path:

diameter dynamic-dictionary dyn1 /flash/diameter_custom1.sndd
**diameter-host-template**

Specifies the name of a Diameter host template and enters the Diameter Host Select mode. A Diameter host template is a table of peer servers that can be shared by multiple services.

**Product**
GGSN
HA
HSGW
IPSG
PDSN
P-GW
SAEGW
S-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
diameter-host-template name [ -noconfirm ]

no diameter-host-template name
```

- **name**
  Specifies the name of the template as an alphanumeric string of 1 through 63 characters.

- **[ -noconfirm ]**
  Executes the command without prompting for further input from the user.

**Usage**

Specifies the name of a new or existing Diameter host template and opens the Diameter Host Select mode. You can configure up to 256 templates on the system. To use the template, Diameter applications must be associated with the template. When an association is made to the template, the system selects the Diameter peer to be contacted based on rows configured in the table and the algorithm configured for selecting rows in the table.
**Important:** Currently, only Gx service can be associated with the template.

If more than one service is using the same set of `peer-select` commands, then it is better to define all the peer selection CLIs in the template and associate the services to the template. Entering this command results in the following prompt:

```
[context_name]hostname(config-host-template)#
```

Diameter host select configuration commands are defined in the *Diameter Host Select Configuration Mode Commands* chapter.

**Example**

The following command specifies a Diameter host template named `diamtemplate`:

```
diameter-host-template diamtemplate
```
diameter-proxy ramdisk

This command configures the amount of extra RAM disk space in MB to be allocated to Diamproxy task when local storage (hard disk) is enabled.

Product
HSGW
P-GW
SAEGW
S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

diameter-proxy ramdisk mb space_mb

default diameter-proxy ramdisk mb

default
Configures the default setting.
Default: 32 MB

mb space_mb
Specifies the storage space in MB.
space_mb must be an integer from 10 through 256.

Usage
Specifies the additional storage space to be allocated to Diamproxy for file write, in MB. The specified memory in MB is added to the existing memory allocated to Diamproxy only if HDD storage is enabled. By default, 32 MB is additionally allocated.

Example
The following command specifies that 100 MB of additional storage space be allocated to the Diamproxy task:

diameter-proxy ramdisk mb 100
ecmp-lag hash

This command provides the configuration to select source Boxer Internal Address (SBIA) as the input to the hashing function for ECMP-LAG distribution.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
[no] ecmp-lag hash use-sbia-only
```

- **no**
  
  Disables the hashing function selection and sets the system to use IP Source Address, IP Destination Address, IP Protocol and Source BIA as inputs to the hashing algorithm for ECMP-LAG distribution.

**Usage**

Use this command to allow the operator to change the way hashing works in deciding which link to use for ECMP and Link Aggregation. In the default hashing algorithm the IP Source Address, IP Destination Address, IP Protocol and Source BIA are used in the hashing function. When “use-sbia-only” option is selected, only the Source BIA is used in the hashing function.

⚠️ **Caution:** When using ECMP-LAG on a HNB-GW, this configuration is mandatory for standalone HNB-GW deployment and highly recommended in other deployment scenarios where HNB-GW is used in combination with other services.

**Example**

The following command enables the SBIA as input to hash function for ECMP-LAG on the HNB-GW:

```
ecmp-lag hash use-sbia-only
```

The following commands sets the hashing function to use standard inputs for ECMP-LAG on HNB-GW:

```
no ecmp-lag hash use-sbia-only
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

end

**Usage**

Use this command to return to the Exec mode.
enforce imsi-min equivalence

Enables the PDSN/HA to treat IMSI and MIN as the same for identifying the PDSN/HA session.

Product
PDSN
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config)#

Syntax

[ no | default ] enforce imsi-min equivalence

default

Returns the command to its default setting of disabled.

no

Disables the PDSN/HA from treating IMSI and MIN as the same for identifying the PDSN/HA session.

Usage

Generally on an HA, the IMSI and MIN are treated as different and hence the RRQs with 1x and DO PDSNs are processed as different sessions. You can use this feature to treat the IMSI and MIN with the matching lower 10-digit as the same for identifying a session. The 10-digit MIN and the 15-digit IMSI are treated as equivalent for the purpose of matching sessions if the lower 10 digits are the same. Any handoff from 1x to DO or vice-versa is treated as the same session if the NAI and HoA also match. If the NAI and/or HoA do not match, then the duplicate IMSI session detect and terminate feature is applicable.

Generally on a PDSN, the IMSI and MIN are treated as different and hence RP messages from 1x and DO PDSNs are processed as different sessions. You can use this feature to treat the IMSI and MIN with the matching lower 10-digit as the same for identifying a session. The 10-digit MIN and the 15-digit IMSI are treated as equivalent for the purpose of matching PDSN sessions if the lower 10 digits are the same. Any handoff from 1x to DO or vice-versa is treated as the same session.

Example

To monitor or clear subscriber session information filtered by on IMSI/MIN refer to the show subscribers msid command.

Important: This command must be executed at startup only and will not take effect when reconfigured without rebooting.
Example

The following command enables the treatment of the IMSI and MIN as the same for identifying the session:

```
enforce imsi-min equivalence
```

Either of the following commands disables the treatment of the IMSI and MIN as the same for identifying sessions:

```
no enforce imsi-min equivalence
default enforce imsi-min equivalence
```
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
fa-spi-list

Replaces a duplicate Foreign Agent- Security Parameter Index (FA-SPI) remote address list applied to multiple FA services with a list name.

**Product**
PDSN
FA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
 configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
fa-spi-list fa_spi_list
```

- **fa_spi_list**
  Remote address list name expressed as an alphanumeric string of 1 through 64 characters.

**Usage**

Use this command to Replace duplicate FA-SPI remote address list applied to multiple FA or HA services with a list name.

**Example**

The following command configures the list FA SPI list to *fa-list2*:

```
fa-spi-list fa-list2
```
fabric egress drop-threshold

Enables or disables the generation of a syslog event message when the number of egress Fabric Access Processor (FAP) packet drops exceeds a set threshold within a window of time on an ASR 5500.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

fabric egress drop-threshold enable count number interval-secs seconds

fabric egress drop-threshold disable

enable

Enables the specified egress dropped-packet threshold settings. Settings are disabled by default.

count number

Specifies the maximum number of egress traffic packets that can be dropped before a syslog event message is generated. The count is specified as an integer from 10 through 5000.

interval-secs seconds

Specifies the time interval (window) within which the maximum egress packet drop count can be exceeded. The interval is specified in seconds as an integer from 30 through 600.

Usage

Use this command to enable or disable the generation of a syslog event message when the number of egress FAP packet drops exceeds a set threshold within a window of time on an ASR 5500. When the threshold is exceed, the syslog event message is generated once, until the condition clears. Only then will it be generated again. By default this feature is disabled.

Example

The following command sets the egress FAP dropped-packet threshold at 2000 packets within a 60-second window:

fabric egress drop-threshold enable count 2000 interval-secs 60
failure-handling-template

This command allows the user to create/modify/delete a Diameter failure handling template at the global configuration level. This command specifies the name of failure handling template and enters the Failure Handling Template mode. The users can define the failure handling configurations within this template.

**Important:** A maximum of 64 templates can be configured on the system.

**Product**
- GGSN
- HA
- HSGW
- IPSG
- PDSN
- P-GW
- SAEGW
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
- configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
failure-handling-template name [ -noconfirm ]

no failure-handling-template name
```

- **no**
  - Removes the specified failure handling template from the Global Configuration.

- **name**
  - Specifies the name of the failure handling template as an alphanumeric string of 1 through 63 characters.

- **[ -noconfirm ]**
  - Executes the command without prompting for further input from the user.
Usage

Specifies the name of a new or existing failure handling template and opens the Failure Handling Template mode. Depending on which application is using the failure handling template, some of the syntactically possible configurations within the template are not applicable.

To use the template, Diameter applications must be associated with the template. When an association is made to the template, in the event of a failure, the system takes the action as defined in the failure handling template. Both IMS Authorization (Gx) and Diameter Credit Control Application (DCCA) (Gy) services can be associated with the template.

Entering this command results in the following prompt:

```
[context_name]hostname(config-fh-template)#
```

Failure handling template configuration commands are defined in the *Diameter Failure Handling Template Configuration Mode Commands* chapter.

Example

The following command specifies a failure handling template named *FHtemplate*:

```
failure-handling-template FHtemplate
```
get context-list

Generates an XML-formatted list of all currently configured contexts within the system.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
get context list | { grep grep_options | more }
```

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.

For details on the usage of `grep` and `more`, refer to the Regulating a Command’s Output section of the Command Line Interface Overview chapter.

Usage

Generates a list of all currently configured contexts in XML format. The output can be copied and pasted into compatible applications.

Example

```
get context-list
```
get ip

Generates an XML-formatted display of IPv4-based information.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
get ip { access-list | arp [vrf name] | bgp neighbors | interface [vrf name] | ospf { interface | neighbor | vrf name | route [vrf name] | vrf } [ | { grep grep_options | more } ]
```

---

**access-list**

Generates an XML-formatted display of all IPv4 Access Control Lists (ACLs).

---

**arp**

Generates an XML-formatted display of all Allocation Retention Priorities (ARPs) or the ARPs for the named Virtual Routing and Forwarding (VRF) table.

---

**bgp neighbors**

Generates an XML-formatted display of all Border Gateway Protocol (BGP) neighbors.

---

**interface [vrf name]**

Generates an XML-formatted display of all interfaces or for only those associated with a specified VRF table (optional).

---

**ospf { interface | neighbor | vrf name }**

Generates an XML-formatted display of all Open Shortest Path First (OSPF) routing information.

- **interface**: Displays interface information for OSPF.
- **neighbor**: Displays summarized information about all known OSPF neighbors.
- **vrf name**: Displays information for the named VRF table.

---

**route [vrf name]**

Generates an XML-formatted display of all IPv4-based routes or for only those associated with a specified VRF table (optional).

---
**vrf**

Generates an XML-formatted display of all VRF tables.

`| { grep grep_options | more }`

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.

For details on the usage of `grep` and `more`, refer to the Regulating a Command’s Output section of the Command Line Interface Overview chapter.

**Usage**

Generates a display of IPv4-based information in XML format. The output can be copied and pasted into compatible applications.

**Example**

```plaintext
get ip access-list
```
get ipv6

Generates an XML-formatted display of IPv6-based information.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure
Entering the above command sequence results in the following prompt:

[local]host_name(config) #

Syntax

get ip { access-list | interface [vrf name] | ospf { interface | neighbor } | route [vrf name] } | { grep grep_options | more } |

access-list
Generates an XML-formatted display of all IPv6 Access Control Lists (ACLs).

interface [vrf name]
Generates an XML-formatted display of all IPv6 interfaces or for only those associated with a specified VRF table (optional).

ospf { interface | neighbor }
Generates an XML-formatted display of all Open Shortest Path First version 3 (OSPFv3) routing information.
  • interface: Displays interface information for OSPFv3.
  • neighbor: Displays summarized information about all known OSPFv3 neighbors.

route [vrf name]
Generates an XML-formatted display of IPv6 routes or for only those associated with a specified VRF table (optional).

| { grep grep_options | more } |

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.

For details on the usage of grep and more, refer to the Regulating a Command’s Output section of the Command Line Interface Overview chapter.

Usage
Generates a display of IPv6-based information in XML format. The output can be copied and pasted into compatible applications.
Example

```
get ipv6 access-list
```
get port info

Generates an XML-formatted display for all physical ports or a specific port in the system.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**
```
get port info [slot/port] [ | { grep grep_options | more } ]
```

**slot/port**
Generates an XML-formatted display of information for the port specified by its chassis slot and card port number.

```
| { grep grep_options | more }
```

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.

For details on the usage of `grep` and `more`, refer to the *Regulating a Command’s Output* section of the *Command Line Interface Overview* chapter.

**Usage**
Generates a display of IP-based information in XML format. The output can be copied and pasted into compatible applications.

**Example**
```
get ip port
```
global-title-translation address-map

Creates an instance of a Global Title Translation (GTT) address-map, a database, for global titles (ISDN-type address) used for SCCP routing. Upon creating the instance, the system enters global title translation address-map configuration mode. For the commands to configure the database, go to the Global Title Translation Address-Map Configuration Mode Commands chapter.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

global-title-translation address-map instance instance

no global-title-translation address-map instance instance

no
Removes the specified GTT address-map database from the SCCP portion of the configuration.

instance
This value uniquely identifies a specific instance of a GTT address-map.
instance must be an integer from 1 through 4096.

Usage
Create a GTT address-map with a unique identifier and enter the GTT address-map configuration mode.

Example

    global-title-translation address-map instance 324
global-title-translation association

Creates an instance of a Global Title Translation (GTT) association which defines the rules for handling global title translation. Upon creating the instance, the system enters global title translation association configuration mode. For the commands to configure the rules, go to the Global Title Translation Association Configuration Mode Commands chapter.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

global-title-translation association instance instance

no global-title-translation association instance instance

no

Removes the specified instance of a GTT association from the SCCP portion of the configuration.

instance

This value uniquely identifies a specific instance of a GTT association. instance must be an integer from 1 through 16.

Usage

Create a GTT association with a unique identifier and enter the GTT association configuration mode.

Example

global-title-translation association instance 2

### gtpp compression-process

This command configures the maximum number of child compression processes that AAA proxy can have.

**Product**
- GGSN
- SAEGW
- SGSN

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
  ```
  configure
  ```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
gtpp compression-process max_number

default gtpp compression-process
```

<table>
<thead>
<tr>
<th><strong>default</strong></th>
<th>Restores the system to the default settings for the number of child compression processes allowed.</th>
</tr>
</thead>
</table>
| **max_number** | Specifies the maximum number of child processes. The default is 1 
**max_number**: must be an integer from 1 through 4. |

**Usage**

This command configures the maximum number of child compression processes that AAA proxy can have only if hard disk storage is enabled.

**Example**

```
gtpp compression-process 3
```
gtpp push-to-active

This command enables/disables Push-To-Active feature to automatically transfer CDR files from new standby chassis to new active chassis when the ICSR switchover occurs.

**Important:** This CLI command is applicable only to GTPP groups having streaming mode.

Product

GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

Syntax

```
gtpp push-to-active [ encrypted ] url url via-context context_name
```

no gtpp push-to-active

no

Disables Push-To-Active feature to automatically transfer CDR files from new standby chassis to new active chassis.

```
[ encrypted ] url url
```

Specifies the peer chassis URL where the CDR files are to be transferred when the chassis becomes standby. This keyword denotes the peer chassis URL in this format: sftp://user:password@host:[port]/hdraid/records/cdr/. It accepts a string of size 1 through 1024.

```
[ encrypted ] - Indicates that the URL is encrypted for security reasons.
```

```
via-context context_name
```

Specifies the name of the context through which the active chassis is reachable. context name must be an alphanumeric string of 1 through 79 characters.
Usage

During an ICSR switchover, the GTPP charging interface between the active chassis and CGF server goes down and all pending CDRs are written to internal hard disk. Once the chassis becomes standby, the CDRs will remain on HDD until the chassis becomes active. This feature provides a way to move the stranded CDRs from the new standby chassis to the new active chassis and stream them to the OCG. This CLI command enables/disables the Push-To-Active feature to automatically transfer CDR files from new standby chassis to new active chassis. Releases prior to 16.0, CDRs from current standby chassis were manually transferred to current active chassis using the CLI command “gtpp storage-server streaming start”. Once the transfer is complete, a CLI command in the Exec mode is configured to stream the CDRs to CGF. In 16.0 and later releases, the stranded CDRs in the standby ICSR node (moved from active to standby) are automatically transferred to the newly active ICSR node. This automation process is achieved through the use of “gtpp push-to-active” CLI command in the global configuration mode. This feature could lead to duplicate CDRs. When streaming is in progress and ICSR switchover happens, the current file being streamed, will not complete the streaming as interface with CGF went down. This file will be transferred to new active chassis and streamed from beginning from new chassis. In case AAAProxy restarts during file transfer, the file transfer statistics will not be accurate. The accounting contexts should be in same order in both the chassis. The directory names are created using vpn-id. If the accounting contexts are in different order, vpn-id will be different and the sub-directories in HDD will be different in both the chassis for same GTPP group.

Example

The following command enables the Push-To-Active feature to automatically transfer CDR files from new standby chassis to new active chassis.:

```
gtp push-to-active url sftp://user:password@host:5000 via-context aaa
```
gtpp ram-disk-limit

This command configures additional storage space to be allocated for writing files.

Product
- GGSN
- SAEGW
- SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
gtpp ram-disk-limit mb mega_bytes
```

```
default gtpp ram-disk-limit
```

```
default
  Restores the system to the default settings of 32 MB of storage.

mb mega_bytes
  Specifies the number of megabytes of storage allocated for files.
  mega_bytes: must be an integer from 10 through 256. The default is 32 MB.
```

Usage
The memory specified with this command would be added to the existing memory allocated to the AAA proxy only if hard disk storage is enabled.

Example

```
gtpp ram-disk-limit mb 256
```
**gtpp single-source**

Configures the system to reserve a CPU for performing a proxy function for accounting.

**Product**
- GGSN
- SGSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
  - `configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
  gtpp single-source [ centralized-lrsn-creation | private-extensions ]
  no gtpp single-source
```

- `centralized-lrsn-creation`
  - Defines Log Record Sequence Number (LRSN) generation at proxy. The AAA proxy will generate the LRSN for all CDR types generated by either the GGSN or the SGSN.
  - Default: disabled

- `private-extensions`
  - This optional keyword enables the proprietary use of customer-specific GTPP extensions.
  - If `private-extensions` is not configured, all customer specific private extensions related to GTPP message transfer with CGF and recovery through GSS are disabled.

**Important:** In order for the customer-specific extensions to work properly, the `gtpp max-pdu-size` command in the Context Configuration Mode should be set to 65400 and the `gtpp server` command’s `max` value should be set to “1”.

- `no`
  - Disables GTPP single-sourcing. This is the default setting.

**Caution:** Entering this command while PDP contexts are in process could cause the loss of pending CDRs. The configuration must be saved and the chassis reloaded for this option to take effect.
**Usage**

When GTPP single-sourcing is enabled, the system’s AAA proxy function generates requests to the accounting server using a single UDP source port number, instead of having each AAA Manager generate independent requests with unique UDP source port numbers. This is accomplished by the AAA Managers forwarding their GTPP PDUs to the AAA Proxy function that runs on a reserved packet processing card CPU. Since a packet processing card CPU is being reserved, fewer Session Managers and AAA Managers will be started on that card.

⚠️ **Caution:** This command must be entered prior to the configuration of other services. Specifying it later may return an error due to a lack of CPU availability.

**Example**

The following command enables GTPP single-sourcing with the use of private GTPP extensions:

```
  gtpp single-source private-extensions
```

The following command disables GTPP single-sourcing:

```
  no gtpp single-source
```
ha-spi-list

Replaces a duplicate Home Agent-Security Parameters Index (HA-SPI) remote address list applied to multiple HA services with a list name.

Product
PDSN
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

ha-spi-list ha_spi_list

  ha_spi_list

  Remote address list name expressed as an alphanumeric string of 1 through 64 characters.

Usage

Use this command to Replace duplicate HA-SPI remote address list applied to multiple HA services with a list name.

Example

The following command configures the list HA SPI list to ha-list2:

  ha-spi-list ha-list2
**hd raid**

Performs RAID management operations on the platform hard disk drives.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

*configure*

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

For the ASR 5000:

```
hd raid { check | create | insert | overwrite | remove select } local1 | remote1 } [ -force ] [ -noconfirm ]
```

For the ASR 5500:

```
hd raid { check | create | insert | overwrite | remove select } hd_num [ -force ] [ -noconfirm ]
```

For VPC:

```
hd raid { check | create | insert | overwrite | remove select } { | local1 | local2 } [ -force ] [ -noconfirm ]
```

**check**

Starts a background check on RAID disks unless the RAID is running in degraded mode.

**create**

```
create local1 | remote1
```

On the ASR 5000, creates a new RAID that could run in degraded mode on the specified drive: 

`local1` specifies the RAID is to be established on the primary SMC. `remote1` specifies the RAID is to be established on the backup SMC.

**create**

```
create hd_num
```

On the ASR 5500, creates a new RAID that could run in degraded mode on the hard drive array of a specific FSC.

`hd_num` specifies the RAID is to be established on the FSC in slot numbers 13 through 18 (hd13, hd14, ... hd18).

**create**

```
create { | local1 | local2 }
```

On VPC, creates a new virtual RAID as vHD Local1 or vHD Local2.
**insert local1 | remotel**
On the ASR 5000, inserts the specified disk to the running RAID causing it to recover from degraded mode.
*local1:* specifies the primary SMC is to be inserted into the RAID. *remotel:* specifies the backup SMC is to be inserted into the RAID.

**insert hd_num**
On the ASR 5000, inserts the specified FSC disk array into the running RAID causing it to recover from degraded mode.
*hd_num:* specifies the RAID is to be established on the FSC in slot numbers 13 through 18 (hd13, hd14, ... hd18).

**insert { | local1 | local2 }**
On VPC, inserts the specified vHD into the running RAID causing it to recover from degraded mode.

**overwrite local1 | remotel**
On the ASR 5000, overwrites the specified disk and adds it to the current running RAID to construct a fully mirrored array.
*local1:* specifies the primary SMC is to be added to the current RAID. *remotel:* specifies the backup SMC is to be added to the current RAID.

**overwrite hd_num**
On the ASR 5500, overwrites the specified FSC disk array and adds it to the current running RAID to construct a fully mirrored array.
*hd_num:* specifies the RAID is to be established on the FSC in slot numbers 13 through 18 (hd13, hd14, ... hd18).

**overwrite { | local1 | local2 }**
On VPC, overwrites the specified vHD and adds it to the current running RAID to construct a fully mirrored array.

**remove local1 | remotel**
On the ASR 5000, removes the specified disk from the running RAID causing it to run in degraded mode or to fail.
*local1:* specifies the primary SMC is to be removed from the RAID. *remotel:* specifies the backup SMC is to be removed from the RAID.

**remove hd_num**
On the ASR 5500, removes the specified FSC disk array from the running RAID causing it to run in degraded mode or to fail.
*hd_num:* specifies the RAID is to be established on the FSC in slot numbers 13 through 18 (hd13, hd14, ... hd18).

**remove { | local1 | local2 }**
On the VPC, removes the specified vHD from the running RAID causing it to run in degraded mode or to fail.
select local1 | remotel

On the ASR 5000, selects the specified disk to assemble a RAID when two unrelated RAID disks are present in the system. The resulting RAID runs in degraded mode.

local1: specifies the primary SMC is to assemble the RAID. remotel: specifies the backup SMC is to assemble the RAID.

select hd_num

On the ASR 5500, selects the specified FSC disk array to assemble a RAID when two or more unrelated RAID disks are present in the system. The resulting RAID runs in degraded mode.

hd_num specifies the RAID is to be established on the FSC in slot numbers 13 through 18 (hd13, hd14, ..., hd18).

select { | local1 | local2 }

On VPC, selects the specified vHD to assemble a RAID when two or more unrelated RAID disks are present in the system. The resulting RAID runs in degraded mode.

-noconfirm

Executes the command without displaying “are you sure” prompts.

-force

Executes the command and overrides warnings.

Usage

All commands need confirmation unless the -noconfirm is included in the command. If the result will bring down a running RAID, you have to force the command using -force.

RAID commands are needed to intervene in the following situations:

- the hard disk controller task can not determine the correct operation,
- administrator action is required by policy
- the administrator wants to wipe out an unused disk.

In an automated system, the policies created with this CLI address the possibility of a manually partitioned disk, a disk resulting from a different version of software, a partially constructed disk, or the case of two unrelated disks in the system.

To reduce administrator intervention, a set of policies can be configured to set the default action using the commands in the HD RAID configuration mode. These commands are described in the HD Storage Policy Configuration Mode Commands chapter of this guide.

Example

The following instructs the system to setup a RAID on the primary ASR 5000 SMC hard drive.

    hd raid create local1 -force
hd storage-policy

Provides access to the local hard drive configuration mode in order to manage parameters supporting local storage of records.

Product

GGSN
SGSN
HSGW
P-GW
SAEGW
S-GW

Privilege

Administrator

Mode

Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

[ no ] hd storage-policy name

no

Removes a configured HD storage policy from the system.

storage-policy name

Specifies a name for an HD storage policy and then enters the HD Storage Policy Configuration Mode. name must be an alphanumeric string of 1 through 63 characters.

Usage

Creates a new policy or specifies an existing policy and enters the HD Storage Policy Configuration Mode. Entering this command results in the following prompt:

[context_name]hostname(config-hd-storage-policy)#

HD Storage Policy Configuration Mode commands are defined in the HD Storage Policy Configuration Mode Commands chapter.

Example

The following command creates an HD storage policy named policy3 and enters the HD Storage Policy Configuration Mode:

hd storage-policy policy3
high-availability

Configures the speed for detection of packet processing card task failures.

Product

PDSN
GGSN
ASN-GW

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

high-availability fault-detection speed { aggressive | normal }

default high-availability fault-detection speed

{ aggressive | normal }

Default: normal
- aggressive: Initiates packet processing card failover without performing additional checks.
- normal: Initiates packet processing card failover after additional checks are performed.

Usage

Use this command to increase the fault detection speed for faster switchovers after a packet processing card task failure.

Setting fault detection speed to aggressive will trigger packet processing card failover as soon as possible if a potential failure is detected. Aggressive mode will reduce the duration of subscriber outages caused by a failed packet processing card if session recovery is enabled.

Aggressive mode also bypasses most information gathering steps and logs that can be used to determine the root cause of the failure.

In normal mode, additional checks are performed before triggering a packet processing card failover to ensure that the card has actually failed. In aggressive mode these checks are bypassed so that session recovery can start as soon as possible. These additional checks reduce the likelihood of a false positive failure.

Example

The following command sets the fault detection speed for packet processing card tasks to aggressive:

    high-availability fault-detection speed aggressive
hybrid-mode

Enables an ASR 5000 chassis to run a mix of Packet Services Cards (PSCs) and PSC Type A (PSCAs). When enabled, PSCAs will boot and be compatible with the PSCs as long as encryption services are disabled. The default is to run the chassis in non-hybrid mode; PSCAs will not boot when inserted in the chassis.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
 configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

[ no ] hybrid-mode [ force ]

- **no**
  
  Returns the chassis to non-hybrid mode. PSCAs will not boot.

- **force**
  
  Always updates the configuration, even if the encryption services could not be disabled. However, the PSC and PSCA cards will continue to be incompatible until encryption services are manually disabled.

**Usage**

To allow a chassis to run in PSC/PSCA hybrid-mode with encryption services disabled you must configure `hybrid-mode force` once.

To go from hybrid mode to non-hybrid mode, you must enter the `no hybrid-mode force` command. Non-hybrid chassis mode allows encryption services to be started through the appropriate CLI commands. However, all PSCAs in the chassis will be disabled.

For additional information, see the *ASR 5000 Installation Guide*.

**Example**

The following command enables the chassis to run a mix of PSCs and PSCAs without encryption services:

    hybrid-mode force
imei-profile

Creates an instance of an International Mobile Equipment Identity (IMEI) profile.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

[ no ] imei-profile imei_profile_name

no

Deletes the IMEI profile instance from the configuration.

imei_profile_name

Specifies the name of the IMEI profile as an alphanumeric string of 1 through 64 characters.

Usage

Use this command to create an instance of an IMEI profile and to enter the IMEI Profile Configuration mode. An IMEI profile is a template which groups a set of device instructions, such as blacklisting, that may be applicable to one or more calling devices. See the IMEI Profile Configuration Mode Commands chapter for information regarding the definition of the rules contained within the profile and the use of the profile.

Important: An IMEI profile is a key element of the Operator Policy feature and is only valid when associated with at least one operator policy.

To see what IMEI profiles have already been created, return to the Exec mode and enter the show imei-profile all command.

Example

The following command creates a configuration instance of an IMEI profile:

imei-profile imeiprof1
Chapter 142
Global Configuration Mode Commands (L-S)

This section includes the commands license through system.
The Global Configuration Mode is used to configure basic system-wide parameters.

Mode

Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
license

Configures the session license key.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

license key key_value [ -force ] session-limit

no license key key_value [ -force ] session-limit

no

Removes the license key(s) installed.

key key_value

Installs the license key specified by key_value. key_value is provided by Cisco operations staff.

session-limit

Use this keyword to suppress fail-over calls from being rejected if the licensed threshold is crossed.

Important: This is a customer-specific command that is available for HA, PDSN, EHA, and PDIF. Please contact your local Cisco sales representative for more information.

-force

Sets the license key even if resources are not available. The system supports the dynamic resizing of demultiplexor software tasks based on the licensed session capacity and feature type. When installing a license, the system automatically attempts to resize currently functioning tasks. Warning messages are displayed if there is an issue. Though its use is not recommended, the -force keyword can be used to suppress these warning messages.

Caution: Use of this option is not recommended.

Usage

Install or update system session keys when necessary due to expiration and/or capacity needs.

Example
license key sampleKeyValue

no license key
line

Enters the terminal display line configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

```
line
```

Usage

Change the terminal display configuration based upon the users own terminal characteristics.
link-aggregation

Configures system MAC address and priority for Link Aggregation. These parameters are usually changed to match the feature requirements of the remote Ethernet switch.

Product
WiMAX
PDSN
HA
FA
GGSN
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

link-aggregation { system-mac { MAC_address | auto } | system-priority priority } [-noconfirm ]

{ default | no } link-aggregation { system-mac | system-priority } [-noconfirm ]

default
Resets the configuration to the default.

system-mac { MAC_address | auto }
Sets the system MAC address used along with the system priority to form the system ID.
MAC_address is manually entered as six groups of two hexadecimal digits separated by hyphens (for example, 01-23-45-67-89-ab).
Auto is the default and is the MAC address of the LAG master port.

system-priority priority
This command sets the system priority used by Link Aggregation Control Protocol (LACP) to form the system ID.
priority is a hexadecimal value from 0x0000 through 0xFFFF. Default is 0x8000 (32768).

-noconfirm
Executes the command without additional prompting for command confirmation.
### Usage
The system MAC address (6 bytes) and system priority (2 bytes) combine to form the system ID. A system consists of a packet processing card and its associated QGLC or XGLC traffic ports. The highest system ID priority (the lowest number) handles dynamic changes.

For additional usage and configuration information for the link aggregation feature, refer to the *System Administration Guide*.

### Important:
Not supported on all platforms

### Example
The following command configures the link aggregation system-priority to 10640 (0x2990):

```
link-aggregation system-priority 0x2990
```
**local-policy-service**

This command enables creating, configuring, or deleting a local QoS policy.

**Product**
- P-GW
- SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
local-policy-service name [ -noconfirm ]
no local-policy-service name
```

- **name**
  Specifies name of the local QoS policy service as an alphanumeric string of 1 through 63 characters.

**Important:**
The name must be unique across all contexts.

If the named local QoS policy service does not exist, it is created, and the CLI mode changes to the Local Policy Service Configuration Mode wherein the local QoS policy service can be configured. If the named local QoS policy service already exists, the CLI mode changes to the Local Policy Service Configuration Mode for that local QoS policy service.

- **-noconfirm**
  Specifies that the command must execute without prompting for confirmation.

**Usage**
Use this command to specify a local QoS policy service name to allow configuration of a local QoS policy service.

**Important:** This feature is license dependent. Please contact your local sales representative for more information.
A local QoS policy service can be used to control different aspects of a session, such as QoS, data usage, subscription profiles, or server usage, by means of locally defined policies. Local QoS policies are triggered when certain events occur and the associated conditions are satisfied. For example, when a new call is initiated, the QoS to be applied for the call could be decided based on the IMSI, MSISDN, and APN.

**Important:** A maximum of 16 local QoS policy services are supported.

Entering this command results in the following prompt:

```
[context_name]hostname(config-local-policy-service)#
```

Local Policy Service Configuration Mode commands are defined in the *Local Policy Service Configuration Mode Commands* chapter.

**Example**

The following command creates a local QoS policy service named *lctest* and enters the Local Policy Service Configuration Mode:

```
local-policy-service lctest
```
local-user allow-aaa-authentication

Enables or disables the use of administrative accounts other than local-user administrative accounts.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
[ default | no ] local-user allow-aaa-authentication
```

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
</table>
| Returns this parameter to its default setting of enabled.

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
</table>
| Disables administrative user accounts other than local-user accounts.

**Usage**

Local-user administrative accounts are separate from other administrative user accounts configured at the context level (Security Administrator, Administrator, Operator, and Inspector). Context-level administrative users rely on the system’s AAA subsystems for validating user names and passwords during login. This is true for both administrative user accounts configured locally through a configuration file or on an external RADIUS server. Since the T1.276-2003 password security mechanisms are supported only for local-user administrative accounts and not for the AAA-based administrative accounts, this command provides a mechanism for disabling AAA-based administrative accounts. By default, AAA-based administrative accounts are allowed.

**Example**

The following command forces the system to authenticate local-user accounts based only on the information in the security account file on its CompactFlash:

```
no local-user allow-aaa-authentication
```
local-user lockout-time

 Configures the lockout period for local-user administrative accounts.

 Product
 All

 Privilege
 Security Administrator, Administrator

 Mode
 Exec > Global Configuration
 configure
 Entering the above command sequence results in the following prompt:

 [local] host_name(config) #

 Syntax

 local-user lockout-time time

default local-user lockout-time

 - default
   Restores the parameter to its default setting.

 - time
   Default: 60
   Specifies the amount of time (in minutes) that must elapse before a previously locked-out local-user account can attempt to login again. time is an integer from 1 through 10080.

 Usage
 Local-user administrative accounts can become locked for reasons such as exceeding the configured maximum number of login failures.
 Once an account is locked, this parameter specifies the lockout duration. Once the amount of time configured by this parameter has elapsed, the local-user can once again attempt to login.

 Example
 The following command configures a lockout time of 120 minutes (2 hours):

     local-user lockout-time 120
local-user max-failed-logins

Configures the maximum number of failed login attempts a local-user can have before their account is locked out.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

local-user max-failed-logins number

[ default | no ] local-user max-failed-logins

no

Disables this functionality.

default

Restores this parameter to its default setting.

number

Default: 5
Specifies the maximum number of times a local-user could experience a login failure before their account is locked out. number is an integer from 2 through 100.

Usage

This command configures the maximum number of failed login attempts a local-user can have before their account is locked out. For example if, this parameter is configured to “3” then after the third failed login attempt, the account would be locked.

Important: Local-user accounts can be configured to either enforce or reject a lockout due to the maximum number of failed login being reached. Refer to the local-user username command for more information.

Example

Refer to the local-user lockout-time command for more information.

The following command configures a maximum of three login attempts:

local-user max-failed-logins 3
local-user password

Configures local-user administrative account password properties.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
local-user password [ { complexity { ansi-t1.276-2003 | none } } [ history length number [ duration days ] ] [ max-age days ] [ min-change-char number ] [ min-change-interval days ] [ min-length number ] }

no local-user password [ { history } [ max-age ] [ min-change-interval ] }

default local-user password [ { complexity } [ history ] [ max-age ] [ min-change-char ] [ min-change-interval ] [ min-length ] }
```

**no**
Disables the specified parameter.

**default**
Restores the specified parameter to its default setting.

```
[ complexity { ansi-t1.276-2003 | none } ]
```

Default: ansi-t1.276-2003

Specifies the password strength as one of the following:

- **ansi-t1.276-2003**: If this option is selected, the following rules are enforced:
  - Passwords may not contain the username or the reverse of the username
  - Passwords may contain no more than three of the same characters used consecutively
  - Passwords must contain at least three of the following:
    - uppercase alpha character
    - lowercase alpha character
    - numeric character
    - special character
- **none**: No additional password checks are performed.
[ history length number [ duration days ] ]
Default: length is 5
Specifies the number of previous password entries kept in the history list maintained by the system. A password cannot be reused if it is one of the entries kept in the history list unless the time it was last used was more than the number of days specified by the duration keyword.
If the duration keyword is not used, the only check performed by the system is that it is not in the history list.
number is the number of entries for each account stored in the history list entered as an integer from 1 through 100. days is the number of days during which a password can not be reused entered an integer from 1 through 365.

[ max-age days ]
Default: 90
Specifies the maximum age for a password. Users logging in with a password older than the specified limit are locked out. Once the lockout period expires, at their next login attempt, they are prompted to change their password before accessing the CLI.

Important: Local-user accounts can be configured to either enforce or reject a lockout due to a password’s maximum age being reached. Refer to the local-user username command for more information.

days is the number of days that passwords remain valid entered as an integer from 1 through 365.

[ min-change-char number ]
Default: 2
Specifies the minimum number of characters that must be changed (in comparison to the current password) when a user changes their password.

Important: Changes in password length are counted as “character” changes. For example: changing a password from “password” to “passwo” is a 2-character change, changing a password from “password” to “password2” is a 1-character change, and changing a password from “password” to “apassword” is a 9-character change.

number is the number of characters entered as an integer from 0 through 16.

[ min-change-interval days ]
Default: 1
Specifies the frequency that passwords can be changed (other than first login).
days is the minimum number of days that must pass before a user can change their password. It is an integer from 1 through 365.

Important: If the no local-user password min-change-interval command is used, users may change their password as often as desired which could allow them to circumvent the password history function.

[ min-length number ]
Default: 8
Specifies the minimum length allowed for user-defined password.
number is the minimum number of alphanumeric characters that the password must contain, entered as an integer from 3 through 32.
Usage

This command is used to set the property requirements for user-defined passwords and system behavior in relation to those passwords. Information pertaining to user passwords, login failures, and password history are stored on the packet processing cards and in the software’s Shared Configuration Task (SCT). The system uses the information in the SCT for runtime operations such as determining password ages and determining if new passwords meet the criteria specified by this command.

Example

The following command configures a minimum password length requirement of 6 characters:

```
local-user password min-length 6
```

The following command configures the system to store the 4 most recently used passwords per user-account in the history list:

```
local-user password history length 4
```
local-user username

Adds or removes local-user administrative accounts.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

local-user username name [ authorization-level { administrator | inspector | operator | security-admin } ] [ ecs | noecs ] [ ftp | noftp ] [ timeout-min-absolute time ] [ no-lockout-login-failure ] [ no-lockout-password-aging ] [ password password | nopassword ] [ timeout-min-idle time ]

no local-user username name

no

Removes a previously configured user.

name

Specifies the name of the user as an alphanumeric string of 3 through 16 characters that is case sensitive.

[ authorization-level { administrator | inspector | operator | security-admin } ]

Default: Operator

Configures the authorization level for the user as one of the following:

*administrator*: Administrator users have read-write privileges and can execute any command throughout the CLI except for a few security functions allowed only in the administrator mode. Administrators can configure or modify the system and are able to execute all system commands, including those available to the operator and inspector user. This level corresponds to the both the System Administrator and Application Administrator levels in the T1.276-2003.

*inspector*: Inspector users are limited to a small number of read-only Exec Mode commands. The bulk of these are "show" commands giving the inspector the ability to view a variety of statistics and conditions. The Inspector cannot execute show configuration commands and do not have the privilege to enter the Config Mode.

*operator*: Operator users have read-only privileges to a larger subset of the Exec Mode commands as depicted in the following figure. Operator users can execute all commands that are part of the inspector mode, plus some system monitoring, statistical, and fault management functions. Operators do not have the ability to enter the Config Mode.
**security-admin**: Security Administrator users have read-write privileges and can execute any command throughout the CLI. Security Administrators can execute all system commands, including those available to the administrator, operator, and inspector users. This level corresponds to both the System Security Administrator and Application Security Administrator levels in T1.276-2003.

[ `ecs` | `noecs` ]

Specifies whether or not the user has access to Active Charging Service configuration parameters.

- `ecs`: The user has access.
- `noecs`: The user does not have access.

Default: `ecs`

[ `ftp` | `noftp` ]

Default: `ftp`

Specifies whether or not the user is allowed to access the system via the File Transfer Protocol (FTP) and/or the Secure File Transfer Protocol (SFTP).

- `ftp`: The user has access.
- `noftp`: The user does not have access.

[ `no-lockout-login-failure` ]

Default: Disabled

Specifies that this user will never be locked out due to login attempt failures.

[ `no-lockout-password-aging` ]

Default: Disabled

Specifies that this user will never be locked out due to the age of their password.

[ `password password` | `nopassword` ]

Specifies the initial password for this user. `password` must an alphanumeric string of 6 through 32 characters that is case sensitive.

**Important**: The user is requested to change their password upon their first login.

[ `timeout-min-absolute time` ]

Default: 0

Specifies the maximum session time (in minutes) for this user. `time` is an integer from 0 through 525600. A value of “0” indicates no limit.

**Important**: This limit applies only to the user’s CLI sessions.

[ `timeout-min-idle time` ]

Default: 0

Specifies the maximum idle time (in minutes) for this user. `time` is an integer from 0 through 525600. A value of “0” indicates no limit.
Important: This limit applies only to the user’s CLI sessions.

Usage

The ability to configure administrative local-users is provided in support of the login security mechanisms specified in ANSI T1.276-2003. Like administrative users configured at the context level, local-users can be assigned one of 4 security levels:

<table>
<thead>
<tr>
<th>Local-User Level User</th>
<th>Context Level User</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security Administrator</td>
<td>Administrator</td>
</tr>
<tr>
<td>Administrator</td>
<td>Config-Administrator</td>
</tr>
<tr>
<td>Operator</td>
<td>Operator</td>
</tr>
<tr>
<td>Inspector</td>
<td>Inspector</td>
</tr>
</tbody>
</table>

Local-user configuration support is handled differently from that provided for administrative users configured at the context level. Context-level administrative users rely on the system’s AAA subsystems for validating user names and passwords during login. This is true for both administrative user accounts configured locally through a configuration file or on an external RADIUS server. Passwords for these user types are assigned once and are accessible in the configuration file.

Local-user account information (passwords, password history, lockout states, etc.) is maintained in non-volatile memory and in the software’s Shared Configuration Task (SCT). This information is maintained in a separate file – not in configuration files used by the system. As such, the configured local-user accounts are not visible with the rest of the system configuration. Local-user and context-level administrative accounts can be used in parallel.

Example

The following command configures a security-administrator level local-user administrative account for a user named User672 that has FTP privileges, a temporary password of abc123, and that does not lockout due to either login attempt failures or password aging:

```
local-user username User672 authorization-level security-admin ftp no-lockout-login-failure no-lockout-password-aging password abc123
```

The following command deletes a previously configured local-user administrative account called admin32:

```
no local-user username admin32
```
logging console

Enables the output of logged events to be displayed on the console terminal.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

[ no ] logging console

no
Disables the output of events to the console port.

Usage
Log console output to allow for offline review during system monitoring and/or trouble shooting.
logging disable

Enables/disables the logging of the specified event ID or range of IDs.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

logging disable eventid id [ to to_id ]

no logging disable eventid id [ to to_id ]

no
Indicates the event IDs specified are to be enabled for logging.

eventid id
Specifies the event for which no logging is to occur.
In 14.1 and earlier releases, id is an integer from 1 through 202699.
In 15.0 and later releases, id is an integer from 1 through 204999.

to to_id
Specifies the end ID of the events when a range of event ID is to be disabled from being logged. to_id must be an integer from 1 through 204999. The to_id must be equal to or larger than the id specified.

Usage

Disable common events which may occur with a normal frequency are not of interest in monitoring the system for troubles.

Example

The following commands disables the logging of event ID 4580 and the range of events from 4500 through 4599, respectively.

logging disable eventid 4580 4580

logging disable eventid 4500 to 4599

The following enables the subset of disabled event IDs:

no logging disable eventid 4500 to 4549
logging display

Configures the level of detail for information to be logged.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

logging display event-verbosity evt_level ] [ pdu-data format ] [ pdu-verbosity pdu_level ]

<table>
<thead>
<tr>
<th>event-verbosity evt_level</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the level of verboseness to use in logging of events as one of:</td>
</tr>
<tr>
<td>• min</td>
</tr>
<tr>
<td>• concise</td>
</tr>
<tr>
<td>• full</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>pdu-data format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies output format for packet data units when logged as one of:</td>
</tr>
<tr>
<td>• none: outputs in raw format</td>
</tr>
<tr>
<td>• hex; displays out in hexadecimal format</td>
</tr>
<tr>
<td>• hex-ascii; displays output in hexadecimal and ASCII similar to a main-frame dump</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>pdu-verbosity pdu_level</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the level of verboseness to use in logging of packet data units as an integer from 1 through 5, where 5 is the most detailed.</td>
</tr>
</tbody>
</table>

Usage
Tune the level of information to be logged so as to avoid flooding a log file with information which is not useful or critical.

Example
The following sets the logging display for events to the maximum.

logging display event-verbosity full

The following command sets the logging display level of detail for packet data units to level 3 and sets the output format to the main-frame style hex-ascii:
logging display pdu-data hex-ascii pdu-verbosity 3
logging filter

Configures the logging of events to be performed in real time for the specified facility.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure
Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

logging filter runtime facility facility level report_level [ critical-info | no-critical-info ]

facility facility

Specifies the facility to modify the filtering of logged information. The following list displays the valid facilities for this command:

- a10: A10 interface facility
- a11: A11 interface facility
- a11mgr: A11 Manager facility
- aaa-client: Authentication, Authorization and Accounting (AAA) client facility
- aaamgr: AAA manager logging facility
- aaaproxy: AAA Proxy facility
- aal2: ATM Adaptation Layer 2 (AAL2) protocol logging facility
- acl-log: Access Control List (ACL) logging facility
- acsctrl: Active Charging Service (ACS) Controller facility
- acsmgr: ACS Manager facility
- afctrl: Fabric Controller facility [ASR 5500 only]
- afmgr: Fabric Manager logging facility [ASR 5500 only]
- alarmctrl: Alarm Controller facility
- alcap: Access Link Control Application Part (ALCAP) protocol logging facility
- alcapmgr: ALCAP manager logging facility
- all: All facilities
- asngwmg: Access Service Network (ASN) Gateway Manager facility
- asnpcmgr: ASN Paging Controller Manager facility
- bfd: Bidirectional Forwarding Detection (BFD) protocol logging facility
• bgp: Border Gateway Protocol (BGP) facility
• bindmux: IPCF BindMux-Demux Manager logging facility
• bngmgr: Broadband Network Gateway (BNG) Demux Manager logging facility
• bssap+: Base Station Sub-system Application Part+ protocol facility for the login interface between the SGSN and the MSC/VLR (2.5G and 3G)
• bssgp: Base Station Sub-system GPRS Protocol logging facility handles exchange information between the SGSN and the BSS (2.5G only)
• callhome: Call Home application logging facility
• cap: CAMEL Application Part (CAP) logging facility for protocol used in prepaid applications (2.5G and 3G)
• cbsmgr: Cell Broadcasting Service (CBS) logging facility [HNBGW]
• cdf: Charging Data Function (CDF) logging facility
• cgw: Converged Access Gateway (CGW) logging facility
• cli: Command Line Interface (CLI) logging facility
• cmp: Certificate Management Protocol (IPSec) logging facility
• connectedapps: SecGW ASR 9000 oneP communication protocol
• connproxy: Controller Proxy logging facility
• credit-control: Credit Control (CC) facility
• cscf: IMS/MMD Call Session Control Function (CSCF)
• cscfcpmgr: CSCFCPMGR logging facility
• cscfmgr: SIP CSCF Manager facility
• cscfnpdb: CSCF Number Portability Database (NPDB) logging facility
• cscfrtcp: IMS/MMD CSCF RTCP log facility
• cscfrtp: IMS/MMD CSCF RTP log facility
• cscfttmgr: SIP CSCF Tunnel and Transport Manager facility
• csp: Card/Slot/Port controller facility
• css: Content Service Selection (CSS) facility
• css-sig: CSS RADIUS Signaling facility
• cx-diameter: Cx Diameter Messages facility [CSCF <-> HSS]
• dcardctrl: IPSec Daughter Card Controller logging facility
• dcardmgr: IPSec Daughter Card Manager logging facility
• demuxmgr: Demux Manager API facility
• dmgmbmgr: Diameter Gmb Application Manager logging facility
• dhcp: Dynamic Host Configuration Protocol (DHCP) logging facility
• dhcpv6: DHCPv6
• dhost: Distributed Host logging facility
• diabase: Diabase messages facility
• diameter: Diameter endpoint logging facility
• **diameter-acct**: Diameter Accounting
• **diameter-auth**: Diameter Authentication
• **diameter-dns**: Diameter DNS subsystem
• **diameter-ecs**: ACS Diameter signaling facility
• **diameter-hdd**: Diameter Horizontal Directional Drilling (HDD) Interface facility
• **diameter-svc**: Diameter Service
• **diamproxy**: DiamProxy logging facility
• **dpath**: IPSec Data Path facility
• **drvctrl**: Driver Controller facility
• **dpath**: IPSec Data Path logging facility
• **drvctrl**: Driver Controller logging facility
• **doulosuemgr**: Doulos (IMS-IPSec-Tool) user equipment manager
• **eap-diameter**: Extensible Authentication Protocol (EAP) Security facility
• **eap-ipsec**: Extensible Authentication Protocol (EAP) IPSec facility
• **eap-sta-s6a-s13-s6b-diameter**: EAP/STA/S6A/S13/S6B Diameter messages facility
• **ecs-css**: ACSMGR <-> Session Manager Signalling Interface facility
• **egtpc**: eGTP-C logging facility
• **egtpmgr**: enhanced GPRS Tunneling Protocol (eGTP) manager logging facility
• **egtpu**: eGTP-U logging facility
• **embms**: evolved Multimedia Broadcast Multicast Services Gateway facility
• **embms**: eMBMS Gateway Demux facility
• **epdg**: evolved Packet Data (ePDG) gateway logging facility
• **event-notif**: Event Notification Interface logging facility
• **evlog**: Event log facility
• **famgr**: Foreign Agent manager logging facility
• **firewall**: Firewall logging facility
• **fng**: Femto Network Gateway (FNG) logging facility
• **gbmgr**: SGSN Gb Interface Manager facility
• **gmm**:
  • For 2.5G: Logs the GPRS Mobility Management (GMM) layer (above LLC layer)
  • For 3G: Logs the access application layer (above the RANAP layer)
• **gprs-app**: GPRS Application logging facility
• **gprs-ns**: GPRS Network Service Protocol (layer between SGSN and the BSS) logging facility
• **gq-rx-tx-diameter**: Gq/Rx/Tx Diameter messages facility
• **gss-gcdr**: GTPP Storage Server GCDR facility
• **gtpc**: GTP-C protocol logging facility
• **gtpcmgr**: GTP-C protocol manager logging facility
• **gtp**: GTP-prime protocol logging facility
• **gtpu**: GTP-U protocol logging facility
• **gtpumgr**: GTP-U Demux manager
• **gx-ty-diameter**: Gx/Ty Diameter messages facility
• **gy-diameter**: Gy Diameter messages facility
• **h248p**: H.248 port manager facility
• **hamgr**: Home Agent manager logging facility
• **hat**: High Availability Task (HAT) process facility
• **hdctrl**: HD Controller logging facility
• **henbapp**: Home Evolved NodeB (HENB) App facility
• **henbgw**: HENB-GW facility
• **henbgw-pws**: HENB-GW Public Warning System logging facility
• **henbgw-sctp-acs**: HENB-GW access Stream Control Transmission Protocol (SCTP) facility
• **henbgw-sctp-n**: HENBGW network SCTP facility
• **henbgwdemux**: HENB-GW Demux facility
• **henbgwmgr**: HENB-GW Manager facility
• **hnb**: HNB-GW (3G Femto GW) logging facility
• **hnbmgr**: HNB-GW Demux Manager logging facility
• **hss-peer-service**: Home Subscriber Server (HSS) Peer Service facility
• **igmp**: Internet Group Management Protocol (IGMP)
• **ikev2**: Internet Key Exchange version 2 (IKEv2)
• **ims-authoriztn**: IP Multimedia Subsystem (IMS) Authorization Service facility
• **ims-sh**: HSS Diameter Sh Interface Service facility
• **imsimgr**: SGSN IMSI Manager facility
• **imsue**: IMS User Equipment (IMSUE) facility
• **ip-arp**: IP Address Resolution Protocol facility
• **ip-interface**: IP interface facility
• **ip-route**: IP route facility
• **ipms**: Intelligent Packet Monitoring System (IPMS) logging facility
• **ipne**: IP Network Enabler (IPNE) facility
• **ipsec**: IP Security logging facility
• **ipscedemux**: IPSec demux logging facility
• **ips**: IP Service Gateway interface logging facility
• **ipsgm**: IP Services Gateway facility
• **ipps**: IP Pool Sharing Protocol logging facility
• **kvstore**: Key/Value Store (KVSTORE) Store facility
• **l2tp-control**: Layer 2 Tunneling Precool (L2TP) control logging facility
• **l2tp-data**: L2TP data logging facility
• **l2tpdemux**: L2TP Demux Manager logging facility
• **l2tpmgr**: L2TP Manager logging facility
• **lagmgr**: Link Aggregation Group (LAG) manager logging facility
• **lcs**: Location Services (LCS) logging facility
• **ldap**: Lightweight Directory Access Protocol (LDAP) messages logging facility
• **li**: Refer to the *Lawful Intercept Interface Reference* for a description of this command.
• **linkmgr**: SGSN/BSS SS7 Link Manager logging facility (2.5G only)
• **llc**: Logical Link Control (LLC) Protocol logging facility; for SGSN: logs the LLC layer between the GMM and the BSSGP layers for logical links between the MS and the SGSN
• **local-policy**: Local Policy Service facility
• **location-service**: Location Services facility
• **m3ua**: M3UA Protocol logging facility
• **magmgr**: Mobile Access Gateway manager logging facility
• **map**: Mobile Application Part (MAP) protocol logging facility
• **megadiammgr**: MegaDiameter Manager (SLF Service) logging facility
• **mme-app**: Mobility Management Entity (MME) Application logging facility
• **mme-misc**: MME miscellaneous logging facility
• **mmedemux**: MME Demux Manager logging facility
• **mmemgr**: MME Manager facility
• **mmgr**: Master Manager logging facility
• **mobile-ip**: Mobile IP processes
• **mobile-ip-data**: Mobile IP data facility
• **mobile-ipv6**: Mobile IPv6 logging facility
• **mpls**: Multiprotocol Label Switching (MPLS) protocol logging facility
• **mrme**: Multi Radio Mobility Entity (MRME) logging facility
• **mseg-app**: Mobile Services Edge Gateway (MSEG) application logging facility (This option is not supported in this release.)
• **mseg-gtpc**: MSEG GTP-C application logging facility (This option is not supported in this release.)
• **mseg-gtpu**: MSEG GTP-U application logging facility (This option is not supported in this release.)
• **msegmgr**: MSEG Demux Manager logging facility (This option is not supported in this release.)
• **mtp2**: Message Transfer Part 2 (MTP2) Service logging facility
• **mtp3**: Message Transfer Part 3 (MTP3) Protocol logging facility
• **multicast-proxy**: Multicast Proxy logging facility
• **nas**: Non-Access Stratum (NAS) protocol logging facility [MME 4G]
• **netwstrg**: Network Storage facility
• **npuctrl**: Network Processor Unit Control facility

- **vmgctrl**: VMG Content Manager facility
- **vpn**: Virtual Private Network logging facility
- **wimax-data**: WiMAX DATA
- **wimax-r6**: WiMAX R6
- **wsg**: Wireless Security Gateway (ASR 9000 Security Gateway)

```
level report_level [ critical-info | no-critical-info ]
```

**level report_level**: specifies the level of information to be logged, `report_level`, as one of:
- `critical`
- `debug`
• error
• info
• trace
• unusual
• warning

critical-info | no-critical-info: indicates if critical information is to be displayed or not. The keyword critical-info specifies that events with a category attribute of critical information are to be displayed. Examples of these types of events can be seen at bootup when system processes and tasks are being initiated. The no-critical-info keyword specifies that events with a category attribute of critical information are not to be displayed.

Usage
This command is useful when it is necessary to get real time output of events. Event output may be cached otherwise which may make it difficult to trouble shoot problems which do not allow the last cache of events to be output prior to system problems.

⚠️ Caution: Issuing this command could negatively impact system performance depending on system loading, the log level, and/or the type of facility(ies) being logged.

Example
Set real time output for the point-to-point protocol facility and all facilities, respectively, to avoid logging of excessive information.

    logging filter runtime facility ppp

    logging filter runtime facility all level warning
logging monitor

Enables or disables the monitoring of a specified user.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

[ no ] logging monitor { ipaddr ip_address | ipv6addr ipv6_address | msid ms_id | username user_name }

no
Disables the monitoring of the user specified by the options given.

ipaddr ip_address
Specifies the IP address of the user for which the monitoring filter is to be set. ip_address must be entered using IPv4 dotted-decimal notation.

ipv6addr ipv6_address
Specifies the IPv6 address of the user for which the monitoring filter is to be set. ipv6_address must be followed by IPv6 address in a xx:yy::zz format.

msid ms_id
msid ms_id: specifies the mobile subscriber ID for which the monitoring filter is to be set. ms_id must be from 7 to 16 digits.
This keyword/option can be used to specify the Mobile Subscriber ISDN (MSISDN) for GGSN calls which enables logging based on MSISDN.

username user_name
username user_name: specifies a user for which the monitoring filter is to be set. user_name must refer to a previously configured user.

Usage

Monitor subscribers which have complaints of service availability or to monitor a test user for system verification.

**Caution:** Issuing this command could negatively impact system performance depending on the number of subscribers for which monitoring is performed and/or the amount of data they’re passing.

**Example**

The following command enables the monitoring of user *user1* and mobile subscriber ID 4441235555, respectively.

```plaintext
logging monitor username user1
logging monitor msid 4441235555
```

The following disables the monitoring of user *user1*.

```plaintext
no logging monitor username user1
```
logging runtime

Enables events to be filtered and logged in real time.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

logging runtime buffer store { all-events | filtered-events-only }

buffer store { all-events | filtered-events-only }

Determines which logs are stored in internal logging daemon runtime buffer.

*all-events*: Logging daemon runtime buffer stores all logs that come to it.

*filtered-events-only*: Logging daemon runtime buffer stores only logs that pass the runtime filter.

**Usage**

Sets the filtering of logged information to log in real time.

**Example**

The following command enables storage of logs that pass the runtime filter:

logging runtime buffer store filtered-events-only
**lte-policy**

This command enters the LTE Policy Configuration Mode where LTE policy parameters can be configured.

**Product**
- MME
- SAEGW
- S-GW
- SGSN

**Privilege**
Administrator

**Mode**
Exec > Global Configuration
`configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
lte-policy
```

**Usage**
Enters the LTE Policy Configuration Mode.
Entering this command results in the following prompt:

```
[context_name] host_name(lte-policy)#
```

LTE Policy Configuration Mode commands are defined in the *LTE Policy Configuration Mode Commands* chapter.
mediation-device

This command is obsolete. Even though the CLI accepts the command no function is performed.

Product

mobile-services-edge-gateway

This command is not supported in this release.
network-overload-protection mme-new-connections-per-second

This command configures an attach rate throttle mechanism to control the number of new connections allowed on a per second basis.

Product
MME

Privilege
Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

network-overload-protection mme-new-connections-per-second #_new_connections action
att { drop | reject-with-emm-cause { congestion | network-failure | no-suitable-cell-in-tracking-area } } tau { drop | reject-with-emm-cause { congestion | network-failure | no-sec-ctxt-in-nw | no-suitable-cell-in-tracking-area } } fwd-reloc { drop | reject } [ queue-size queue_size ] [ wait-time wait_time ]

default network-overload-protection mme-new-connections-per-second

default
Disables the MME attach rate throttle feature.

mme-new-connections-per-second #_new_connections

Define the number of new connections to be accepted per second.

#_new_connections: Must be an integer from 50 to 5000.

action

Specifies the action to be taken by the MME when the new connection queue is full. Specific actions can be defined for each of the following connection types:

• UE-initiated attaches (see attach keyword).

• UE-initiated inter-CN node TAU requests (see tau keyword).

• Peer SGSN/MME initiated forward relocation requests (see fwd-reloc keyword).

attach { drop | reject-with-emm-cause { congestion | network-failure | no-suitable-cell-in-tracking-area } }

Specifies the action to be taken for all types of UE-initiated initial attaches (IMSI, local GUTI, foreign GUTI, mapped GUTI, etc.). Select one of the following actions:

• drop: Drop the new connection request.
*reject-with-cause:* Reject the new connection request. Include one of the following as the cause in the reject message:

- congestion
- network-failure
- no-suitable-cell-in-tracking-area

`tau { drop | reject-with-emm-cause { congestion | network-failure | no-sec-ctxt-in-nw | no-suitable-cell-in-tracking-area } }`

Specifies the action to be taken for UE-initiated inter-CN TAU requests requiring context transfer from old MME/SGSN, including TAU requests with foreign GUTI or mapped GUTI. Select one of the following actions:

- *drop:* Drop the new connection request.
- *reject-with-cause:* Reject the new connection request. Include one of the following as the cause in the reject message:
  
  - congestion
  - network-failure
  - no-sec-ctxt-in-nw
  - no-suitable-cell-in-tracking-area

`fwd-reloc { drop | reject }`

Specifies the action to be taken for peer SGSN/MME initiated forward relocation requests via Gn/S10/S3. Select one of the following actions:

- *drop:* Drop the new connection request.
- *reject:* Reject the new connection request. If the inbound forward-relocation requests are rejected, the following cause codes shall be used:
  
  - GTPv1 - No resources available (199)
  - GTPv2 - No resources available (73)

In the event of an MME failure, the surviving MME in the pool may receive a very large number of IMSI requests, which may overwhelm the IMSI Manager. To avoid congestion, the MME can be configured using this keyword to throttle the IMSI-based DDN requests it receives if the configured #new_connections rate is exceeded. Select one of the following actions:

- *drop:* Drop new IMSI-based DDN requests.
- *reject:* Reject the IMSI-based DDN request. Include one of the following as the cause in the reject message:
  
  - unable-to-page-ue
  - context-not-found
queue-size queue_size

Defines the maximum size of the pacing queue used for buffering the packets. If configured, the queue-size should be greater than or equal to the \texttt{#_new_connections} value and less than or equal to the optimal value (the \texttt{wait_time*#_new_connections}). This validation is done in the CLI.

- \texttt{queue_size} Must be an integer from 250 to 25000.
- Default: unconfigured. The default value is the \texttt{#_new_connections * wait-time}. This will be the optimal value.

wait-time wait_time

Defines the maximum life-time (number of seconds) of the packets in the queue beyond which the packets are considered to be “stale” and are dropped.

- \texttt{wait_time} Must be an integer from 1 to 15
- Default: 5

Usage

Use this command to configure attach rate throttling on the MME.

When enabled, new connections (except emergency requests) are buffered and paced through the queue. Messages in the queue are processed (FIFO) until they age-out when the queued message's lifetime crosses the configured wait-time. The wait-time and the attach rate decide the optimal size of the queue. If the queue is full, packets are rejected or dropped based on the configured action.

This feature functions at a system (chassis) level for all MME services. All MME services on the system are controlled by a single pacing queue. For a combo MME-SGSN node, each type of service shall be controlled by its own queue and its own configuration.

Emergency attaches are not be throttled when this feature is enabled.

**Important:** This command is available only if a valid license (MME Resiliency) is installed. Contact your Cisco account representative for more information.

Example

Configure the new connections per second rate at 2500, reject all (non-emergency) attaches and TAU requests, and drop forward relocation requests if the new connection rate is exceeded. Rejects will return emm cause code “Congestion”.

```bash
network-overload-protection mme-new-connections-per-second 2500 action
attach reject-with-emm-cause congestion tau reject-with-emm-cause
congestion fwd-reloc drop ddn drop wait-time 5
```

Set the attach rate to 500 per second, the same actions as the previous example, but set the wait time to 5 seconds, and the queue size to be calculated (as follows: \texttt{wait_time*#_new_connections} - i.e., 2500)

```bash
network-overload-protection mme-new-connections-per-second 500 action
attach reject-with-emm-cause congestion tau reject-with-emm-cause
congestion fwd-reloc drop ddn drop wait-time 5 5
```
network-overload-protection mme-tx-msg-rate-control

Enables and configures the S1 Paging Rate Limit feature as well as UE Deactivation Rates upon EGTPC path failure feature.

**Product**
MME

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**

```
network-overload-protection mme-tx-msg-rate-control { egtp-pathfail ecm-idle rate ecm-connected rate | enb s1-paging rate }

[ default ] network-overload-protection mme-tx-msg-rate-control
```

**default**
Applies the default MME message rate control configuration; S1 paging rate limit is disabled and a path failure processing rate of 1000 per second per session manager without distinguishing between ECM idle/connected sessions.

```
egtp-pathfail ecm-idle rate ecm-connected rate
```

Configures the UE deactivation pacing rate for MME S11/S10/S3 interfaces (any EGTPC service with interface type “interface-mme”).

- **ecm-idle rate**: This keyword defines the deactivation rate for UEs in ECM Idle mode.
- **ecm-connected rate**: This keyword defines the deactivation rate for UEs in ECM Connected mode.
- **rate**: Specifies a rate threshold in sessions per second per session manager (SessMgr) as an integer from 1 through 5000.

**Note**: Configuring a high deactivation rate can have a negative effect on performance. Appropriate dimensioning exercises should be performed to arrive at the optimum rate.

```
enb s1-paging rate
```

Configures an S1 paging rate limit applicable to all eNodeBs connected all MME services. S1 Paging requests to an eNodeB will be rate limited at this threshold value. S1 Paging requests to an eNodeB exceeding this threshold will be dropped.

- **rate**: Specifies the rate threshold in messages per second per eNodeB as an integer from 1 through 65535.

**Usage**
Use this command to enable and configure the S1 Paging Rate Limit feature as well as UE Deactivation Rates upon EGTPC path failure feature.
Example

The following command configures S1 Paging rate limit of 150 messages per second per eNodeB.

```
network-overload-protection mme-tx-msg-rate-control enb s1-paging 150
```

The following command configures EGTP path failure processing rate limit for UE sessions in ECM-Idle mode to 10 sessions per second per session manager and for UE sessions in ECM-Connected mode to 20 sessions per second per session manager.

```
network-overload-protection mme-tx-msg-rate-control egtp-pathfail ecm-idle 10 ecm-connected 20
```
network-overload-protection sgsn-new-connections-per-second

This command configures an attach rate throttle mechanism to control the number of new connections (attaches or inter-SGSN RAUs), through the SGSN, on a per second basis.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

network-overload-protection sgsn-new-connections-per-second #_new_connections action { drop | reject with cause { congestion | network failure } } [ queue-size queue_size ] [ wait-time wait_time ]

default network-overload-protection sgsn-new-connections-per-second

default

Using default in the command, disables this attach rate throttle feature that provides network overload protection.

sgsn-new-connections-per-second #_new_connections

Define the number of new connections to be accepted per second.
#_new_connections: Must be an integer from 50 to 5000.

action

Specifies the action to be taken by the SGSN when the attach rate exceeds the configured limit on the number of attaches. Select one of the following actions:

• drop: Drop the new connection request.

• reject-with-cause: Reject the new connection request. Include one of the following as the cause in the reject message:

• congestion

• network failure

queue-size queue_size

Defines the maximum size of the pacing queue used for buffering the packets. If configured, the queue-size should be greater than or equal to the #_new_connections value and less than or equal to the optimal value (the wait_time * #_new_connections). This validation is done in the CLI.
queue_size: Must be an integer from 250 to 25000.
Global Configuration Mode Commands (L-S)

network-overload-protection sgsn-new-connections-per-second

Default: unconfigured. The default value is the \( \#_{new\_connections} \times wait\_time \). This will be the optimal value.

\[ \text{wait-time } wait\_time \]

Defines the maximum life-time (number of seconds) of the packets in the queue beyond which the packets are considered to be “stale”.

**wait_time** Must be an integer from 1 to 15
Default: 5

**Usage**

Use this command to configure the rate at which the SGSN must process new connection requests. The rate is the number of new connections to be accepted per second.

With basic network overload protection, the incoming new connection rate is higher than this configured rate. When this occurs, all of the new connection requests cannot be processed. This command can also be used to configure the action to be taken when the rate limit is exceeded. The new connection requests, which cannot be processed, can be either dropped or rejected with a specific reject cause.

The SGSN’s *optimized* network overload protection performs attach-rate throttling to avoid overloading Gr, Gn and Gf interfaces. This is enabled with *queue-size* and *wait-time* keywords so that the IMSIMgr throttles the attach rate to values configured with these keywords.

If the SGSN receives more than the configured number of attaches in a second, then the attaches are buffered in the pacing queue and requests are only dropped when the buffer overflows due to high incoming attach rate. Messages in the queue are processed (FIFO) until they age-out when the queued message’s lifetime crosses the configured wait-time. The wait-time and the attach rate decide the optimal size of the queue.

Counters for this feature are available in the *show gmm-sm statistics* command display in the Network Overload Protection portion of the table.

**Example**

Configure the throttle rate or limit to 2500 attaches per second and to drop all requests if the limit is exceeded.

```
network-overload-protection sgsn-new-connections-per-second 2500 action drop
```

Disables the network-overload protection feature and set the default queue size to 1000 and the wait time to 5 seconds:

```
default network-overload-protection sgsn-new-connections-per-second
```

Set the attach rate to 500 per second, the action to drop, the wait time to 5 seconds, and the queue size to be calculated (as follows: \( wait\_time \times \#_{new\_connections} \), i.e., 2500)

```
network-overload-protection sgsn-new-connections-per-second 500 action drop wait-time 5
```
**network-service-entity**

This command creates a new instance of an SGSN network service entity (NSE) for either the IP environment or the Frame Relay environment.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
  
  **configure**
  
  Entering the above command sequence results in the following prompt:

  `[local] host_name(config)#`

**Syntax**

```
[ no ] network-service-entity ( ip-local | peer-nsei peer_nsei_number frame-relay )
```

- **no**
  
  Deletes the network service entity definition from the system configuration.

- **ip-local**
  
  Configures the local endpoint for NS/IP and enters the NSE-IP configuration mode. The prompt will change to:

  `[local]<hostname>(nse-ip-local)#`

- **peer-nsei peer_nsei_number frame-relay**
  
  Configures a peer NSE with frame relay connectivity. This set of keywords also provides access to the NSE-FR Configuration mode. The prompt will change to:

  `[local]<hostname>(nse-fr-peer-nsei-<peer_nsei_number>)#`

**Usage**

Use this command to access the configuration modes for either the IP or Frame Relay network service entities.

**Example**

Enter the NSE for a Frame Relay configuration instance identified as 4554:

```
network-service-entity peer-nsei 4554 frame-relay
```
network-service-entity ip

This command has been deprecated. See the replacement command network-service-entity.
**ntp**

Enters the Network Time Protocol (NTP) configuration mode or disables the use of NTP on the system.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
[ no ] ntp
```

no

Disables the use of NTP for clock synchronization. When omitted, NTP client support is enabled on the chassis. By default NTP synchronization to external servers is disabled.

**Important:** If the use of NTP is disabled the system clock may drift over a period of time. This may require manual updates to the system clock to synchronize the clock with other network elements.

**Usage**

Used when it is necessary to enable or configure NTP settings. For additional information refer to the NTP Configuration Mode Commands chapter and the System Administration Guide.

**Example**

The following command enters the NTP configuration mode:

```
ntp
```

The following disables the use of the network timing protocol for system clock synchronization.

```
no ntp
```
**ntsr pool-id**

Configures a pool ID and pool type (either MME or S4-SGSN) for Network Triggered Service Restoration (NTSR). Once executed, the user is placed in NTSR Pool Configuration Mode.

**Product**  
S-GW

**Privilege**  
Administrator, Security Administrator

**Mode**  
Exec > Global Configuration  
**configure**

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
ntsr pool-id number pool-type [ mme | s4-sgsn ]
```

```
no ntsr pool-id
```

```
ntsr pool-id
```

Specifies an ID number for this NTSR pool. Valid entries are from 1 to 65535.

```
pool-type
```

Specifies the type of pool for the pool-id. Options are MME or S4-SGSN.

**Usage**

This command is used to configure a pool ID and pool type (either MME or S4-SGSN) for NTSR. Once executed, the operator must configure a peer IP address in NTSR Pool Configuration mode using the `peer-ip-address` command.

**Example**

This example configures an NTSR pool ID of 1 and a pool type of mme.

```
ntsr pool-id 1 pool-type mme
```
**operator-policy**

This command creates an operator policy and enters the operator policy configuration mode. Commands for configuration of the policies are available in the *Operator Policy Configuration Mode Commands* chapter.

**Product**
- MME
- SGSN
- SAEGW
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration

```bash
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```bash
operator-policy ( default | name policy_name ) [ -noconfirm ]
no operator-policy ( default | name policy_name )
```

- **-noconfirm**
  Indicates that the command is to execute without any additional prompt and confirmation from the user.

- **no**
  Removes the specified operator policy from the system configuration.

- **default**
  
  *default*, in this case, is the *name* of a specific operator policy. This default policy is used when no other defined operator policy matches the incoming IMSI.

**Important**: You should configure this default operator policy to be it available to handle IMSIs that are not matched with other defined policies.

- **name policy_name**

  Specifies the unique name of an operator policy. *policy_name* is entered as an alphanumeric string of 1 through 64 characters.
Usage

Use this command to create an operator policy and to enter the operator policy configuration mode to define or modify policies.

An operator policy associates APNs, APN profiles, IMEI ranges, IMEI profiles, an APN remap table and a call-control profile to ranges of IMSIs. These profiles and tables are created and defined within their own configuration modes to generate sets of rules and instructions that can be reused and assigned to multiple policies. In this manner, an operator policy manages the application of rules governing the services, facilities and privileges available to subscribers. These policies can override standard behaviors and provide mechanisms for an operator to get around the limitations of other infrastructure elements such as DNS servers and HLRs.

The system supports up to 1,000 operator policies, including the `default` operator policy.

**Important:** An operator policy is **the** key element of the Operator Policy feature. After defining an instance of an operator policy, you must go to the SGSN Global Configuration Mode (from the Global Configuration mode) to define the IMSI range(s). This requirement does not hold if you are using a `default` operator policy.

Example

To see what operator policies have already been created, return to the Exec mode and enter the `show operator-policy all` command.

The following command accesses the default operator policy and enters the operator policy configuration mode to view or modify the specified policy:

```
operator-policy default
```
orbem

Enters the Object Request Broker Element Manager (ORBEM) Configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

orbem

Usage
Set the configuration mode to allow modification of the ORBEM configuration data.
pac-standby-priority

This command has been renamed to card-standby-priority. Please refer to that command for details. Note that for backwards compatibility, the system accepts this command as valid.
pdu-session-recovery

Enables or disables support for early PDU recovery of VoLTE calls during Transaction Protocol Data Unit (TPDU) based session recovery. When this CLI is enabled, data is allowed for VoLTE-only calls when Session Manager is recovering.

Product
- GGSN
- P-GW
- S-GW
- SAE-GW

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration
  - configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

pdu-session-recovery call-type ims-media services { ggsn [pgw] [sgw] | pgw [ggsn] [sgw] | sgw [ggsn] [pgw] }  

no pdu-session-recovery call-type ims-media

Usage

Usage
Use this command to enable or disable support for early PDU recovery of VoLTE calls during TPDU based session recovery. When this CLI is enabled, data is allowed for VoLTE-only calls when Session Manager is recovering.

Even with GnGp association, the pgw option needs to be explicitly configured for PGW calls.

Example

The following command enables early PDU recovery for P-GW services:

pdu-session-recovery call-type ims-media services pgw
peer-profile

This command creates a peer profile based on service type and interface and enters the Peer-Profile Configuration mode. Commands for configuration of the policies are available in the Peer Profile Configuration Mode Commands chapter.

Product

- GGSN
- P-GW
- SAEGW
- S-GW

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

peer-profile service-type { ggsn-access | pgw-access | sgw-access | sgw-network } { default | name peer_profile_name } [ -noconfirm ]

no peer-profile service-type { ggsn-access | pgw-access | sgw-access | sgw-network } name peer_profile_name [ -noconfirm ]

Indicates that the command is to execute without any additional prompt and confirmation from the user.

no

Removes the specified peer profile for specific service type from the system configuration.

service-type

 Specifies service type for which peer profile is being configured.
- ggsn-access configure profile for peer nodes of GGSN.
- pgw-access configures profile for peer nodes of P-GW.
- sgw-access configures profile for peer nodes of S-GW toward S4/S11 interfaces.
- sgw-network configures profile for peer nodes of S-GW toward S5/S8 interfaces.

name peer_profile_name

Specifies the unique name of a peer profile for specific service type.

peer_profile_name is entered as an alphanumeric string of 1 through 64 characters.
```
default

default, in this case, is the *name* of a specific peer profile. This default profile is used when no other defined peer profile matches.
```

**Important:** When there is no association of peer-map in any of the services, then “default” peer profile of the corresponding service-interface type shall be applied, except for GTP-C parameters. In addition, GTP-C parameter configuration shall be applied from eGTP service-level configuration for P-GW/S-GW service and GGSN service-level configuration for GGSN.

**Usage**
Use this command to create a peer profile for specific service type and to enter the service specific Peer Profile configuration mode to define or modify the peer profile parameters.

The peer profile feature allows flexible profile-based configuration to accommodate growing requirements of customizable parameters with default values and actions for peer nodes of GGSN/P-GW/S-GW. With this feature, configuration of GTP-C echo parameters and disabling/enabling of Lawful intercept per MCC/MNC or IP address based on rules can be managed.

Before StarOS Release 15.0, the GGSN service allowed operator to configure list of SGSNs. Using this configuration, operator can also control some parameters associated with the configured SGSN, such as RAT type. This would be taken from configuration if CPC request does not have RAT type.

**Important:** The system supports up to 64 peer profiles configured for each of the peer profile types; there can be up to 1024 peer map rules configured, including all the peer maps.

**Example**
The following command accesses the default peer profile for GGSN service and enters the GGSN Peer Profile configuration mode to view or modify the specified profile:

```
peer-profile service-type ggsn-access default
```
plugin

Specifies a previously installed software plugin module and enters the Plugin Configuration Mode. This function is associated with the patch process for dynamic software upgrades. A plugin module is a loadable dynamic link library (DLL) of shared objects.

Product
ADC

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

plugin module_name

Specifies the name of an existing plugin module that you want to downgrade as an alphanumeric string of 1 through 16 characters. If the named module is not known to the system, an error message is displayed.

Usage

Specify a previously loaded software plugin module that you wish to configure. The specified module must have been previously copied onto the system and unpacked/verified via the patch plugin and install patch plugin commands.
For additional information, refer to the Plugin Configuration Mode Commands chapter.

Example

To specify the plugin module named p2p_odyssey enter the following command:

plugin p2p_odyssey
port atm

Identifies a physical port on a line card that supports ATM signaling and then enters the configuration mode for the specific interface-type. For the commands to configure the port interface, see the CLI chapter ATM Port Configuration Mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
port atm slot/port

atm
Indicates the port identified is an ATM interface port.

slot/port
To determine valid ATM slot and port numbers, use the Exec mode’s command `show port table`.
slot: Identifies the chassis slot holding the line card that supplies ATM ports. The slot ID number can be an integer from 1 through 48.
port: Identifies the physical port that is to be configured to support ATM signaling. The ID number can be an integer from 1 through 4.
```

**Usage**
Change the current configuration mode to Ethernet Port Configuration mode.

**Important:** This command is not supported on all platforms.

**Example**
The following enters the ATM port configuration mode for ATM port 1 on the card in slot 19:

```
port atm 19/1
```
port bits

Enters the Building Integrated Timing Supply (BITS) port configuration mode by identifying the BITS port on the active or standby SPIO.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

port bits slot/port

<table>
<thead>
<tr>
<th>bits</th>
<th>Identifies the BITS port.</th>
</tr>
</thead>
<tbody>
<tr>
<td>slot/port</td>
<td>slot: Identifies the chassis slot holding the SPIO. The slot ID can be either 24 (active SPIO) or 25 (standby SPIO).</td>
</tr>
<tr>
<td></td>
<td>port: Identifies the BITS port on the SPIO. The port ID number must be 4.</td>
</tr>
</tbody>
</table>

Usage

Change the current configuration mode to BITS port configuration mode.

Important: This command is not supported on all platforms.

Example

The following enters the BITS port configuration mode for the active SPIO:

    port bits 24/4
port channelized

Identifies a physical port on a Channelized Line Card (CLC) that supports Frame Relay signaling and creates a Frame Relay interface. This command enters the configuration mode for the commands that configure the Frame Relay interface and the channelized port interface. For additional information, see the Channelized Port Configuration Mode Commands chapter.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
port channelized slot/port
```

*channelized*

Selects the channelized frame relay interface for the selected line card and port.

*slot/port*

To determine valid slots and port numbers, use the Exec mode’s command `show port table` to find the channelized line card.

*slot:* Identifies the chassis slot holding the Channelized Line Card that sources Frame Relay ports. The slot ID number can be an integer from 17 through 48.

*port:* Identifies the physical port that is to be configured to support Frame Relay signaling. The ID number can only be 1.

**Usage**

Change the current configuration mode to Channelized Port configuration mode.

**Example**

The following enters the Channelized port configuration mode for port 1 on the card in slot 20:

```
port channelized 20/1
```
**port ethernet**

Enters the Ethernet Port Configuration mode for the identified port.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**configure**
Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
port ethernet slot/port
```

- **ethernet**
  Indicates the port identified is an Ethernet interface port.

- **slot/port**
  Specifies the slot and port for which Ethernet Port Configuration mode is being entered. The slot and port must refer to an installed card and port.

---

**Important:** The range of slot and port numbers varies by platform type – ASR 5x00 versus VPC.

**Usage**
Change the current configuration mode to Ethernet Port Configuration mode.

**Example**
The following command enters the Ethernet Port Configuration mode for ethernet port 1 in slot 17 (ASR 5000):

```
port ethernet 17/1
```

The following command enters the Ethernet Port Configuration mode for ethernet port 11 in slot 5 (ASR 5500):

```
port ethernet 5/11
```
port mac-address virtual-base-address

This command defines a block of 256 consecutive media access control (MAC) addresses and enables virtual MAC addressing for Ethernet line card ports. Not available for the XT2 platform.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
port mac-address virtual-base-address MAC_Address

no port mac-address virtual-base-address
```

- **no**
  Disables virtual MAC addressing for Ethernet line card ports. The block of virtual MAC addresses is not saved.

- **MAC_Address**
  Specifies the beginning address of a block of 256 MAC addresses that are used for virtual MAC addressing.

**Usage**

Use this command to disregard the MAC addresses assigned and stored in card firmware and assign MAC addresses for all Ethernet ports from the specified block of virtual MAC addresses. This command does not affect the MAC addresses on SPIO cards.

There are 65536 MAC addresses (00:05:47:FF:00:00 - 00:05:47:FF:FF:FF) reserved for use by customers. This range allows for the creation of 256 address blocks each containing 256 MAC addresses (for example, 00:05:47:FF:00:00, 00:05:47:FF:01:00, 00:05:47:FF:02:00, 00:05:47:FF:03:00, 00:05:47:FF:04:00, etc.).

⚠️ **Caution:** This configuration requires the configuration of a valid block of unique MAC addresses that are not used anywhere else. Use of non-unique MAC addresses can degrade and impair the operation of your network.

⚠️ **Important:** This command is not supported on all platforms.

**Example**

To enable virtual MAC addressing for Ethernet ports on all Ethernet line cards in the system using a block of MAC addresses starting at 00:05:47:FF:00:00, enter the following command:
port mac-address virtual-base-address 00:05:47:FF:00:00
port rs232

Enters the RS-232 Port Configuration mode for the RS-232 console port on the specified SPIO card. Not available on the XT2 platform.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
  configure
Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

port rs232 slot 3

---

rs232
Indicates the port identified is an RS-232 port on a SPIO card.

slot 3
Specifies the slot of the SPIO for which RS-232 Port Configuration mode is being entered. The slot must refer to an installed SPIO card. The specified port must always be 3 for an RS-232 port. The value for slot must be either 24 or 25.

Usage
Change the current configuration mode to RS-232 Port Configuration mode.

Example

The following command enters the RS-232 Port Configuration mode for the SPIO in slot 24;

port rs232 24 3
profile-id-qci-mapping

Creates a Qos Class-Identifier-Radio Access Network (QCI-RAN) ID mapping table or specifies an existing table and enters the QCI Mapping Configuration mode for the system.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration

**Syntax**

```plaintext
[ no ] profile-id-qci-mapping name [ -noconfirm ]
```

- **no**
  Removes the specified mapping table from the system

- **name**
  Creates a new or enters an existing mapping table configuration. `name` must be an alphanumeric string of 1 through 63 alphanumeric.

- **-noconfirm**
  Indicates that the command is to execute without any additional prompt and confirmation from the user.

**Usage**

Enters the QCI-RAN ID mapping configuration mode for an existing table or for a newly defined table. This command is also used to remove an existing table.

Entering this command results in the following prompt:

```
[context_name]hostname(config-hsgw-association-table)#
```

QCI Mapping Configuration Mode commands are defined in the *QCI Mapping Configuration Mode Commands* chapter.

Use this command when configuring the HSGW eHRPD component.

**Important:** This command creates a mapping table available to any HSGW context configured on the system.

**Example**

The following command enters the existing QCI mapping configuration mode (or creates it if it doesn’t already exist) for a mapping table named `qci_table1`:
**profile-id-qci-mapping**

```
profile-id-qci-mapping qci_table1
```

The following command will remove `qci_table1` from the system:

```
no profile-id-qci-mapping qci_table1
```
ps-network

This command creates/removes an HNB-PS network configuration instance for Femto UMTS access over Iu-PS/Iu-Flex interface between Home NodeB Gateway (HNB-GW) service and PS networks elements; i.e. SGSN. This command also configures an existing HNB-CS network instance and enters the HNB-CS Network Configuration mode on a system.

Product
HNB-GW

Privilege
Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

[ no ] ps-network ps_instance [ -noconfirm ]

no ps-network ps_instance

- no

Removes the specified HNB-PS network instance from the system.

⚠️ Caution: Removing the HNB-PS network instance is a disruptive operation and it will affect all UEs accessing SGSN(s) in specific PS core network through the HNB-GW service.

⚠️ Caution: If any HNB-PS Network instance is removed from the system, all parameters configured in that mode will be deleted and Iu-PS/Iu-Flex interface will be disabled.

ps_instance

Specifies the name of the Packet Switched Core Networks instance which needs to be associated with HNB Radio Network PLMN in HNB RN-PLMN configuration mode. If ps_instance does not refer to an existing HNB-PS instance, the new HNB-PS network instance is created.

ps_instance must be an alphanumeric string of 1 through 63 characters.

-noconfirm

Indicates that the command is to execute without any additional prompt and confirmation from the user.

Usage

Use this command to enter the HNB-PS Network Configuration mode for an existing PS network instance or for a newly defined HNB-PS network instance. This command is also used to remove an existing HNB-PS network instance.
This configuration enables the Iu-PS/Iu-Flex interface on HNB-GW service with CS core network elements; i.e. MSC/VLR.
A maximum of 1 HNB-PS networks instance which is further limited to a maximum of 256 services (regardless of type) can be configured per system.

⚠️ Caution: This is a critical configuration. The HNBs can not access SGSNs in PS core network without this configuration. Any change to this configuration would lead to disruption in HNB access to PS core network.

Entering this command results in the following prompt:

```
[context_name]hostname(config-ps-network)#
```

The various parameters available for configuration of an HNB-PS network instance are defined in the HNB-PS Network Configuration Mode Commands chapter.

Example

The following command enters the existing HNB-PS Network configuration mode (or creates it if it doesn’t already exist) for the instance named `hnb-ps1`:

```
ps-network hnb-ps1
```

The following command will remove HNB-PS network instance `hnb-ps1` from the system without any prompt to user:

```
no ps-network hnb-ps1
```
**qci-qos-mapping**

Global QCI-QoS mapping tables are used to map QoS Class Identifier (QCI) values to appropriate Quality of Service (QoS) parameters.

**Product**
- ePDG
- GGSN
- HSGW
- P-GW
- SAEGW
- S-GW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration
**configure**
Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
qci-qos-mapping name [ -noconfirm ]

no qci-qos-mapping name
```

**Usage**

Enter the QCI-QoS mapping configuration mode for an existing table or for a newly defined table. This command is also used to remove an existing table.

Entering this command results in the following prompt:

```
[context_name]hostname(config-qci-qos-mapping)#
```
QCI - QoS Mapping Configuration Mode commands are defined in the QCI - QoS Mapping Configuration Mode Commands chapter.
Use this command when configuring the following eHRPD component: HSGW, P-GW, SAEGW, S-GW.

**Important:** This command creates a mapping configuration available to any GGSN, HSGW, P-GW, SAEGW, S-GW context configured on the system.

**Example**

The following command enters the existing QCI - QoS mapping configuration mode (or creates it if it doesn’t already exist) for a mapping configuration named `qci-qos3`:

```
qci-qos-mapping qci-qos3
```
quality-of-service-profile

This command allows you to create a Quality of Service profile and enter the Quality of Service Profile Configuration Mode. This mode is used to configure Quality of Service parameters.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```bash
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```bash
quality-of-service-profile qos_profile_name [ -noconfirm ]
```

```bash
no quality-of-service-profile qos_profile_name
```

**Usage**

- **no**
  Removes the specified Quality of Service profile.

- **noconfirm**
  Do not prompt for additional verification when executing this command.

- **qos_profile_name**
  The name of the Quality of Service profile to create or remove, it must be an alphanumeric string of 1 through 64 characters.

**Example**

Enter the following command to create a Quality of Service profile named `test`:

```bash
quality-of-service-profile test
```
**qci**

Defines QCI value.

**Product**
- ePDG
- HSGW
- P-GW
- SAEGW
- S-GW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > qci-qos-mapping  
configure > qci-qos-mapping mapping_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpu-service)#
```

**Syntax**

```
qci num [ delay-class delay-class-value [ precedence-class precedence-class-value ] ] [ downlink [ 802.1p-value value ] [ encaps-header { copy-inner | dscp-marking dscp-marking-value | copy-outer } ] [ gbr ] [ max-packet-delay max-packet-delay-value max-error-rate max-error-rate ] [ non-gbr ] [ traffic-policing interval value ] [ uplink [ 802.1p-value value ] [ encaps-header { copy-inner | dscp-marking dscp-marking-value | copy-outer } ] [ mpls-exp-value value ] [ user-datagram dscp-marking dscp-marking-value ] ]
```

no | default qci num

`no`

Removes the specified QCI value.

`default`

Sets the default QCI value.

`qci num`

`num` must be an integer from 1 through 256.

`delay-class delay-class-value`

Defines Pre Release 8 value for configuring packet delay.

`delay-class delay-class-value: Defines Pre Release 8 value for configuring packet delay as an integer from 1 through 9.`
precedence-class precedence-class-value
Defines Pre Release 8 value for configuring packet precedence.
precedence-class precedence-class-value: Defines Pre Release 8 value for configuring packet precedence as an integer from 1 through 32.

reliability-class reliability-class-value
Defines Pre Release 8 value for configuring packet reliability.
reliability-class reliability-class-value: Defines Pre Release 8 value for configuring packet reliability as an integer from 1 through 32.

downlink
Configures for downlink traffic.

802.1p-value
802.1p-value: Configures for downlink traffic 802.1p-value as an integer from 1 through 7.

encaps-header { copy-inner | dscp-marking  dscp-marking-value  | copy-outer}
encaps-header: Defines the DSCP value to be applied to encaps header.
copy-inner: Copy inner DSCP to outer.
dscp-marking  dscp-marking-value: Defines the DSCP value to be applied to packets with this QCI.
dscp-marking-value: A Hexadecimal number between 0x0 and 0x3F.
copy-outer: Copies the DSCP value coming in an encapsulation header from the S1u interface to the encapsulation header sent on the S5 interface and vice-versa.

gbr
Sets the type of the QCI to GBR.

max-packet-delay max-packet-delay-value
Defines the maximum packet delay in ms for the data with the QCI as an integer from 10 through 1000.

max-error-rate max-error-rate
Defines the maximum error rate that the data stream can handle in power of 10 as an integer from 1 through 6.

non-gbr
Sets the type of the QCI to non GBR.

traffic-policing interval value
Sets the parameters for traffic policing interval in seconds as an integer from 1 through 100.

uplink
Configures for uplink traffic.

mpls-exp-value value
Configures for uplink traffic mpls-exp-value as an integer from 1 through 7.
**user-datagram**

Defines DSCP value to be applied to user data gram.

**Usage**

Use this command to define QCI value in qci-qos-mapping.

**Example**

The following command defines QCI value as 56:

```
qci 56
```
qos ip-dscp-iphb-mapping

Manages internal QoS (Internal-Per-Hop-Behavior/IPHB).

Product
- ePDG
- HSGW
- P-GW
- SAEGW
- S-GW

Privilege
Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

qos ip-dscp-iphb-mapping dscp dscp_value internal-priority cos class_of_service_value

default qos ip-dscp-iphb-mapping dscp dscp_value

Usage
Use this command to manage internal QoS.

Example
The following command maps DSCP values in a packet to internal-QoS COS marking values:

    qos ip-dscp-iphb-mapping dscp 0x3 internal-priority cos 0x5
qos l2-mapping-table

Creates or modifies a Level 2 mapping table and enters the QoS L2 Mapping Configuration Mode to map internal QoS priority.

Product
- ePDG
- HSGW
- P-GW
- SAEGW
- S-GW

Privilege
Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name (config)#

Syntax
qos l2-mapping-table { name map_table_name | system-default }

no qos l2-mapping-table name map_table_name

no

Deletes the specified L2 mapping table.

**Important:** The system-default table cannot be deleted. Only named tables that were previously created using this CLI command can be deleted.

name map_table_name

Specifies the name of an internal table from which to map QoS to L2 values.

map_table_name must be an alphanumeric string of 0 through 80 characters.

system-default

Configure the system default mapping.

Usage
Use this command to create or modify an L2 mapping table and enter the QoS L2 Mapping Configuration Mode, which is used to map internal QoS values to L2 values.

Entering this command results in the following prompt:
QoS L2 Mapping Configuration Mode commands are defined in the QoS L2 Mapping Configuration Mode Commands chapter.

Example

The following command creates an L2 mapping table and enters the QoS L2 Mapping Configuration Mode:

```
qos l2-mapping-table name qostable1
```
qos npu inter-subscriber traffic bandwidth

Configures NPU QoS bandwidth allocations for the system.

Product

- PDSN
- GGSN

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
qos npu inter-subscriber traffic bandwidth gold percent silver percent bronze percent best-effort percent

no qos npu inter-subscriber traffic bandwidth
```

- no
  
  Removes a previous bandwidth allocation.

- gold percent
  
  Default: 10%
  Specifies the maximum percentage of bandwidth to be allocated to the gold queue priority.
  percent can be configured to an integer from 0 through 100.

- silver percent
  
  Default: 20%
  Specifies the maximum percentage of bandwidth to be allocated to the silver queue priority.
  percent can be configured to an integer from 0 through 100.

- bronze percent
  
  Default: 30%
  Specifies the maximum percentage of bandwidth to be allocated to the bronze queue priority.
  percent can be configured to an integer from 0 through 100.

- best-effort percent
  
  Default: 40%
  Specifies the maximum percentage of bandwidth to be allocated to the best-effort queue priority.
  percent can be configured to an integer from 0 through 100.
Usage

The bandwidth of a subscriber queue is maintained by rate limiting functions which implement packet-rate limiting at the first level and bit-rate limiting at the next level. The packet-rate limit of a queue is defined by the number of packets-per-second (PPS) permitted for queuing. Before queuing a packet on a subscriber queue, the NPU ensures that the packet falls within the limit. If the packet to be queued exceeds the packet rate limit, it is dropped.

Each subscriber queue is configured with a bit rate limit, measured in megabits-per-second (Mbps), referred to as CP-BPS (bit-per-second to CP). The CP-BPS is available as the total bandwidth for the subscriber traffic that a CP can sustain. Each subscriber queue receives an allocation of a certain percentage of the CP-BPS. The following maximum CP-BPS values are supported:

- Lead CP (CP0) = 128 Mbps
- Remaining CPs (CP1, CP2, CP3) = 256 Mbps

For additional information on the NPU QoS functionality, refer to the System Administration and Configuration Guide.

Important: This functionality is not supported for use with the PDSN at this time.

Example

The following command configures bandwidth allocations of 20, 30, 40, and 50% for the gold, silver, bronze, and best-effort queues respectively:

```
qos npu inter-subscriber traffic bandwidth gold 20 silver 30 bronze 40 best-effort 50
```

Upon executing this command, the priority queues will have the following packet processing card CP bandwidth allocations based on the maximum CP bandwidth specifications:

<table>
<thead>
<tr>
<th>Priority</th>
<th>Lead CP (CP 0) Bandwidth (Mbps)</th>
<th>CP 1 through CP 3 Bandwidth (Mbps)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gold</td>
<td>25.6</td>
<td>51.2</td>
</tr>
<tr>
<td>Silver</td>
<td>38.4</td>
<td>76.8</td>
</tr>
<tr>
<td>Bronze</td>
<td>51.2</td>
<td>102.4</td>
</tr>
<tr>
<td>Best-effort</td>
<td>64</td>
<td>128</td>
</tr>
</tbody>
</table>
qos npu inter-subscriber traffic bandwidth-sharing

Configures NPU QoS bandwidth sharing properties for the system.

**Product**
- PDSN
- GGSN

**Privilege**
- Administrator

**Mode**
- Exec > Global Configuration
  - configure
  Entering the above command sequence results in the following prompt:
  
  [local] host_name(config)#

**Syntax**

```
qos npu inter-subscriber traffic bandwidth-sharing { { enable | disable } { all | slot slot_num cpu cpu_num } }
```

**enable**

Enables bandwidth sharing for the specified criteria.

**disable**

Disables bandwidth sharing for the specified criteria.

**all**

Specifies that the bandwidth action is to be applied to all packet processing cards and every CPU on each packet processing card.

**slot slot_num**

Specifies that the bandwidth action is to be applied to a packet processing card in a specific chassis slot number.

- `slot_num` is the slot in which a packet processing card is installed. These cards can be installed in slots 1 through 8 and 10 through 16 on the ASR 5000, or 1 through 4 and 7 through 10 on the ASR 5500.

**cpu cpu_num**

Specifies a specific control processor (CP) on a packet processing card for which to perform the bandwidth action.

- `cpu_num` is an integer value from 0 to 3. 0 represents the lead CP.

**Usage**

The available bandwidth of a subscriber queue can be shared equally among the other subscriber queues. Any unutilized bandwidth of a queue can be shared with the other queues equally. For example, if only one DSCP
is configured and it is mapped to best-effort, that DSCP would get the bandwidth allocated to the best-effort in addition to the rest of the bandwidth allocated to the gold, silver, and bronze. By default, the system enables sharing for all packet processing cards and their CPs. For additional information on the NPU QoS functionality, refer to the System Administration Guide.

**Important:** This functionality is not supported for use with the PDSN at this time.

**Example**

The following command disables bandwidth sharing for the fourth CP (CP 3) on a packet processing card installed in chassis slot 3:

```
qos npu inter-subscriber traffic bandwidth-sharing disable slot 4 cpu 3
```
qos npu inter-subscriber traffic priority

Configures the DSCP-to-Priority assignments for the system.

Product
- PDSN
- GGSN

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration
  - configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
qos npu inter-subscriber traffic priority { best-effort | bronze | gold | silver }
assigned-to dscp { af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 |
af42 | af43 | be | ef | dscp_num } }

no qos npu inter-subscriber traffic priority [ assigned-to dscp { af11 | af12 | af13 |
af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | ef } ]
```

- **best-effort**
  Specifies the best-effort queue priority.

- **bronze**
  Specifies the bronze queue priority.

- **gold**
  Specifies the gold queue priority.

- **silver**
  Specifies the silver queue priority.

- **afXX**
  Assigns the Assured Forwarding $XX$ PHB (per-hop behavior) DSCP.
  Each Assured Forwarding PHB has a corresponding DSCP value as follows:
  - af11 through af13: DSCP values 5 through 7 respectively
  - af21 through af23: DSCP values 9 through 11 respectively
  - af31 through af33: DSCP values 13 through 15 respectively
  - af41 through af43: DSCP values 17 through 19 respectively
**be**

Assigns the Best Effort forwarding PHB which has a corresponding DSCP value of 0.

**ef**

Assigns the Expedited Forwarding PHB which has a corresponding DSCP value of 23.

**dscp_num**

Specifies a specific DSCP value as an integer from 0 through 31.

---

**Usage**

The differentiated services (DS) field of a packet contains six bits (0-5) that represent the differentiated service code point (DSCP) value.

Five of the bits (1-5) represent the DSCP. Therefore, up to 32 (2^5) DSCPs can be assigned to the various priorities. By default, they're all assigned to the lowest priority (best-effort).

For additional information on the NPU QoS functionality, refer to the *System Administration Guide*.

---

**Important:** This functionality is not supported for use with the PDSN at this time.

---

**Example**

The following command maps the ef DSCP to the gold priority queue:

```
qos npu inter-subscriber traffic priority gold assigned-to dscp ef
```
ran-peer-map

Creates a Radio Access Network (RAN) Peer Map and enters the RAN Peer Map Configuration Mode.

**Product**

ASN-GW

PHSGW

**Privilege**

Administrator

**Mode**

Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
[ no ] ran-peer-map name [ -noconfirm ]
```

- **no**
  - Removes the RAN Peer Map from the system.

- **name**
  - Specifies the name of the RAN Peer Map. `name` must be an alphanumeric string of 1 through 31 characters.

**Usage**

Use this command to create a new RAN Peer Map or edit an existing one. RAN peer maps reconcile base station MAC addresses received in R6 protocol messages to the base station’s IP address.

Entering this command results in the following prompt:

```
[context_name] host_name(config-ran-peer-map)#
```

RAN Peer Map Configuration Mode commands are defined in the ASN RAN Peer Map Configuration Mode Commands chapter in this guide.

**Example**

The following command creates a RAN peer map named `ran12`:

```
ran-peer-map ran12
```
require active-charging

This command enables/disables Active Charging Service (ACS) with or without the Category-based Content Filtering application.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
```
configure
```
Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
require active-charging [ isolated-mode ] [ content-filtering category [ static-and-
dynamic ] ] [ optimized-mode ]
```

```
no require active-charging
```

---

**isolated-mode**

Enables ACS and separates ACS-related resources from other sub-system resource sharing.

**Important:** In 8.1 and later releases, this keyword is not supported.

**optimized-mode**

Enables ACS in Optimized mode, wherein ACS functionality is managed by SessMgrs.

**Important:** In 8.0 and earlier releases and in 9.0 and later releases, this keyword is not supported.

**Important:** In Release 8.1, ACS must be configured in the Optimized mode.

**Important:** In Release 8.1, if the active-charging mode is changed from the default (non-optimized) mode to the Optimized mode, or vice-versa, the system must be rebooted for the change to take effect.

**Important:** In Release 8.3, this keyword is obsolete. With or without this keyword ACS is always enabled in the Optimized mode.
Use the `require active-charging` command to enable ACS in the non-optimized mode. Wherein, ACS Managers will spawn to support ACS.

Use the `require active-charging optimized-mode` command to enable ACS in the Optimized mode. Wherein, ACS is enabled as part of Session Managers.

```
content-filtering category [ static-and-dynamic ]
```

Enables the Category-based Content Filtering application with ACS support and creates the necessary Static Rating Database (SRDB) tasks to utilize the internal database of static/dynamic URLs.

For Dynamic Content Filtering support, the `static-and-dynamic` keyword must be configured to specify that the Dynamic Rater Package (model and feature files) must be distributed to rating modules on startup, recovery, etc. If not configured, by default, the static-only mode is enabled.

**Usage**

Use this command to enable/disable ACS with or without Category-based Content Filtering application on the chassis.

**Important:** This command triggers the resource subsystem to switch to ACS-enabled mode and start ACS-related tasks. This CLI command must be configured before any services are configured, so that the resource subsystem can appropriately reserve adequate memory for the ACS-related tasks. After configuring this command, the configuration must be saved and the system rebooted in order to allocate the resources for ACS upon system startup.

In 8.0 and 8.1 releases, this command must be configured before configuring any services. This is to ensure that the resource subsystem can appropriately reserve adequate memory for ACS Manager tasks. If this command is configured after all the Session Manager tasks are already active, the ACS Manager tasks will not be started even if additional cards are added to the chassis—instead, the chassis must be rebooted.

**Example**

In Release 8.0, the following command enables resource subsystem to configure ACS in isolated mode:

```
require active-charging isolated-mode
```

In Release 8.1, the following command enables ACS in Optimized mode:

```
require active-charging optimized-mode
```

In Release 8.3, the following command enables ACS in Optimized mode:

```
require active-charging
```
require cipher ssl resource-percentage

Assigns the 8 processing cores on the PSC2 card and splits the hardware acceleration resources between SSL protocol and IPSec protocol processing.

Product  
SCM (P-CSCF, A-BG)

Privilege  
Security Administrator, Administrator

Mode  
Exec > Global Configuration  
configure  
Entering the above command sequence results in the following prompt:  
[local]host_name(config)#

Syntax

```
require cipher ssl resource-percentage percentage_value  
declaration require cipher ssl resource-percentage

default require cipher ssl resource-percentage
```

```
percentage_value  
The system converts the specified resource percentage value to the nearest number of processing cores assigned to SSL processing. The system assigns the remaining processing cores to IPSec processing. This value can be within the range of 0 to 100.  
For example, if 20% of the hardware acceleration resources are assigned to SSL processing, the system translates this value to INT((20*8+50)/100) = 2 processing cores assigned to SSL processing, and (8-2) = 6 processing cores assigned to IPSec processing.
```

```
default  
Sets the default percentage value to 0%, assigning all 8 processing cores to IPSec processing.
```

Usage

Use this command to split the 8 processing cores on the PSC2 card between SSL protocol and IPSec protocol processing.

Example

The following command assigns 20% of the hardware acceleration resources on the PSC2 card (2 processing cores) to SSL processing, and 80% of the hardware acceleration resources (6 processing cores) to IPSec processing:

```
require cipher ssl resource-percentage 20
```
require cscf-connection-proxy

Configures one Diameter proxy per card (multiple) or one proxy per system (single).

Product
SCM (P-CSCF, A-BG)

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax
require cscf-connection-proxy { multiple | single }

{ multiple | single }
Configures one Diameter proxy per card (support for multiple proxies) or one CSCF proxy per system.

Usage
Use this command to establish a single Diameter proxy per system or multiple Diameter proxies (one per card). For additional information refer to the CSCF Proxy-CSCF Configuration Mode Commands chapter.

Example
The following command allows one Diameter proxy per system:

require cscf-connection-proxy single
**require demux**

Enables or disables demux capabilities on an ASR 5x00 system. On an ASR 5500 when demux tasks are enabled on a management card, the Active and Standby MIOs will host and migrate all demux tasks.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
[ default | no ] require demux { card | management-card | processing-card }
```

- **default**
  
  Demux functions will be run on a processing card.

- **no**
  
  Disables the demux capabilities except when session recovery is enabled.

---

**Important:** On a system with session recovery licensed and enabled, a processing or management card must be designated to run demux functions.

**card | management-card | processing-card**

- **card** — Prior to Release 15.0, this is an accepted keyword (defaults to **processing-card**).

- **management-card** — Release 15.0+, enables demux functionality on a management (ASR 5500 MIO) card

- **processing-card** — Enables demux functionality on a processing card (default). This is the only option on an ASR 5000.

**Usage**

Use this command to configure the system to direct demux task placement.

The following restrictions apply when enabling an MIO/UMIO as a demux card:

- The **require demux management-card** command must be configured before any service or contexts have been created on the system. The command will not execute after a mode of operation has been selected for the chassis.

- Only the following services currently support the designation of an MIO/UMIO card for demux functions: GGSN, SGW, PGW, HA and SAE-GW.

- Ex-GW, L2TP, MME, NEMO and SGSN are **not** supported.
• After the ASR 5500 has booted with demux functions running on an MIO/UMIO, you cannot configure non-supported services. A maximum of eight Demux Managers are supported. Any attempt to add more than eight Demux Managers will be blocked.

• Service/products requiring a large number of VPN Managers, VRFs and/or Demux Managers must not enable demux functions on an MIO.

• With demux functions running on an MIO, the ASR 5500 supports a maximum of 10 contexts, 15 interfaces per context, with a maximum of 64 interfaces and 250 VRFs per system.

Implementation of this feature assumes that CEPS (Call Events Per Second) and the number of subscribers will remain constant, and only the data rate will increase. This ensures that the CPU demand will not increase on the MIO/UMIO.

⚠️ **Caution:** Enabling the Demux on MIO/UMIO feature changes resource allocations within the system. This directly impacts an upgrade or downgrade between StarOS versions in ICSR configurations. Contact Cisco TAC for procedural assistance prior to upgrading or downgrading your ICSR deployment.

⚠️ **Important:** Contact Cisco TAC for additional assistance when assessing the impact to system configurations when enabling the Demux on MIO/UMIO feature.

**Example**

For releases prior to 15.0, to configure a DPC/UDPC as a demux card enter the following CLI commands:

```
require demux card
```

For release 15.0+, to configure a DPC/UDPC as a demux card enter the following CLI commands:

```
require demux processing-card
```

To configure an MIO/UMIO as a demux card enter the following CLI commands:

```
require demux management-card
```
require detailed-rohc-stats

Enables or disables context-specific Robust Header Compression (RoHC) statistics.

**Product**
- HSGW
- PDSN

**Privilege**
- Administrator

**Mode**
- Exec > Global Configuration

**Syntax**

```
[ no ] require detailed-rohc-stats
```

- `no`
  - Disables statistics for RoHC calls. This is the default condition.

**Usage**
Enables context-specific statistics for RoHC calls.

**Example**
Enter the following command to enable context specific statistics for RoHC calls:

```
require detailed-rohc-stats
```
require diameter-proxy

This command enables or disables Diameter Proxy mode.

Product
IPCF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:
[local]host_name(config)#

Syntax
require diameter-proxy { master-slave | multiple | single }
no require diameter-proxy

no
Disables Diameter Proxy mode. This is the default configuration.

master-slave
Sets the Diameter-Proxy to Master-Slave mode.
In Master-Slave mode, multiple Diameter proxies are running, one on each packet processing card. One proxy serves as the Master and the other proxies are Slaves. The Master proxy relays the traffic across multiple Slave Diameter proxies.

multiple
Configures one Diameter proxy for each active packet processing card.

single
Configures one Diameter proxy for the entire chassis.

Usage
When the Diameter Proxy mode is enabled, each proxy process is a Diameter host, instead of requiring every Diameter application user (such as, every ACSMgr and/or every SessMgr, depending on the application) to be a host.
In Master-Slave mode, multiple Diameter proxies are running, one on each packet processing card. One proxy serves as the Master and the other proxies are Slaves. The Master relays the traffic from an incoming connection to a specific Slave Diameter proxy.

Example
The following command configures a Diameter proxy for each active packet processing card:

require diameter-proxy multiple
The following command configures a single Diameter proxy for the entire chassis:

```plaintext
require diameter-proxy single
```
require ecs credit-control

This command configures the Diameter Credit-Control Application (DCCA) to work in per subscriber-PDN level Gy mode.

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

In 14.0 and earlier releases:

[ no ] require ecs credit-control subscriber-mode

In 14.1 and later releases:

[ no ] require ecs credit-control session-mode per-subscriber

no
Creates DCCA/Gy sessions per bearer/PDP-context.

Usage

In 14.0 and earlier releases:

This command is applicable to all products using the Gy interface. Use this command to configure DCCA/Gy to work in per subscriber-PDN level Gy mode, wherein one Diameter session is created per subscriber PDN rather than per bearer, and only one DCCA/Gy session is created for multi-bearer PDNs. If this command is not configured, or the no require ecs credit-control subscriber-mode command is configured, DCCA/Gy sessions are created per bearer/PDP-context, and as a result when there are multiple PDP contexts or multiple bearers in a PDN as many DCCA/Gy sessions are created.

Important: This command will take effect only when the system is booted/rebooted. When configured after the system comes up, the command will be accepted but will not be applied until after the system is rebooted with the saved configuration.
**Important:** This command is independent of the `require active-charging` command. The `ecs` keyword in this command is license dependent.

**In 14.1 and later releases:**
This CLI command is made configurable on the fly, that means, the credit control mode can be seamlessly changed from subscriber (PDN) to sub-session and vice-versa without requiring a system reboot.

This change is done to align with the new CLI commands “`credit-control-client override session-mode { per-sub-session | per-subscriber }`” introduced in APN and Subscriber Group configuration modes.

This will be the default mode for all subscribers unless overwritten by APN/Subscriber configuration mode CLI commands.

Releases prior to 14.1, subscriber mode Gy and bearer mode Gy were implemented based on the configuration of CLI command `require ecs credit-control subscriber-mode`. This CLI is used as a chassis level configuration which mandates that all subscribers anchored to this chassis should always be running in only one of these two modes. Enabling and disabling the CLI requires system reboot. ICSR switchover between two chassis running in two different modes will not work.

Release 14.1 and later, the Subscriber/Bearer mode Gy is selected based on APN/Subscriber mode instead of chassis wide configuration. This will provide the following:

- Flexibility to configure different modes for different subscriber.
- Flexibility to switch between modes without system reboot.
- Flexibility to switchover between two chassis working in different modes.
**require session recovery**

Enables session recovery when hardware or software fault occurs within system.

**Product**
- ePDG
- GGSN
- ASN-GW
- HA
- HSGW
- LNS
- MME
- PDG/TTG
- PDIF
- PDSN
- P-GW
- SAEGW
- SGSN

**Privilege**

**Mode**
- Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
[ no ] require session recovery
```

```no```

Disables session recovery feature after configuration file is saved and system is restarted.

**Usage**

When this feature is enabled, the system attempts to recover any home agent-based Mobile IP sessions that would normally be lost due to a hardware or software fault within the system. This functionality is available for the following call types:

- ASN-GW services supporting simple IP, Mobile IP, and Proxy Mobile IP
- PDSN services supporting simple IP, Mobile IP, and Proxy Mobile IP
- HA services supporting Mobile IP and/or Proxy Mobile IP session types with or without per-user Layer 3 tunnels
• GGSN services for IPv4 and PPP PDP contexts
• SGSN services for all attached and/or activated subscribers
• LNS session types
• PDIF services supporting Simple-IP, Mobile-IP and Proxy Mobile-P
• MME services

The default setting for this command is disabled. The no option of this command disables this feature. This command only works when the Session Recovery feature is enabled through a valid Session and Feature Use License Key.

**Important:** After entering this command, you must restart the system for the command takes effect. Remember to save the configuration file before issuing the `reload` command.
reveal disabled commands

Enables the input of commands for features that do not have license keys installed. The output of the command `show cli` indicates when this is enabled. This command effects all future CLI sessions. This is disabled by default.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`
Entering the above command sequence results in the following prompt:

```
[local] host_name (config) #
```

**Syntax**

```
[ no ] reveal disabled commands
```

- `no`
  Do not show disabled commands.

**Usage**

When this is enabled and a disabled command is entered, a message is displayed that informs you that the required feature is not enabled and also lists the name of the feature that you need to support the command.

When this is disabled and a disabled command is entered, the CLI does not acknowledge the existence of the command and displays a message that the keyword is unrecognized.

**Example**

Set the CLI to accept disabled commands and display the required feature for all future CLI sessions with the following command:

```
reveal disabled commands
```

Set the CLI to reject disabled commands and return an error message for all future CLI sessions:

```
no reveal disabled commands
```
**rlf-template**

This command enters the Rate Limiting Function (RLF) Template Configuration Mode. This mode is used to configure the RLF template to control the throttling parameters.

---

**Important:** RLF template cannot be deleted if it is bound to any application (peers/endpoints).

---

**Product**

GGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

``` 
configure
```

Entering the above command sequence results in the following prompt:

``` 
[local]host_name(config)#
```

**Syntax**

```
[ no ] rlf-template rlf_template_name
```

- **no**
  - Remove the specified RLF template from global configuration.

- **rlf_template_name**
  - The name of the RLF template to create or remove. `rlf_template_name` must be an alphanumeric string of 1 through 127 characters.

**Usage**

Use this command to enter the RLF Template Configuration mode. The users can define the rate limiting configurations within this template.

---

**Important:** Rate Limiting Function (RLF) is a license-controlled feature. A valid feature license must be installed prior to configuring this feature. Contact your Cisco account representative for more information.

This feature implements a generic framework that can be used by multiple interfaces and products for rate-limiting/throttling outgoing messages like Diameter messages on Gx, Gy interface towards PCRF.

When applications send messages to peers at a high rate, (e.g. when a large number of sessions goes down at the same time, accounting stop messages for all the sessions are generated at the same time) the peer may not be able to handle the messages at such high rates. To overcome this situation, the Rate Limiting Function (RLF) framework is developed so that the application sends messages at an optimal rate such that peer is capable of receiving all the messages and does not enter an overload condition.
When RLF feature is enabled, all the messages from the application are pushed to the RLF module for throttling and rate control, and depending on the message-rate configured the RLF module sends the messages to the peer. Once the rate or a threshold value is reached, the RLF module notifies the application to slow down or stop sending messages. RLF module also notifies the application when it is capable of accepting more messages to be sent to the peer. RLF module typically uses a Token Bucket Algorithm to achieve rate limiting.

Currently in the deployment of the Diameter applications (Gx, Gy, etc.), many operators make use of “max-outstanding <number>” as a means of achieving some rate-limiting on the outgoing control traffic. With RLF in place, this is no longer required since RLF takes care of rate-limiting in all cases. If RLF is used and max-outstanding is also used, there might be undesirable results.

**Important:** If RLF is being used with an "diameter endpoint", then set the max-outstanding value of the peer to be 255.

To use the template, Diameter or any other applications must be associated with the template. The RLF provides only the framework to perform the rate limiting at the configured Transactions Per Second (TPS). The applications (like Diameter) should perform the configuration specific to each application. Entering this command results in the following prompt:

```
[context_name]host_name(cfg-rlf-template)#
```

RLF Template Configuration Mode commands are defined in the RLF Template Configuration Mode Commands chapter.

**Example**

The following command creates an RLF template named *rlf_1* and enters the RLF Template Configuration mode:

```
rlf-template rlf_1
```
rohc-profile

This command allows you to create an RoHC (Robust Header Compression) profile and enter the RoHC Profile Configuration Mode. This mode is used to configure RoHC Compressor and Decompressor parameters. RoHC profiles can then be assigned to specific subscriber sessions when RoHC header compression is configured.

Product
HSGW
PDSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

Syntax

```
rohc-profile profile-name name [ -noconfirm ] [ common-options | compression-options | decompression-options ]

no rohc-profile profile-name name
```

---

**common-options**

Confirms common parameters for compressor and decompressor.

**compression-options**

Confirms ROHC compression options.

**decompression-options**

Confirms ROHC decompression options.

**no**

Remove the specified RoHC profile.

**name**

The name of the RoHC profile to create or remove. *name* must be an alphanumeric string of 1 through 63 characters.

**-noconfirm**

Do not prompt for additional verification when executing this command.
Usage
Use this command to enter the RoHC Profile Configuration mode.
Entering this command results in the following prompt:

```
[context_name]host(config-rohcprofile-<profile_name>)#
```

RoHC Profile Configuration Mode commands are defined in the *RoHC Profile Configuration Mode Commands* chapter.

Example
Enter the following command to create an RoHC profile named *HomeUsers* and enter the RoHC Configuration mode without prompting for verification:

```
rohc-profile profile-name HomeUsers
```

The following command removes the RoHC profile named *HomeUsers*:

```
no rohc-profile profile-name HomeUsers
```
scipp-network

This command creates or removes a Signaling Connection Control Part (SCCP) network instance which is used to define the SS7 end-to-end routing in a UMTS network. As well, this command enters the SCCP network configuration mode. The SGSN supports up to 12 SCCP network instances at one time.

Product
SGSN
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

scipp-network sccpp_net_id [ -noconfirm ]

no scipp-network sccpp_net_id

no
Remove the SCCP network configuration with the specified index number from the system configuration.

sccpp_net_id
This number identifies a specific SCCP network configuration.

sccpp_net_id: must be an integer from 1 through 12.

-noconfirm
Indicates that the command is to execute without any additional prompt and confirmation from the user.

Usage
Use this command to create or modify an SCCP network and enter the SCCP network configuration mode. The SCCP network is not a standard SS7 or UMTS concept - this concept is specific to this platform. For details about the commands and parameters needed to create and edit the SCCP Network configuration, check the SCCP Network Configuration Mode chapter.

Example
The following command creates an SCCP network with the index number of 1:

    sccpp-network 1

The following command creates an SCCP network with the index number of 2 to associate with HNB-GW service for HNB access network users without any prompt.:
sccp-network 2 -noconfirm
sctp-param-template

This command allows you to create an SCTP parameter template and enter the SCTP Parameter Template Configuration Mode. This mode is used to configure parameters for SCTP associations.

**Product**
MME

**Privilege**
Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
[ no ] sctp-param-template name
```

- **no**
  - Removes the specified SCTP parameter template from the system.

- **name**
  - Specifies the name of the SCTP parameter template being created or accessed. *name* must be an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to enter the SCTP Parameter Template Configuration mode. Entering this command results in the following prompt:

```
[context_name]host(sctp-param-template)#
```

SCTP Parameter Template Configuration Mode commands are defined in the *SCTP Parameter Template Configuration Mode Commands* chapter.

**Example**

The following command creates a new SCTP parameter template or enters an existing template named *sctptmpl2*:

```
sctp-param-template sctp-tmpl2
```
session trace

This command configures the type of network elements, file transfer protocol, and Trace collection entity mode to be used for the transportation of trace files collected for the subscriber session tracing on the UMTS/EPC network element(s) along with network connection parameters and timers.

Product
- GGSN
- MME
- P-GW
- SAEGW
- S-GW

Privilege
Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
session trace network-element { all | mme | pgw | sgw | ggsn | saegw } [ collection-timer sec ] [ file-type { a-type | b-type } ] [ tce-mode { none | push transport sftp path string username name { encrypted password enc_pw | password password } } ]
```

```
no session trace network-element { all | mme | pgw | sgw | ggsn saegw }
```

---

**Important:** To modify the session trace network-element configuration, you must first enter the `no session trace network-element` form of the command to remove the session trace configuration and then enter an entirely new configuration.

```
network-element { all | mme | pgw | sgw | ggsn saegw }
```

Identifies the type of service to the session trace application in order to determine the applicable interfaces.
- `all`: Specifies that all network elements and their associated interfaces are to be made available to the session trace application.
- `ggsn`: Specifies that the GGSN and its associated interfaces is to be made available to the session trace application.
- `mme`: Specifies that the MME and its associated interfaces is to be made available to the session trace application.
Global Configuration Mode Commands (L-S)

**pgw**: Specifies that the P-GW and its associated interfaces is to be made available to the session trace application.

**sgw**: Specifies that the S-GW and its associated interfaces is to be made available to the session trace application.

**saegw**: Specifies that the SAEGW and its associated interfaces is to be made available to the session trace application.

**collection-timer** `sec`

Specifies the amount of time (in seconds) to wait from initial activation/data collection before data is reported to the Trace Collection Entity (TCE). `sec` must be an integer from 0 through 255.

**tce-mode none**

Specifies that session trace files are to be stored locally and must be pulled by the TCE.

**tce-mode push transport sftp path string username name { encrypted password enc_pw | password password }**

Specifies that session trace files are to be pushed to the Trace Collection Entity (TCE).

**sftp**: Specifies that Secure FTP is used to push session trace files to the TCE.

**path string**: Specifies the directory path on the TCE where files will be placed.

**username name**: Specifies the username to be used when pushing files to the TCE.

**encrypted password enc_pw**: Specifies the encrypted password to be used when pushing files to the TCE.

**password password**: Specifies the password to be used when pushing files to the TCE.

**Usage**

Use this command to configure the file transfer methods and modes for subscriber session trace functionality and to how and where session trace files are sent after collection.

This configuration contains collection timer, UMTS/EPC network element, type of file transfer, and user credentials setting to send the collected trace files to the TCE.

**Example**

The following command configures the collection time for session traces to 30 seconds, identifies the network element as all elements (GGSN, MME, S-GW, SAEGW, and P-GW), and pushes session trace files to a TCE via SFTP into a directory named `/trace/agw` using a username `admin` and a password of `pw123`:

```
session trace network-element all collection-timer 30 tce-mode push transport sftp path /trace/agw username admin password pw123
```

The following command configures the collection time for session traces to 30 seconds, identifies the network element as an MME, and pushes session trace files to a TCE via SFTP into a directory named `/trace/sgw` using a username `admin` and a password of `pw123`:

```
session trace network-element mme collection-timer 30 tce-mode push transport sftp path /trace/sgw username admin password pw123
```

The following command configures the collection time for session traces to 30 seconds, identifies the network element as GGSN, and pushes session trace files to a TCE via SFTP into a directory named `/trace/ggsn` using a username `admin` and a password of `pw123`:

```
session trace network-element ggsn collection-timer 30 tce-mode push transport sftp path /trace/ggsn username admin password pw123
```
sgsn-global

This command gives access to the SGSN Global configuration mode to set parameters relevant to the SGSN and HNB-GW as a whole.

Product
SGSN
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

sgsn-global

Usage
Using this command moves into SGSN Global Configuration mode. In this mode, you can set system-wide parameters on SGSN and HNB-GW to perform the following tasks:

On SGSN:
• monitoring and managing TLLIs in the BSSGP layer.
• defining IMSI ranges used as filters in the operator policy selection process.

On HNB-GW:
• setting system-wide IPC message aggregation parameters

Example
Enter the SGSN Global configuration mode with the following:

sgsn-global
**snmp authentication-failure-trap**

Enables or disables the SNMP traps for authentication failures.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#
```

**Syntax**

```
[ no ] snmp authentication-failure-trap
```

- **no**
  
  Disables SNMP traps for authentication failures. When omitted, SNMP traps for authentication failures will be generated.

**Usage**

Disables authentication failure traps if they are not of interest. At this time the option may be changed to support trouble shooting. By default SNMP authentication failure traps are disabled.
**snmp community**

Configures the SNMP v1 and v2 community strings.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

```configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

In StarOS 12.3 and later releases:

```shell
snmp community [ encrypted ] name string [ context context_name | read-only | read-write | view view_name ]
```

```shell
no snmp community [ encrypted ] name string
```

In StarOS 12.2:

```shell
snmp community [ encrypted ] name string [ read-only | read-write ]
```

```shell
no snmp community [ encrypted ] name string
```

In StarOS 12.1 and earlier releases:

```shell
snmp community string [ read-only | read-write ]
```

```shell
no snmp community string
```

**no**

The specified community string is removed from the configuration.

**encrypted**

Specifies the use of an encrypted string when entering the community name. Without the encrypted option, the plain-text community name must be provided.

**name string**

Specifies a community string whose options are to be modified. An unencrypted string must be an alphanumeric string of 1 through 31 characters. An encrypted string is an alphanumeric string of 1 through 80 characters.
context context_name
Default: community string applies to all contexts.
Specifies a the context to which the community string shall be applied. context_name must be an alphanumeric string of 1 through 31 characters.

read-only | read-write
Default: read-only
Specifies if access rights for the community string.
read-only: the configuration may only be viewed.
read-write: the configuration may be viewed and edited.

view view_name
Default: community string applies to all views.
Specifies the view to which the community string shall be applied. view_name must be an alphanumeric string of 1 through 31 characters.

Usage
The community strings define the privileges of SNMP users. It may be desirable to give read-only access to front line operators.

Example

    snmp community name plain_text_string
    snmp community encrypted name encrypted_string
    snmp community name plain_text_string context sampleContext
    snmp community name plain_text_string context sampleContext view sampleView
    snmp community name plain_text_string read-write view sampleView
    no snmp community plain_text_string
**snmp discard-snmpv3-pdu**

Configures the system to discard all SNMPv3 protocol data units (PDUs) received.

**Product**
All

**Privilege**
Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
snmp discard-snmpv3-pdu

no snmp discard-snmpv3-pdu
```

**Usage**
Use this command to configure the system to discard all SNMPv3 messages received. By default, the system processes SNMPv3 PDUs.

**Example**
The following command configures the system to discard all SNMPv3 messages received.

```
snmp discard-snmpv3-pdu arg1
```
**snmp engine-id**

Configures the SNMP engine to use for SNMP requests when SNMPv3 agents are utilized.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
snmp engine-id local id
```

*id*

Specifies the SNMPv3 engine to employ. *id* must be an alphanumeric string of 1 through 31 characters.

**Usage**
When SNMPv3 is used for SNMP access to the chassis the engine ID can be used to quickly change which schema is used for SNMP access.

**Important:** The system can send either SNMPv1, SNMPv2c, or SNMPv3 traps to numerous target devices. However, the Web Element Manager can only process SNMP version 1 (SNMPv1) and SNMP version 2c (SNMPv2c) traps. If the SNMP target being configured is Web Element Manager application, then you must not configure this command to use.

**Example**

```
snmp engine-id local id
```
snmp heartbeat

Enables the sending of periodic “heartbeat” notifications (traps).

Product
All

Privilege
Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

snmp heartbeat { interval [ minutes ] | second-interval [ seconds ] } 

[ default | no ] snmp heartbeat

default

Returns the command to its default setting of disabled.

no

Disables the feature.

interval [ minutes ]

Default: 60
Specifies the interval time (in minutes) between notifications. minutes must be an integer from 1 through 1440.

second-interval [ seconds ]

Default: 30
Specifies the secondary interval time, in seconds, between notifications. seconds must be an integer from 10 through 50.

Usage

Use this command to enable the sending of a heartbeat notification periodically to confirm a system is up and communicating.

Example

The following command sets the SNMP heartbeat notification interval to 2 hours, 15 minutes and 30 seconds:

    snmp heartbeat interval 135 second-interval 30
snmp history heartbeat

Enables the recording of heartbeat notifications in SNMP history.

Product
All

Privilege
Administrator

Mode
Exec > Global Configuration

configure
Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

[ default | no ] snmp history heartbeat

default
Returns the command to the default setting of enabled.

no
Disables the history recording feature.

Usage

Use this command to enable the recording of SNMP heartbeat notifications in SNMP history files.
### snmp mib

Enables or disables a specified SNMP Management Information Base (MIB).

**Product**

All

**Privilege**

Administrator

**Mode**

Exec > Global Configuration

**Syntax**

```
[ no ] snmp mib mib_name
```

- **no**
  
  Disables the specified MIB.

- **mib_name**
  
  Specifies a MIB by its name. You can find the currently supported MIBs by running the Exec mode `show snmp server` command. Enter the MIB name as a text string exactly as displayed under “SNMP Agent Mib Configuration”, By default the STARENT-MIB is enabled.

**Usage**

Use this command to enable or disable system support for an SNMP MIB.

**Example**

The following command enables the SNMP MIB entitled “CISCO-MOBILE-WIRELESS-SERVICE-MIB”.

```
snmp mib CISCO-MOBILE-WIRELESS-SERVICE-MIB
```
snmp notif-threshold

 Configures the number of SNMP notification that need to be generated for a given event before it is propagated to the SNMP users.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
snmp notif-threshold count [ low low_count ] [ period seconds ]

no snmp notif-threshold
```

**no**

Removes all SNMP notification thresholds. All notifications will be broadcast to SNMP users.

**count**

Default: 100

The traps creation rate will be monitored periodically (as configured by the `period` field). If the number of traps created over one period cycle exceeds the `count` value configured, then the trap creation will be disabled. `count` must be an integer from 1 through 10000.

**low low_count**

Default: 20

The traps creation rate will be monitored periodically (as configured by the `period` field). The trap creation will be enabled again only if the number of trap creation drops below the `low_count` value configured. Otherwise, trap creation remains disabled. `low_count` must be an integer from 1 through 10000.

**period seconds**

Default: 300

Specifies the number of seconds of the monitoring window size before any subsequent notification may be broadcast to users. `seconds` must be an integer from 10 through 3600.

**Usage**

Set the notification threshold to avoid a flood of events which may be the result of a single failure or maintenance activity.

**Example**
snmp notif-threshold 100

snmp notif-threshold 100 period 30
**snmp server**

Enables the SNMP server as well the configuration of the SNMP server port.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
snmp server [ port number ]

no snmp server
```

- **no**
  Restores the default SNMP port assignment.

- **port number**
  Default: 161
  Specifies the port number to use for SNMP communications. *number* must be an integer from 1 to 65535.

**Usage**

Set the SNMP port for communications when SNMP is enabled.

**Important:** This will result in restarting the SNMP agent when the **no** keyword is omitted. SNMP queries as well as notifications/traps will be blocked until the agent has restarted.

**Example**

```
snmp server port 100

no snmp server
```
snmp target

Configures remote receivers for SNMP notifications.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
snmp target name ip_address [ port number ] [ non-default ] [ security-name string ] [ version { 1 | 2c | 3 | view } [ security-level { noauth | { auth | priv-auth privacy [ encrypted ] des privpassword } ] [ informs | traps ]

no snmp target name
```

```
no
```

Removes the specified target as a receiver of unsolicited SNMP messages (traps).

```
authentication { md5 | sha } authpassword
```

Reads the authentication type and password if the security level of the SNMP messages is set to auth or priv-auth. Authentication types are:

- **md5**: Configures the hash-algorithm to implement MD5 per RFC 1321.
- **sha**: Specifies that the hash protocol is Secure Hash Algorithm.

```
security-level { noauth | { auth | priv-auth privacy [ encrypted ] des privpassword }
```

Sets the security level of the SNMPv3 messages, as follows:

- **noauth**: No authentication and encryption is used.
- **auth**: Only authentication will be used.
- **priv-auth**: Both authentication and encryption will be used.
- **privacy des privpassword**: Reads the privacy type and password.

```
name
```

Specifies a logical name to use to refer to the remote receiver. *name* must be an alphanumeric string of 1 through 31 characters.
Global Configuration Mode Commands (L-S)

snmp target

---

**ip_address**

Specifies the IP address of the receiver. `ip_address` must be specified using IPv4 dotted-decimal notation.

---

**non-default**

Specifies that this destination is only used for SNMP traps which have been specifically identified.

---

**port number**

Default: 162

Specifies the port which is to be used in communicating with the remote receivers. `number` must be an integer from 0 through 65535.

---

**security-name string**

Default: no community string included

Specifies the community string to use in the unsolicited messages. `string` must be an alphanumeric string of 1 through 31 characters.

---

**version { 1 | 2c | 3 } | view**

Default: 1

Specifies the SNMP version the target supports and consequently the version of the SNMP protocol to use for communications.

---

**Important:** The system can send either SNMPv1, SNMPv2c, or SNMPv3 traps to numerous target devices. However, the Web Element Manager can only process SNMP version 1 (SNMPv1) and SNMP version 2c (SNMPv2c) traps. If the SNMP target being configured is Web Element Manager application, then you must configure this command to use version 1 or version 2c.

---

**informs | traps**

Default: traps

Specifies the type of SNMP event to use to send notifications to SNMP targets. `traps` are unacknowledged (fire and forget) whereas `informs` require a response from the SNMP target.

If the notification type is set to `informs`, the notification is resent if no response is received within 5 seconds. The notification is resent at most two times.

---

**Usage**

The target manages the list of remote receivers to which unsolicited messages are sent. Use this command to add/remove a monitoring system to/from a network.

---

**Example**

```
   snmp target sampleReceiver 1.2.3.4 security-name sampleComm
   snmp target sampleReceiver 1.2.5.6 port 100
   snmp target sampleReceiver 1.2.7.8 version 2c traps
   no snmp target sampleReceiver
```
snmp trap

This command enables or disables generation of specific or all SNMP traps.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure
Entering the above command sequence results in the following prompt:

[local]host_name(config) #

Syntax

```
snmp trap { enable | suppress } [ trap_name1 trap_name2 ... trap_nameN | all ]
```

---

**enable**

Enables or allows the generation of one or more SNMP traps by the system.

**suppress**

Disables the generation of one or more SNMP traps by the system.

**trap_name1 trap_name2 ... trap_nameN**

The name of the specific SNMP trap to enable or disable. Multiple traps can be listed for a single instance of this command.

---

**Important:** The system disregards character case (case insensitive) when entering trap names.

---

**all**

Default: Enable All

Specifies that all SNMP traps will be affected by the specified operation (enable or suppress).

---

**Usage**

SNMP traps are used by the system to indicate that certain events have occurred. A complete listing of the traps supported by the system and their descriptions can be found in the *SNMP MIB Reference*. Additionally, a trap listing can be viewed using the following command:

```
snmp trap { enable | suppress } ?
```

By default, the system enables the generation of all traps. However, individual traps can be disabled allowing only traps of a certain type or alarm level to be generated. This command can be used to disable un-desired traps and/or re-enable previously suppressed traps.

---

**Example**

The following command suppresses the LogMessage trap:
The following command suppresses the CLISessEnd and CLISessStart:

```
snmp trap suppress clisessend clisessstart
```
**snmp trap-timestamps**

Adds an additional system-time varbind to generated traps.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```bash
configure
```
Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
[ no ] snmp trap-timestamps
```

- **no**
  Disables the adding of timestamps to generated traps.

**Usage**

The timestamp added to the generated trap reflects the current system time. The timestamp is proprietary. This functionality is disabled by default.

**Important:** If the Web Element Manager application is used as your alarm server, the application relies on the timestamp provided by enabling this command to identify duplicate traps. As a result, it is recommended that this parameter be enabled for this case.

**Example**

The following command enables the inclusion of a timestamp with each generated trap:

```bash
snmp trap-timestamps
```
**snmp user**

Configures an SNMPv3 user for SNMP access.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

%configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

snmp user user_name [ [ encrypted ] password password | engine id | group grp_name | security-model model auth [ [ encrypted ] password password ] ]

no snmp user user_name

---

**no**

Removes the specified user from the list of valid SNMPv3 users.

**user_name**

Specifies the user which is to use SNMPv3 interfaces to the system. `user_name` must be an alphanumeric string of 1 through 31 characters.

**engine id**

The SNMP engine ID. `id` must be an alphanumeric string of 1 through 31 characters.

**group grp_name**

Default: undefined (not a member of any group)

Specifies the user SNMPv3 group the into which user will be added. `grp_name` must be an alphanumeric string of 1 to 1023 characters.

**security-model model auth**

Default: USM

Specifies the security model used to authenticate the user. `model` must be configured to the following:

- `usm`: User Security Model

**[ encrypted ] password password**

Default: undefined

Specifies the password for authenticating the user when the security model is set to User-based Security Model (USM).
The `encrypted` keyword indicates the password will be received in an encrypted form. `password` must be an alphanumeric string of 8 through 31 characters. The `encrypted` keyword is intended only for use by the chassis while saving configuration scripts. The system displays the `encrypted` keyword in the configuration file as a flag that the variable following the `password` keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file.

**Usage**

Add and remove SNMPv3 users as operations staff or automated systems are updated. The security model will be user dependant based upon the support the users system provides.

**Important:** The system can send either SNMPv1, SNMPv2c, or SNMPv3 traps to numerous target devices. However, the Web Element Manager can only process SNMP version 1 (SNMPv1) and SNMP version 2c (SNMPv2c) traps. If the SNMP target being configured is Web Element Manager application, then you must not configure this command to use.

**Example**

```
snmp user user1
snmp user user1 security-model 2c auth
snmp user user1 group user1 group sampleGroup security-model usm auth
no snmp user user1
```
ss7-routing-domain

This command creates an SS7 routing domain instance and enters the SS7 Routing Domain Configuration mode.

**Product**
SGSN
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
ss7-routing-domain rd_id variant v_type [ -noconfirm ]
no ss7-routing-domain rd_id
```

- **rd_id**
  Identifies a specific SS7 routing domain. Once it has been created, it can be accessed for further configuration and modification by entering the `rd_id` without entering the variant.
  `rd_id` must be an integer from 1 through 12.

- **variant v_type**
  Identifies the national standard to be used for call setup, routing and control, signaling. Select one of the following:
  - **ansi**: American National Standards Institute (U.S.A.)
  - **bici**: Broadband Intercarrier Interface standard
  - **china**: Chinese standard
  - **itu**: International Telecommunication Union (ITU-T) Telecommunication Standardization Sector
  - **ntt**: Japanese standard
  - **ttc**: Japanese standard

- **-noconfirm**
  Indicates that the command is to execute without any additional prompt and confirmation from the user.

- **no**
  Removes the specified SS7 routing domain from the system configuration.
**Usage**

Use this command to create an SS7 routing domain configuration instance or to enter the SS7 routing domain configuration mode to edit the configuration.

A routing domain groups configuration items to facilitate the management of the SS7 connection resources for an SGSN service. An Access Gateway supports up to 12 configured SS7 routing domains at one time. After entering this command, the prompt appears as:

```
[context_name]<hostname>(config-ss7-routing-domain-routing_domain_id)#
```

For details about the commands and parameters used to define or edit an SS7 routing domain, refer SS7 Routing Domain Configuration Mode chapter.

**Example**

The following creates an SS7 routing domain with an index of 1 and the variant selection of Broadcast Intercarrier Interface (bici):

```
ss7-routing-domain 1 variant bici
```

The following command creates an SS7 routing domain instance with an index of 2 and the variant selection of Broadcast Intercarrier Interface (bici) to be associated with HNB RN-PLMN in an HNB access network:

```
ss7-routing-domain 1 variant bici
```
statistics-backup-interval

This command defines the time between backups of the service’s key KPI statistics.

Product
MME
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

statistics-backup-interval  minutes

no statistics-backup-interval

no

Disables the interval configuration.

minutes

Enter an integer from 1 to 60 to define the number of minutes for the interval between each backup.

Usage

This interval should only be defined after the statistics-backup command has been entered to configure the MME or SGSN to enable backup of statistics. For details on the feature, refer to the Backup and Recovery of Key KPI Statistics feature chapter in either the MME Administration Guide or the SGSN Administration Guide.

Example

Set the interval between backups to 30 minutes with the following command:

statistics-backup-interval 30
**support collection**

Modifies and/or enables the Support Data Collector (SDC) process. If record collection has been previously disabled, this command enables the collection activity. If the record collection is currently enabled, this command may be used to modify the sleep-duration interval and/or the maximum number of Support Data Records (SDRs) that can be collected and stored.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

**Syntax**

```
support collection sleep-duration { hours | minutes } value max-records number_records
no support collection
default support collection
```

- **no**
  
  Removes the settings for support collection and effectively disables the SDC.

- **default**
  
  Resets the sleep duration and maximum number of records to their default values.

- **support collection**
  
  Enables the SDC.

- **sleep-duration { hours | minutes } value**
  
  Specifies the hours and/or minutes between record collection activity. **value** must be an integer from 1 through 1000. The default setting is one hour (60 minutes).

  **Important:** The period between SDRs is equal to the configured sleep-duration interval + the time taken to collect the previous record.

- **max-records number_records**
  
  Specifies the maximum number of records to maintain within the record collection. **number_records** must be an integer from 1 through 1000. When this value is exceeded, a new SDR overwrites the oldest SDR. Default is 168.
Usage

Use this command to control the amount of support information that is collected by the Support Data Collector. Increasing the sleep interval for data collection and reducing the number of records to be collected frees system resources for processing calls and storing other data records. For additional information, refer to the System Administration Guide.

Example

The following command sets the collection sleep interval to 30 minutes with a maximum of 100 records being stored:

```
support collection sleep-duration minutes 30 max-records 100
```
**support record**

Specifies the `show` commands that will be collected and output by the Support Data Collector (SDC) process in the specified record section(s). The order in which the record section commands are specified defines the order in which the collected support data record sections are saved.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
support record section section_name command "command_string" [ section section_name command "command_string"
] ... 
```

```
no support record { all | section section_name }
```

```
default support record section { all | section section_name }
```

```
no support record { all | section section_name }
```

Removes the specified record section or all sections from the output of the SDC. This effectively disables the support data collector mechanism.

```
default support record section { all | section section_name }
```

Resets all support record sections or the specified section to the default command listing.

```
section section_name
```

Identifies the record section as an alphanumeric string of 1 through 64 characters.

```
command "command_string"
```

Identifies a CLI `show` command to be included in the record section as an alphanumeric string of 1 through 256 characters enclosed in double quotation marks.

---

**Important:** Refer to the *System Administration Guide* for a comprehensive list of command strings that can be entered via this keyword.

You can add command strings to the record section by repeating the `section section_name command "command_string"` keywords.
Usage
Use this command to tune the output of the Support Data Collector to meet specific site requirements. Refer to the *System Administration Guide* for a complete description of the SDC feature.

**Important:** If the `support record section` command is not explicitly configured by the user, a default set of record section commands are used. These default record section commands are displayed when you run the `show configuration verbose` command. If support record section commands are explicitly configured, they replace the default commands.

Example
The following command creates a record section named `show_ip_vrf` containing the CLI command `show ip vrf`:

```
support record section vrf command "show ip vrf"
```
suspend local-user

Suspends a local-user administrative account.

**Product**
All

**Privilege**
Administrator

**Mode**
Exec > Global Configuration

```configure```
Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
[ no ] suspend local-user name
```

- **no**
  Removes the suspended status for the specified local-user account.

- **name**
  The name of the local-user account expressed as an alphanumeric string of 3 through 16 characters that is case sensitive.

**Usage**
This command allows a security administrator to suspend local-user administrative accounts. A “suspended” user cannot login to the system. The user’s account information (passwords, password history, etc.), however, is preserved.

**Example**
The following command suspends a local-user account called Inspector1:

```
suspend local-user Inspector1
```

The following command removes the suspension from a local-user account called Admin300:

```
no suspend local-user Admin300
```
system

Configures system information which is accessible via SNMP.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

system { carrier-id mcc mcc_id mnc mnc_id | contact who | description string | hostname host_name | location text | serial-number ser_number | sysdesc-sysoid-style [ default | new ] }

default system { contact | location }

default

Removes the configured system contact and system location form the system.

carrier-id mcc mcc_id mnc mnc_id

Important: This carrier ID is not used by the GGSN.

Specifies a carrier-id that is a unique identifier for the carrier that has installed the system. When the carrier ID values are set, the carrier-id and gmt_offset attributes are included in access-request and accounting packets when using the following RADIUS dictionaries:

• 3gpp2
• 3gpp2-835
• starent
• starent-835
• starent-vsa1
• starent-vsa1-835
• custom9

mcc mcc_id: The mobile country code. This must be specified as a 3-digit string from 001 through 999.

mnc mnc_id: The mobile network code. This must be specified as a 2- or 3-digit string from 01 through 999.

contact who

Default: No contact specified.
**contact** *who*: specifies the contact information for the chassis. *who* must be an alphanumeric string of 0 through 255 characters. The string must be embedded in double quotes (") if spaces and special punctuation is to be used.

**description** *string*

Allows a user to describe the system for identification purposes. The system description can be comprised of a mix of alphanumeric characters, as follows:

- %version% - software version.
- %build% - software build number
- %chassis% - chassis type (ST16, ASR 5000, or ASR 5500)
- %staros% - OS type
- %hostname% - system name
- %release% - release number
- %kerver% - kernel version
- %machine% - machine hardware name
- *string* - an alphanumeric string of 1 through 255 characters.

**hostname** *host_name*

**hostname** *host_name*: configures the chassis host name where *host_name* must be an alphanumeric string of 1 through 63 characters.

**Important:** Please note that changing the chassis host name results in the command prompt changing as well to reflect the new name. This may affect any previously scripted interfaces from an OSS or maintenance facility.

**location** *text*

Default: No location specified.

**location** *text*: specifies the system location expressed as an alphanumeric string of 0 through 255 characters. The text specified must be embedded in double quotes (") if spaces are to be used.

**serial-number** *ser_number*

Default: None.

Specifies a system identifier as an alphanumeric string of 1 through 11 characters.

**sysdesc-sysoid-style** [ default | new ]

Allows the user to select the SNMP return for the objects sysDescr and sysOId.

- **default** - SNMP returns old style system description and old style system OID string.
- **new** - SNMP returns Cisco style system description and Cisco style OID string.

**Usage**

Specify system basic information which is useful back at a network operations center which uses the SNMP interfaces for management.

**Example**
The following commands configure the contact information, system host name, and location text, or remove configured location and system respectively.

```plaintext
system contact user1@company.com
system hostname system16
system location "Clark Street Closet\nBasement Rack 4"
```

The following commands remove the configured contact and location from system respectively

```plaintext
default system contact
default system location
```
Chapter 143
Global Configuration Mode Commands (T-threshold phspc)

This section includes the commands tacacs mode through threshold phspc-sm-entry-denial.
The Global Configuration Mode is used to configure basic system-wide parameters.

Mode

Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
tacacs mode

Enters the TACACS+ (Terminal Access Controller Access Control System+) configuration mode. Use this mode to configure up to three TACACS+ servers for use in authenticating administrative users via the TACACS+ protocol.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

tacacs mode

Usage
Enter TACACS Configuration Mode to configure up to three TACACS+ servers for use in authenticating administrative users via the TACACS+ protocol. For additional information, see the TACACS+ Configuration Mode Commands chapter.

Example

Use the following command to enter TACACS mode:

tacacs mode
**task facility acsmgr**

This command configures ACSMgr task settings.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```console
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```console
task facility acsmgr start [ aggressive | normal ]
no task facility acsmgr start
```

- **aggressive**
  Specifies to start the maximum possible ACSMgr tasks.

- **normal**
  Configures the resource subsystem to start/stop ACSMgr tasks on an as-needed basis.

**Usage**

This command provides option for the resource subsystem to start maximum possible ACSMgr tasks based on the license configured and the available system configuration.

**Example**

The following command starts the maximum possible ACSMgr tasks:

```console
task facility acsmgr start aggressive
```
task facility imsimgr

This command is used to configure the IMSI Manager parameters.

**Product**
- SGSN
- MME

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration

**Syntax**

```
task facility imsimgr { avoid-sessmgr-broadcast | required-sessmgr no_sess_mgrs | sessmgr-sessions-threshold high-watermark <high_value> low-watermark <low_value> }
```

```
no task facility imsimgr [ avoid-sessmgr-broadcast | required-sessmgr ]
```

```
default task facility imsimgr sessmgr-sessions-threshold
```

**no**
Disables the selected parameter’s functionality in the configuration.

**default**
This prefix is only used with the `sessmgr-sessions-threshold` parameter. By default, the threshold levels are set to the maximum allowed sessions per Session Manager based on the card type. Both high and low watermarks are set to “100”% by default to ensure backward compatibility.

**avoid-sessmgr-broadcast**
This keyword configures the IMSIMgr to avoid or disable broadcast requests to all SessMgrs when the IMSIMgr finds a particular IMSI is unknown. With this keyword, broadcasting can be disabled ‘on the fly’ if CPU usage is too high due to a large number of broadcast messages.
By default, broadcasting is enabled.

**required-sessmgr**
SGSN only.
This keyword configures the required number of Session Manager instances at the IMSI Manager. By default, this parameter is disabled to ensure backward compatibility.

`no_sess_mgrs`: The number of required Session Managers can be an integer value from “1” through “384”.
**Command**

**Usage**

For the MME:

Typically, the `avoid-sessmgr-broadcast` and `sessmgr-sessions-threshold` keywords are available for configuration but not used.

For the SGSN:

This command configures the number of Session Manager instances required at the IMSI Manager before forwarding any calls from the Gb Manager or Link Manager, as well, it configures the high watermark and low watermark threshold levels per Session Manager.

If the required number of Session Managers are configured through this command, once the Link Manager or Gb Manager comes up, it sends a query to the IMSI Manager to verify if the IMSI Manager has learnt the configured number of Session Manager instances. IMSI Manager readiness status is determined based on the number of Session Manager instances present in the list maintained. Once the IMSI Manager has completed learning about all the required number Session Manager instances, it informs the Link Manager and Gb Manager. Runtime enabling and modification of Session Manager instance is disabled except disabling this configuration. Disabling of this configuration does not affect the call forwarding to the IMSI Manager as the default behavior is to always forward the calls to the IMSI Manager. This configuration is used to avoid the session imbalance across Session Manager instances due to call forwarding to the same Session Manager instance during or after re-load, if the IMSI Manager has learnt only few Session Manager instances. By default, this feature is disabled and Gb Manager or Link Manager start forwarding calls immediately during or after re-load to the IMSI Manager which in turn forwards the request to the available Session Manager instances. It is recommended to have this configuration before re-load. This option is available only under a SGSN license.

The high and low watermark limits allow the IMSI Manager to decide and select the Session Manager for processing new calls and eliminate the chances of it receiving a “call reject” in instances where the Session Manager has reached its maximum allowed session limits and the IMSI Manager is not aware of the same. The IMSI Manager converts the high and low watermark percentage to the maximum session allowed for the configured percentage based on the card type. It uses the calculated session values for both high and low watermark to decide and select the Session Manager for processing new calls. Once the Session Manager active session count reaches the calculated high watermark sessions the IMSI Manager stops forwarding the new calls to the Session Manager until the active session count becomes less than the calculated low watermark value. This option is available only under SGSN and MME licenses.

**Example**

Use the following command to configure the required session manager count to be learnt by IMSI Manager for processing new calls to “28”:

```
task facility imsimgr required-sessmgr 28
```

Use the following command to configure the threshold for the sessions per Session Manager:

```
task facility imsimgr sessmgr-sessions-threshold high-watermark 95 low-watermark 85
```
task facility ipsecmgr

Configures IPSec manager settings.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
task facility ipsecmgr { ikev1 { task-count { increased | normal } } | task-count { increased | normal } }
```

ikev1 { task-count { increased | normal } }

Default: normal

Adjusts the IPSec manager task count to support EHA for IKEv1. See task-count below.

```
task-count { increased | normal }
```

Default: normal

Adjusts the IPSec manager task count to support EHA.

increased: Starts additional IPSec manager tasks operating on the packet processing cards. In increased mode, they run on all but demux packet processing cards. Also, all the IPSec managers start at the same time when an active non-demux card is detected and IPSec is configured.

normal: Uses the standard algorithm for allocating memory for IPSec manager tasks. In normal mode, IPSec managers do not run on session packet processing cards.

⚠️ Caution: If task-count is set to normal and session recovery is enabled, IPSec manager tasks are not allowed to start on most packet processing cards. Because the resources are not reserved, IPSec managers in normal mode only run on demux packet processing cards.

Usage
Sets IPSec manager parameters for all IPSec managers in the system.

Example

Use the following command to set the IPSec manager task count to increased mode:

```
task facility ipsecmgr task-count increased
```
task facility linkmgr

This command controls the maximum number of Link Managers that can be configured for an SGSN.

Product
SGSN

Privilege
Security Administrator, Administrator.

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
task facility linkmgr max max_linkmgrs
```

default task facility linkmgr max

```
default

 Resets the value to 4.
```

```
max max_linkmgrs

 Sets the maximum number of LinkMgrs configurable for the SGSN.
max_linkmgrs is an integer from 1 to 4. With Release 15.0, the range is from 1 to 12.
```

Usage

By default, 4 LinkMgrs will be started in the system when an SGSN service configuration is present. Use this command to change the maximum number of LinkMgrs to be started in the system.

Important: If a change to the default is needed, this command must be used before configuring any SGSN service-related configuration, including SS7 Routing Domain and SCCP Network configurations.

The number of LinkMgrs configurable impacts the following SS7 routing domain components:

- The number of Application Server Process (ASP) instances that can be configured (maximum of 12).
- The number of peer-servers that can be configured across all SS7RDs (maximum of 512).
- The number of peer-servers that can be configured per SS7RD (maximum of 256).
- The number of Peer-Server Process (PSP) instances that can be configured per SS7 Peer (maximum of 12).
**Important:** This command cannot be set dynamically. If the LinkMgr count is modified dynamically, the system must be rebooted for the change to take effect.

**Example**

Change the maximum number of LinkMgs that can be configured for an SGSN from 4 to 8:

```
task facility linkmgr max 8
```
task facility mmedemux

Configures wait-time and percentage parameters related to the MMEDEMUX. The MMEDEMUX distributes the incoming traffic to the associated MMEMGRs based on the percentage value and wait-time configured in this command.

Product
MME.

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

task facility mmedemux mmemgr-startup-percentage percent_value [ mmemgr-startup-wait-time wait_time ]

[ default | no ] task facility mmedemux mmemgr-startup-percentage mmemgr-startup-wait-time

[ default | no ]
Either of these command filters disables the operator defined configuration and replaces the configuration with default values.

mmemgr-startup-percentage percent_value

The percentage parameter allows the operator to configure the percentage of MMEMGRs to be associated with the MMEDEMUX.

percent_value must be an integer from 1 to 100. Default is 90%.

mmemgr-startup-wait-time wait_time

This parameter enables the operator to configure the time (in seconds) that the MMEDEMUX waits for MMEMGRs to start before processing incoming traffic.

wait_time must be an integer from 300 to 3600. Default is 600 (10 minutes).

Usage
This command gives operators some control over the MMEDEMUX system. It allows operators to configure the percentage of MMEMGRs to be associated with the MMEDEMUX. It also assigns the waiting time before processing the incoming traffic. Incoming traffic is distributed to the MMEMGRs based on a combination of the configured values of the two parameters.

By default, the MME waits for ten minutes to check if 90% of the MMEMGRs have started.

Example
The following configures the MMEDEMUX to distribute incoming traffic after a minimum of 5 minutes after the MME starts and as soon as 75% of the MMEMGRs are up and running:

```
task facility mmedemux mmemgr-startup-percentage 75 mmemgr-startup-wait-time 5
```
task facility sessmgr

Configures system information which is accessible via SNMP.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
task { facility sessmgr start { aggressive | normal }
```

```
facility sessmgr start { aggressive | normal }
```

Default: Normal
Specifies the facility options for the session manager.
- **aggressive**: specifies the maximum number of session manager processes are started immediately.

**Caution**: The `task facility sessmgr start aggressive` command should only be used if the system will reach capacity (for the existing configuration) during the first few minutes of service.

**Caution**: This command must only be executed last during configuration (or appended to the end of the configuration file) to ensure the availability of memory resources to contexts and services.

- **normal**: indicates the session manager processes are started as needed.

Usage

Set the session manager start policy to aggressive on heavily utilized systems to avoid undue delays in processing subscriber sessions.

Example

```
task facility sessmgr start aggressive
```
```
task facility sessmgr start normal
```
task resource cpu-memory-low

Configures the system action for SNMP trap generation and logging whenever CPU memory falls below 12MB. An SNMP TRAP and CORBA notification are generated and the event is logged. Once the free memory threshold is crossed, the Resource Manager examines all tasks on that CPU and finds the most over limit task and kills it. If there are no over limit tasks nothing happens. Resource Manager takes preference on killing a non-sessmgr task over a sessmgr task.

kill: The task most over memory limit (if any) is killed and recovered.

warn: The event is logged and no tasks are killed.

Syntax

```
task resource cpu-memory-low { kill | warn } }
```

Usage

Set the CPU memory low action to only log CPU low memory events.

Example

```
task resource cpu-memory-low warn
```
tech-support test-commands password

Configures the password that protects access to the cli test-commands mode in the Exec mode and Global Configuration mode. This command is only visible to a user logged in as a Security Administrator.

Product
All

Privilege
Security Administrator

⚠️ Caution: The cli test-commands are for use by or under the supervision of Cisco TAC.

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
tech-support test-commands [encrypted] password password
no tech-support test-commands password
```

no

Disables the use of a test-commands password. All subsequent attempts to execute cli test-commands in Exec or Global Configuration modes will fail.

Default: no password, access disabled

[encrypted]

If this optional keyword is specified, the <password> argument is interpreted as an encrypted string containing the password value. If the encrypted keyword is not specified, then the <password> argument is interpreted as the actual plain text value. In the output of show configuration and save configuration commands, only the encrypted option of this command syntax appears.

password

Specifies the password to be used when executing the cli test-commands command in Exec or Global Configuration modes. For a plain text password, password is an alphanumeric string of 1 through 64 characters. For an encrypted password, password is an alphanumeric string of 1 through 524 characters.

If a password is not entered via this command, the cli test-commands command remains disabled in the Exec and Global Configuration modes.

Default: no password, access disabled

⚠️ Important: An SNMP trap is generated when an administrator enters or edits a password via this command (starTechSupportPasswordChanged). Refer to the SNMP MIB Reference for additional information.
**Usage**

Sets the password required to execute the `cli test-commands` command in the Exec and Global Configuration mode.

---

**Important:** Access to the `cli test-commands` command also requires that a Security Administrator or Administrator enabled the Global Configuration mode `cli hidden` command.

---

**Example**

The following command sets the password for `cli test-commands` to `testCommander`.

```
  tech-support test-commands password testCommander
```
terminal

Configures the console port on the SPIO.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

terminal [ carrierdetect { off | on } | databits { 7 | 8 } | flowcontrol { hardware { off | on } | none } | parity { even | none | odd } | speed { 115200 | 19200 | 38400 | 57600 | 9600 } | stopbits { 1 | 2 } ]

carrierdetect { off | on }

Specifies whether or not the console port is to use Data Carrier Detect (DCD) when connecting to a terminal. Default: off
off: Do not use DCD.
on: Use DCD.

databits { 7 | 8 }

Specifies the number of data bits used to transmit and receive characters. Default: 8
7: Use 7 databits to transmit and receive characters.
8: Use 8 databits to transmit and receive characters.

flowcontrol { hardware { off | on } | none }

Specifies how the flow of data is controlled between the SPIO and a terminal. Default: none
hardware: Enables or disables the use of hardware-based flow control
off: Disables the use of Ready to Send (RTS) and Clear to Send (CTS).
on: Enables the use of Ready to Send (RTS) and Clear to Send (CTS).
none: Disables the use of DCD, RTS and CTS.

parity { even | none | odd }

Specifies the type of error checking used on the port. Default: none
even - Enables error checking by setting the parity bit to 1 (if needed) making the number of 1s in the data bits even.
one - Disables error checking.
odd - Enables error checking by setting the parity bit to 1 (if needed) making the number of 1s in the data bits odd.

**speed { 115200 | 19200 | 38400 | 57600 | 9600 }**

Specifies the flow of data in bits per second between the console port and terminal.
Default: 9600

**stopbits { 1 | 2 }**

Specifies the number of stop bits between each transmitted character.
Default: 1
1: Use one stop bit between each transmitted character.
2: Use two stop bits between each transmitted character.

**Usage**

Sets the SPIO’s console port parameters for communication with the terminal device.

**Example**

The following command sets the SPIO’s console port. The terminal must support these values.

```
terminal carrierdetect off databits 7 flowcontrol hardware on parity even speed 115200 stopbits 1
```
threshold 10sec-cpu-utilization

Configures alarm or alert thresholds that measure a 10-second average of CPU utilization. Its polling interval can be set down to 30 seconds.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
threshold 10sec-cpu-utilization percent [ clear percent ]
```

<table>
<thead>
<tr>
<th><strong>percent</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0</td>
</tr>
<tr>
<td>Configures Specifies the high threshold for 10-second average cpu-utilization. If the monitored CPU utilization is greater than or equal to the specified percentage an alert is sent. Regardless of the length of the polling interval, only one sample at the end of the polling interval is tested.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>clear percent</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0:</td>
</tr>
<tr>
<td>This is a low watermark value that sets the alarm clearing threshold value. If not specified it is taken from the first value.</td>
</tr>
</tbody>
</table>

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set a threshold that sends an alert when CPU utilization over a 10-second average exceeds the limit set.

Alerts or alarms are triggered for 10-second sample of CPU utilization based on the following rules:

- **Enter condition:** 10-second average percentage of CPU utilization is greater than or equal to the high threshold.

- **Clear condition:** 10-second average percentage of CPU utilization is less than the low threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.
Important: This command is not supported on all platforms.

Example

The following command generates an alert when the 10-second average CPU utilization reaches 45 percent:

```bash
threshold 10sec-cpu-utilization 45
```
threshold aaa-acct-archive-queue-size

Configures AAA accounting archive, alarm or alert thresholds based on the maximum values of session manager and ACS manager archive queue size.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold aaa-acct-archive-queue-size1 percent [ clear percent ]
default threshold aaa-acct-archive-queue-size1 percent [ clear percent ]
threshold aaa-acct-archive-queue-size2 percent [ clear percent ]
default threshold aaa-acct-archive-queue-size2 percent [ clear percent ]
threshold aaa-acct-archive-queue-size3 percent [ clear percent ]
default threshold aaa-acct-archive-queue-size3 percent [ clear percent ]
```

**percent**

Configures Specifies the high threshold for monitoring the accounting message archive queue length. If the queue length is greater than or equal to the specified percentage an alarm is sent.

Default value for `aaa-acct-archive-queue-size1`: 25%
Default value for `aaa-acct-archive-queue-size2`: 50%
Default value for `aaa-acct-archive-queue-size3`: 90%

**clear percent**

This is a low watermark value that sets the alarm clearing threshold value. If not specified it is taken from the first value.

Default value for `aaa-acct-archive-queue-size1`: 25%
Default value for `aaa-acct-archive-queue-size2`: 50%
Default value for `aaa-acct-archive-queue-size3`: 90%

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.
Usage
In the event that the system cannot communicate with configured AAA accounting servers (RADIUS or CGFs), either due to the server being busy or loss of network connectivity, the system buffers, or archives, the accounting messages.
Accounting message archive queue size thresholds generate alerts or alarms based on the queue length of AAA accounting messages buffered in the archive during the specified polling interval. Accounting requests are counted for all AAA accounting servers that the system is configured to communicate with.
Alerts or alarms are triggered for accounting message archive queue size thresholds based on the following rules:
- **Enter condition:** Actual number of archived messages is greater than or equal to the high threshold.
- **Clear condition:** Actual number of archived messages less than the low threshold.
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

Example
The following command generates an alarm when 70% of the AAA accounting message archive buffer is filled, and clears the alarm when the buffer size is reduced to 30%:

```
threshold aaa-acct-archive-queue-size 70 clear 30
```
threshold aaa-acct-archive-size

Configures accounting message archive size, alarm or alert thresholds.

Product

- ASN-GW

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold aaa-acct-archive-size high_thresh [ clear low_thresh ]

default threshold aaa-acct-archive-size

high_thresh

Default: 1
Specifies the high threshold number of archived accounting messages that must be met or exceeded within the polling interval to generate an alert or alarm. high_thresh is an integer from 0 through 1044000.

clear low_thresh

Default: 1
Specifies the low threshold number of archived accounting messages that maintains a previously generated alarm condition. If the number of failures falls beneath the low threshold within the polling interval, a clear alarm will be generated. low_thresh is an integer from 0 through 1044000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

In the event that the system cannot communicate with configured AAA accounting servers (RADIUS or CGFs), either due to the server being busy or loss of network connectivity, the system buffers, or archives, the accounting messages.

Accounting message archive size thresholds generate alerts or alarms based on the number of AAA accounting messages buffered in the archive during the specified polling interval. Accounting requests are counted for all AAA accounting servers that the system is configured to communicate with.
Alerts or alarms are triggered for accounting failures based on the following rules:

- **Enter condition:** Actual number of archived messages that is greater than or equal to the high threshold.

- **Clear condition:** Actual number of archived messages that is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 250 AAA accounting archived messages and low threshold of 100 for a system using the Alarm thresholding model:

```
threshold aaa-acct-archive-size 250 clear 100
```
threshold aaa-acct-failure

Configures accounting failure, alarm or alert thresholds for the system.

**Product**
PDSN
GGSN
HA
ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold aaa-acct-failure high_thresh [ clear low_thresh ]

default threshold aaa-acct-failure
```

---

- **high_thresh**
  - Default: 0
  - Specifies the high threshold number of accounting failures that must be met or exceeded within the polling interval to generate an alert or alarm. `high_thresh` is an integer from 0 through 10000000. A value of 0 disables the threshold.

- **clear low_thresh**
  - Default: 0
  - Specifies the low threshold number of accounting failures that maintains a previously generated alarm condition. If the number of failures falls beneath the low threshold within the polling interval, a clear alarm will be generated. `low_thresh` is an integer from 0 through 10000000. A value of 0 disables the threshold.

---

**Important**: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Accounting failure thresholds generate alerts or alarms based on the number of failed AAA accounting message requests that occur during the specified polling interval. Accounting requests are counted for all AAA accounting servers that the system is configured to communicate with. Alerts or alarms are triggered for accounting failures based on the following rules:

- **Enter condition**: Actual number of failures is greater than or equal to the high threshold.
**Clear condition:** Actual number of failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 100 AAA accounting failures and low threshold of 25 for a system using the Alarm thresholding model:

```plaintext
threshold aaa-acct-failure 100 clear 25
```
threshold aaa-acct-failure-rate

Configures accounting failure rate, alarm or alert thresholds for the system.

Product
PDSN
GGSN
HA
ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold aaa-acct-failure-rate high_thresh [ clear low_thresh ]

default threshold aaa-acct-failure-rate

| high_thresh |
| Default: 1 |
| Specifies the high threshold percent of accounting failures that must be met or exceeded within the polling interval to generate an alert or alarm. high_thresh is an integer from 0 and 100. |

| clear low_thresh |
| Default: 1 |
| Specifies the low threshold percent of accounting failures that maintains a previously generated alarm condition. If the percentage of failures falls beneath the low threshold within the polling interval, a clear alarm will be generated. low_thresh is an integer from 0 through 100. |

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
Accounting failure rate thresholds generate alerts or alarms based on the percentage of AAA accounting message requests that failed during the specified polling interval. Accounting requests are counted for all AAA accounting servers that the system is configured to communicate with.

Alerts or alarms are triggered for accounting failure rates based on the following rules:

- **Enter condition:** Actual failure percentage is greater than or equal to the high threshold.
- **Clear condition:** Actual failure percentage is less than the low threshold.
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the \texttt{threshold poll} command to configure the polling interval and the \texttt{threshold monitoring} command to enable thresholding for this value.

\textbf{Example}

The following command configures a AAA accounting failure rate high threshold percentage of 30 and a low threshold percentage of 10 for a system using the Alarm thresholding model:

\begin{verbatim}
threshold aaa-acct-failure-rate 30 clear 10
\end{verbatim}
**threshold aaa-auth-failure**

Configures authentication failure, alarm or alert thresholds for the system.

**Product**
- PDSN
- GGSN
- HA
- ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold aaa-auth-failure high_thresh [ clear low_thresh ]
default threshold aaa-auth-failure
```

- **high_thresh**
  Default: 0
  Specifies the high threshold number of authentication failures that must be met or exceeded within the polling interval to generate an alert or alarm. `high_thresh` is an integer from 0 through 10000000. A value of 0 disables the threshold.

- **clear low_thresh**
  Default: 0
  Specifies the low threshold number of authentication failures that maintains a previously generated alarm condition. If the number of failures falls beneath the low threshold within the polling interval, a clear alarm will be generated. `low_thresh` is an integer from 0 through 10000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Authentication failure thresholds generate alerts or alarms based on the number of failed AAA authentication message requests that occur during the specified polling interval. Authentication requests are counted for all AAA authentication servers that the system is configured to communicate with.

Alerts or alarms are triggered for authentication failures based on the following rules:
- **Enter condition**: Actual number of failures is greater than or equal to the high threshold.
- **Clear condition**: Actual number of failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 100 AAA authentication failures for a system using the Alert thresholding model:

```
threshold aaa-auth-failure 100
```
threshold aaa-auth-failure-rate

Configures authentication failure rate, alarm or alert thresholds for the system.

**Product**
- PDSN
- GGSN
- HA
- ASN-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
- **configure**

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold aaa-auth-failure-rate high_thresh [ clear low_thresh ]
```

**default threshold aaa-auth-failure-rate**

- **high_thresh**
  - Default: 5
  - Specifies the high threshold percent of authentication failures that must be met or exceeded within the polling interval to generate an alert or alarm. **high_thresh** is an integer from 0 through 100.

- **clear**
  - Allows the configuration of Specifies the low threshold.

- **low_thresh**
  - Default: 5
  - Specifies the low threshold percent of authentication failures that maintains a previously generated alarm condition. If the percentage of failures falls beneath the low threshold within the polling interval, a clear alarm will be generated. **low_thresh** is an integer from 0 through 100.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.
**Usage**

Authentication failure rate thresholds generate alerts or alarms based on the percentage of AAA authentication message requests that failed during the specified polling interval. Authentication requests are counted for all AAA authentication servers that the system is configured to communicate with.

Alerts or alarms are triggered for authentication failures based on the following rules:

- **Enter condition:** Actual failure percentage is greater than or equal to the high threshold.
- **Clear condition:** Actual failure percentage is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a AAA authentication failure rate high threshold percentage of **30** for a system using the Alert thresholding model:

```
threshold aaa-auth-failure-rate 30
```
threshold aaa-retry-rate

Configures AAA retry rate, alarm or alert thresholds for the system.

Product
- PDSN
- GGSN
- HA
- ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold aaa-retry-rate high_thres [ clear low_thres ]

default threshold aaa-retry-rate

high_thres
Default: 5
Specifies the high threshold percent of AAA request message retries that must be met or exceeded within the polling interval to generate an alert or alarm. high_thres is an integer from 0 through 100.

clear low_thres
Default: 5
Specifies the low threshold percent of AAA request message retries that maintains a previously generated alarm condition. If the percentage of retries falls beneath the low threshold within the polling interval, a clear alarm will be generated. low_thres is an integer from 0 through 100.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
AAA request message retry rate thresholds generate alerts or alarms based on the percentage of request messages (both authentication and accounting) that were retried during the specified polling interval. The percentage is based on a message count taken for all AAA authentication and accounting servers that the system is configured to communicate with.

Alerts or alarms are triggered for request message retries based on the following rules:

- **Enter condition**: Actual retry percentage is greater than or equal to the high threshold.
• **Clear condition:** Actual retry percentage is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a AAA message retry rate high threshold percentage of 25 and a low threshold percentage of 10 for a system using the Alarm thresholding model:

```
threshold aaa-retry-rate 25 clear 10
```
### threshold aaamgr-request-queue

Configures the AAA Manager internal request queue, alarm or alert thresholds.

**Product**
- PDSN
- GGSN
- HA
- ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
```
configure
```

Entering the above command sequence results in the following prompt:
```
[local]host_name(config)#
```

**Syntax**
```
threshold aaamgr-request-queue high_thresh [ clear low_thresh ]
default threshold aaamgr-request-queue
```

**high_thresh**
- Default: 0
- Specifies the high threshold number of AAA Manager Requests that must be met or exceeded within the polling interval to generate an alert or alarm. `high_thresh` is an integer from 1 through 100.

**clear**
- Allows the configuration of Specifies the low threshold.

**low_thresh**
- Default: 5
- Specifies the low threshold number of AAA Manager Requests that maintains a previously generated alarm condition. If the percentage of failures falls beneath the low threshold within the polling interval, a clear alarm is generated. `low_thresh` is an integer from 0 through 100.

**Important**: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**
AAA Manager Request thresholds generate alerts or alarms based on the number of AAA Manager Requests for an AAA manager process during the specified polling interval.

Alerts or alarms are triggered for AAA Manager Requests based on the following rules:
**Enter condition:** Actual number of AAA Manager Requests per AAA manager is greater than or equal to the high threshold.

**Clear condition:** Actual number of AAA Manager Requests per AAA manager process is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm is not generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a AAA authentication failure rate high threshold percentage of 30 for a system using the Alert thresholding model:

```plaintext
threshold aaamgr-request-queue 30
```
threshold asngw-auth-failure

Configures authentication failure, alarm or alert thresholds for the ASN-GW system.

**Product**
ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```bash
[local]host_name(config)#
```

**Syntax**

```bash
threshold asngw-auth-failure high_thresh [ clear low_thresh ]
```

**default threshold asngw-auth-failure**

- **high_thresh**
  Default: 0
  Specifies the high threshold number of authentication failures that must be met or exceeded within the polling interval to generate an alert or alarm.
  `high_thresh` is an integer from 0 through 10000000. A value of 0 disables the threshold.

- **clear low_thresh**
  Default: 0
  Specifies the low threshold number of authentication failures that maintains a previously generated alarm condition. If the number of failures falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  `low_thresh` is an integer from 0 through 10000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to configure threshold limits to generate alerts or alarms based on the number of failed ASN-GW authentication message requests that occur during the specified polling interval. Authentication requests are counted for all ASN Gateway authentication servers with which the system is configured to communicate.

Alerts or alarms are triggered for authentication failures based on the following rules:
- **Enter condition:** Actual number of failures is greater than or equal to the high threshold.
- **Clear condition:** Actual number of failures is less than the low threshold.
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 100 authentication failures for an ASN-GW using the Alert thresholding model:

```
threshold asgw-auth-failure 100
```
threshold asngw-handoff-denial

Configures alarm or alert thresholds for hand-off denials within the ASN-GW service.

**Product**
ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold asngw-handoff-denial high_thresh [ clear low_thresh ]
```

default threshold asngw-handoff-denial

**high_thresh**

Default: 0
Specifies the high threshold number of hand-off denials that must be met or exceeded within the polling interval to generate an alert or alarm. 

**clear low_thresh**

Default: 0
Specifies the low threshold number of hand-off denials that maintains a previously generated alarm condition. If the number of hand-off denials falls beneath the low threshold within the polling interval, a clear alarm will be generated.

**Usage**

Use this command to set threshold limits to generate alerts or alarms based on the number of denied hand-off that occurred during the specified polling interval. Hand-off denial messages are counted for all ASN Gateways that the system is configured to communicate with.

Alerts or alarms are triggered for hand-off denials based on the following rules:

- **Enter condition:** Actual number of failures is greater than or equal to the high threshold.
- **Clear condition:** Actual number of failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 100 hand-off denials using the Alert thresholding model:

```
threshold asngw-handoff-denial 100
```
### threshold asngw-max-eap-retry

Configures alarm or alert thresholds for maximum retries for Extensible Authentication Protocol (EAP) authentication within an ASN-GW service.

**Product**
ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold asngw-max-eap-retry high_thresh [ clear low_thresh ]
```

**default threshold asngw-max-eap-retry**

- **high_thresh**
  
  Default: 0
  
  Specifies the high threshold number of retries for EAP authentication that must be met or exceeded within the polling interval to generate an alert or alarm.
  
  `high_thresh` is an integer from 0 through 10000000. A value of 0 disables the threshold.

- **clear low_thresh**
  
  Default: 0
  
  Specifies the low threshold number of retries for EAP authentication that maintains a previously generated alarm condition. If the number of retries falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  
  `low_thresh` is an integer from 0 through 10000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to set threshold limits to generate alerts or alarms based on the number of retries for EAP authentication that occur during the specified polling interval. Alerts or alarms are triggered for maximum number of retries for EAP authentication based on the following rules:

- **Enter condition:** Actual number of failures is greater than or equal to the high threshold.
- **Clear condition:** Actual number of failures is less than the low threshold.
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 100 alerts or alarms generated on maximum number of retries for EAP authentication for an ASN Gateway using the Alert thresholding model:

```
threshold asngw-max-eap-retry 100
```
threshold asngw-network-entry-denial

Configures alarm or alert thresholds for denials of network entry to an MS within the ASN-GW service.

Product
ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

Syntax

```
threshold asngw-network-entry-denial high_thresh [ clear low_thresh ]

default threshold asngw-network-entry-denial
```

**high_thresh**
Default: 0
Specifies the high threshold number of denial of network entry to an MS that must be met or exceeded within the polling interval to generate an alert or alarm.

**low_thresh**
Default: 0
Specifies the low threshold number of denial of network entry to an MS that maintains a previously generated alarm condition. If the number of denials falls beneath the low threshold within the polling interval, a clear alarm will be generated.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set threshold limits to generate alerts or alarms based on the number of network entry denials that occurred during the specified polling interval. Network denial messages are counted for an MS with which the system is configured to communicate.

Alerts or alarms are triggered for network entry denials based on the following rules:

- **Enter condition:** Actual number of failures is greater than or equal to the high threshold.
- **Clear condition:** Actual number of failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 100 network entry denials for an MS using the Alert thresholding model:

```
threshold asngw-network-entry-denial 100
```
threshold asngw-session-setup-timeout

Configures alarm or alert thresholds for session setup timeouts in an ASN-GW service.

**Product**
ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
c

config
t

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
threshold asngw-session-setup-timeout high_thresh [ clear low_thresh ]
default threshold asngw-session-setup-timeout
```

**Syntax**

- `high_thresh`
  - Default: 0
  - Specifies the high threshold number of timeouts during session setup that must be met or exceeded within the polling interval to generate an alert or alarm.
  - `high_thresh` is an integer from 0 through 10000000. A value of 0 disables the threshold.

- `clear low_thresh`
  - Default: 0
  - Specifies the low threshold number of timeouts during session setup that maintains a previously generated alarm condition. If the number of denials falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - `low_thresh` is an integer from 0 through 10000000. A value of 0 disables the threshold.

**Important**: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to set threshold limits to generate alerts or alarms based on the number of timeouts during session setup that occurred during the specified polling interval.

Alerts or alarms are triggered for session setup timeouts based on the following rules:

- **Enter condition**: Actual number of failures is greater than or equal to the high threshold.
- **Clear condition**: Actual number of failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 100 timeouts during session setup using the Alert thresholding model:

```
threshold asngw-session-setup-timeout 100
```
threshold asngw-session-timeout

Configures alarm or alert thresholds for session timeouts in an ASN-GW service.

configure

Entering the above command sequence results in the following prompt:

[local]\(host\textunderscore name(config)\)#

Syntax

\[\text{threshold asngw-session-timeout } \text{high\_thresh} \ [\text{clear } \text{low\_thresh}]\]

default threshold asngw-session-timeout

\[\text{high\_thresh}\]

Default: 0

Specifies the high threshold number of timeouts during session that must be met or exceeded within the polling interval to generate an alert or alarm.

\text{high\_thresh} is an integer from 0 through 10000000. A value of 0 disables the threshold.

\[\text{clear } \text{low\_thresh}\]

Default: 0

Specifies the low threshold number of timeouts during session that maintains a previously generated alarm condition. If the number of session timeouts falls beneath the low threshold within the polling interval, a clear alarm will be generated.

\text{low\_thresh} is an integer from 0 through 10000000. A value of 0 disables the threshold.

\textcolor{red}{\textbf{Important:}} This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set threshold limits to generate alerts or alarms based on the number of timeouts during a session that occurred during the specified polling interval.

Alerts or alarms are triggered for session timeouts based on the following rules:

\textbullet\textbf{Enter condition:} Actual number of failures is greater than or equal to the high threshold.

\textbullet\textbf{Clear condition:} Actual number of failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 100 timeouts during a session using the Alert thresholding model:

```
threshold asngw-session-timeout 100
```
threshold asnpc-idle-mode-timeout

Configures alarm or alert thresholds for ASNPC Instant Messenger idle mode timeouts.

**Product**
ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold asnpc-idle-mode-timeout high_thresh [ clear low_thresh ]
```

*high_thresh*

Default: 0
Specifies the high threshold number of ASNPC idle mode timeouts that must be met or exceeded within the polling interval to generate an alert or alarm.
*high_thresh* is an integer from 0 through 10000000. A value of 0 disables the threshold.

*clear low_thresh*

Default: 0
Specifies the low threshold number of ASNPC idle mode timeouts during session that maintains a previously generated alarm condition. If the number of session timeouts falls beneath the low threshold within the polling interval, a clear alarm will be generated.
*low_thresh* is an integer from 0 through 10000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Set the maximum number of idle mode timeouts allowed in the ASNPC service.
Alerts or alarms are triggered for session timeouts based on the following rules:

- **Enter condition:** Actual number of timeouts is greater than or equal to the high threshold.

- **Clear condition:** Actual number of timeouts is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

**Example**

The following command configures the high threshold for ASNPC idle mode timeouts at **10000**: 
threshold asnpc-idle-mode-timeout

threshold asnpc-idle-mode-timeout 10000
threshold asnpc-im-entry-denial

Configures the ASNPC Instant Messenger (IM) entry denial, alarm or alert thresholds.

**Product**
ASN-GW

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Set the maximum number of IM session denials allowed in the ASNPC service. Alerts or alarms are triggered for session timeouts based on the following rules:

- **Enter condition:** Actual number of failures is greater than or equal to the high threshold.
- **Clear condition:** Actual number of failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures the high threshold for IM session counts at 10000:

```
threshold asnpc-im-entry-denial high_thresh 10000
```
threshold asnpc-im-entry-denial

threshold asnpc-im-entry-denial 10000
threshold asnpc-lu-denial

Configures the alarm or alert thresholds for Location Update (LU) denials.

**Product**
ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**

```
threshold asnpc-lu-denial high_thresh [ clear low_thresh ]
```

- **high_thresh**
  Default: 0
  Specifies the high threshold number of LU denials during session that must be met or exceeded within the polling interval to generate an alert or alarm.
  *high_thresh* is an integer from 0 through 10000000. A value of 0 disables the threshold.

- **clear low_thresh**
  Default: 0
  Specifies the low threshold number of LU denials during session that maintains a previously generated alarm condition. If the number of session timeouts falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  *low_thresh* is an integer from 0 through 10000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**
Set the maximum number of Location Update denials allowed in the ASNPC service.

**Example**
The following command configures high threshold of 10000 LU denials:
```
threshold asnpc-lu-denial 10000
```
threshold asnpc-session-setup-timeout

Configures alarm or alert thresholds for ASNPC session setup timeouts in an ASN-GW service.

**Product**
ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`
Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold asnpc-session-setup-timeout value
```

**default threshold asnpc-session-setup-timeout**

```
value
```

**value** is an integer from 1 through 1000000.

**Usage**

Use this command to set threshold limits to generate alerts or alarms based on the number of timeouts during session setup that occurred during the specified polling interval. If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 100 timeouts during session setup using the Alert thresholding model:

```
threshold asnpc-session-setup-timeout 100
```
threshold call-reject-no-resource

Configures alarm or alert thresholds on the system for calls rejected due to insufficient resources.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
threshold call-reject-no-resource high_thresh [ clear low_thresh ]
```

**high_thresh**
Default: 0
Specifies the high threshold number of no-resource call rejects issued by the system that must be met or exceeded within the polling interval to generate an alert or alarm.
The number is an integer from 0 through 100000. A value of 0 disables the threshold.

**clear low_thresh**
Default: 0
Specifies the low threshold number of no-resource call rejects issued by the system that maintains a previously generated alarm condition. If the number of rejections falls beneath the low threshold within the polling interval, a clear alarm will be generated.
The number is an integer from 0 through 100000. A value of 0 disables the threshold.

---

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

---

**Usage**

No resource call reject thresholds generate alerts or alarms based on the total number of calls that were rejected by the system due to insufficient or no resources (memory and/or session licenses) during the specified polling interval.

Alerts or alarms are triggered for no-resource-rejected calls based on the following rules:

- **Enter condition:** Actual number of calls rejected due to no resources is greater than or equal to the high threshold.
- **Clear condition:** Actual number of calls rejected due to no resources is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count for the number of calls rejected by the system due to insufficient or no resources to 100 and allow threshold of 40 for a system using the Alarm thresholding model:

```
threshold call-reject-no-resource 100 clear 40
```
threshold call-setup

Configures call setup, alarm or alert thresholds for the system.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold call-setup high_thresh [ clear low_thresh ]

- **high_thresh**
  - Default: 0
  - Specifies the high threshold number of calls setup by the system that must be met or exceeded within the polling interval to generate an alert or alarm.
  - *high_thresh* is an integer from 0 through 100000. A value of 0 disables the threshold.

- **clear low_thresh**
  - Default: 0
  - Specifies the low threshold number of calls setup by the system that maintains a previously generated alarm condition. If the number of setups falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - *low_thresh* is an integer from 0 through 100000. A value of 0 disables the threshold.

**Important**: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Call setup thresholds generate alerts or alarms based on the total number of calls setup by the system during the specified polling interval.

Alerts or alarms are triggered for call setups based on the following rules:

- **Enter condition**: Actual number of call setups is greater than or equal to the high threshold.
- **Clear condition**: Actual number of call setups is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

Example
The following command configures a high threshold count of 100 calls setup for a system using the Alert thresholding model:

```
threshold call-setup 100
```
threshold call-setup-failure

Configures call setup failure, alarm or alert thresholds for the system.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

```configure```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

`threshold call-setup-failure high_thresh [ clear low_thresh ]`

- `high_thresh`
  - Default: 0
  - Specifies the high threshold number of call setup failures experienced by the system that must be met or exceeded within the polling interval to generate an alert or alarm.
  - `high_thresh` is an integer from 0 through 100000. A value of 0 disables the threshold.

- `clear low_thresh`
  - Default: 0
  - Specifies the low threshold number of call setup failures experienced by the system that maintains a previously generated alarm condition. If the number of setup failures falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - `low_thresh` is an integer from 0 through 100000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Call setup failure thresholds generate alerts or alarms based on the total number of call setup failures experienced by the system during the specified polling interval.

- **Enter condition:** Actual number of call setup failures is greater than or equal to the high threshold.
- **Clear condition:** Actual number of call setup failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**
The following command configures a high threshold count of 100 call setup failures and a low threshold of 80 for a system using the Alarm thresholding model:

```
threshold call-setup-failure 100 clear 80
```
threshold card-temperature-near-power-off-limit

Configures alarm or alert thresholds for triggering and clearing high card temperature alarms.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold card-temperature-near-power-off-limit high_temp [ clear low_temp ]
```

- **high_thresh**

  Default: 0
  Specifies the high card temperature (in degrees Celsius) that must be met or exceeded within the polling interval to generate an alert or alarm.
  `high_thresh` is an integer from 0 through 100. A value of 0 disables the threshold.

- **clear low_thresh**

  Default: 0
  Specifies the low card temperature (in degrees Celsius) before a high temperature alarm is cleared.
  `low_thresh` is an integer from 0 through 100. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Set the high and low temperatures in degrees Celsius that generate and clear alarms.

**Example**

The following command configures sets the high and low temperatures to 40 and 35 degrees:

```
threshold card-temperature-near-power-off-limit 40 clear 35
```
threshold cdr-file-space

Configures, alarm or alert thresholds for monitoring the percentage of total file space allocated for Charging Data Records (CDRs) used during the polling interval.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
```
configure
```
Entering the above command sequence results in the following prompt:
```
[local] host_name(config) #
```

**Syntax**

```
threshold cdr-file-space high_thresh [ clear low_thresh ]
```

**default threshold cdr-file-space**

```
default
```
Configures this command with the default threshold settings.

```
high_thresh
```
Specifies the high threshold for percentage of total allocated CDR file space used that must be met or exceeded at the end of the polling interval to generate an alert or alarm.

`high_thresh` is measured in percentage of total allocated CDR file space used and is an integer from 0 through 100. A value of 0 disables the threshold.

Default: 90

```
clear low_thresh
```
Specifies the low threshold for percentage of total allocated CDR file space used that maintains a previously generated alarm condition. If the space usage falls below `low_thresh` within the polling interval, a clear alarm is generated.

`low_thresh` is measured in percentage of total allocated CDR file space used and is an integer from 0 through 100. A value of 0 disables the threshold.

Default: 0

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to `low_thresh`.

**Usage**
CDR file space usage generate alerts or alarms based on the percentage of total allocated CDR file space used during the polling interval.
Alerts or alarms are triggered for CDR file space usage session based on the following rules:

- **Enter condition:** Actual percentage of allocated CDR file space usage is greater than or equal to the specified percentage of total CDR file space.

- **Clear condition:** Actual CDR file space used is less than the specified clear percentage of total allocated CDR file space usage.

If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a threshold of 65 percent of total allocated CDR file space usage and a clear threshold of 35 percent:

```
threshold cdr-file-space 65 clear 35
```
threshold contfilt-block

Configures, alarm or alert thresholds for Content Filtering rating operations blocked during a polling interval at which the threshold are raised or cleared.

Product
CF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold contfilt-block high_thresh_value [ clear low_thresh_value ]

default threshold contfilt-block

default

Configures this command with the default threshold settings.

high_thresh

Specifies the high threshold for number of rating operations blocked for content filtering service that must be met or exceeded at the end of the polling interval to generate an alert or alarm.

high_thresh is measured in numbers of total rating operations blocked and is an integer from 0 through 1000000. A value of 0 disables the threshold.

clear low_thresh

Specifies the low threshold for the total number of rating operations blocked for a content filtering service that maintains a previously generated alarm condition. If the threshold falls below Specifies the low threshold within the polling interval, a clear alarm is generated.

low_thresh is measured in numbers of total rating operations blocked and is an integer from 0 through 1000000. A value of 0 disables the threshold.

Default: 0

Usage

Use this command to configure the threshold for a content filtering service to generates alerts or alarms based on the number of rating operations blocked for a content filtering service during the polling interval. If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the threshold poll contfilt-block command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

Example
The following command configures a threshold of 65000 rating operations blocked and a clear threshold of 35000 operations:

```bash
threshold contfilt-block 65000 clear 35000
```
threshold contfilt-rating

Configures, alarm or alert thresholds for Content Filtering rating operations performed during a polling interval at which the threshold are raised or cleared.

**Product**
CF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```
Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold contfilt-rating high_thresh_value [ clear low_thresh_value ]
```

**default threshold contfilt-rating**

```
default
```

Configures this command with the default threshold settings.

```
high_thresh
```

Specifies the high threshold for number of rating operations performed for content filtering service that must be met or exceeded at the end of the polling interval to generate an alert or alarm.

*high_thresh* is measured in numbers of total rating operations performed and is an integer from 0 through 1000000. A value of 0 disables the threshold.

```
clear low_thresh
```

Specifies the low threshold for the total number of rating operations performed for a content filtering service that maintains a previously generated alarm condition. If the threshold falls below the specified low threshold within the polling interval, a clear alarm is generated.

*low_thresh* is measured in number of total rating operations performed and is an integer from 0 through 1000000. A value of 0 disables the threshold.

Default: 0

**Usage**

Use this command to configure the threshold for a content filtering service to generate alerts or alarms based on the number of rating operations performed for a content filtering service during the polling interval. If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll contfilt-rating` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**
The following command configures a threshold of 65000 percent of total rating operations performed and a clear threshold of 35000 percent:

```
threshold contfilt-rating 65000 clear 35000
```
threshold cpu-available-memory

Configures alarm or alert thresholds for available CPU memory in the system.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold cpu-available-memory low_thresh [ clear high_thresh ]
```

<table>

</tr>
<tr>
<td><code>high_thresh</code> is measured in megabytes (MB) and is an integer from 0 through 2048.</td>
</tr>
</tbody>
</table>

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

**Usage**

CPU available memory thresholds generate alerts or alarms based on the amount of available memory for each packet processing card CPU at the polling time. Although, a single threshold is configured for all CPUs, separate alerts or alarms can be generated for each CPU.

Alerts or alarms are triggered for available CPU memory based on the following rules:

- **Enter condition:** Average measured amount of memory/CPU for the last 5 minutes is less than or equal to the low threshold.

- **Clear condition:** Average measured amount of memory/CPU for the last 5 minutes is greater than the high threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Important:** This command is not supported on all platforms.

**Example**

The following command configures a low threshold count of 50 MB CPU memory available and a high threshold of 112 MB for a system using the Alarm thresholding model:

```
threshold cpu-available-memory 50 clear 112```
threshold cpu-load

Configures alarm or alert thresholds for monitoring packet processing card CPU loads using a 5-minute average measurement. The threshold is enabled by enabling CPU resource monitoring.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

threshold cpu-load high_thresh [ clear low_thresh ]

high_thresh

Default: 0
If the monitored CPU load is greater than or equal to the specified number an alert is sent. high_thresh must be an integer from 0 through 15.

clear low_thresh

Default: 0
This is a low watermark value that sets the alarm clearing threshold value. If not present it is taken from the first value. low_thresh must be an integer from 0 through 15.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to Specifies the low threshold.

Usage

Use this command to set an alert when the card’s CPU load is equal to or greater than the number specified. Alerts or alarms are triggered for CPU load based on the following rules:

- **Enter condition:** Actual CPU load is greater than or equal to the high threshold.
  
  **Clear condition:** Actual CPU load is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

**Important:** This command is not supported on all platforms.
Example

To set an alert when the packet processing card CPU load is over 10 and set an alert clear when the CPU load drops down equal or less than 7, enter the following command:

```
threshold cpu-load 10 clear 7
```

threshold cpu-memory-usage

Configures, alarm or alert thresholds for monitoring the percentage of total CPU memory used during the polling interval.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax
threshold cpu-memory-usage high_thresh [ clear low_thresh ]

high_thresh
Default: 0
Specifies the high threshold for percentage of total memory used that must be met or exceeded at the end of the polling interval to generate an alert or alarm.
high_thresh is measured as a percentage of total CPU memory used and is an integer from 0 and 100. A value of 0 disables the threshold.

clear low_thresh
Default: 0
Specifies the low threshold for percentage of total CPU memory used that maintains a previously generated alarm condition. If the memory usage falls below the low threshold within the polling interval, a clear alarm is generated.
low_thresh is measured as a percentage of total CPU memory used and is an integer from 0 and 100. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to Specifies the low threshold.

Usage
CPU memory usage generate alerts or alarms based on the percentage of total CPU memory used during the polling interval.
Alerts or alarms are triggered for CPU memory usage session based on the following rules:

• Enter condition: Actual percentage of CPU memory usage is greater than or equal to the specified percentage of total CPU memory.
• Clear condition: Actual CPU memory usage is less than the specified clear percentage of total CPU memory usage.
If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a threshold of 65 percent of total packet processing card CPU memory usage and a clear threshold of 35 percent:

```
threshold cpu-memory-usage 65 clear 35
```
threshold cpu-orbs-crit

Configures thresholds for generating critical-level alerts or alarms based on the percentage of CPU utilization by the Object Request Broker System (ORBS) software task.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold cpu-orbs-crit high_thresh [ clear low_thresh ]
[ default ] threshold cpu-orbs-crit
```

default
Restores this parameter to its default setting.

**high_thresh**

Default: 60
Specifies the high threshold percent of CPU utilization by the ORB software task that must be exceeded as measured at the time of polling to generate a critical-level alert or alarm. *high_thresh* is measured in percentage of total CPU utilization and is an integer from 0 through 100. A value of 0 disables the threshold.

**clear low_thresh**

Default: 60
Specifies the low threshold percent of CPU utilization by the ORB software task that maintains a previously generated alarm condition. If the percentage is measured as less than or equal to *low_thresh* at the time of polling, a clear alarm will be generated. *low_thresh* is measured in percentage of total CPU utilization and is an integer from 0 through 100. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to *low_thresh*.

**Usage**

Object Request Broker (ORB) software task CPU utilization thresholds generate critical-level alerts or alarms based on the percentage of packet processing card CPU resources it is consuming at the time of polling.
Critical-level alerts or alarms are triggered for CPU usage by the ORBs software task based on the following rules:

- **Enter condition:** Actual CPU usage percentage is greater than the high threshold.
- **Clear condition:** Actual CPU usage percentage is less than or equal to the low threshold.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a critical-level alarm threshold of 35 percent of CPU utilization by the ORBS task and a clear threshold of 30 percent:

```
threshold cpu-orbs-crit 35 clear 30
```
threshold cpu-orbs-warn

Configures thresholds for generating warning-level alerts or alarms based on the percentage of CPU utilization by the Object Request Broker System (ORBS) software task.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold cpu-orbs-warn high_thresh [ clear low_thresh ]
[ default ] threshold cpu-orbs-warn

<table>

A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to Specifies the low threshold.
Usage

Object Request Broker (ORB) software task CPU utilization thresholds generate warning-level alerts or alarms based on the percentage of packet processing card CPU resources it is consuming at the time of polling.

Warning-level alerts or alarms are triggered for CPU usage by the ORBS software task based on the following rules:

- **Enter condition:** Actual CPU usage percentage is greater than the high threshold.
- **Clear condition:** Actual CPU usage percentage is less than or equal to the low threshold.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

Example

The following command configures a warning-level alarm threshold of 25 percent of CPU utilization by the ORBS task and a clear threshold of 20 percent:

```
threshold cpu-orbs-warn 25 clear 20
```
threshold cpu-session-throughput

Configures alarm or alert thresholds for CPU session throughput within the system.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold cpu-session-throughput high_thresh [ clear low_thresh ]
```

<table>
<thead>
<tr>
<th>high_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0</td>
</tr>
<tr>
<td>Specifies the high threshold session throughput that must be met or exceeded within the polling interval to generate an alert or alarm.</td>
</tr>
<tr>
<td>high_thresh is measured in kilobytes per second (Kbps) and is an integer from 0 through 1000000000. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>clear low_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0</td>
</tr>
<tr>
<td>Specifies the low threshold session thereabout that maintains a previously generated alarm condition. If the throughput falls below Specified the low threshold within the polling interval, a clear alarm will be generated.</td>
</tr>
<tr>
<td>low_thresh is measured in kilobytes per second (Kbps) and is an integer from 0 through 1000000000. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

CPU session throughput thresholds generate alerts or alarms based on total throughput for all Session Manager tasks running on each packet processing card CPU during the polling interval. Although, a single threshold is configured for all CPUs, separate alerts or alarms can be generated for each CPU. Alerts or alarms are triggered for CPU session throughput based on the following rules:

- **Enter condition:** Actual CPU session throughput is greater than or equal to the high threshold.
- **Clear condition:** Actual CPU session throughput is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Important:** This command is not supported on all platforms.

**Example**

The following command configures a high threshold count of 900 Kbps session throughput and a low threshold of 500 KBps for a system using the Alarm thresholding model:

```
threshold cpu-session-throughput 900 clear 500
```
threshold cpu-utilization

Configures alarm or alert thresholds for CPU utilization within the system.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
`configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold cpu-utilization high_thres [ clear low_thres ]
```

**high_thres**
Default: 85
Specifies the high threshold CPU utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm. 
`high_thres` is an integer from 0 through 100.

**clear low_thres**
Default: 85
Specifies the low threshold CPU utilization percentage that maintains a previously generated alarm condition. If the utilization percentage falls below the low threshold within the polling interval, a clear alarm will be generated.

`low_thres` is an integer from 0 through 100.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

CPU utilization thresholds generate alerts or alarms based on the utilization percentage of each packet processing card CPU during the specified polling interval. Although, a single threshold is configured for all CPUs, separate alerts or alarms can be generated for each CPU. Alerts or alarms are triggered for CPU utilization based on the following rules:

- **Enter condition:** Average measured CPU utilization for the last 5 minutes
- **Clear condition:** Average measured CPU utilization for the last 5 minutes is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Important:** This command is not supported on all platforms.

**Example**

The following command configures a high threshold CPU utilization percentage of 90 for a system using the Alert thresholding model:

```
threshold cpu-utilization 90
```
threshold dcca-bad-answers

Configures alarm or alert thresholds for invalid or bad responses to the system from Diameter servers.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
threshold dcca-bad-answers high_thresh [ clear low_thresh ]
```

**default threshold dcca-bad-answers**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Disables the threshold for configured alarm and sets the high_thresh and low_thresh values to 0.</td>
</tr>
<tr>
<td>high_thresh</td>
<td>Specifies the high threshold number of invalid messages or responses that must be met or exceeded within the polling interval to generate an alert or alarm. high_thresh is an integer from 0 through 1000000.</td>
</tr>
<tr>
<td>clear</td>
<td>Specifies the low threshold number of invalid messages/responses that maintains a previously generated alarm condition. If the number of failures falls beneath the low threshold within the polling interval, a clear alarm will be generated. low_thresh is an integer from 0 through 1000000.</td>
</tr>
</tbody>
</table>

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

In the event that the system receives invalid message or response from Diameter server dcca-bad-answers is generated. DCCA bad answer messages size threshold generates alerts or alarms based on the number of invalid response or messages received during the specified polling interval. Alerts or alarms are triggered for DCCA bad answers based on the following rules:
**Enter condition:** Actual number of DCCA bad answer messages is greater than or equal to the high threshold.

**Clear condition:** Actual number of DCCA bad answer messages is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

**Example**

The following command configures a high threshold count of 250 DCCA bad answer messages and low threshold of 100 for a system using the Alarm thresholding model:

```
threshold dcca-bad-answers 250 clear 100
```
threshold dcca-protocol-error

Configures alarm or alert thresholds for Diameter Credit Control Application (DCCA) protocol errors from the Diameter server.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold dcca-protocol-error high_thresh [ clear low_thresh ]

default threshold dcca-protocol-error

default

Disables the threshold for configured alarm and sets the high_thresh and low_thresh values to 0.

high_thresh

Default: 0
Specifies the high threshold number of protocol error received from Diameter server that must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 1000000.

clear low_thresh

Default: 0
Specifies the low threshold number of protocol error received from Diameter server that maintains a previously generated alarm condition. If the number of errors falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 through 1000000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

In the event that the system receives the protocol errors from Diameter server, dcca-protocol-error is generated.
DCCA protocol error threshold generates alerts or alarms based on the number of protocol error messages received from Diameter server during the specified polling interval.
Alerts or alarms are triggered for DCCA protocol error based on the following rules:

- **Enter condition**: Actual number of DCCA protocol error is greater than or equal to the high threshold.
- **Clear condition**: Actual number of DCCA protocol errors is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

**Example**

The following command configures a high threshold count of 250 protocol errors and low threshold of 100 for a system using the Alarm thresholding model:

```
threshold dcca-protocol-error 250 clear 100
```
threshold dcca-rating-failed

Configures Diameter Credit Control Application (DCCA) Rating Group (content-id) request reject, alarm or alert thresholds.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold dcca-rating-failed high_thresh [ clear low_thresh ]

default threshold dcca-rating-failed

default
Disables the threshold for configured alarm and sets the high_thresh and low_thresh values to 0.

high_thresh
Default: 0
Specifies the high threshold number of requests for a block of credits due to invalid Rating Group (content-id), rejected from the Diameter server that must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 1000000.

clear low_thresh
Default: 0
Specifies the low threshold number of requests for a block of credits due to invalid Rating Group (content-id), rejected from the Diameter server that maintains a previously generated alarm condition. If the number of errors falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 through 1000000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
In the event that the Diameter server rejects the system request for a block of credits due to invalid Rating Group, defined as content-id, dcca-rating-failed message is generated.
Rating Group failed threshold generates alerts or alarms based on the number of requests rejected from Diameter server during the specified polling interval.

Alerts or alarms are triggered for Rating Group failed based on the following rules:

- **Enter condition:** Actual number of DCCA Rating Group failed is greater than or equal to the high threshold.
- **Clear condition:** Actual number of DCCA Rating Group failed is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

**Example**

The following command configures a high threshold count of 250 requests rejected and low threshold of 100 for a system using the Alarm thresholding model:

```
threshold dcca-rating-failed 250 clear 100
```
threshold dcca-unknown-rating-group

Configures alarm or alert thresholds for the unknown Diameter Credit Control Application (DCCA) Rating Group (content-id) messages returned by Diameter servers.

Product
ACS
Privilege
Security Administrator, Administrator
Mode
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax
threshold dcca-unknown-rating-group  high_thresh  [ clear  low_thresh ]
default threshold dcca-unknown-rating-group

default
Disables the threshold for configured alarm and sets the high_thresh and low_thresh values to 0.

high_thresh
Default: 0
Specifies the high threshold number of unknown Rating Group (content-id) messages sent by the Diameter server that must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 1000000.

clear  low_thresh
Default: 0
Specifies the low threshold number of unknown Rating Group (content-id) sent by Diameter server and received by system that maintains a previously generated alarm condition. If the number of errors falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 through 1000000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
In the event that the Diameter server sends invalid Rating Groups, content-ids to the system, dcca-unk-
rating-group message is generated.
Unknown Rating Group threshold generates alerts or alarms based on the number of unknown Rating Groups received by the system from Diameter server during the specified polling interval.
Alerts or alarms are triggered for unknown rating groups based on the following rules:

- **Enter condition:** Actual number of unknown rating groups is greater than or equal to the high threshold.

- **Clear condition:** Actual number of unknown rating groups is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

**Example**

The following command configures a high threshold count of 250 unknown rating groups and low threshold of 100 for a system using the Alarm thresholding model:

```
threshold dcca-unknown-rating-group 250 clear 100
```
threshold diameter diameter-retry-rate

Configures Diameter Retry Rate, alarm or alert thresholds based on the percentage of Diameter requests that were retried during the polling interval.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax
threshold diameter diameter-retry-rate high_thresh [ clear low_thresh ]

default threshold diameter diameter-retry-rate

default

Configures this command with the default threshold settings.
Default: 0—disabled

high_thresh

Specifies the high threshold. If, within the polling interval, the percentage of Diameter requests retried equals or exceeds high_thresh an alert or alarm is generated.
high_thresh is an integer from 0 through 100.
Default: 0

clear low_thresh

Specifies the low threshold. If, within the polling interval, the percentage of Diameter requests retried falls below low_thresh, a clear alarm is generated.
low_thresh is an integer from 0 through 100.
Default: 0

Important: This value is applicable for the Alarm mode, and ignored for the Alert mode. In addition, if this value is not configured for the Alarm mode, the system assumes it is identical to the high threshold.

Usage
Diameter Retry Rate threshold generates alerts or alarms based on the percentage of Diameter requests that were retried during the specified polling interval.
Alerts or alarms are triggered based on the following rules:
• Enter condition: Percentage of Diameter requests retried is greater than or equal to the high threshold.
• **Clear condition**: Percentage of Diameter requests retried is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

**Example**

The following command configures a high threshold of 75 percent, and a low threshold of 50 percent for a system using the Alarm thresholding model:

```
threshold diameter diameter-retry-rate 75 clear 50
```
threshold dns-learnt-ip-max-entries

Configures alarm or alert thresholds for the percentage of total DNS-learnt IP entries in relation to the ACS DNS Snooping feature.

Important: In 16.0 and later releases, this command has been deprecated and replaced by the `threshold dns-learnt-ipv4-max-entries` and `threshold dns-learnt-ipv6-max-entries` commands to configure alarm or alert thresholds for the percentage of total DNS-learnt IPv4 entries and total DNS-learnt IPv6 entries respectively.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
threshold dns-learnt-ip-max-entries high_thresh [ clear low_thresh ]

default threshold dns-learnt-ip-max-entries
```

default

Configures this command with the default threshold setting.
Default: 90 percent. It is the same for both high and low thresholds.

```
high_thresh
```

Default: 90 percent
Specifies the high threshold for percentage of total DNS-learnt IP entries. When the percentage of total DNS-learnt IP entries meets or exceeds the high threshold at the end of the polling interval, an alert or alarm is generated.
When the percentage of total DNS-learnt IPv4 entries meets or exceeds the high threshold, the ECSTotalDNSLearntIPv4Threshold trap is generated.
When the percentage of total DNS-learnt IPv6 entries meets or exceeds the high threshold, the ECSTotalDNSLearntIPv6Threshold trap is generated.

`high_thresh` is an integer value from 0 through 100. When configured to 0 the threshold is disabled.

```
clear low_thresh
```

Default: 90 percent
Specifies the low threshold for percentage of total DNS-learnt IP entries. When the percentage of total DNS-learnt IP entries goes below the low threshold within the polling interval, a clear alarm is generated.
When the percentage of total DNS-learnt IPv4 entries goes below the low threshold, the ECSTotalDNSLearntIPv4ThresholdClear trap is generated.
When the percentage of total DNS-learnt IPv6 entries goes below the low threshold, the ECSTotalDNSLearntIPv6ThresholdClear trap is generated.
When the percentage of total DNS-learnt IPv6 entries goes below the low threshold, the ECSTotalDNSLearntIPv6ThresholdClear trap is generated.

`low_thresh` is an integer value from 0 through 100. When configured to 0 the threshold is disabled.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

### Usage

Use this command to configure thresholds for the percentage of total DNS-learnt IP entries in relation to the ACS DNS Snooping feature. Note that this threshold applies to both IPv4 and IPv6 DNS entries.

Alerts or alarms are triggered based on the following rules:

- **Enter condition:** Actual percentage of total DNS-learnt IP entries is greater than or equal to the specified percentage of total DNS-learnt IP entries.
- **Clear condition:** Actual of total DNS-learnt IP entries is less than the specified clear percentage of total DNS-learnt IP entries.

If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval, and the `threshold monitoring` command to enable thresholding for this value.

### Example

The following command configures a high threshold of 65 percent and a clear threshold of 35 percent for total DNS-learnt IP entries:

```
threshold dns-learnt-ip-max-entries 65 clear 35
```
threshold dns-leart-t-ipv4-max-entries

Configures alarm or alert thresholds for the percentage of total DNS-leart-t IPv4 entries in relation to the ACS DNS Snooping feature.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold dns-leart-t-ipv4-max-entries high_thresh [ clear low_thresh ]

**high_thresh**

Specifies the high threshold for percentage of total DNS-leart-t IPv4 entries. When the percentage of total DNS-leart-t IPv4 entries meets or exceeds the high threshold at the end of the polling interval, an alert or alarm is generated.

When the percentage of total DNS-leart-t IPv4 entries meets or exceeds the high threshold, the ECSTotalDNSLeart-tIPv4Threshold trap is generated.

**high_thresh** is an integer value from 0 through 100. When configured to 0 the threshold is disabled.

Default: 90 percent

**clear low_thresh**

Specifies the low threshold for percentage of total DNS-leart-t IPv4 entries. When the percentage of total DNS-leart-t IPv4 entries goes below the low threshold within the polling interval, a clear alarm is generated.

When the percentage of total DNS-leart-t IPv4 entries goes below the low threshold, the ECSTotalDNSLeart-tIPv4ThresholdClear trap is generated.

**low_thresh** is an integer value from 0 through 100. When configured to 0 the threshold is disabled.

Default: 90 percent

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

**Usage**

Use this command to configure thresholds for the percentage of total DNS-leart-t IPv4 entries in relation to the ACS DNS Snooping feature.

Alerts or alarms are triggered based on the following rules:

- **Enter condition:** Actual percentage of total DNS-leart-t IPv4 entries is greater than or equal to the specified percentage of total DNS-leart-t IPv4 entries.
**Clear condition**: Actual percentage of total DNS-learnt IPv4 entries is less than the specified clear percentage of total DNS-learnt IPv4 entries.

If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval, and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold of 60 percent and a clear threshold of 30 percent for total DNS-learnt IPv4 entries:

```
threshold dns-learnt-ipv4-max-entries 60 clear 30
```
threshold dns-lookup-failure

Configures alarm or alert thresholds based on the percentage of total DNS lookup failures.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```configure
```
Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold dns-lookup-failure
```

**default**
Configures this command with the default threshold setting.
Default: 90 percent. It is the same for both high and low thresholds.

```
high_thresh
```

Default: 90 percent
Specifies the high threshold for percentage of total DNS lookup failures. When the percentage of total failures meets or exceeds the high threshold at the end of the polling interval, an alert or alarm is generated. `high_thresh` is an integer value from 0 through 100. When configured to 0 the threshold is disabled.

```
clear low_thresh
```

Default: 90 percent
Specifies the low threshold for percentage of total DNS lookup failures. When the percentage of total failures goes below the low threshold within the polling interval, a clear alarm is generated. `low_thresh` is an integer value from 0 through 100. When configured to 0 the threshold is disabled.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

**Usage**
Use this command to configure thresholds for the percentage of total DNS lookup failures. Note that this threshold applies to both IPv4 and IPv6 DNS entries.

Alerts or alarms are triggered based on the following rules:

- **Enter condition:** Actual percentage of total DNS lookup failures is greater than or equal to the specified percentage of total DNS lookup failures.
- **Clear condition**: Actual of total DNS lookup failures is less than the specified clear percentage of total DNS lookup failures.

If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval, and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold of 65 percent and a clear threshold of 35 percent for total DNS lookup failures:

```
threshold dns-lookup-failure 65 clear 35
```
threshold edr-file-space

Configures alarm or alert thresholds for monitoring the percentage of total file space allocated for Event Data Records (EDRs) used during the polling interval.

Product
ACS

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config)#

Syntax

[ default ] threshold edr-file-space high_thresh [ clear low_thresh ]

<table>
<thead>
<tr>
<th>high_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 90</td>
</tr>
<tr>
<td>Specifies the high threshold for percentage of total allocated EDR file space used that must be met or exceeded at the end of the polling interval to generate an alert or alarm.</td>
</tr>
<tr>
<td>high_thresh is measured in percentage of total allocated EDR file space used and is an integer from 0 through 100. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>clear low_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0</td>
</tr>
<tr>
<td>Specifies the low threshold for percentage of total allocated EDR file space used that maintains a previously generated alarm condition. If the space usage falls below the low threshold within the polling interval, a clear alarm is generated.</td>
</tr>
<tr>
<td>low_thresh is measured in percentage of total allocated EDR file space used and is an integer from 0 through 100. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

Usage
EDR file space usage generate alerts or alarms based on the percentage of total allocated EDR file space used during the polling interval. Alerts or alarms are triggered for EDR file space usage session based on the following rules:
- **Enter condition:** Actual percentage of allocated EDR file space usage is greater than or equal to the specified percentage of total EDR file space.
- **Clear condition:** Actual EDR file space used is less than the specified clear percentage of total allocated EDR file space usage.
If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold of 65 percent and a clear threshold of 35 percent for total allocated EDR file space usage:

```
threshold edr-file-space 65 clear 35
```
threshold edr-udr-dropped flow control

Configures alarm or alert thresholds to monitor the total number of Event Data Records (EDRs) and Usage Data Records (UDRs) discarded due to flow control.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold edr-udr-dropped-flow-control high_thresh [ clear low_thresh ]
default threshold edr-udr-dropped-flow-control
```

**default threshold edr-udr-dropped-flow-control**

```
default
   Configures this command with the default threshold settings.
   Default: High threshold: 90; Low threshold: 10
```

```
high_thresh
   Specifies the high threshold for total number of EDRs + UDRs dropped due to flow control, which must be
   met or exceeded within the polling interval to generate an alert or alarm.
   high_thresh must be an integer from 0 through 100000.
   A value of 0 disables the threshold.
   Default: 90
```

```
clear low_thresh
   Specifies the low threshold for total number of EDRs + UDRs dropped that maintains a previously generated
   alarm condition. If the total number of EDRs + UDRs dropped falls below low_thresh during
   the polling interval, a clear alarm is generated.
   low_thresh must be an integer from 0 through 100000 that must be lower than high_thresh.
   A value of 0 disables the threshold.
   Default: 10
```

**Usage**

Use this command to configure thresholds to monitor the total number of EDRs + UDRs discarded due to flow control. Alerts or alarms are generated based on the total number of EDRs + UDRs dropped during polling interval.

Alerts or alarms are triggered for EDR file space usage session based on the following rules:

---

Global Configuration Mode Commands (T-threshold phspc)
• **Enter condition:** Actual number of EDRs + UDRs dropped greater than or equal to the specified number of EDRs + UDRs dropped.

• **Clear condition:** Actual number of EDR + UDRs dropped is less than the specified clear number of EDRs + UDRs dropped.

If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold of 90 and a clear threshold of 45 to monitor EDRs + UDRs dropped due to flow control:

```
threshold edr-udr-dropped-flow-control 90 clear 45
```
threshold epdg-current-sessions

Configures alarm or alert thresholds for the number of subscribers currently in Evolved Packet Date Gateway (ePDG) sessions.

Product

ePDG

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config) #

Syntax

threshold epdg-current-sessions

default threshold epdg-current-sessions

default

Disables the threshold for configured alarm and sets the high_thresh and low_thresh values to 0.

high_thresh

Default: 0

Specifies the high threshold number of the total number of ePDG subscriber sessions that must be met or exceeded within the polling interval to generate an alert or alarm. high_thresh is an integer from 0 through 1000000.

clear low_thresh

Default: 0

Specifies the low threshold number of the total number of ePDG subscriber sessions that maintains a previously generated alarm condition. If the number of errors falls beneath the low threshold within the polling interval, a clear alarm will be generated. low_thresh is an integer from 0 through 1000000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Sets the upper and power thresholds for the total number of ePDG subscriber sessions that will generate and clear alerts or alarms. Alerts or alarms are triggered based on the following rules:
• **Enter condition:** Actual number of ePDG subscriber sessions is greater than or equal to the high threshold.

• **Clear condition:** Actual number of ePDG subscriber sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

**Example**

The following command configures sets the upper threshold of ePDG subscriber sessions at 100000 and the lower threshold at 90000:

```
threshold epdg-current-sessions 100000 clear 90000
```
threshold fng-current-active-sessions

Configures alarm or alert thresholds for the number of subscribers currently active Femto Network Gateway (FNG) sessions.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config) #

Syntax

threshold fng-current-active-sessions

default threshold fng-current-active-sessions

default
Disables the threshold for configured alarm and sets the high_thresh and low_thresh values to 0.

high_thresh
Default: 0
Specifies the high threshold number of the total number of active FNG subscriber sessions that must be met or exceeded within the polling interval to generate an alert or alarm.

low_thresh
Default: 0
Specifies the low threshold number of the total number of active FNG subscriber sessions that maintains a previously generated alarm condition. If the number of errors falls beneath the low threshold within the polling interval, a clear alarm will be generated.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Sets the upper and power thresholds for the total number of active FNG subscriber sessions that will generate and clear alerts or alarms.
Alerts or alarms are triggered based on the following rules:
- **Enter condition**: Actual number of active FNG subscriber sessions is greater than or equal to the high threshold.
- **Clear condition**: Actual number of active FNG subscriber sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

**Example**

The following command configures sets the upper threshold of active FNG subscriber sessions at 100000 and the lower threshold at 90000:

```
threshold fng-current-active-sessions 100000 clear 90000
```
threshold fng-current-sessions

Configures alarm or alert thresholds for the number of subscribers currently in Femto Network Gateway (FNG) sessions, including inactive sessions.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold fng-current-sessions

default threshold fng-current-sessions

default

Configures this command with the default threshold settings.
Default: High threshold: 90; Low threshold: 10

high_thresh

Default: 0
Specifies the high threshold number of the total number of FNG subscriber sessions that must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 1000000.

clear low_thresh

Default: 0
Specifies the low threshold number of the total number of FNG subscriber sessions that maintains a previously generated alarm condition. If the number of errors falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 through 1000000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Sets the upper and power thresholds for the total number of FNG subscriber sessions that will generate and clear alerts or alarms.
Alerts or alarms are triggered based on the following rules:
- **Enter condition**: Actual number of FNG subscriber sessions is greater than or equal to the high threshold.

- **Clear condition**: Actual number of FNG subscriber sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

**Example** The following command configures sets the upper threshold of FNG subscriber sessions at 200000 and the lower threshold at 190000:

```
threshold fng-current-sessions 200000 clear 190000
```
threshold fw-deny-rule

Configures alarm or alert thresholds for the Stateful Firewall Deny Rule.

**Product**
PSF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```configure
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold fw-deny-rule high_thresh [ clear low_thresh ]
```

**default threshold fw-deny-rule**

- `default`
  
  Configures this command with the default threshold settings.
  
  Default: 0—disabled
  
- `high_thresh`
  
  Specifies the Stateful Firewall Deny-Rule threshold value, which if met or exceeded generates an alert or alarm.
  
  `high_thresh` must be an integer from 0 through 1000000.
  
  Default: 0
  
- `clear low_thresh`
  
  Specifies the Stateful Firewall Deny-Rule alarm clear threshold value. If, in the same polling interval, the threshold falls below `low_thresh` a clear alarm is generated.
  
  `low_thresh` must be an integer from 0 through 1000000.
  
  Default: 0

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

**Usage**

When the number of Deny-Rule instances exceeds a given value, an alarm or alert is raised; it is cleared when the number of Deny-Rule instances falls below a value within the polling interval.

Refer to the `threshold poll` command to configure the polling interval, and the `threshold monitoring` command to enable thresholding for this value.

**Example**

```
```
The following command configures a Stateful Firewall Deny Rule high threshold of 1000 and a low threshold of 900 for a system using the Alarm Thresholding model:

```
threshold fw-deny-rule 1000 clear 900
```
threshold fw-dos-attack

Configures alarm or alert thresholds for Stateful Firewall Denial-of-Service (DoS) attacks.

Product
PSF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:
[local] host_name(config)#

Syntax

threshold fw-dos-attack high_thresh [ clear low_thresh ]

default threshold fw-dos-attack

default
Configures this command with the default threshold settings.
Default: 0—disabled

high_thresh
Specifies the Stateful Firewall DoS attacks threshold value, which if met or exceeded generates an alert or alarm.
high_thresh must be an integer from 0 through 1000000.
Default: 0

clear low_thresh
Specifies the Stateful Firewall DoS attacks clear threshold value. If, in the same polling interval, the threshold falls below low_thresh a clear alarm is generated.
low_thresh must be an integer from 0 through 1000000.
Default: 0

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

Usage

When the number of DoS attacks exceed a given value, a threshold is raised and it is cleared when the number of DoS attacks fall below a value within the polling interval.
Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

Example
The following command configures a Stateful Firewall DoS attacks high threshold of **1000** and a low threshold of **100** for a system using the Alarm Thresholding model:

```
threshold fw-dos-attack 1000 clear 100
```
threshold fw-drop-packet

Configures alarm or alert thresholds for Stateful Firewall dropped packets.

Product
PSF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

=localhost host_name(config) #

Syntax

threshold fw-drop-packet high_thresh [ clear low_thresh ]

default threshold fw-drop-packet

default
Configures this command with the default threshold settings.
Default: 0—disabled

high_thresh
Specifies the Stateful Firewall dropped packets threshold value, which if met or exceeded generates an alert or alarm.
high_thresh must be an integer from 0 through 1000000.
Default: 0

clear low_thresh
Specifies the Stateful Firewall dropped packets clear threshold value. If, in the same polling interval, the threshold falls below low_thresh a clear alarm is generated.
low_thresh must be an integer from 0 through 1000000.
Default: 0

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

Usage

When the number of dropped packets exceed a given value, a threshold is raised and it is cleared when the number of dropped packets fall below a value within the polling interval.
Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

Example

Command Line Interface Reference, StarOS Release 16

5532
The following command configures a Stateful Firewall dropped packets high threshold of 1000 and a low threshold of 900 for a system using the Alarm thresholding model:

```
threshold fw-drop-packet 1000 clear 900
```
threshold fw-no-rule

Configures alarm or alert thresholds for Stateful Firewall no rule occurrences.

Product
PSF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

Syntax

```
threshold fw-no-rule high_thresh [ clear low_thresh ]
default threshold fw-no-rule
```

**default**

Configures this command with the default threshold settings.
Default: 0—disabled

**high_thresh**

Specifies the Stateful Firewall no rules threshold value, which if met or exceeded generates an alert or alarm.
Default: 0

**clear low_thresh**

Specifies the Stateful Firewall no rules clear threshold value. If, in the same polling interval, the threshold falls below `low_thresh` a clear alarm is generated.
Default: 0

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

**Usage**

When the number of no rule occurrences exceeds a given value, a threshold is raised and it is cleared when the number of no rules fall below a value within the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**
The following command configures a Stateful Firewall no rule high threshold of 1000 and a low threshold of 900 for a system using the Alarm Thresholding model:

```
threshold fw-no-rule 1000 clear 900
```
threshold license remaining-sessions

Configures alarm or alert thresholds for the percentage of session license utilization by the system.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

[ no ] threshold license remaining-sessions low_thresh clear high_thresh

no low_thresh
Disables threshold session license utilization alerts or alarms.

remaining-sessions low_thresh
Default: 10
Specifies the low threshold session license utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm.
low_thresh is an integer from 0 through 100.

clear high_thresh
Default: 10
Specifies the high threshold session license utilization percentage that maintains a previously generated alarm condition. If the utilization percentage rises above the high threshold within the polling interval, a clear alarm will be generated.
high_thresh is an integer from 0 through 100.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to Specifies the low threshold.

Usage
Session license utilization thresholds generate alerts or alarms based on the utilization percentage of all session capacity licenses during the specified polling interval.
The system uses session capacity license to dictate the maximum number of simultaneous sessions that can be supported. There are multiple session types that require licenses. Although, a single threshold is configured for all session types, alerts or alarms can be generated for each type.
Alerts or alarms are triggered for session license utilization based on the following rules:
Global Configuration Mode Commands (T-threshold phspc)

threshold license remaining-sessions

- **Enter condition**: Actual session license utilization percentage per session type is greater than or equal to the low threshold.
- **Clear condition**: Actual session license utilization percentage per session type is greater than the high threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a session license low threshold percentage of 10 and a high threshold of 35 for a system using the Alarm thresholding model:

```
threshold license remaining-sessions 10 clear 35
```
threshold mgmt-cpu-memory-usage

Configures alarm or alert thresholds for the percentage of CPU memory usage on management cards.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold mgmt-cpu-memory-usage high_thresh [ clear low_thresh ]

**high_thresh**
Default: 0
Specifies the high threshold percent of CPU memory usage that must be met or exceeded within the polling interval to generate an alert or alarm.

*high_thresh* is measured in percentage of total memory used and can be configured to an integer from 0 through 100. A value of 0 disables the threshold.

**clear low_thresh**
Specifies the low threshold percent of CPU memory usage that maintains a previously generated alarm condition. If the percentage falls beneath the low threshold within the polling interval, a clear alarm will be generated.

*low_thresh* is measured in percentage of total memory used and can be configured to an integer from 0 through 100. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

CPU memory usage thresholds generate alerts or alarms based on memory usage for the SPC, SMC, or MIO CPU during the polling interval. A single threshold enables CPU monitoring for both the active and standby SPCs, SMCs, or MIOs allowing for alerts or alarms to be generated for each CPU.

Alerts or alarms are triggered for SPC, SMC, or MIO CPU memory usage based on the following rules:

- **Enter condition:** Actual CPU memory usage is greater than or equal to the high threshold

- **Clear condition:** Actual CPU memory usage is less than the low threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

**Important:** This command is not supported on all platforms.

**Example**

The following command configures a threshold of 65 percent of total SPC, SMC, or MIO CPU memory usage and a clear threshold of 35 percent:

```
threshold mgmt-cpu-memory-usage 65 clear 35
```
threshold mgmt-cpu-utilization

Configures alarm or alert thresholds for the percentage of CPU utilization on management cards.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

threshold mgmt-cpu-utilization high_thresh [ clear low_thresh ]

high_thresh
Default: 0
Specifies the high threshold CPU utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 100.

clear low_thresh
Specifies the low threshold CPU utilization percentage that maintains a previously generated alarm condition. If the utilization percentage falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 through 100.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

CPU utilization thresholds generate alerts or alarms based on the utilization percentage of each SPC, SMC, or MIO CPU during the specified polling interval. Although, a single threshold is configured for both SPC, SMC, or MIO CPUs, separate alerts or alarms can be generated for each CPU.
Alerts or alarms are triggered for SPC, SMC, or MIO CPU utilization based on the following rules:

• Enter condition: Average measured CPU utilization for the last 5 minutes is greater than or equal to the high threshold.
• Clear condition: Average measured CPU utilization for the last 5 minutes is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Important:** This command is not supported on all platforms.

**Example**

The following command configures a high threshold SPC, SMC, or MIO CPU utilization percentage of 90 for a system using the Alert thresholding model:

```
threshold mgmt-cpu-utilization 90
```
threshold mme-attach-failure

Configures alarm or alert thresholds for the total number of MME Attach Failure messages across all the MME services in the system.

Product
MME

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Syntax

threshold total-mme-attach-failure high_thresh [ clear low_thresh ]

high_thresh
Default: 0 (Disabled)
Specifies the high threshold number of total MME Attach Failure messages across all services on a system that must be met or exceeded within the polling interval to generate an alert or alarm.

low_thresh
Specifies the low threshold number of total MME Attach Failure messages across all services on a system that maintains a previously generated alarm condition. If the number of MME Attach Failure messages across all the services in a system, falls beneath the low threshold within the polling interval, a clear alarm will be generated.

Usage
Use this command to monitor and set alarms or alerts when the total number of MME Attach Failure message across all the MME services in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for the total number of MME Attach Failure message based on the following rules:

- **Enter condition**: Actual total number of MME Attach Failure messages is greater than or equal to the high threshold.
- **Clear condition**: Actual total number of MME Attach Failure messages is less than the low threshold.
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the `threshold poll mme-attach-failure` command to configure the polling interval and the `threshold monitoring mme-service` command to enable thresholding for this value.

**Example**

The following command configures the limit of MME Attach Failure high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold mme-attach-failure 10000
```
threshold mme-auth-failure

Configures alarm or alert thresholds for the total number of MME Auth Failure messages across all the MME services.

Product
MME

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold total-mme-auth-failure high_thresh [ clear low_thresh ]

<table>
<thead>
<tr>
<th>high_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0 (Disabled)</td>
</tr>
<tr>
<td>Specifies the high threshold number of total MME Auth Failure messages across all MMM services on a system that must be met or exceeded within the polling interval to generate an alert or alarm.</td>
</tr>
<tr>
<td>high_thresh can be configured to an integer from 0 through 100000. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>clear low_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0 (Disabled)</td>
</tr>
<tr>
<td>Specifies the low threshold number of total MME Auth Failure messages across all services on a system that maintains a previously generated alarm condition. If the number of MME Attach Failure messages across all the services in a system, falls beneath the low threshold within the polling interval, a clear alarm will be generated.</td>
</tr>
<tr>
<td>low_thresh is an integer from 0 through 100000. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to monitor and set alarms or alerts when the total number of MME Auth Failure message across all the MME services in the system is equal to or greater than the set limit.
Alerts or alarms are triggered for the total number of MME Auth Failure message based on the following rules:

- **Enter condition:** Actual total number of MME Auth Failure messages is greater than or equal to the high threshold.

- **Clear condition:** Actual total number of MME Auth Failure messages is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll mme-auth-failure` command to configure the polling interval and the `threshold monitoring mme-service` command to enable thresholding for this value.

**Example**

The following command configures a total MME Auth Failure high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold mme-auth-failure 10000
```
threshold model

Configures the thresholding model, alarm or alert, for the system to use.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```configure
```
Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```threshold model { alarm | alert }```

- **alarm**
  Selects the alarm thresholding model as described in the *Usage* section for this command.

- **alert**
  Selects the alert thresholding model as described in the *Usage* section for this command.

**Usage**

The system supports the following thresholding models:

- **Alert**: A value is monitored and an alert condition occurs when the value reaches or exceeds the configured high threshold within the specified polling interval. The alert is generated and/or sent at the end of the polling interval.

  In the example shown in the figure below, this model generates alerts during period 2, 3, and 5 at the point where the count exceeded the high threshold.

- **Alarm**: Both high and low threshold are defined for a value. An alarm condition occurs when the value reaches or exceeds the configured high threshold within the specified polling interval. The alert is generated and/or sent at the end of the polling interval.

  The alarm is cleared at the end of the first interval where the measured value is below the low threshold.

  In the example shown in the figure below, this model generates an alarm during period 2 when the count exceeds the high threshold. A second alarm is generated in period 6 when the count falls beneath low threshold. The second alarm indicates a “clear” condition.
**Important:** For certain values the alert or alarm serves to warn of low quantities (such as, memory, session licenses, etc.). In these cases, the low threshold is the condition that must be met or exceeded within the polling interval to generate the alert or alarm. When the high threshold is exceeded during an interval, the low quantity condition is cleared.

Refer to the `threshold monitoring` command for additional information on thresholding.

**Example**

The following command configures the system to support the Alarm thresholding model:

```
threshold model alarm
```
threshold monitoring

Enables threshold monitoring for the selected value.

**Product**
All

**Privilege**
Administrator

**Mode**
Exec > Global Configuration

**Syntax**

```
```

**no**
Disables threshold monitoring for the specified value.

**default**
Sets or restores the default value assigned to the specified parameter.

**aaa-acct-archive-queue**
Enables threshold monitoring for the AAA accounting archive message queue size. Refer to the `threshold aaa-acct-archive-queue-size` command for additional information on these values.

**aaa-acct-archive-size**
Enables threshold monitoring for the size of the AAA accounting record archive.

**aaa-acct-failure**
Enables threshold monitoring for AAA accounting failures and AAA accounting failure rate values. Refer to the `threshold aaa-acct-failure` and `threshold aaa-acct-failure-rate` commands for additional information on these values.

**aaa-auth-failure**
Enables threshold monitoring for AAA authentication failures and AAA authentication failure rate values.
Refer to the `threshold aaa-auth-failure` and `threshold aaa-auth-failure-rate` commands for additional information on these values.

**aaa-retry-rate**

Enables threshold monitoring for the AAA retry rate value.
Refer to the `threshold aaa-retry-rate` command for additional information on this value.

**aaamgr-request-queue**

Enables threshold monitoring for AAA Manager Requests for each AAA manager process. Refer to the `threshold aaamgr-request-queue` command for additional information on these values.

**asngw**

Enables the threshold monitoring for ASN-GW services.

**call-setup**

Enables threshold monitoring for the call setup, call setup failures, and no-resource rejected call values.
Refer to the `threshold call-setup`, `threshold call-setup-failure`, `threshold ppp-setup-fail-rate`, `threshold rp-setup-fail-rate`, and `threshold call-reject-no-resource` commands for additional information on these values.

**cpu-resource**

Enables threshold monitoring for CPU thresholds.

**cpu-session-throughput**

Enables threshold monitoring for the CPU session throughput value.
Refer to the `threshold cpu-session-throughput` command for additional information on this value.

**content-filtering**

Enables threshold monitoring for the Content Filtering in-line service.

**diameter**

Enables threshold monitoring for Diameter.

**ecs**

Enables threshold monitoring for the Active Charging Service (ACS)/Enhanced Charging Service (ECS).

**epdg-service**

Enables threshold monitoring for Evolved Packet Data Gateway (ePDG) service.
Refer to the `threshold epdg-current-sessions` command for additional information on this value.
<table>

</tbody>
</table>
**saegw-service**
Enables threshold monitoring for SAEGW services.
Refer to the `threshold total-saegw-sessions` for more information on SAEGW thresholds.

**sess-flow-count**
Enables threshold monitoring for Session Flow Count.
Default: 90%
Refer to the `threshold sess-flow-count` for more information on Session Flow Count Thresholds

**sgw-service**
Enables threshold monitoring for S-GW services.
Refer to the `threshold total-sgw-sessions` for more information on S-GW thresholds.

**subscriber**
Enables threshold monitoring for the subscriber and session values.
Refer to the `threshold subscriber active`, `threshold subscriber total`, `threshold total-ggsn-sessions`, `threshold total-gprs-sessions`, `threshold total-gprs-pdp-sessions`, `threshold total-ha-sessions`, `threshold total-lns-sessions`, `threshold total-pdsn-sessions`, `threshold total-pgw-sessions`, `threshold total-sgw-sessions`, `threshold total-saegw-sessions`, `threshold total-sgsn-sessions`, `threshold total-sgsn-pdp-sessions`, `threshold per-service-ggsn-sessions`, `threshold per-service-ha-sessions`, `threshold per-service-lns-sessions`, and `threshold per-service-pdsn-sessions` commands for additional information on these values.

**system**
Enables system (chassis) thresholds monitoring.

**tpo**

**Important:** The Traffic Performance Optimization (TPO) in-line service is not supported in this release.

**Usage**
Thresholding on the system is used to monitor the system for conditions that could potentially cause errors or outage. Typically, these conditions are temporary (i.e., high CPU utilization, or packet collisions on a network) and are quickly resolved. However, continuous or large numbers of these error conditions within a specific time interval may be indicative of larger, more severe issues. The purpose of thresholding is to help identify potentially severe conditions so that immediate action can be taken to minimize and/or avoid system downtime.

Thresholding reports conditions using one of the following mechanisms:

- **SNMP traps:** SNMP traps have been created that indicate the condition (high threshold crossing and/or clear) of each of the monitored values. Complete descriptions and other information pertaining to these traps is located in the starentMIB(8164).starentTraps(2) section of the SNMP MIB Reference.

The generation of specific traps can be enabled or disabled on the system allowing you to view only those traps that are most important to you.
• **Logs**: The system provides a facility called threshold for which active and event logs can be generated. As with other system facilities, logs are generated. Log messages pertaining to the condition of a monitored value are generated with a severity level of WARNING.

• **Alarm System**: High threshold alarms generated within the specified polling interval are considered “outstanding” until a condition no longer exists and/or a condition clear alarm is generated. “Outstanding” alarms are reported through the system’s alarm subsystem and are viewable through the CLI.

The following table indicates the reporting mechanisms supported by each of the above models.

**Table 30. ASR 5000 Thresholding Reporting Mechanisms by Model**

In addition to the values that can be enabled by this command, the system supports the enabling of threshold monitoring for IP pool address availability (refer to the `ip pool` and `threshold` commands in this reference) and port utilization (refer to the `threshold` commands in this chapter).

**Example**

The following command enables thresholding for subscriber totals:

```
threshold monitoring subscriber
```
threshold nat-port-chunks-usage

Configures alarm or alert thresholds for the percentage of Network Address Translation (NAT) port chunk utilization.

**Important:** This command is only available in 8.3 and later releases.

**Product**
NAT

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`
Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold nat-port-chunks-usage high_thresh [ clear low_thresh ]

default threshold nat-port-chunks-usage
```

**default**

Configures this command with the default threshold settings.
Default: 0—disabled

**high_thresh**

Specifies the high NAT-port-chunks-usage percentage threshold that must be met or exceeded within the polling interval to generate an alert or alarm.

*high_thresh* must be an integer from 0 through 100. A value of 0 disables the threshold.
Default: 0

**clear low_thresh**

Specifies the low nat-port-chunks-usage percentage threshold that must be met within the polling interval for a clear alarm to be generated.

*low_thresh* must be an integer from 0 through 100. A value of 0 disables the threshold. If not set, the
*high_thresh* will be the high and low threshold setting.
Default: 0

**Usage**

Use this command to configure the NAT port chunk utilization threshold settings.

**Example**

The following command sets the NAT port chunk utilization threshold settings to a high of 75% and a low of 15%:
threshold nat-port-chunks-usage 75 clear 15
threshold npu-utilization

Configures alarm or alert thresholds for the percentage of network processing unit (NPU) utilization.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```bash
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold npu-utilization high_thresh clear low_thresh
```

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Configures this command with the default threshold settings. Default: 0—disabled</td>
</tr>
<tr>
<td>high_thresh</td>
<td>Specifies the high percentage threshold for NPU utilization that must be met or exceeded within the polling interval to generate an alert or alarm. <code>high_thresh</code> must be an integer from 0 through 100. A value of 0 disables the threshold. Default: 0</td>
</tr>
<tr>
<td>clear low_thresh</td>
<td>Specifies the low percentage threshold for NPU utilization that must be met within the polling interval for a clear alarm to be generated. <code>low_thresh</code> must be an integer from 0 through 100. A value of 0 disables the threshold. If not set, the <code>high_thresh</code> will be the high and low threshold setting. Default: 0</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to configure the NPU utilization threshold settings.

**Example**

The following command sets the NPU utilization threshold settings to a high of 90% and a low of 75%:

```
threshold npu-utilization 90 clear 75
```
**threshold packets-filtered-dropped**

Configures alarm or alert thresholds for filtered or dropped packets within the system.

**Product**
- PDSN
- GGSN
- HA
- P-GW
- SAEGW
- SGSN
- ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**

```
threshold packets-filtered-dropped high_thresh [ clear low_thresh ]
```

- **high_thresh**
  
  Default: 0
  Specifies the high threshold number of filtered/dropped packets experienced by the system resulting from access control list (ACL) rules that must be met or exceeded within the polling interval to generate an alert or alarm.
  
  *high_thresh* is an integer from 0 through 1000000000. A value of 0 disables the threshold.

- **clear low_thresh**
  
  Default: 0
  Specifies the low threshold number of filtered/dropped packets experienced by the system resulting from ACL rules that maintains a previously generated alarm condition. If the number of packets falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  
  *low_thresh* is an integer from 0 through 1000000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.
Usage
Filtered/dropped packet thresholds generate alerts or alarms based on the total number of packets that were filtered or dropped by the system as a result of ACL rules during the specified polling interval. Alerts or alarms are triggered for filtered/dropped packets based on the following rules:

- **Enter condition:** Actual number of filtered/dropped packets is greater than or equal to the high threshold.
- **Clear condition:** Actual number of filtered/dropped packets is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value. In addition, refer to information on ACLs in this reference.

Example
The following command configures a filtered/dropped packet high threshold count of 150000 for a system using the Alert thresholding model:

```
threshold packets-filtered-dropped 150000
```
threshold packets-forwarded-to-cpu

Configures alarm or alert thresholds for packets forwarded to active system CPUs in the system.

**Product**

- PDSN
- GGSN
- HA
- P-GW
- SAEGW
- SGSN
- ASN-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

**Syntax**

```
threshold packets-forwarded-to-cpu high_thresh [ clear low_thresh ]
```

- **high_thresh**
  
  Default: 0
  
  Specifies the high threshold number of packets forwarded to CPUs that must be met or exceeded within the polling interval to generate an alert or alarm.
  
  `high_thresh` is an integer from 0 through 1000000000. A value of 0 disables the threshold.

- **clear low_thresh**
  
  Default: 0
  
  Specifies the low threshold number of packets forwarded to CPUs that maintains a previously generated alarm condition. If the number of packets falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  
  `low_thresh` is an integer from 0 through 1000000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.
**Usage**

Forwarded packet thresholds generate alerts or alarms based on the total number of packets that were forwarded to active system CPU(s) during the specified polling interval. Packets are forwarded to active system CPUs when the NPUs do not have adequate information to properly route them.

**Important:** Ping and/or traceroute packets are intentionally forwarded to system CPUs for processing. These packet types are included in the packet count for this threshold.

Alerts or alarms are triggered for forwarded packets based on the following rules:

- **Enter condition:** Actual number of forwarded packets is greater than or equal to the high threshold
- **Clear condition:** Actual number of forwarded packets is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a forwarded packet high threshold count of 100000 for a system using the Alert thresholding model:

```
threshold packets-forwarded-to-cpu 100000
```
threshold pdg-current-active-sessions

Configures alarm or alert thresholds for monitoring the total number of currently active Packet Data Gateway/Tunnel Termination Gateway (PDG/TTG) sessions.

**Product**

PDG/TTG

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

**Syntax**

```
threshold pdg-current-active-sessions high_thresh [ clear low_thresh ]
```

- **high_thresh**
  
  Configures the total number of active PDG sessions to be monitored on a chassis. `high_thresh` is an integer from 0 through 1000000. There is no default, but 0 means that there is no threshold monitoring.

- **clear low_thresh**
  
  Clears the number of sessions being monitored using the `high_thresh` variable defined above. `low_thresh` is an integer from 0 through 1000000.

**Usage**

Thresholds are provided for monitoring the overall PDG usage on a chassis. This command is used to monitor the total number of active PDG sessions for an entire chassis.

**Example**

The following command configures a monitoring threshold of 300000 and a clearing threshold of 100000 active PDG sessions on a chassis:

```
threshold pdg-current-active-sessions 300000 clear 100000
```
threshold pdg-current-sessions

Configures alarm or alert thresholds for monitoring the total number of current Packet Data Gateway/Tunnel Termination Gateway (PDG/TTG) sessions, including inactive sessions.

Product
PDG/TTG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold pdg-current-sessions high_thresh [ clear low_thresh ]

high_thresh

Configures the total number of PDG sessions on a chassis, both active and inactive. high_thresh is any integer from 0 through 1000000. There is no default, but 0 means that there is no threshold monitoring.

clear low_thresh

Clears any number of sessions being monitored using the high_thresh variable defined above. low_thresh is any integer from 0 through 1000000.

Usage

Thresholds are provided for monitoring the overall PDG usage on a chassis. This command is used to monitor the total number of PDG sessions, both active and inactive, for an entire chassis.

Example

The following command configures a monitoring threshold of 300000 and a clearing threshold of 100000 active and inactive PDG sessions on a chassis:

threshold pdg-current-sessions 300000 clear 100000
threshold pdif-current-active-sessions

Configures alarm or alert thresholds for monitoring the total number of currently active Packet Data Interworking Function (PDIF) sessions.

Product
PDIF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold pdif-current-active sessions high_thresh [ clear low_thres ]

high_thresh
Configures the total number of active PDIF sessions to be monitored on a chassis. high_thresh is any integer from 0 through 100000. There is no default, but 0 means that there is no threshold monitoring.

clear low_thresh
Clears the specified number of sessions being monitored using the high_thresh variable defined above. low_thresh is any integer from 0 through 100000.

Usage

Thresholds are provided for monitoring the overall PDIF usage on a chassis. This command is used to monitor the total number of active PDIF sessions for an entire chassis.

Example

The following command configures a monitoring threshold of 300000 and a clearing threshold of 100000 active PDIF sessions on a chassis:

    threshold pdif-current-active-sessions 300000 clear 100000
threshold pdif-current-sessions

Configures alarm or alert thresholds for monitoring the total number of current Packet Data Interworking Function (PDIF) sessions, including inactive sessions.

Product
PDIF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold pdif-current-sessions high_thresh [ clear low_thresh ]

high_thresh

Configures the total number of PDIF sessions on a chassis, both active and inactive. high_thresh is an integer from 0 through 1000000.
There is no default, but 0 means that there is no threshold monitoring.

clear low_thresh

Clears the specified number of sessions being monitored using the high_thresh variable defined above. low_thresh is an integer from 0 through 1000000.

Usage

Thresholds are provided for monitoring the overall PDIF usage on a chassis. This command is used to monitor the total number of PDIF sessions, both active and inactive, for an entire chassis.

Example

The following command configures a monitoring threshold of 300000 and a clearing threshold of 100000 active and inactive PDIF sessions on a chassis:

threshold pdif-current-sessions 300000 clear 100000
**threshold per-service-asngw-sessions**

Configures alarm or alert thresholds for the number of sessions per ASN-GW service in the system.

**Product**

ASN-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold per-service-asngw-sessions high_thresh [ clear low_thresh ]
```

- **`high_thresh`**
  - Default: 0
  - Specifies the high threshold number of PDP contexts for any one ASN-GW service that must be met or exceeded within the polling interval to generate an alert or alarm.
  - `high_thresh` is an integer from 0 through 2500000. A value of 0 disables the threshold.

- **`clear low_thresh`**
  - Default: 0
  - Specifies the low threshold number of PDP contexts for any one ASN-GW service that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - `low_thresh` is an integer from 0 through 2500000. A value of 0 disables the threshold.

---

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Monitor and set alarms or alerts when the number of PDP contexts for any ASN-GW service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for PDP contexts based on the following rules:

- **Enter condition:** Actual number of PDP contexts for any ASN-GW service is greater than or equal to the high threshold

- **Clear condition:** Actual number of PDP contexts is less than the low threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.
Example

The following command configures a high threshold count of 10000 subscriber attaches per GGSN service for the Alert thresholding model:

```
threshold per-service-asngw-sessions 10000
```
threshold per-service-ggsn-sessions

Configures alarm or alert thresholds for the number of PDP contexts per GGSN service in the system.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold per-service-ggsn-sessions high_thresh [ clear low_thresh ]
```

**high_thresh**
Default: 0
Specifies the high threshold number of PDP contexts for any one GGSN service that must be met or exceeded within the polling interval to generate an alert or alarm.

**clear low_thresh**
Default: 0
Specifies the low threshold number of PDP contexts for any one GGSN service that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Monitor and set alarms or alerts when the number of PDP contexts for any GGSN service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for PDP contexts based on the following rules:

- **Enter condition:** Actual number of PDP contexts for any GGSN service is greater than or equal to the high threshold
- **Clear condition:** Actual number of PDP contexts is less than the low threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.
Example

The following command configures a high threshold count of 10000 subscriber attaches per GGSN service for the Alert thresholding model:

```
threshold per-service-ggsn-sessions 10000
```
threshold per-service-gprs-pdp-sessions

Configures alarm or alert thresholds for the number of 2G-activated PDP contexts per GPRS service.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold per-service-gprs-pdp-sessions high_thresh [ clear low_thresh ]

high_thresh
Default: 0
Specifies the high threshold number of 2G-activated PDP contexts for any one GPRS service. This number must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 4000000. A value of 0 disables the threshold.

clear low_thresh
Default: 0
Specifies the low threshold number of 2G-activated PDP contexts for any one GPRS service. This number or higher maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, then a clear alarm will be generated.
low_thresh is an integer from 0 through 4000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
Monitor and set alarms or alerts when the number of 2G-activated PDP contexts for any GPRS service in the system is equal to or greater than the set limit.
Alerts or alarms are triggered for PDP contexts based on the following rules:

Enter condition: Actual number of PDP contexts for any GPRS service is greater than or equal to the high threshold.

Clear condition: Actual number of PDP contexts is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.
Example

The following command configures a high threshold count of 10000 2G-activated PDP contexts per GPRS service for the Alert thresholding model:

```
threshold per-service-gprs-sessions 10000
```
threshold per-service-gprs-sessions

Configures alarm or alert thresholds for the number of 2G-attached subscribers per GPRS service.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
threshold per-service-gprs-sessions high_thresh [ clear low_thresh ]
```

**high_thresh**

Default: 0
Specifies the high threshold number of 2G-attached subscribers for any one GPRS service. This threshold number must be met or exceeded within the polling interval to generate an alert or alarm. **high_threshold** is an integer from 0 through 2000000. A value of 0 disables the threshold.

**clear low_thresh**

Default: 0
Specifies the low threshold number of 2G-attached subscribers for any one GPRS service. The number of subscribers must remain above this threshold in order to maintain a previously generated alarm condition. If the number of 2G subscribers falls beneath the low threshold within the polling interval, then a clear alarm will be generated. **low_threshold** is an integer from 0 through 2000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the number of 2G-attached subscribers for any GPRS service in the system is equal to or greater than the set limit. Alerts or alarms are triggered for PDP contexts based on the following rules:

- **Enter condition:** Actual number of 2G-attached subscribers for any GPRS service is greater than or equal to the high threshold.
- **Clear condition:** Actual number of 2G-attached subscribers is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 10000 2G-attaches per GPRS service for the Alert thresholding model:

```
threshold per-service-gprs-sessions 10000
```
threshold per-service-ha-sessions

Configures alarm or alert thresholds for the number of HA sessions per Home Agent (HA) service in the system.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
threshold per-service-ha-sessions high_thresh [ clear low_thresh ]
```

- **high_thresh**
  
  Default: 0
  Specifies the high threshold number of HA sessions for any one HA service that must be met or exceeded within the polling interval to generate an alert or alarm.
  `high_thresh` is an integer from 0 through 4000000. A value of 0 disables the threshold.

- **clear low_thresh**
  
  Default: 0
  Specifies the low threshold number of HA sessions for any one HA service that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  `low_thresh` is an integer from 0 through 4000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Monitor and set alarms or alerts when the number of HA sessions for any HA service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for HA sessions based on the following rules:

- **Enter condition:** Actual number of HA sessions for any HA service is greater than or equal to the high threshold.

- **Clear condition:** Actual number of HA sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.
Example

The following command configures a HA session per service high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold per-service-ha-sessions 10000
```
threshold per-service-lns-sessions

Configures alarm or alert thresholds for the number of L2TP Network Server (LNS) sessions per LNS service in the system.

**Product**
- PDSN
- GGSN
- HA
- ASN-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration  
  `configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold per-service-lns-sessions high_thresh [ clear low_thresh ]
```

- **high_thresh**
  - Default: 0
  - Specifies the high threshold number of LNS sessions for any one LNS service that must be met or exceeded within the polling interval to generate an alert or alarm.
  - `high_thresh` is an integer from 0 through 2500000. A value of 0 disables the threshold.

- **clear low_thresh**
  - Default: 0
  - Specifies the low threshold number of LNS sessions for any one LNS service that maintains a previously generated alarm condition. If the number of LNS sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - `low_thresh` is an integer from 0 through 2500000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Monitor and set alarms or alerts when the number of LNS sessions for any LNS service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for LNS sessions based on the following rules:

- **Enter condition:** Actual number of LNS sessions for any LNS service is greater than or equal to the high threshold.
• **Clear condition:** Actual number of LNS sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a LNS session per service high threshold count of 10000 for a system using the Alert thresholding model:

```bash
threshold per-service-Ins-sessions 10000
```
threshold per-service-pdg-sessions

Configures alarm or alert thresholds for the number of Packet Data Gateway (PDG) sessions per PDG service in the system.

Product
PDG/TTG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold per-service-pdg-sessions high_thresh [ clear low_thresh ]

---

**high_thresh**

Default: 0

Specifies the high threshold number of PDG sessions for any one PDG service that must be met or exceeded within the polling interval to generate an alert or alarm.

*high_thresh* is an integer from 0 through 1000000. A value of 0 disables the threshold.

---

**clear low_thresh**

Default: 0

Specifies the low threshold number of PDG sessions for any one PDG service that maintains a previously generated alarm condition. If the number of PDG sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

*low_thresh* is an integer from 0 through 1000000. A value of 0 disables the threshold.

---

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

---

Usage

Monitor and set alarms or alerts when the number of PDG sessions for any PDG service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for PDSN sessions based on the following rules:

- **Enter condition:** Actual number of PDG sessions for any PDG service is greater than or equal to the high threshold.

- **Clear condition:** Actual number of PDSN sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a PDG session per service high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold per-service-pdg-sessions 10000
```
threshold per-service-samog-sessions

Configures alarm or alert thresholds for the number of S2a Mobility over GTP (SaMOG) sessions per SaMOG service in the system.

**Product**
SaMOG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold per-service-samog-sessions high_thresh [ clear low_thresh ]
```

- `high_thresh`
  - Default: 0
  - Specifies the high threshold number of SaMOG sessions for any one SaMOG service that must be met or exceeded within the polling interval to generate an alert or alarm.
  - `high_thresh` is an integer from 0 through 4,000,000. A value of 0 disables the threshold.

- `clear low_thresh`
  - Default: 0
  - Specifies the low threshold number of SaMOG sessions for any one SaMOG service that maintains a previously generated alarm condition. If the number of SaMOG sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - `low_thresh` is an integer from 0 through 4,000,000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Monitor and set alarms or alerts when the number of SaMOG sessions for any SaMOG service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for SaMOG sessions based on the following rules:

- **Enter condition:** Actual number of SaMOG sessions for any SaMOG service is greater than or equal to the high threshold.

- **Clear condition:** Actual number of SaMOG sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval for this value.
Example

The following command configures a SaMOG session per service high threshold count of 15000 for a system using the Alert thresholding model:

```
threshold per-service-samog-sessions 15000
```
threshold per-service-pdsn-sessions

Configures alarm or alert thresholds for the number of Packet Data Serving Node (PDSN) sessions per PDSN service in the system.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold per-service-pdsn-sessions high_thresh [ clear low_thres ]
```

**high_thresh**
Default: 0
Specifies the high threshold number of PDSN sessions for any one PDSN service that must be met or exceeded within the polling interval to generate an alert or alarm.

**clear low_thres**
Default: 0
Specifies the low threshold number of PDSN sessions for any one PDSN service that maintains a previously generated alarm condition. If the number of PDSN sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**
Monitor and set alarms or alerts when the number of PDSN sessions for any PDSN service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for PDSN sessions based on the following rules:

- **Enter condition:** Actual number of PDSN sessions for any PDSN service is greater than or equal to the high threshold.
- **Clear condition:** Actual number of PDSN sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a PDSN session per service high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold per-service-pdsn-sessions 10000
```
threshold per-service-sgsn-pdp-sessions

Configures alarm or alert thresholds for the number of 3G-activated PDP contexts per SGSN service on the system.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**
```
threshold per-service-sgsn-pdp-sessions high_thresh [ clear low_thresh ]
```

- `high_thresh`
Default: 0
Specifies the high threshold number of 3G-activated PDP contexts for any one SGSN service. This number must be met or exceeded within the polling interval to generate an alert or alarm.

- `low_thresh`
Default: 0
Specifies the low threshold number of 3G-activated PDP contexts for any one SGSN service. This number or higher maintains a previously generated alarm condition. If the number of 3G-activated PDP contexts falls beneath the low threshold within the polling interval, a clear alarm will be generated.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**
Monitor and set alarms or alerts when the number of 3G-activated PDP contexts for any SGSN service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for PDP contexts based on the following rules:

- **Enter condition:** Actual number of 3G-activated PDP contexts for any SGSN service is greater than or equal to the high threshold.

- **Clear condition:** Actual number of 3G-activated PDP contexts is less than the low threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.
Example

The following command configures a high threshold count of 10000 3G-activated PDP contexts per SGSN service for the system’s Alert thresholding model:

```
threshold per-service-sgsn-sessions 10000
```
threshold per-service-sgsn-sessions

Configures alarm or alert thresholds for the number of 3G-attached subscribers per SGSN service in the system.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold per-service-sgsn-sessions high_thresh [ clear low_thresh ]

| high_thresh
| Default: 0
| Specifies the high threshold number of 3G-attached subscribers for any one SGSN service. This number must be met or exceeded within the polling interval to generate an alert or alarm.
| high_thresh is an integer from 0 through 2000000. A value of 0 disables the threshold.

| clear low_thresh
| Default: 0
| Specifies the low threshold number of 3G-attached subscribers for any one SGSN service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.
| low_thresh is an integer from 0 through 2000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the number of 3G-attached subscribers for any one SGSN service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for PDP contexts based on the following rules:

- **Enter condition:** Actual number of 3G-attached subscribers for any single SGSN service is greater than or equal to the high threshold.
- **Clear condition:** Actual number of 3G-attached subscribers for any single SGSN service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a high threshold count of 10000 3G-attached subscribers per SGSN service for a system using the Alert thresholding model:

```
threshold per-service-sgsn-sessions 10000
```
**threshold phsgw-auth-failure**

Configures alarm or alert thresholds for the number of authentication failures in Personal Handyphone Service Gateway (PHSGW) service.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold phsgw-auth-failure high_thresh [ clear low_thresh ]
```

**high_thresh**

Default: 0

Specifies the high threshold number for PHSGW authentication failures in any one PHSGW service. This number must be met or exceeded within the polling interval to generate an alert or alarm.

```
high_thresh
```

**clear low_thresh**

Default: 0

Specifies the low threshold number of PHSGW authentication failures in any one PHSGW service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.

```
low_thresh
```

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Set the monitoring and clearing thresholds for PHSGW authentication failures. Alerts or alarms are triggered for authentication failures based on the following rules:

- **Enter condition:** Actual number of PHSGW authentication failures in any one PHSGW service is greater than or equal to the high threshold.

- **Clear condition:** Actual number of PHSGW authentication failures in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

Example

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSGW authentication failures:

```
threshold phsgw-auth-failure 100000 clear 50000
```
threshold phsgw-eapol-auth-failure

Configures alarm or alert thresholds for authentication failures for a PHSGW service using Extensible Authentication Protocol Over LAN (EAPOL).

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]hostname(config)#

**Syntax**

```
threshold phsgw-eapol-auth-failure high_thresh [ clear low_thresh ]
```

- **high_thresh**
  Default: 0
  Specifies the high threshold number for PHSGW EAPOL failures in any one PHSGW service. This number must be met or exceeded within the polling interval to generate an alert or alarm.
  `high_thresh` is an integer from 0 through 1000000. A value of 0 disables the threshold.

- **clear low_thresh**
  Default: 0
  Specifies the low threshold number of PHSGW EAPOL failures in any one PHSGW service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  `low_thresh` is an integer from 0 through 1000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Set the monitoring and clearing thresholds for PHSGW EAPOL failures.
Alerts or alarms are triggered for EAPOL failures based on the following rules:

- **Enter condition:** Actual number of PHSGW EAPOL failures in any one PHSGW service is greater than or equal to the high threshold.

- **Clear condition:** Actual number of PHSGW EAPOL failures in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSGW EAPOL failures:

```
threshold phsgw-eapol-auth-failure 100000 clear 50000
```
threshold phsgw-handoff-denial

Configures alarm or alert thresholds for handoff denials in PHSGW.

Product
PHSGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config) #

Syntax

threshold phsgw-handoff-denial high_thresh  [ clear low_thresh ]

high_thresh
Default: 0
Specifies the high threshold number of handoff denials for any one PHSGW service. This number must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 1000000. A value of 0 disables the threshold.

clear low_thresh
Default: 0
Specifies the low threshold number of handoff denials for any one PHSGW service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 through 1000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Set the monitoring and clearing thresholds for PHSGW handoff denials.
Alerts or alarms are triggered for handoff denials based on the following rules:

• Enter condition: Actual number of PHSGW handoff denials in any one PHSGW service is greater than or equal to the high threshold.

• Clear condition: Actual number of PHSGW handoff denials in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.
Example

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSGW handoff denials:

```
threshold phsgw-handoff-denial 100000 clear 50000
```
threshold phsgw-max-eap-retry

Configures alarm or alert thresholds for the maximum number of Extensible Authentication Protocol (EAP) retries in PHSGW.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
threshold phsgw-max-eap-retry high_thresh [ clear low_thresh ]
```

- **high_thresh**
  
  Default: 0
  
  Specifies the high threshold number of EAP retries for any one PHSGW service. This number must be met or exceeded within the polling interval to generate an alert or alarm.

  high_thresh is an integer from 0 through 1000000. A value of 0 disables the threshold.

- **clear low_thresh**

  Default: 0
  
  Specifies the low threshold number of EAP retries for any one PHSGW service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.

  low_thresh is an integer from 0 through 1000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Set the monitoring and clearing thresholds for PHSGW EAP retries.

Alerts or alarms are triggered for handoff denials based on the following rules:

- **Enter condition:** Actual number of PHSGW EAP retries in any one PHSGW service is greater than or equal to the high threshold.

- **Clear condition:** Actual number of PHSGW EAP retries in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSGW EAP retries:

```
threshold phsgw-max-eap-retry 100000 clear 50000
```
threshold phsgw-max-eapol-retry

Configures alarm or alert thresholds for the maximum number of Extensible Authentication Protocol over LAN (EAPOL) retries in PHSGW.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold phsgw-max-eapol-retry high_thresh [ clear low_thresh ]
```

**high_thresh**
Default: 0
Specifies the high threshold number of EAPOL retries for any one PHSGW service. This number must be met or exceeded within the polling interval to generate an alert or alarm. 
`high_thresh` is an integer from 0 through 1000000. A value of 0 disables the threshold.

**clear low_thresh**
Default: 0
Specifies the low threshold number of EAPOL retries for any one PHSGW service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.

`low_thresh` is an integer from 0 through 1000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**
Set the monitoring and clearing thresholds for PHSGW EAPOL retries.
Alerts or alarms are triggered for handoff denials based on the following rules:

- **Enter condition:** Actual number of PHSGW EAPOL retries in any one PHSGW service is greater than or equal to the high threshold.
  - **Clear condition:** Actual number of PHSGW EAPOL retries in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSGW EAPOL retries:

```
threshold phsgw-max-eapol-retry 100000 clear 50000
```
threshold phsgw-network-entry-denial

Configures, alarm or alert thresholds for the number of network entry denials in PHSGW.

Product
PHSGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold phsgw-max-network-entry-denial high_thresh  [ clear low_thresh ]

high_thresh
Default: 0
Specifies the high threshold number of network entry denials for any one PHSGW service. This number must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 1000000. A value of 0 disables the threshold.

clear low_thresh
Default: 0
Specifies the low threshold number of network entry denials for any one PHSGW service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 through 1000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Set the monitoring and clearing thresholds for PHSGW network entry denials. Alerts or alarms are triggered for handoff denials based on the following rules:

• Enter condition: Actual number of PHSGW network entry denials in any one PHSGW service is greater than or equal to the high threshold.

• Clear condition: Actual number of PHSGW network entry denials in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.
Example

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSGW network entry denials:

\[
\text{threshold phsgw-network-entry-denial 100000 clear 50000}
\]
threshold phsgw-session-setup-timeout

Configures alarm or alert thresholds for the number of PHSGW sessions that timed out during setup.

Product
PHSGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold phsgw-session-setup-timeout high_thresh [ clear low_thresh ]

high_thresh
Default: 0
Specifies the high threshold number of session setup timeouts for any one PHSGW service. This number must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 1000000. A value of 0 disables the threshold.

clear low_thresh
Default: 0
Specifies the low threshold number of session setup timeouts for any one PHSGW service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 through 1000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Set the monitoring and clearing thresholds for PHSGW session setup timeouts.
Alerts or alarms are triggered for handoff denials based on the following rules:

- Enter condition: Actual number of PHSGW session setup timeouts in any one PHSGW service is greater than or equal to the high threshold.
- Clear condition: Actual number of PHSGW session setup timeouts in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.
Example

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSGW session setup timeouts:

```
threshold phsgw-session-setup-timeout 100000 clear 50000
```
threshold phsgw-session-timeout

Configures alarm or alert thresholds for the number of PHSGW sessions that timed out.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
threshold phsgw-session-timeout high_thresh [ clear low_thresh ]
```

**high_thresh**
Default: 0
Specifies the high threshold number of session timeouts for any one PHSGW service. This number must be met or exceeded within the polling interval to generate an alert or alarm.

**clear low_thresh**
Default: 0
Specifies the low threshold number of session timeouts for any one PHSGW service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.

low_thresh is an integer from 0 through 1000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Set the monitoring and clearing thresholds for PHSGW session timeouts.
Alerts or alarms are triggered for handoff denials based on the following rules:

- **Enter condition:** Actual number of PHSGW session timeouts in any one PHSGW service is greater than or equal to the high threshold.
- **Clear condition:** Actual number of PHSGW session timeouts in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.
Example

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSGW session timeouts:

```
threshold phsgw-session-timeout 100000 clear 50000
```
threshold phspc-session-setup-timeout

Configures alarm or alert thresholds for the number of Personal Handyphone System - Personal Computer (PHSPC) sessions that timed out during setup.

Product
PHSGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
threshold phspc-session-setup-timeout high_thresh [ clear low_thresh ]
```

- **high_thresh**
  Default: 0
  Specifies the high threshold number of session setup timeouts for any one PHSPC service. This number must be met or exceeded within the polling interval to generate an alert or alarm.
  *high_thresh* is an integer from 0 through 1000000. A value of 0 disables the threshold.

- **clear low_thresh**
  Default: 0
  Specifies the low threshold number of session setup timeouts for any one PHSPC service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  *low_thresh* is an integer from 0 through 1000000. A value of 0 disables the threshold.

### Important:
This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Set the monitoring and clearing thresholds for PHSPC session setup timeouts.
Alerts or alarms are triggered for handoff denials based on the following rules:

- **Enter condition:** Actual number of PHSPC session setup timeouts in any one PHSGW service is greater than or equal to the high threshold.

- **Clear condition:** Actual number of PHSPC session setup timeouts in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a monitoring threshold of **100000** and a clearing threshold of **50000** for PHSPC session setup timeouts:

```
threshold phspc-session-setup-timeout 100000 clear 50000
```
threshold phspc-sleep-mode-timeout

Configures alarm or alert thresholds for the number of PHSPC sessions that timed out when the personal computer went into sleep mode.

Product
PHSGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

\texttt{threshold \textit{phspc}} \texttt{-sleep} \texttt{-mode} \texttt{-timeout} \texttt{hi} \texttt{gh}_\texttt{thresh} \texttt{[ clear low}_\texttt{thresh ]}

\texttt{high}_\texttt{thresh}

Default: 0
Specifies the high threshold number of sleep mode timeouts for any one PHSPC service. This number must be met or exceeded within the polling interval to generate an alert or alarm. \texttt{high}_\texttt{thresh} is an integer from 0 through 1000000. A value of 0 disables the threshold.

\texttt{clear low}_\texttt{thresh}

Default: 0
Specifies the low threshold number of sleep mode timeouts for any one PHSPC service. This number must be met or exceeded to maintain a previously generated alert condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated. \texttt{low}_\texttt{thresh} is an integer from 0 through 1000000. A value of 0 disables the threshold.

\textbf{Important:} This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Set the monitoring and clearing thresholds for PHSPC sleep mode timeouts. Alerts or alarms are triggered for handoff denials based on the following rules:

\textbf{Enter condition:} Actual number of PHSPC sleep mode timeouts in any one PHSGW service is greater than or equal to the high threshold.

\textbf{Clear condition:} Actual number of PHSPC sleep mode timeouts in any one PHSGW service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSPC sleep mode timeouts:

```
threshold phspc-sleep-mode-timeout 100000 clear 50000
```
threshold phspc-sm-entry-denial

Configures alarm or alert thresholds for the number of denied PHSPC short message (SM) sessions.

Product
PHSGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold phspc-sm-entry-denial high_thresh [ clear low_thresh ]

high_thresh

Default: 0
Specifies the high threshold number of SM entry denials for any one PHSPC service. This number must be met or exceeded within the polling interval to generate an alert or alarm.

low_thresh is an integer from 0 through 1000000. A value of 0 disables the threshold.

clear low_thresh

Default: 0
Specifies the low threshold number of SM entry denials for any one PHSPC service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.

low_thresh is an integer from 0 through 1000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
Set the monitoring and clearing thresholds for PHSPC SM entry denials.
Alerts or alarms are triggered for handoff denials based on the following rules:

- **Enter condition:** Actual number of PHSPC SM entry denials in any one PHSPC service is greater than or equal to the high threshold.
- **Clear condition:** Actual number of PHSPC SM entry denials in any one PHSPC service is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.
Example

The following command configures a monitoring threshold of 100000 and a clearing threshold of 50000 for PHSPC SM entry denials:

```
threshold phsgw-sm-entry-denyal 100000 clear 50000
```
Chapter 144
Global Configuration Mode Commands (threshold poll commands A - N)

This section includes the commands `threshold poll 10sec-cpu-utilization interval` through `threshold poll npu-utilization interval`.

The Global Configuration Mode is used to configure basic system-wide parameters.

Mode

Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
threshold poll 10sec-cpu-utilization interval

Configures the polling interval over which to measure a 10-second average of CPU utilization.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold poll 10sec-cpu-utilization interval duration
```

```
default threshold poll 10sec-cpu-utilization interval
```

```
default
```

Restores the specified parameter to its default value 300 seconds.

```
interval duration
```

Default: 300 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

*duration* is an integer from 30 through 60000 in multiples of 30.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the *threshold monitoring* and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshCPUUtilization10Sec` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the 10-second CPU utilization threshold:

```
threshold poll 10sec-cpu-utilization 600
```
threshold poll a11-ppp-send-discard interval

Configures the polling interval for PDSN service over which to count the number of packets that the PPP protocol processing layer internally discarded on transmit for any reason.

Product

PDSN

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config) #

Syntax

threshold poll all-ppp-send-discard interval duration

default threshold poll all-ppp-send-discard interval

default

Restores the specified parameter to its default value 0 seconds.

interval duration

Default: 0 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration is an integer from 60 through 900 in multiples of 30.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshPDSNSvcA11PPPSendDiscard command in this mode.

Example

The following command configures the polling interval to 600 seconds for the A11 PPP send discard threshold:
threshold poll all-ppp-send-discard interval 600
threshold poll a11-rac-msg-discard interval

Configures the polling interval for PDSN service over which to count the number of Discarded A11 Registration Acknowledgements.

**Product**

PDSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll a11-rac-msg-discard interval duration

default threshold poll a11-rac-msg-discard interval
```

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>restores the specified parameter to its default value 0 seconds.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>interval duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>specifies the amount of time (in seconds) that comprises the polling interval. duration is an integer from 60 through 900 in multiples of 30.</td>
</tr>
</tbody>
</table>

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshPDSNSvcA11RACMsgDiscard command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the A11 RAC message discard threshold:
threshold poll all-rac-msg-discard interval 600
**threshold poll aa11-rrp-failure interval**

Configures the polling interval for PDSN service over which to count A11 Registration Response failures.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll a11-rrp-failure interval duration
```

```
default threshold poll a11-rrp-failure interval
```

```
default
```

Restores the specified parameter to its default value 0 seconds.

```
interval duration
```

Default: 0 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

`duration` is an integer from 60 through 900 in multiples of 30.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPDSNSvcA11RRPFailure` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the A11 RRP failure threshold:

```
threshold poll a11-rrp-failure interval 600
```
threshold poll a11-rrq-msg-discard interval

Configures the polling interval for PDSN service over which to count how many A11 Registration Request messages are discarded.

Product
PDSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

threshold poll all-rrq-msg-discard interval duration

default threshold poll all-rrq-msg-discard interval

default
Restores the specified parameter to its default value 0 seconds.

interval duration
Default: 0 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration is an integer from 60 through 900 in multiples of 30.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshPDSNSvcAllRRQMsgDiscard command in this mode.

Example

The following command configures the polling interval to 600 seconds for the A11 RRQ message discard threshold:
threshold poll all-rrq-msg-discard interval 600
threshold poll aaa-acct-archive-queue-size interval

Configures the polling interval over which to measure AAA accounting archive message queue size.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold poll aaa-acct-archive-queue-size1 interval duration
default threshold poll aaa-acct-archive-queue-size1 interval

threshold poll aaa-acct-archive-queue-size2 interval duration
default threshold poll aaa-acct-archive-queue-size2 interval

threshold poll aaa-acct-archive-queue-size3 interval duration
default threshold poll aaa-acct-archive-queue-size3 interval
```

default

Restores the specified parameter to its default value 900 seconds.

```
interval duration
```

Default: 900 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

`duration` is an integer from 60 through 60000 in multiples of 30.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.
Global Configuration Mode Commands (threshold poll commands A - N)

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable` `ThreshAAAacctArchiveQueue-<1-3>` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the AAA accounting archive queue size 1 threshold:

```
threshold poll aaa-acct-archive-queue-size1 interval 600
```
threshold poll aaa-acct-archive-size interval

Configures the polling interval over which to count archived AAA accounting messages.

Product

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll aaamgr-request-queue interval duration

default threshold poll aaamgr-request-queue interval

default
Restores the specified parameter to its default value 0 seconds.

interval duration
Default: 0 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration is an integer from 60 through 60000 in multiples of 30.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshAAAMgrQueue command in this mode.

Example

The following command configures the polling interval to 600 seconds for the AAA manager request queue threshold:
threshold poll aaamgr-request-queue interval 600
threshold poll active-subscriber interval

Configures the polling interval over which to count the total number of active subscriber sessions.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold poll active-subscriber interval duration
```

```
default threshold poll active-subscriber interval
```

- `default`
  Restores the specified parameter to its default value 300 seconds.

- `interval duration`
  Default: 300 seconds.
  Specifies the amount of time (in seconds) that comprises the polling interval.
  `duration` is an integer from 60 through 60000 in multiples of 30.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThresholdSubscriberActive` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the active subscriber threshold:

```
threshold poll active-subscriber interval 600
```
threshold poll asngw-auth-failure interval

Configures the polling interval over which to count or measure the thresholding value for ASN Gateway authentication failure.

**Product**
ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll asngw-auth-failure interval dur
```

```
default threshold poll asngw-auth-failure interval
```

---

**default**

Restores the specified parameter to its default value 300 seconds.

---

**interval dur**
Default: 300 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

`dur` is an integer from 30 through 60000 in multiples of 30.

---

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

---

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

---

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshASNGWAuthFail` command in this mode.

---

**Example**

The following command configures the polling interval to 600 seconds for the ASN Gateway authentication failure threshold:
threshold poll asngw-auth-failure interval 600
threshold poll asngw-handoff-denial interval

Configures the polling interval over which to count or measure the thresholding value for ASN Gateway hand-off denial.

Product
ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config) #

Syntax

threshold poll asngw-handoff-denial interval dur

default threshold poll asngw-handoff-denial interval

default
Restores the specified parameter to its default value 300 seconds.

interval dur
Default: 300 seconds.
Specifies the polling interval time in seconds.
dur is an integer from 30 through 60000 in multiples of 30.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshASNGWHandoffDenial command in this mode.

Example

The following command configures the polling interval to 600 seconds for the hand-off denial threshold:

threshold poll asngw-handoff-denial interval 600
threshold poll asngw-max-eap-retry interval

Configures the polling interval over which to count or measure the thresholding value for maximum Extensible Authentication Protocol (EAP) authentication retries.

Product
ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll asngw-max-eap-retry interval dur

default threshold poll asngw-max-eap-retry interval

- default
  Restores the specified parameter to its default value 300 seconds.

- interval dur
  Default: 300 seconds.
  Specifies the amount of time (in seconds) that comprises the polling interval.
  dur is an integer from 30 through 60000 in multiples of 30.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshASNGWMaxEAPretry` command in this mode.

Example

The following command configures the polling interval to 600 seconds for the maximum EAP authentication retry threshold:
threshold poll asngw-max-eap-retry interval 600
threshold poll asngw-network-entry-denial interval

Configures the polling interval over which to count or measure the thresholding value for network entry denial to an MS.

**Product**
ASN-GW

**Privilege**

**Mode**
Exec > Global Configuration

**Syntax**

```
threshold poll asngw-network-entry-denial interval dur
```

default threshold poll asngw-network-entry-denial interval

```
default
```

Restores the specified parameter to its default value 300 seconds.

```
interval dur
```

Default: 300 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

```
dur is an integer from 30 through 60000 in multiples of 30.
```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable` ThreshASNGWNW EntryDenial command in this mode.

**Example**
The following command configures the polling interval to 600 seconds for the network entry denial threshold:
threshold poll asngw-network-entry-denial interval 600
threshold poll asngw-session-setup-timeout interval

Configures the polling interval over which to count or measure the thresholding value for session setup timeout.

interval dur

Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

⚠️ Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

⚠️ Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshCPUload command in this mode.

Example

The following command configures the polling interval to 600 seconds for the CPU load threshold:

threshold poll cpu-load interval 600
threshold poll cpu-memory-usage interval

Configures the polling interval over which to measure the percentage of total packet processing card CPU memory used.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll cpu-memory-usage interval duration

default threshold poll cpu-memory-usage interval

default
Uses the default threshold polling interval.
Default: 300 seconds

interval dur
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshCPUMemUsage command in this mode.

Example

The following command configures the polling interval to 600 seconds for the CPU memory usage threshold:

threshold poll cpu-memory-usage interval 600
threshold poll cpu-orbs-crit interval

Configures the polling interval over which to measure the percentage of CPU utilization by the ORBS software task for critical-level alerts.

Product

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll cpu-orbs-crit interval duration

default threshold poll cpu-orbs-crit interval

default
Uses the default threshold polling interval.
Default: 300 seconds

interval dur
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 60 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThresholdCPUOrbsCritical command in this mode.

Example

The following command configures the polling interval to 600 seconds for the CPU ORBS critical threshold:

    threshold poll cpu-orbs-crit interval 600
threshold poll cpu-orbs-warn interval

Configures the polling interval over which to measure the percentage of CPU utilization by the ORBS software task for warning-level alerts.

Product

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll cpu-orbs-warn interval duration

default threshold poll cpu-orbs-warn interval

default

Uses the default threshold polling interval.
Default: 300 seconds

interval dur

Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 60 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshCPUOrbsWarn command in this mode.

Example

The following command configures the polling interval to 600 seconds for the CPU ORBS warning threshold:
threshold poll cpu-orbs-warn interval 600
threshold poll cpu-session-throughput interval

Configures the polling interval over which to measure total throughput for all Session Manager tasks running on each packet processing card CPU.

Product

All

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```plaintext
threshold poll cpu-session-throughput interval duration

default threshold poll cpu-session-throughput interval

default

Uses the default threshold polling interval.
Default: 300 seconds

interval dur

Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 60 through 60000.
```

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable ThreshSessCPUThroughput** command in this mode.

Example

The following command configures the polling interval to **600 seconds** for the CPU session throughput threshold:
threshold poll cpu-session-throughput interval

threshold poll cpu-session-throughput interval 600
threshold poll cpu-utilization interval

Configures the polling interval over which to measure the percentage of CPU utilization.

</thead>
<tbody>
<tr>
<td>default</td>
<td>Uses the default threshold polling interval. Default: 900 seconds</td>
</tr>
<tr>
<td>interval duration</td>
<td>Specifies the polling interval (in seconds) for the DCCA Bad Answers threshold. duration must be an integer from 60 through 60000.</td>
</tr>
</tbody>
</table>
```

Usage

This command configures the polling interval for DCCA Bad Answers threshold.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholding in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshDCCABadAnswers` command in this mode.

Example

The following command configures the polling interval to 600 seconds for invalid or bad response threshold to the system from Diameter server:
threshold poll dcca-bad-answers interval

threshold poll dcca-rating-failed interval 600
**threshold poll dcca-protocol-error interval**

Configures the polling interval for Diameter Credit-Control Application (DCCA) Protocol Error threshold.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold poll dcca-protocol-error interval duration
```

**default threshold poll dcca-protocol-error interval**

```
default
Uses the default threshold polling interval.
Default: 900 seconds
```

```
interval duration
Specifies the polling interval (in seconds) for the DCCA Protocol Error threshold.
duration must be an integer from 60 through 60000.
```

**Usage**

Use this the polling interval for DCCA Protocol Error threshold.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholding in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshDCCAProtocolError` command in this mode.

**Example**

The following command configures the polling interval to **600** seconds for the DCCA protocol error threshold:

```
threshold poll dcca-protocol-error interval 600
```
threshold poll dcca-rating-failed interval

Configures the polling interval for Diameter Credit-Control Application (DCCA) Rating Failed threshold.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll dcca-rating-failed interval duration

default threshold poll dcca-rating-failed interval
```

**Usage**

This command configures the polling interval for DCCA Rating Failed threshold.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholding in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshDCCARatingFailed` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the Diameter Credit Control Application (DCCA) Rating Group (content-id) request reject thresholds:

```
threshold poll dcca-rating-failed interval 600
```
**threshold poll dcca-unknown-rating-group interval**

Configures the polling interval for Diameter Credit-Control Application (DCCA) Unknown Rating Group threshold.

[local]host_name(config)#
```

**Syntax**

```
threshold poll dcca-unknown-rating-group interval duration
```

```
default threshold poll dcca-unknown-rating-group interval
```

- **default**
  Uses the default polling interval.
  Default: 900 seconds

- **interval duration**
  Specifies the polling interval (in seconds) for the DCCA Unknown Rating Group threshold.
  duration must be an integer from 60 through 6000.

**Usage**
This command configures the polling interval for DCCA Unknown Rating Group threshold.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholding in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable** ThreshDCCAUnknownRatingGroup command in this mode.

**Example**
The following command configures the polling interval to 600 seconds to threshold for the unknown DCCA Rating Group (content-id) returned by Diameter to system:

```
threshold poll dcca-unknown-rating-group interval 600
```
threshold poll dereg-reply-error interval

Configures the polling interval to count the number of de-registration reply errors per HA service.

Product
HA

threshold poll fng-current-active-sessions interval duration

interval duration
Default: 0 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 60 through 60000.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshFNGCurrActSess command in this mode.

Example

The following command configures the polling interval to 600 seconds for the FNG current active sessions threshold:

threshold poll fng-current-active-sessions interval 600
threshold poll fng-current-sessions interval

Configures the polling interval in seconds over which to count Femto Network Gateway (FNG) current sessions, including inactive sessions.

**Product**
FNG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll fng-current-sessions interval duration
```

- `interval duration`
  - Default: 0 seconds.
  - Specifies the amount of time (in seconds) that comprises the polling interval.
  - `duration` must be an integer from 60 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshFNGCurrSess` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the FNG current sessions threshold:

```
threshold poll fng-current-sessions interval 600
```
threshold poll fw-deny-rule interval

Configures the Stateful Firewall Deny Rule threshold polling interval.

Product
PSF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure
Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

threshold poll fw-deny-rule interval duration

interval duration
Default: 900 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 60 through 900.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshFWDenyRule command in this mode.

Example

The following command configures the polling interval to 600 seconds for the Stateful Firewall Deny Rule threshold:

threshold poll fw-deny-rule interval 600
**threshold poll fw-dos-attack interval**

Configures the Stateful Firewall Denial of Service (DoS) Attacks threshold polling interval.

**Product**
PSF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll fw-dos-attack interval duration
```

interval duration

Default: 900 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 60 through 900.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable` **ThreshFWDosAttack** command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the Stateful Firewall DoS Attacks threshold:

```
threshold poll fw-dos-attack interval 600
```
threshold poll fw-drop-packet interval

Configures the Stateful Firewall Drop-Packet threshold polling interval.

**Product**
PSF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold poll fw-drop-packet interval duration
```

```
interval duration
Default: 900 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 60 through 900.
```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshFWDropPacket` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the Stateful Firewall Drop-Packet threshold:

```
threshold poll fw-drop-packet interval 600
```
threshold poll fw-no-rule interval

Configures the Stateful Firewall No-Rule threshold polling interval.

**Product**
PSF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
threshold poll fw no rule interval duration
```

- **interval duration**
  - Default: 900 seconds.
  - Specifies the amount of time (in seconds) that comprises the polling interval.
  - **duration** must be an integer from 60 through 900.

**Usage**
This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

- Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable ThreshFWNoRule** command in this mode.

**Example**

The following command configures the polling interval to **600** seconds for the Stateful Firewall No-Rule threshold:

```
threshold poll fw-no-rule interval 600
```
threshold poll ha-init-rrq-rcvd-rate interval

Configures the polling interval for Home Agent (HA) service over which to measure the average number of calls setup per minute.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

threshold poll ha-init-rrq-rcvd-rate interval duration

interval duration

Default: 0 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 60 through 900.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshHACallSetupRate command in this mode.

Example
The following command configures the polling interval to 600 seconds for the average number of HA calls setup per minute:

threshold poll ha-init-rrq-rcvd-rate interval 600
threshold poll ha-svc-init-rrq-rcvd-rate interval

Configures the polling interval over which to measure the average number of calls setup per minute for HA services.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold poll ha-svc-init-rrq-rcvd-rate interval duration
```

- `interval duration`
  - Default: 0 seconds.
  - Specifies the amount of time (in seconds) that comprises the polling interval.
  - `duration` must be an integer from 60 through 900.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshHASvcCallSetupRate` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the average number of calls setup per minute for HA services:

```
threshold poll ha-svc-init-rrq-rcvd-rate interval 600
```
threshold poll henbgw-paging-messages interval

Configures how frequently the HeNB-GW paging messages are polled.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config)#

Syntax

threshold poll henbgw-paging-messages interval duration

interval duration
Default: 0 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 6000.

Usage
This command configures how frequently the HeNB-GW paging messages are polled.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshHeNBGWPagingMessages` command in this mode.

Example
The following command configures the polling interval to 6000 seconds for the HeNB-GW service:

threshold poll henbgw-paging-messages interval 6000
threshold poll ip-pool-free interval

Configures the polling interval over which to measure the percentage of the IP pool addresses that are in the Free state.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**

```
threshold poll ip-pool-free interval duration
```

- `interval duration`
  
  Default: 300 seconds.
  Specifies the amount of time (in seconds) that comprises the polling interval.
  `duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable** **ThreshIPPoolFree** command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the average number of Free IP pools:

```
threshold poll ip-pool-free interval interval 600
```
threshold poll ip-pool-hold interval

Configures the polling interval over which to measure the percentage of the IP pool addresses that are in the Hold state.

**Product**

All

**Privilege**

Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold poll ip-pool-hold interval duration
```

```
interval duration
```

Default: 300 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable` ThreshIPPoolHold command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for the average number of IP pool addresses in Hold state:

```
threshold poll ip-pool-hold interval 600
```
threshold poll ip-pool-release interval

Configures the polling interval over which to measure the percentage of IP pool addresses that are in the Release state.

**Syntax**

```
threshold poll mgmt-cpu-memory-usage interval duration
```

```
interval duration
```

Default: 300 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

`duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Example**

The following command configures the polling interval to 600 seconds for management card CPU memory usage:

```
threshold poll mgmt-cpu-memory-usage interval 600
```
threshold poll mgmt-cpu-utilization interval

Configures the polling interval over which to measure management card CPU utilization.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll mgmt-cpu-utilization interval duration

- interval duration
  - Default: 300 seconds.
  - Specifies the amount of time (in seconds) that comprises the polling interval.
  - duration must be an integer from 30 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Example

The following command configures the polling interval to 600 seconds for management card CPU memory usage:

threshold poll mgmt-cpu-utilization interval 600
threshold poll mme-attach-failure interval

Configures the polling interval to count the MME Attach Failure messages across all MME services in the system.

Product

MME

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

threshold poll mme-attach-failure interval dur

default threshold poll mme-attach-failure interval

- **default**
  
  Restores the polling interval value to its default value of 900 seconds.

- **interval dur**
  
  Default: 900 seconds.
  
  Specifies the polling interval (in seconds) for counting MME Attach Failure messages across all MME services in the system.
  
  *dur* must be an integer from 30 through 60000 in multiples of 30.

Usage

Use this command to configure the polling interval to count the MME Attach Failure messages across all MME services in the system to generate threshold value.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring mme-service** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable ThreshMMEAttachFail** command in this mode.

Example

The following command configures the polling interval of 600 seconds to count the MME Attach Failure messages for threshold limit:
threshold poll mme-attach-failure interval 600
threshold poll mme-auth-failure interval

Configures the polling interval to count the MME Authentication Failure messages across all MME services in the system.

**Product**
MME

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
`configure`
Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold poll mme-auth-failure interval dur

default threshold poll mme-auth-failure interval

default

Restores the specified poll interval value to its default value of 900 seconds.

interval dur

Default: 900 seconds.
Specifies the polling interval (in seconds) for counting MME Authentication Failure messages across all MME services in the system.
`dur` must be an integer from 30 through 60000 in multiples of 30.

**Usage**

Use this command to configure the polling interval to count the MME Auth Failure messages across all MME services in the system to generate threshold value.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring mme-service` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshMMEEAuthFail` command in this mode.

**Example**

Command Line Interface Reference, StarOS Release 16
The following command configures the polling interval of 600 seconds to count the MME Auth Failure messages for threshold limit:

```
threshold poll mme-auth-failure interval 600```

threshold poll nat-port-chunks-usage interval

Configures the polling interval over which to measure the percentage of Network Address Translation (NAT) port chunk utilization.

Product
NAT

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll nat-port-chunks-usage interval duration

default threshold poll nat-port-chunks-usage interval

- default
  Restores the specified poll interval value to its default value of 900 seconds.

- interval duration
  Specifies the amount of time (in seconds) that comprises the polling interval.
  duration must be an integer from 30 through 60000.
  Default: 900 seconds.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshNATPortChunksUsage command in this mode.

Example

The following command configures the polling interval to 600 seconds for (NAT) port chunk utilization:

threshold poll nat-port-chunks-usage interval 600
threshold poll npu-utilization interval

Configures the polling interval over which to measure the percentage of network processing unit (NPU) utilization.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure
Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll npu-utilization interval duration
```

- `interval` `duration`
  - Default: 300 seconds.
  - Specifies the amount of time (in seconds) that comprises the polling interval.
  - `duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshNPUUtilization` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for NPU utilization:

```
threshold poll npu-utilization interval 600
```
Chapter 145
Global Configuration Mode Commands (threshold poll commands O - Z)

This section includes the commands `threshold poll packets-filtered-dropped interval` through `threshold poll tpo-rto-timeout`.
The Global Configuration Mode is used to configure basic system-wide parameters.

Mode

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
threshold poll packets-filtered-dropped interval

Configures the polling interval over which to count the filtered/dropped packets.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll packets-filtered-dropped interval duration
```

<table>
<thead>
<tr>
<th>interval duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 300 seconds.</td>
</tr>
<tr>
<td>Specifies the amount of time (in seconds) that comprises the polling interval.</td>
</tr>
<tr>
<td>duration must be an integer from 30 through 60000.</td>
</tr>
</tbody>
</table>

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPacketsFilteredDropped` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for filtered/dropped packets:

```
threshold poll packets-filtered-dropped interval 600
```
**threshold poll packets-forwarded-to-cpu interval**

Configures the polling interval over which to count packets forwarded to active system CPUs in the system.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll packets-forwarded-to-cpu interval duration
```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable ThreshPacketsForwarded** command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for packets forwarded to active system CPUs in the system:

```
threshold poll packets-forwarded-to-cpu interval 600
```
### threshold poll pdg-current-active-sessions interval

Configures the polling interval over which to count the total number of currently active Packet Data Gateway/Tunnel Termination Gateway (PDG/TTG) sessions.

**Product**
- PDG
- TTG

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration
  - configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold poll pdg-current-active-sessions interval duration
```

*interval duration*

Default: 300 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

`duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPDGCurrActSess` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PDG/TTG sessions:

```
threshold poll pdg-current-active-sessions interval 600
```
threshold poll pdg-current-sessions interval

Configures the polling interval over which to count the total number of current Packet Data Gateway/Tunnel Termination Gateway (PDG/TTG) sessions, including inactive sessions.

**Product**
PDG/TTG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll pdg-current-sessions interval duration
```

*interval duration*

Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
`duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

⚠️ **Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the [threshold monitoring](#) and other threshold commands for additional information on the system’s support for thresholds in this chapter.

⚠️ **Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPDGCurrSess` command in this mode.

**Example**

The following command configures the polling interval to **600 seconds** for PDG/TTG sessions:

```
threshold poll pdg-current-sessions interval 600
```
threshold poll pdif-current-active-sessions interval

Configures the polling interval over which to count the total number of currently active Packet Data Interworking Function (PDIF) sessions.

**Product**
PDIF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
*configure*

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```plaintext
threshold poll pdif-current-active-sessions interval duration
```

<table>
<thead>
<tr>
<th>interval duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 300 seconds.</td>
</tr>
<tr>
<td>Specifies the amount of time (in seconds) that comprises the polling interval.</td>
</tr>
<tr>
<td><code>duration</code> must be an integer from 30 through 60000.</td>
</tr>
</tbody>
</table>

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPDIFCurrActSess` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PDIF sessions:

```
threshold poll pdif-current-active-sessions interval 600
```
threshold poll pdif-current-sessions interval

Configures the polling interval over which to count the total number of current Packet Data Interworking Function (PDIF) sessions, including inactive sessions.

**Product**
PDIF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

**Syntax**

```
threshold poll pdif-current-sessions interval duration
```

- `interval duration`
  
  Default: 300 seconds.
  
  Specifies the amount of time (in seconds) that comprises the polling interval.
  
  `duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPDIFCurrSess` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PDIF sessions:

```
threshold poll pdif-current-sessions interval 600
```
**threshold poll pdsn-init-rrq-rcvd-rate interval**

Configures the polling interval over which to count the total number of current Packet Data Serving Node (PDSN) sessions, including inactive sessions.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll pdsn-init-rrq-rcvd-rate interval duration
```

```
interval duration
```

Default: 0 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

`duration` must be an integer from 60 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

---

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

---

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPDSNCallSetupRate` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PDSN sessions:

```
threshold poll pdsn-init-rrq-rcvd-rate interval 600
```
threshold poll pdsn-svc-init-rrq-rcvd-rate interval

Configures the polling interval over which to count the total number of current Packet Data Serving Node (PDSN) sessions, including inactive sessions.

Product
PDSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll pdsn-svc-init-rrq-rcvd-rate interval duration

interval duration
Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 60000.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshPDNSvcCallSetupRate command in this mode.

Example
The following command configures the polling interval to 600 seconds for PDSN sessions:

threshold poll pdsn-svc-init-rrq-rcvd-rate interval 600
threshold poll per-service-asngw-sessions interval

Configures the polling interval in seconds over which to count the number of PDP contexts per ASN-GW service in the system.

**Product**
ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
`configure`

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold poll per-service-asngw-sessions interval duration
```

*interval duration*

Default: 300 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
`duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPerServiceASNGWSessions` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for ASN-GW sessions:

```
threshold poll per-service-asngw-sessions interval 600
```
threshold poll per-service-ggsn-sessions interval

Configures the polling interval in seconds over which to count the number of PDP contexts per GGSN service in the system.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config) #
```

**Syntax**

```
threshold poll per-service-ggsn-sessions interval duration
```

- **interval duration**
  - Default: 300 seconds.
  - Specifies the amount of time (in seconds) that comprises the polling interval.
  - `duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPerServiceGGSNSessions` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for GGSN sessions:

```
threshold poll per-service-ggsn-sessions interval 600
```
threshold poll per-service-gprs-pdp-sessions interval

Configures the polling interval in seconds over which to count the number of 2G-activated PDP contexts per GPRS service.

Product
SGSN

Privilege

**Syntax**

```
threshold poll per-service-sgsn-sessions interval duration
```

**interval duration**

Default: 300 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

`duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable` ThreshPerServiceSGSNSessions command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for SGSN sessions:

```
threshold poll per-service-sgsn-sessions interval 600
```
Global Configuration Mode Commands (threshold poll commands O - Z)

threshold poll phsgw-auth-failure interval

Configures the polling interval in seconds over which to count the number of Personal Handyphone System Gateway (PHSGW) authentication failures.

Product
PHSGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config) #

Syntax

threshold poll phsgw-auth-failure interval duration

- **interval duration**
  - Default: 0 seconds.
  - Specifies the amount of time (in seconds) that comprises the polling interval.
  - `duration` must be an integer from 30 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the [threshold monitoring](#) and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPHSGWAuthFail` command in this mode.

Example

The following command configures the polling interval to 600 seconds for PHSGW authentication failures:

```
threshold poll phsgw-auth-failure interval 600
```
threshold poll phsgw-eapol-auth-failure interval

Configures the polling interval in seconds over which to count the number of authentication failures for a PHSGW service using Extensible Authentication Protocol Over LAN (EAPOL).

Product
PHSGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

```
threshold poll phsgw-eapol-auth-failure interval duration
```

- **interval duration**
  - Default: 0 seconds.
  - Specifies the amount of time (in seconds) that comprises the polling interval.
  - `duration` must be an integer from 30 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPHSGWEAPOLEAPOLAuthFailure` command in this mode.

Example

The following command configures the polling interval to 600 seconds for PHSGW EAPOL failures:

```
threshold poll phsgw-eapol-auth-failure interval 600
```
threshold poll phsgw-handoff-denial interval

Configures the polling interval in seconds over which to count the number of handoff denials in PHSGW.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```configure
continue
```

Entering the above command sequence results in the following prompt:

```[local]host_name(config) #
```

**Syntax**

```threshold poll phsgw-handoff-denial interval duration```

- **interval**
  - `duration`
  - Default: 0 seconds.
  - Specifies the amount of time (in seconds) that comprises the polling interval.
  - `duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPHSGWMaxEAPOLRetry` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PHSGW handoff denials:

```threshold poll phsgw-handoff-denial interval 600```
threshold poll phsgw-max-eap-retry interval

Configures the polling interval in seconds over which to count the maximum number of Extensible Authentication Protocol (EAP) retries in PHSGW.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```sh
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll phsgw-max-eap-retry interval duration
```

- **interval duration**
  - Default: 0 seconds.
  - Specifies the amount of time (in seconds) that comprises the polling interval.
  - `duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

---

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

---

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PHSGW EAP retries:

```
threshold poll phsgw-max-eap-retry interval 600
```
threshold poll phsgw-max-eapol-retry interval

Configures the polling interval in seconds over which to count the maximum number of Extensible Authentication Protocol Over LAN (EAPOL) retries in PHSGW.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll phsgw-max-eapol-retry interval duration
```

`interval duration`

Default: 0 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

`duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPHSGWMaxEAPOLRetry` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PHSGW EAPOL retries:

```
threshold poll phsgw-max-eapol-retry interval 600
```
threshold poll phsgw-network-entry-denial interval

Configures the polling interval in seconds over which to count the number of network entry denials in PHSGW.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```configure
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold poll phsgw-network-entry-denial interval duration
```

**interval duration**

Default: 0 seconds.

Specifies the amount of time (in seconds) that comprises the polling interval.

*duration* must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPHSGWNWEntryDenial` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PHSGW network entry denials:

```
threshold poll phsgw-network-entry-denial interval 600
```
threshold poll phsgw-session-setup-timeout interval

Configures the polling interval in seconds over which to count the number of PHSGW sessions that timed out during setup.

Product
PHSGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold poll phsgw-session-setup-timeout interval duration

   interval duration
   Default: 0 seconds.
   Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable
ThreshPHSGWSessSetupTimeout command in this mode.

Example

The following command configures the polling interval to 600 seconds for PHSGW session setup timeouts:

threshold poll phsgw-session-setup-timeout interval 600
threshold poll phsgw-session-timeout interval

Configures the polling interval in seconds over which to count the number of PHSGW sessions that timed out.

**Product**

PHSGW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll phspc-session-setup-timeout interval duration
```

- **interval duration**
  - Default: 0 seconds.
  - Specifies the amount of time (in seconds) that comprises the polling interval.
  - `duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable` **ThreshPHSPC.SessSetupTimeout** command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PHSPC session setup timeouts:

```
threshold poll phspc-session-setup-timeout interval 600
```
threshold poll phspc-sleep-mode-timeout interval

Configures the polling interval in seconds over which to count the number of PHSPC sessions that timed out when the personal computer went into sleep mode.

Product
PHSGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

threshold poll phspc-sleep-mode-timeout interval duration

interval duration
Default: 0 seconds.
Specifies the amount of time (in seconds) that comprises the polling interval.
duration must be an integer from 30 through 60000.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThresholdPHSPCSleepModeTimeout command in this mode.

Example

The following command configures the polling interval to 600 seconds for PHSPC sleep mode timeouts:

threshold poll phspc-sleep-mode-timeout interval 600
threshold poll phspc-sm-entry-denial interval

Configures the polling interval in seconds over which to count the number of denied PHSPC short message (SM) sessions.

**Product**
PHSGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll phspc-sm-entry-denial interval duration
```

- `interval duration`

  Default: 0 seconds.
  Specifies the amount of time (in seconds) that comprises the polling interval.
  `duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPHSPCSmEntryDenial` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PHSPC SM session denials:

```
threshold poll phspc-sm-entry-denial interval 600
```
threshold poll port-high-activity interval

Configures the polling interval in seconds over which to measure the overall percentage of port utilization.

Product
All

Privilege
Administrator Security Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config)#

Syntax

```
threshold poll port-high-activity interval seconds
```

```
interval seconds
```

Configures the threshold polling interval in multiples of 30 seconds. `seconds` is an integer from 30 through 60000. Default is 300 seconds.

Usage

High port activity thresholds generate alerts or alarms based on the peak utilization percentage of each configured port during the specified polling interval. This threshold is configured on a per-port basis. Alerts or alarms are triggered for high port activity based on the following rules:

- Enter condition: Actual percent peak utilization of a port is greater than or equal to the high threshold.
- Clear condition: Actual percent peak utilization of a port is less than the low threshold.
- If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. This threshold is configured on a per-port basis configured using the port `port-type slot#/port#` command syntax.

⚠️ **Important:** This command is not available on all platforms

⚠️ **Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPortHighActivity` command in this mode.

⚠️ **Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPortHighActivity` command in this mode.

Example

Use the following example to configure the polling interval over which to measure for high port activity to 300 seconds:
threshold poll port-high-activity interval 300
**threshold poll port-rx-utilization interval**

Configures the polling interval in seconds over which to measure the overall percentage of incoming traffic received over system ports.

**Product**
All

**Privilege**
Administrator Security Administrator

**Mode**
Exec > Global Configuration
`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll port-rx-utilization interval seconds
```

```
interval seconds
```

Configures the threshold polling interval in multiples of 30 seconds. `seconds` is an integer from 30 to 60000. Default is 300 seconds.

**Usage**

Receive port utilization thresholds generate alerts or alarms based on the utilization percentage of each configured port in relation to data received during the specified polling interval. This threshold is configured on a per-port basis configured using the port `port-type slot#/port#` command syntax.

**Important:** This command is not available on all platforms

**Important:** Ports configured for half-duplex do not differentiate between data received and data transmitted. (The transmitted and received percentages are combined.) Therefore, to avoid redundant alarms, it is recommended that only the receive or transmit utilization threshold be configured.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThresholdPortRxUtil` command in this mode.

**Example**

Use the following example to configure a threshold poll interval of 300 seconds (5 minutes)

```
threshold poll port-rx-utilization interval 300
```
threshold poll port-tx-utilization

Configures the polling interval in seconds over which to measure the overall percentage of outgoing traffic sent over system ports.

**Product**

All

**Privilege**

Administrator Security Administrator

**Mode**

Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll port-tx-utilization interval seconds
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>interval</td>
<td>seconds</td>
</tr>
</tbody>
</table>

Configures the threshold polling interval in multiples of 30 seconds. `seconds` is an integer from 30 through 60000. Default is 300 seconds.

**Usage**

Transmit port utilization thresholds generate alerts or alarms based on the utilization percentage of each configured port in relation to data transmitted during the specified polling interval. This threshold is configured on a per-port basis configured using the `port port-type slot#/port#` command syntax.

**Important:** This command is not available on all platforms

**Important:** Ports configured for half-duplex do not differentiate between data received and data transmitted. (The transmitted and received percentages are combined.) Therefore, to avoid redundant alarms, it is recommended that only the receive or transmit utilization threshold be configured.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPortTxUtil` command in this mode.

**Example**

Use the following example to configure a threshold poll interval of 300 seconds (5 minutes)

```
threshold poll port-tx-utilization interval 300
```
**threshold poll ppp-setup-fail-rate interval**

Configures the polling interval in seconds over which to measure for the percentage of point-to-point protocol (PPP) setup failures.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config) #
```

**Syntax**

```
threshold poll ppp-setup-fail-rate interval duration
```

- **interval duration**
- Default: 900 seconds.
- Specifies the amount of time (in seconds) that comprises the polling interval.
- `duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

---

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold monitoring` and other threshold commands for additional information on the system’s support for thresholds in this chapter.

---

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshPPPSetupFailRate` command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for PPP setup failures:

```
threshold poll ppp-setup-fail-rate interval 600```
threshold poll reg-reply-error interval

Configures the polling interval over which to measure number of registration reply errors for Home Agent (HA) services.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config) #

Syntax

threshold poll reg-reply-error interval duration

  interval duration

  Default: 0 seconds.
  Specifies the amount of time (in seconds) that comprises the polling interval.
  duration must be an integer from 30 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

Important: To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshHASvcRegReplyError` command in this mode.

Example

The following command configures the polling interval to 600 seconds for HA registration errors:

```
threshold poll reg-reply-error interval 600
```
threshold poll reg-total-active interval

Configures the polling interval over which to measure CSCF Total Active Registrations.

**Product**

configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config) #
```

**Syntax**

```
threshold poll reg-total-active interval duration
```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold monitoring and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the SNMP trap enable ThreshCSCFSvcTotalActiveReg command in this mode.

**Example**

The following command configures the polling interval to 600 seconds for CSCF active registrations:

```
threshold poll reg-total-active interval 600
```
### threshold poll rereg-reply-error interval

Configures the polling interval over which to measure number of re-registration reply errors for HA services.

**Product**

HA

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration

**Syntax**

```
threshold poll rereg-reply-error interval duration
```

- `interval duration`
  - Default: 0 seconds.
  - Specifies the amount of time (in seconds) that comprises the polling interval.
  - `duration` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system’s support for thresholds in this chapter.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshHASvcReregReplyError` command in this mode.

**Example**

The following command configures the polling interval to **600** seconds for HA re-registration reply errors:

```
threshold poll rereg-reply-error interval 600
```
threshold poll route-service interval

Configures the polling interval over which to count or measure the thresholding value for BGP route services on the system.

Product
All

Privilege
Administrator Security Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

threshold poll route-service interval dur

default threshold poll route-service interval

default
Restores the threshold poll interval value to its default value of 900 seconds.

interval time
Default: 900 seconds
Specifies the amount of time (in seconds) that comprises the polling interval.
dur is any integer from 30 through 60000.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold model and threshold monitoring commands for additional information on the system’s support for thresholding.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshBGPRoutes command in this mode.

Example

The following command configures the polling interval for the total BGP routes threshold polling duration value to 600 seconds (10 minutes):
threshold poll route-service interval 600
**threshold poll rp-setup-fail-rate interval**

Configures the polling interval over which to measure the percentage of RAN PDSN (RP) setup failures.

**Product**

PDSN

**Privilege**

Administrator Security Administrator

**Mode**

Exec > Global Configuration configure

Entering the above command sequence results in the following prompt:

`[local]host_name(config)#`

**Syntax**

`threshold poll rp-setup-fail-rate interval dur`

`default threshold poll route-service interval`

- **default**
  
  Restores the threshold poll interval value to its default value of 900 seconds.

- **interval** *time*
  
  Default: 900 seconds
  
  Specifies the amount of time (in seconds) that comprises the polling interval.
  
  *dur* is any integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold model and threshold monitoring commands for additional information on the system’s support for thresholding.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshRPSetupFailRate` command in this mode.

**Example**

The following command configures the polling interval for the RP setup fail rate polling duration value to 600 seconds (10 minutes):

`threshold poll rp-setup-fail-rate interval 600`
threshold poll sess-flow-count interval

Configures the polling interval over which to measure the percentage of session manager flow count.

```
[local] host_name(config) #
```

**Syntax**

```
threshold poll system-capacity interval dur
```

```
default threshold poll route-service interval
```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold model` and `threshold monitoring` commands for additional information on the system’s support for thresholding.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshSystemCapacity` command in this mode.

**Example**

The following command configures the polling interval for flash memory utilization polling duration value to 600 seconds (10 minutes):

```
threshold poll system-capacity interval 600
```
threshold poll total-asngw-sessions interval

Configures the polling interval over which to count or measure the thresholding value for the total number of sessions across all the ASN-GW services on a system to trigger an alert or alarm.

**Product**
ASN-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll total-asngw-sessions interval time

default threshold poll total-asngw-sessions interval
```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold model` and `threshold monitoring` commands for additional information on the system’s support for thresholding.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable` `ThreshASNGWSessions` command in this mode.

**Example**

The following command configures the polling interval for counting the total number of ASN-GW sessions across all the ASN-GW services on a system, to 600 seconds (10 minutes):
threshold poll total-asngw-sessions interval 600
threshold poll total-ggsn-sessions interval

Configures the polling interval over which to count or measure the thresholding value for the total number of sessions across all the GGSN services on a system to trigger an alert or alarm.

Product  
GGSN

Privilege  
Security Administrator, Administrator

Mode  
Exec > Global Configuration  
configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

```
threshold poll total-ggsn-sessions interval time
```

**default threshold poll total-ggsn-sessions interval**

**default**

Restores the threshold polling interval value to its default value of 300 seconds.

**interval time**

Default: 300 seconds  
Specifies the amount of time (in seconds) that comprises the polling interval.  
`tme` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold model** and **threshold monitoring** commands for additional information on the system’s support for thresholding.

**Important:** To enable an SNMP trap for monitoring this threshold use the **snmp trap enable** command in this mode.

**Example**

The following command configures the polling interval for counting the total number of GGSN sessions across all the GGSN services on a system, to **600** seconds (10 minutes):
threshold poll total-ggsn-sessions interval 600
threshold poll total-gprs-pdp-sessions interval

Configures the polling interval over which to count the total number of 2G-activated PDP contexts per GPRS sessions on the system.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll total-gprs-pdp-sessions interval time
```

```
default threshold poll total-gprs-pdp-sessions interval
```

- **default**
  Restores the threshold polling interval value to its default value of 300 seconds.

- **interval time**
  Default: 300 seconds
  Specifies the amount of time (in seconds) that comprises the polling interval.
  `time` must be an integer from 30 through 60000.

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold model` and `threshold monitoring` commands for additional information on the system’s support for thresholding.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshGPRSPDPSessions` command in this mode.

**Example**

The following command configures the polling interval for counting the total number of 2G-activated PDP contexts per GPRS sessions, to 600 seconds (10 minutes):
threshold poll total-gprs-pdp-sessions interval 600
threshold poll total-gprs-sessions interval

Configures the polling interval over which to count the total number of 2G-attached subscribers on the system.

Product

Mode
Exec > Global Configuration
  configure
Entering the above command sequence results in the following prompt:
  [local] host_name(config) #

Syntax

  threshold poll total-gprs-sessions interval \textit{time}

  default

  default threshold poll total-gprs-sessions interval

  default

  Restores the threshold polling interval value to its default value of 300 seconds.

  \textit{interval} \textit{time}

  Default: 300 seconds
  Specifies the amount of time (in seconds) that comprises the polling interval.
  \textit{time} must be an integer from 30 through 60000.

Usage

This command sets the time period over which to monitor the specified value for threshold crossing.

\textbf{Important:} All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the \textit{threshold model} and \textit{threshold monitoring} commands for additional information on the system’s support for thresholding.

\textbf{Important:} To enable an SNMP trap for monitoring this threshold use the \textbf{snmp trap enable ThreshGPRSSessions} command in this mode.

Example

The following command configures the polling interval for counting the total number of 2G-attached subscribers, to 600 seconds (10 minutes):

  \texttt{threshold poll total-gprs-sessions interval 600}
threshold poll total-ha-sessions interval

Configures the polling interval over which to count the total number of Home Agent (HA) sessions on the system.

**Product**: HA

**Privilege**: Security Administrator, Administrator

**Mode**: Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold poll total-ha-sessions interval time
```

```
default threshold poll total-ha-sessions interval
```

**Usage**

This command sets the time period over which to monitor the specified value for threshold crossing.

**Important**: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the `threshold model` and `threshold monitoring` commands for additional information on the system’s support for thresholding.

**Important**: To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshHASessions` command in this mode.

**Example**

The following command configures the polling interval for counting the total number of HA sessions on the system, to 600 seconds (10 minutes):

```
threshold poll total-ha-sessions interval 600
```
threshold poll total-henbgw-henb-sessions

Configures the polling interval on how frequently the thresholds are polled for total HeNB-GW HeNB sessions.

Product

default
Restores the threshold poll interval value to its default value of 300 seconds.

interval time
Default: 300 seconds
Specifies the amount of time (in seconds) that comprises the polling interval.
*time must be an integer from 30 through 60000.

Usage
This command sets the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the threshold model and threshold monitoring commands for additional information on the system’s support for thresholding.

Important: To enable an SNMP trap for monitoring this threshold use the snmp trap enable ThreshSubscriberTotal command in this mode.

Example

The following command configures the polling interval for the total number of subscribers on a system, to 600 seconds (10 minutes):
threshold poll total-subscriber interval 600
threshold poll tpo-dns-failure

The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
threshold poll tpo-rto-timeout

The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
Chapter 146
Global Configuration Mode Commands (threshold ppp - url-blacklisting)

This section includes the commands `threshold ppp-setup-fail-rate` through `url-blacklisting database`. The Global Configuration Mode is used to configure basic system-wide parameters.

**Mode**

Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
threshold ppp-setup-fail-rate

Configures alarm or alert thresholds for the percentage of point-to-point protocol (PPP) setup failures.

Product
PDSN
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local] <host_name> (config) #

Syntax

threshold ppp-setup-fail-rate high_thresh [ clear low_thresh ]

<table>
<thead>
<tr>
<th>high_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0</td>
</tr>
</tbody>
</table>
| Specifies the high threshold rate percentage for PPP setup failures experienced by the system that must be met or exceeded within the polling interval to generate an alert or alarm.  
| high_thresh is an integer from 0 through 100. A value of 0 disables the threshold. |

<table>
<thead>
<tr>
<th>clear low_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0</td>
</tr>
<tr>
<td>Specifies the low threshold rate percentage for PPP setup failures experienced by the system that maintains a previously generated alarm condition. If the number of setup failures falls beneath the low threshold within the polling interval, a clear alarm will be generated.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>low_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>is an integer from 0 through 100. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

PPP setup failure rate thresholds generate alerts or alarms based on the rate of call setup failures experienced by the system during the specified polling interval. The failure rate is the percentage of failures as determined by number of PPP setup failures divided by the total number of PPP sessions initiated.

Alerts or alarms are triggered for PPP setup failure rates based on the following rules:

- **Enter condition:** Actual number of call setup failures is greater than or equal to the high threshold.
- **Clear condition:** Actual number of call setup failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a PPP setup failure rate high percentage threshold of 50 percent and a clear threshold of 45 percent:

```
threshold ppp-setup-fail-rate 50 clear 45
```
threshold route-service bgp-routes

Configures alarm or alert thresholds for the percentage of route services to BGP routes.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:
[local]host_name(config)#

Syntax

threshold route-service bgp-routes high_thresh [ clear low_thresh ]

<table>
<thead>
<tr>
<th>high_thresh</th>
</tr>
</thead>
</table>
Default: 0  | Specifies the high threshold rate percentage for BGP routes on the system that must be met or exceeded within the polling interval to generate an alert or alarm. |
high_thresh is an integer from 0 through 100. A value of 0 disables the threshold. |

<table>
<thead>
<tr>
<th>clear low_thresh</th>
</tr>
</thead>
</table>
Default: 0  | Specifies the low threshold rate percentage for BGP routes on the system that maintains a previously generated alarm condition. If the number of setup failures falls beneath the low threshold within the polling interval, a clear alarm will be generated. |
low_thresh is an integer from 0 through 100. A value of 0 disables the threshold. |

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
Use this command to configure a threshold in percentage of maximum BGP routes allowed. If the percentage of the number of BGP routes in a context (including all VRFs) reaches high_thresh, a notification is generated. Optionally, if the threshold subsystem is configured in ‘alarm’ mode, a Threshold_Clear notification is generated when the percentage of the number of BGP routes in a context (including all VRFs) goes below low_thresh. The maximum number of BGP routes is also sent by BGP task when getting the statistics.

Alerts or alarms are triggered for BGP routes based on the following rules:
- **Enter condition:** Actual number of call setup failures is greater than the high threshold.
- **Clear condition:** Actual number of call setup failures is less than the low threshold.
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

**Example**

The following command configures the system for a high threshold of 50 percent and a clear threshold of 45 percent:

```
threshold route-service bgp-routes 50 clear 45
```
threshold rp-setup-fail-rate

Configures alarm or alert thresholds for the percentage of RAN PDSN (RP) setup failures.

Product
PDSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local] host_name(config) #

Syntax

threshold rp-setup-fail-rate high_thresh [ clear low_thresh ]

<table>
<thead>
<tr>
<th>high_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0</td>
</tr>
<tr>
<td>Specifies the high threshold rate percentage for RP setup failures experienced by the system that must be met or exceeded within the polling interval to generate an alert or alarm.</td>
</tr>
<tr>
<td>high_thresh is an integer from 0 through 100. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>clear low_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0</td>
</tr>
<tr>
<td>Specifies the low threshold rate percentage for RP setup failures experienced by the system that maintains a previously generated alarm condition. If the number of setup failures falls beneath the low threshold within the polling interval, a clear alarm will be generated.</td>
</tr>
<tr>
<td>low_thresh is an integer from 0 through 100. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

RP setup failure rate thresholds generate alerts or alarms based on the rate of call setup failures experienced by the system during the specified polling interval. The failure rate is the percentage of failures as determined by number of Registration Request Messages rejected divided by the total number of Registration Request Messages received.

Alerts or alarms are triggered for RP setup failure rates based on the following rules:

- Enter condition: Actual number of call setup failures is greater than or equal to the high threshold.

- Clear condition: Actual number of call setup failures is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a RP setup failure rate high threshold of 50 percent and a clear threshold of 45 percent:

```
threshold rp-setup-fail-rate 50 clear 45
```
threshold sess-flow-count

Configures alarm or alert thresholds for the percentage of session manager flow count.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

```
configure
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold sess-flow-count flow_count_thresh [ clear clear_thresh ]
```

- **flow_count_percent**
  
  Default: 90
  
  Specifies the high threshold rate percentage for session manager flow count to generate an alert or alarm.
  
  `flow_count_thresh` is an integer from 1 through 100.

- **clear clear_thresh**
  
  Specifies the low threshold rate percentage for session manager flow count. If the number of session manager flow count falls beneath the low threshold, a clear alarm will be generated.
  
  `clear_thresh` is an integer from 1 through 100. The value chosen for the `clear_thresh` must always be lesser than the `flow_count_thresh`.

**Usage**

Use this command to configure thresholds for monitoring the session flow count.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a session flow count high threshold of 50 percent and a clear threshold of 45 percent:

```
threshold sess-flow-count 50 clear 45
```
threshold spc-cpu-memory-usage

This command has been renamed to threshold mgmt-cpu-memory-usage. Please refer to that command for details. Note that for backwards compatibility, the system accepts this command as valid.

| Important: This command is not supported on all platforms. |
threshold spc-cpu-utilization

This command has been renamed to threshold mgmt-cpu-utilization. Please refer to that command for details. Note that for backwards compatibility, the system accepts this command as valid.
threshold storage-utilization

Configures alarm or alert thresholds for the percentage of management card flash memory utilization.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold storage-utilization high_thresh [ clear low_thresh ]
```

- **high_thresh**
  - Default: 90
  - Specifies the high threshold storage utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm.
  - `high_thresh` is an integer from 0 through 100. A value of 0 disables the threshold.

- **clear low_thresh**
  - Default: 90
  - Specifies the low threshold storage utilization percentage that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - `low_thresh` is an integer from 0 through 100. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Flash memory utilization thresholds generate alerts or alarms based on the utilization percentage of storage available to the system.

Alerts or alarms are triggered for storage utilization based on the following rules:

- **Enter condition:** Actual percentage storage utilization is greater than or equal to the high threshold.
- **Clear condition:** Actual percentage storage utilization is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.
Example

The following command configures a high threshold for storage utilization percentage of 85 for a system using the Alert thresholding model:

```
threshold storage-utilization 85
```
threshold subscriber active

Configures alarm or alert thresholds for the number of active subscribers in the system.

Product
- PDSN
- GGSN
- SGSN
- HA

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration
- configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold subscriber active high_thresh [ clear low_thresh ]

high_thresh
Default: 0
Specifies the high threshold number of active subscriber sessions facilitated by the system that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh is an integer from 0 through 4000000. A value of 0 disables the threshold.

clear low_thresh
Default: 0
Specifies the low threshold number of active subscriber sessions facilitated by the system that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

low_thresh is an integer from 0 and 4000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Active subscriber thresholds generate alerts or alarms based on the total number of active subscriber sessions facilitated by the system during the specified polling interval.
Alerts or alarms are triggered for active subscriber totals based on the following rules:

- **Enter condition:** Actual total number of active subscriber sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of active subscriber sessions is less than the low threshold.
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures an active subscriber high threshold count of 150000 and a low threshold of 100000 for a system using the Alarm thresholding model:

```
threshold subscriber active 150000 clear 100000
```
threshold subscriber total

Configures alarm or alert thresholds for the total number of active and inactive subscribers in the system.

Product
- PDSN
- GGSN
- HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

Syntax

```
threshold subscriber total high_thresh [ clear low_thresh ]
```

### high_thresh

Default: 0
规定的高阈值的订阅者会话数（活跃和休眠）必须在指定的检测间隔内达到或超过，以生成警报或警告。

*high_thresh* 是一个整数范围从 0 到 4000000。值为 0 表示禁用阈值。

### clear low_thresh

Default: 0

规定的低阈值的订阅者会话数（活跃和休眠）必须在指定的检测间隔内维持一个先前生成的警报条件。如果在指定的检测间隔内，实际的会话数低于低阈值，将生成一个清除警报。

*low_thresh* 是一个范围从 0 到 4000000 的整数。值为 0 表示禁用阈值。

**Important**: 这个值对警告模型是忽略的。此外，如果没有配置该值，系统将假设它与高阈值相同。

**Usage**

总订阅者的阈值会根据系统在指定的检测间隔内执行的总订阅者会话数来触发警报。

警报或警告触发的规则包括以下两个条件:

- **Enter condition**: 实际的订阅者会话数大于或等于高阈值。
- **Clear condition**: 实际的订阅者会话数小于低阈值。
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures an active subscriber high threshold count of `450000` and a low threshold of `250000` for a system using the Alarm thresholding model:

```
threshold subscriber total 450000 clear 250000
```
threshold system-capacity

Configures alarm or alert thresholds based on the percentage of current system capacity.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**configure**

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold system high_thresh [ clear low_thresh ]
```

- **high_thresh**
  Default: 90
  Specifies the high threshold system capacity percentage that must be met or exceeded within the polling interval to generate an alert or alarm.
  **high_thresh** is an integer from 0 through 100. A value of 0 disables the threshold.

- **clear low_thresh**
  Default: 90
  Specifies the low threshold system capacity percentage that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  **low_thresh** is an integer from 0 through 100. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Flash memory utilization thresholds generate alerts or alarms based on the system utilization. Alerts or alarms are triggered for system capacity based on the following rules:

- **Enter condition:** Actual percentage of system capacity is greater than or equal to the high threshold.
- **Clear condition:** Actual percentage of system capacity is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

**Example**
The following command configures a high threshold for system capacity percentage of 95 for a system using the Alert thresholding model:

```
threshold system-capacity 95
```
threshold total-asngw-sessions

Configures alarm or alert thresholds for the total number of ASN-GW sessions across all the services in the system.

**Product**
ANS-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold total-asngw-sessions high_thresh [ clear low_thresh ]
```

**high_thresh**

Default: 0 (Disabled)
Specifies the high threshold number of total ASN-GW sessions across all the sessions in the system that must be met or exceeded within the polling interval to generate an alert or alarm.

**clear low_thresh**

Default: 0 (Disabled)
Specifies the low threshold number of total ASN-GW sessions that maintains a previously generated alarm condition. If the number of ASN-GW sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Monitor and set alarms or alerts when the total number of ASN-GW sessions across all the services in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for the total number of ASN-GW sessions based on the following rules:

- **Enter condition:** Actual total number of ASN-GW sessions is greater than or equal to the high threshold.

- **Clear condition:** Actual total number of ASN-GW sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.
Example

The following command configures a total ASN-GW session high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-asngw-sessions 10000
```
threshold total-ggsn-sessions

Configures alarm or alert thresholds for the total number of GGSN sessions across all the services in the system.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold total-ggsn-sessions high_thres [ clear low_thres ]

high_thres
Default: 0 (Disabled)
Specifies the high threshold number of total GGSN sessions across all the sessions in the system that must be met or exceeded within the polling interval to generate an alert or alarm.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

low_thres
Default: 0 (Disabled)
Specifies the low threshold number of total GGSN sessions that maintains a previously generated alarm condition. If the number of GGSN sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

low_thres is an integer from 0 and 4000000. A value of 0 disables the threshold.

Usage
Monitor and set alarms or alerts when the total number of GGSN sessions across all the services in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for the total number of GGSN sessions based on the following rules:

• **Enter condition**: Actual total number of GGSN sessions is greater than or equal to the high threshold.

• **Clear condition**: Actual total number of GGSN sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

Example
The following command configures a total GGSN session high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-ggsn-sessions 10000
```
threshold total-gprs-pdp-sessions

Configures alarm or alert thresholds for the total number of PDP contexts per GPRS sessions in the system.

Product
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold total-gprs-pdp-sessions high_thresh [ clear low_thresh ]

<table>
<thead>
<tr>
<th>high_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0</td>
</tr>
<tr>
<td>Specifies the high threshold number of total PDP contexts per GPRS session for all GPRS services that must be met or exceeded within the polling interval to generate an alert or alarm.</td>
</tr>
<tr>
<td>high_thresh is an integer from 1 through 2000000. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>clear low_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0</td>
</tr>
<tr>
<td>Specifies the low threshold number of total PDP contexts per GPRS session for all GPRS services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.</td>
</tr>
<tr>
<td>low_thresh is an integer from 0 and 2000000. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of GPRS sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for GPRS sessions based on the following rules:

- **Enter condition:** Actual total number of PDP Contexts is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of PDP contexts is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

Example
The following command configures a total number of PDP contexts per GPRS session high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-gprs-pdp-sessions 10000
```
threshold total-gprs-sessions

Configures alarm or alert thresholds for the total number of GPRS sessions in the system.

**Product**
SGSN

**Privilege**
Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold total-gprs-sessions high_thresh [ clear low_thresh ]
```

- **high_thresh**
  Default: 0
  Specifies the high threshold number of total GPRS sessions for all GPRS services that must be met or exceeded within the polling interval to generate an alert or alarm.
  `high_thresh` is an integer from 1 through 2000000. A value of 0 disables the threshold.

- **clear low_thresh**
  Default: 0
  Specifies the low threshold number of total GPRS sessions for all GPRS services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  `low_thresh` is an integer from 0 and 2000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Monitor and set alarms or alerts when the total number of GPRS sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for GPRS sessions based on the following rules:

- **Enter condition:** Actual total number of GPRS sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of GPRS sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**
The following command configures a total number of GPRS sessions high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-gprs-sessions 10000
```
threshold total-ha-sessions

Configures alarm or alert thresholds for the total number of Home Agent (HA) sessions across all services in the system.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold total-ha-sessions high_thresh [ clear low_thresh ]
```

**high_thresh**
Default: 0
Specifies the high threshold number of HA sessions for all HA services that must be met or exceeded within the polling interval to generate an alert or alarm.

**clear low_thresh**
Default: 0
Specifies the low threshold number of HA sessions for all HA services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Monitor and set alarms or alerts when the total number of HA sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for HA sessions based on the following rules:

- **Enter condition:** Actual total number of HA sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of HA sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**
The following command configures a total number of HA sessions high threshold count of 10000 for a system using the Alert thresholding model:

threshold total-ha-sessions 10000
threshold total-hnbgw-hnb-sessions

Configures alarm or alert thresholds for the total number of Home NodeB (HNB) sessions across all the HNB Gateway (HNB-GW) services in the system.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold total-hnbgw-hnb-sessions high_thres [ clear low_thres ]

---

**high_thres**
Default: 0 (Disabled)
Specifies the high threshold for the total number of HNB-HNB-GW sessions on IuH interfaces across all HNB-GW services on a system that must be met or exceeded within the polling interval to generate an alert or alarm.
*high_thres* is an integer from 0 through 1000000. A value of 0 disables the threshold.

---

**clear low_thres**
Default: 0 (Disabled)
Specifies the low threshold for the total number of HNB-HNB-GW sessions on IuH interfaces across all services on a system that maintains a previously generated alarm condition. If the number of HNB-HNB-GW sessions in a system falls beneath the low threshold within the polling interval, a clear alarm will be generated.
*low_thres* is an integer from 0 through 1000000. A value of 0 disables the threshold.

---

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

---

**Usage**
Use this command to monitor and set alarms or alerts when the total number of HNB-HNB-GW sessions on IuH interface across all HNB-GW services in the system is equal to or greater than the set limit. Alerts or alarms are triggered for the total number of HNB-HNB-GW sessions on IuH interface based on the following rules:

- **Enter condition:** Actual total number of HNB-HNB-GW sessions on IuH interface is greater than the high threshold.
Clear condition: Actual total number of HNB-HNB-GW sessions on IuH interfaces is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll total-hnbgw-hnb-sessions` command to configure the polling interval and the `threshold monitoring hnbgw-service` command to enable thresholding for this value.

Important: To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshTotalHNBGWHnbSess` command in this mode.

Example

The following command configures the total number of HNB-GW-HNB sessions on IuH interfaces to a high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-hnbgw-hnb-sessions 10000
```
threshold total-hnb-gw-iu-sessions

Configures alarm or alert thresholds for the total number of subscriber sessions towards the Core Networks (CN) across all HNB-GW services over Iu interfaces (Iu-CS/Iu-PS interface) on a system.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:
[local]host_name(config)#

Syntax

threshold total-hnb-gw-iu-sessions high_thresh [ clear low_thresh ]

high_thresh
Default: 0 (Disabled)
Specifies the high threshold for the total number of subscriber sessions towards CN across all HNB-GW services on a system that must be met or exceeded within the polling interval to generate an alert or alarm. high_thresh is an integer from 0 through 3000000. A value of 0 disables the threshold.

clear low_thresh
Default: 0 (Disabled)
Specifies the low threshold for the total number of subscriber sessions towards CN across all services on a system that maintains a previously generated alarm condition. If the number of subscriber sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated. low_thresh is an integer from 0 through 3000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to monitor and set alarms or alerts when the total number of subscriber sessions towards CN across all HNB-GW services in the system is equal to or greater than the set limit. Alerts or alarms are triggered for the total number of subscriber sessions towards CN across all HNB-GW service on a system based on the following rules:

• **Enter condition:** Actual total number of subscriber sessions across all HNB-GW service on a system is greater than the high threshold.

• **Clear condition:** Actual total number of subscriber sessions across all HNB-GW service on a system is less than the low threshold.
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll total-hnbgw-iu-sessions` command to configure the polling interval and the `threshold monitoring hnbgw-service` command to enable thresholding for this value.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThresholdTotalHNBGWiuSess` command in this mode.

**Example**

The following command configures the total number of subscriber sessions towards CN across all HNB-GW services to a high threshold count of 30000 for a system using the Alert thresholding model:

```
threshold total-hnbgw-iu-sessions 30000
```
threshold total-hnbgw-ue-sessions

Configures alarm or alert thresholds for the total number of UEs connected to an HNB-GW service across all the HNB-GW services in the system.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold total-hnbgw-ue-sessions high_thresh [ clear low_thresh ]

| high_thresh |
Default: 0 (Disabled)
Specifies the high threshold for the total number of UEs connected across all HNB-GW services on a system that must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 0 through 4000000. A value of 0 disables the threshold.

| clear low_thresh |
Default: 0 (Disabled)
Specifies the low threshold for the total number of UEs connected to HNB-GW service across all HNB-GW services that maintains a previously generated alarm condition. If the number of UE sessions across all the services in a system, falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 and 4000000. A value of 0 disables the threshold.

⚠️ Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to monitor and set alarms or alerts when the total number of UEs connected to HNB-GW service across all HNB-GW services in the system is equal to or greater than the set limit.
Alerts or alarms are triggered for the total number of UEs connected across all HNB-GW service on a system based on the following rules:

- **Enter condition:** Actual total number of UEs connected to HNB-GW service across all HNB-GW services on a system is greater than the high threshold.

- **Clear condition:** Actual total number of UEs connected to HNB-GW service across all HNB-GW services on a system is less than the low threshold.
Global Configuration Mode Commands (threshold ppp - url-blacklisting)

threshold total-hnbgw-ue-sessions

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. Refer to the threshold poll total-hnbgw-ue-sessions command to configure the polling interval and the threshold monitoring hnbgw-service command to enable thresholding for this value.

**Important:** To enable an SNMP trap for monitoring this threshold use the `snmp trap enable ThreshTotalHNBGWUESess` command in this mode.

**Example**

The following command configures the total number of UEs connected to HNB-GW service across all HNB-GW services to a high threshold count of **40000** for a system using the Alert thresholding model:

```
threshold total-hnbgw-ue-sessions 40000
```
threshold total-hsgw-sessions

Configures alarm or alert thresholds for the total number of HRPD Serving Gateway (HSGW) sessions across all services in the system.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

Syntax

```
threshold total-hsgw-sessions high_thresh [ clear low_thresh ]
```

- **high_thresh**
  
  Default: 0
  
  Specifies the high threshold for the number of HSGW sessions for all HSGW services that must be met or exceeded within the polling interval to generate an alert or alarm. **high_thresh** is an integer from 1 through 2500000. A value of 0 disables the threshold.

- **clear low_THRESH**
  
  Default: 0
  
  Specifies the low threshold for the number of HSGW sessions for all HSGW services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated. **low_thresh** is an integer from 0 and 2500000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of HSGW sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for HSGW sessions based on the following rules:

- **Enter condition:** Actual total number of HSGW sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of HSGW sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.
Example

The following command configures a total number of HSGW sessions high threshold count of 500000 for a system using the Alert thresholding model:

```
threshold total-hsgw-sessions 500000
```
threshold total-lma-sessions

Configures alarm or alert thresholds for the total number of Local Mobility Anchor (LMA) sessions across all services in the system.

**Product**
P-GW
SAEGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local] host_name(config)#
```

**Syntax**

```
threshold total-lma-sessions high_thresh [ clear low_thresh ]
```

- **high_thresh**
  - Default: 0
  - Specifies the high threshold number of LMA sessions for all LMA services that must be met or exceeded within the polling interval to generate an alert or alarm.
  - `high_thresh` is an integer from 1 through 1500000. A value of 0 disables the threshold.

- **clear low_thresh**
  - Default: 0
  - Specifies the low threshold number of LMA sessions for all LMA services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - `low_thresh` is an integer from 0 through 1500000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Monitor and set alarms or alerts when the total number of LMA sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for LMA sessions based on the following rules:

- **Enter condition:** Actual total number of LMA sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of LMA sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a total number of LMA sessions high threshold count of 500000 for a system using the Alert thresholding model:

```
threshold total-lma-sessions 500000
```
threshold total-Ins-sessions

Configures alarm or alert thresholds for the total number of L2TP Network Server (LNS) sessions in the system.

Product
PDSN
GGSN
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

\texttt{threshold total-Ins-sessions high\_thresh \[ clear low\_thresh \]}

\begin{description}
\item[high\_thresh]
Default: 0
Specifies the high threshold number of total LNS sessions that must be met or exceeded within the polling interval to generate an alert or alarm.\texttt{high\_thresh} is an integer value from 0 through 4000000. A value of 0 disables the threshold.
\item[clear low\_thresh]
Default: 0
Specifies the low threshold number of total LNS sessions that maintains a previously generated alarm condition. If the number of LNS sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.\texttt{low\_thresh} is an integer from 0 and 4000000. A value of 0 disables the threshold.
\end{description}

\textbf{Important:} This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of LNS sessions in the system is equal to or greater than the set limit.
Alerts or alarms are triggered for the total number of LNS sessions based on the following rules:
\begin{itemize}
\item \textbf{Enter condition:} Actual total number of LNS sessions is greater than or equal to the high threshold.
\item \textbf{Clear condition:} Actual total number of LNS sessions is less than the low threshold
\end{itemize}
If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a total LNS session high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-Ins-sessions 10000
```
threshold total-mme-sessions

Configures alarm or alert thresholds for the total number of Mobility Management Entity (MME) sessions across all the MME services in the system.

Product
MME

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

```
threshold total-mme-sessions high_thresh [ clear low_thresh ]
```

- **high_thresh**
  
  Default: 0 (Disabled)
  
  Specifies the high threshold number of total MME sessions that must be met or exceeded within the polling interval to generate an alert or alarm.
  
  `high_thresh` is an integer value from 0 through 2500000. A value of 0 disables the threshold.

- **clear low_thresh**
  
  Default: 0 (Disabled)
  
  Specifies the low threshold number of total MME sessions that maintains a previously generated alarm condition. If the number of MME sessions, across all the services in a system, falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  
  `low_thresh` is an integer from 0 and 2500000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to monitor and set alarms or alerts when the total number of MME sessions across all the MME services in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for the total number of MME sessions based on the following rules:

- **Enter condition:** Actual total number of MME sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of MME sessions is less than the low threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll total-mme-sessions` command to configure the polling interval and the `threshold monitoring mme-service` command to enable thresholding for this value.
Example

The following command configures a total MME session high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-mme-sessions 10000
```
threshold total-pdsn-sessions

Configures alarm or alert thresholds for the total number of Packet Data Serving Node (PDSN) sessions in the system.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host-name(config) #

**Syntax**

`threshold total-pdsn-sessions high_thresh [ clear low_thresh ]`

- `high_thresh`
  
  Default: 0
  
  Specifies the high threshold number of total PDSN sessions that must be met or exceeded within the polling interval to generate an alert or alarm.
  
  `high_thresh` is an integer from 0 through 2500000. A value of 0 disables the threshold.

- `clear low_thresh`
  
  Default: 0
  
  Specifies the low threshold number of total PDSN sessions that maintains a previously generated alarm condition. If the number of PDSN sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  
  `low_thresh` is an integer from 0 and 2500000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Monitor and set alarms or alerts when the total number of PDSN sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for the total number of PDSN sessions based on the following rules:

- **Enter condition:** Actual total number of PDSN sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of PDSN sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**
The following command configures a total PDSN session high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-pdsn-sessions 10000
```
threshold total-pgw-sessions

Configures alarm or alert thresholds for the total number of Packet Data Network Gateway (P-GW) sessions across all services in the system.

Product
P-GW
SAEGW

Privilege
Administrator

Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold total-pgw-sessions high_thresh [ clear low_thresh ]

\[high_thresh\]
Default: 0
Specifies the high threshold number of P-GW sessions for all P-GW services that must be met or exceeded within the polling interval to generate an alert or alarm.
\[high_thresh\] is an integer from 1 through 3000000. A value of 0 disables the threshold.

\[clear\] \[low_thresh\]
Default: 0
Specifies the low threshold number of P-GW sessions for all P-GW services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
\[low_thresh\] is an integer from 0 through 3000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of P-GW sessions in the system is equal to or greater than the set limit.
Alerts or alarms are triggered for P-GW sessions based on the following rules:
- **Enter condition:** Actual total number of P-GW sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of P-GW sessions is less than the low threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a total number of P-GW sessions high threshold count of 500000 for a system using the Alert thresholding model:

```
threshold total-pgw-sessions 500000
```
Global Configuration Mode Commands (threshold ppp - url-blacklisting)

threshold total-saegw-sessions

Configures alarm or alert thresholds for the total number of System Architecture Evolution Gateway (SAEGW) sessions across all services in the system.

**Product**
SAEGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold total-saegw-sessions high_thresh [ clear low_thresh ]
```

- `high_thresh`
  Default: 0
  Specifies the high threshold number of SAEGW sessions for all SAEGW services that must be met or exceeded within the polling interval to generate an alert or alarm.
  `high_thresh` is an integer from 1 through 3000000. A value of 0 disables the threshold.

- `clear low_thresh`
  Default: 0
  Specifies the low threshold number of SAEGW sessions for all SAEGW services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  `low_thresh` is an integer from 0 through 3000000. A value of 0 disables the threshold.

**Important:**
This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Monitor and set alarms or alerts when the total number of SAEGW sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for SAEGW sessions based on the following rules:

- **Enter condition:** Actual total number of SAEGW sessions is greater than or equal to the high threshold.
  - **Clear condition:** Actual total number of SAEGW sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the `threshold poll` command to configure the polling interval and the `threshold monitoring` command to enable thresholding for this value.

**Example**

The following command configures a total number of SAEGW sessions high threshold count of 500000 for a system using the Alert thresholding model:

```
threshold total-saegw-sessions 500000
```
threshold total-sgsn-pdp-sessions

Configures alarm or alert thresholds for the total number of PDP contexts for all Serving GPRS Support Node (SGSN) sessions in the system.

Product
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold total-sgsn-pdp-sessions high_thresh [ clear low_thresh ]

<table>
<thead>
<tr>
<th>high_thresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0</td>
</tr>
<tr>
<td>Specifies the high threshold number of total PDP contexts per SGSN session for all SGSN services that must be met or exceeded within the polling interval to generate an alert or alarm.</td>
</tr>
<tr>
<td>high_thresh is an integer from 1 through 4000000. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>clear low_thresh</th>

<tbody>
<tr>
<td>Default: 0</td>
</tr>
<tr>
<td>Specifies the low threshold number of total PDP contexts per SGSN session for all SGSN services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.</td>
</tr>
<tr>
<td>low_threshold is an integer from 0 through 4000000. A value of 0 disables the threshold.</td>
</tr>
</tbody>
</table>

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of SGSN sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for SGSN sessions based on the following rules:

- **Enter condition:** Actual total number of PDP contexts is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of PDP contexts is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.
Example

The following command configures a total number of PDP contexts per SGSN session high threshold count of 10000 for a system using the Alert thresholding model:

```plaintext
threshold total-sgsn-pdp-sessions 10000
```
**threshold total-sgsn-sessions**

Configures alarm or alert thresholds for the total number of SGSN sessions in the system.

**Product**
SGSN

**Privilege**
Administrator

**Mode**
Exec > Global Configuration
  - configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
threshold total-sgsn-sessions high_thresh [ clear low_thresh ]
```

- **high_thresh**
  - Default: 0
  - Specifies the high threshold number of total SGSN sessions for all SGSN services that must be met or exceeded within the polling interval to generate an alert or alarm.
  - *high_thresh* is an integer from 1 through 2000000. A value of 0 disables the threshold.

- **clear low_thresh**
  - Default: 0
  - Specifies the low threshold number of total SGSN sessions for all SGSN services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
  - *low_thresh* is an integer from 0 through 2000000. A value of 0 disables the threshold.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Monitor and set alarms or alerts when the total number of SGSN sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for SGSN sessions based on the following rules:

- **Enter condition:** Actual total number of SGSN sessions is greater than or equal to the high threshold.
- **Clear condition:** Actual total number of SGSN sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.

**Example**
The following command configures a total number of SGSN sessions high threshold count of 10000 for a system using the Alert thresholding model:

```
threshold total-sgsn-sessions 10000
```
threshold total-sgw-sessions

Configures alarm or alert thresholds for the total number of Serving Gateway (S-GW) sessions across all services in the system.

Product
S-GW

Privilege
Administrator

Mode
Exec > Global Configuration

configure

Entering the above command sequence results in the following prompt:

[local]host_name(config)#

Syntax

threshold total-sgw-sessions high_thresh [ clear low_thresh ]

high_thresh
Default: 0
Specifies the high threshold number of S-GW sessions for all S-GW services that must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh is an integer from 1 through 3000000. A value of 0 disables the threshold.

clear low_thresh
Default: 0
Specifies the low threshold number of S-GW sessions for all S-GW services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.
low_thresh is an integer from 0 through 3000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
Monitor and set alarms or alerts when the total number of S-GW sessions in the system is equal to or greater than the set limit.
Alerts or alarms are triggered for S-GW sessions based on the following rules:

- Enter condition: Actual total number of S-GW sessions is greater than or equal to the high threshold.
- Clear condition: Actual total number of S-GW sessions is less than the low threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the threshold poll command to configure the polling interval and the threshold monitoring command to enable thresholding for this value.
Example

The following command configures a total number of S-GW sessions high threshold count of 500000 for a system using the Alert thresholding model:

```
threshold total-sgw-sessions 500000
```
threshold tpo-dns-failure

The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
threshold tpo-low-compression-gain

The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
threshold tpo-rto-timeout

The Traffic Performance Optimization (TPO) in-line service is not supported in this release.
timestamps

Enables or disables the generation of a timestamp in response to each commands entered. The timestamp does not appear in any logs as it is a CLI output only. This command affects all future CLI sessions. Use the `timestamps` command in the Exec Mode to change the behavior for the current CLI session only.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
timestamps

no timestamps
```

Disables generation of timestamps for each command entered. When omitted, the output of a timestamp for each entered command is enabled.

**Usage**
Enable the timestamps when logging a CLI session on a remote terminal such that each command will have a line of text indicating the time when the command was entered.

**Example**

```
timestamps

no timestamps
```
unexpected-scenario session drop-call

Configures behavior when an unexpected call processing scenario is encountered. Enabling this command sets call clearing logic that replaces the automatic generation of asserts and core dumps for an initial assert.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
unexpected-scenario session drop-call [ disable-core ]

default unexpected-scenario session drop-call
```

**default unexpected-scenario session drop-call**

```
default
```

Disables call clearing logic for a graceful assert. This results in automatic core dump generation for unexpected scenarios resulting in control and data outage for the task instance until the core is fully generated.

```
[ disable-core ]
```

This option disables the automatic generation of core dumps when a call is dropped for a specific session.

**Usage**

Use this command to enable call clearing logic that will minimize the automatic generation of asserts and core dumps during a specific call processing session that may lead to data outage and session manager recovery.

The call clearing logic is only applied to the first assert generated during a call processing session. When that assert occurs, a zero-second timer lets the current stack unwind to avoid reentrancy issues. The call is then dropped from all interfaces. This is considered to be a graceful assert.

A core dump is generated along with any application supplied debug info. The line number and file index of the ASSERT appears in the call-line; the current call-line is marked as being in “assert_hit” scenario.

With the `disable-core` option set, a core dump is not generated following a graceful assert.

An assert generated after a graceful assert for the same unexpected scenario will cause the call to be dropped and trigger an automatic core dump. Depending on the length of time required to generate the associated core dump, a session manager recovery may be initiated. This is a highly unlikely possibility.

**Important:** The graceful assert call clearing logic can only be applied to call processing events, such as VoLTE. It cannot be used for ICSR-SRP scenarios.
Example

The following command enables call clearing logic for graceful asserts of initial call processing failures:

```
unexpected-scenario session drop-call disable-core
```
upgrade limit

Configures upgrade session limits that trigger when the system may execute the software upgrade.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration

**Syntax**

```
upgrade limit [ time session_life ] [ usage session_num ]
```

**Syntax**

- **upgrade limit**
  This command issued with no keywords sets all parameters to their defaults.

- **time session_life**
  Default: 120
  Defines the maximum number of minutes that a session may exist on the system undergoing a software upgrade, before it is terminated by the system. As individual user sessions reach this lifetime limit, the system terminates the individual session(s). `session_life` must be an integer ranging from 1 through 1440.

- **usage session_num**
  Default: 100
  This keyword defines a low threshold limit of sessions running either on a packet processing card or system-wide. When a software upgrade is invoked, this parameter applies to the entire system. When the threshold is crossed (when the number of sessions on the packet processing card or system is less than this value), the remaining sessions on the card or system are terminated allowing the upgrade to begin.
  The remaining sessions on the packet processing card or system are terminated regardless of their session life. `session_num` must be an integer from 0 through 6000.

**Usage**

Use this command to configure upgrade session limits that trigger the system to begin executing the software upgrade.

**Important**: This command is not supported on all platforms.

**Important**: Software Patch Upgrades are not supported in this release.
Example

The following command sets the number of minutes a session can exist to 200, and the minimum number of sessions that may exist before terminating them to 50:

    upgrade limit time 200 usage 50
# url-blacklisting database

This command configures URL Blacklisting database directory parameters.

## Product
CF

## Privilege
Security Administrator, Administrator

## Mode
Exec > Global Configuration
configure

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

## Syntax

```
url-blacklisting database { directory path path | max-versions max_versions | override file file_name }

default url-blacklisting database { directory path | max-versions | override file }
```

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Configures this command with the default settings.</td>
</tr>
</tbody>
</table>
| directory path  | Specifies the path to the directory to be used for storing URL Blacklisting databases.
| path            | path must be an alphanumeric string of 1 through 255 characters.
| max-versions    | Specifies the maximum number of URL Blacklisting database versions to be maintained in the URL Blacklisting database directory path with the base file name specified by the URL Blacklisting database override file.
| max_versions    | max_versions must be an integer from 0 through 3.
| override file   | Specifies the URL Blacklisting database override file name.
| file_name       | file_name must be in name.extension format. For example, abc.bin. And, must be an alphanumeric string of 1 through 10 characters.

## Usage
Use this command to configure URL Blacklisting database directory parameters.

## Example
The following command configures the maximum number of URL Blacklisting database versions to be maintained to 3:

url-blacklisting database max-versions 3
**wsg-lookup**

Enters the WSG lookup priority list configuration mode for site-to-site tunnels.

**Product**
WSG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration  
`configure`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config)#
```

**Syntax**

```
wsg-lookup
```

**Usage**

Use this command to enter the WSG lookup priority list configuration mode for site-to-site tunnels.

**Examples**

```
wsg-lookup
```
Chapter 147
GPRS Service Configuration Mode Commands

The GPRS Service Configuration Mode is used within the context configuration mode to define the criteria the SGSN needs to operate within a GPRS network. The GPRS Service works with other services, such as SGSN GPRS Tunneling Protocol (see SGTP Service Configuration Mode Commands) and Mobile Application Part (see MAP Service Configuration Mode Commands), to handle communication parameters required to work with other network entities such as the base station subsystem (BSS).

Mode

Exec > Global Configuration > Context Configuration > GPRS Service Configuration

configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gprs-service)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
accounting

Defines the accounting context name and enables/disables specific types of CDR generation for the accounting in the GPRS service.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GPRS Service Configuration
configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gprs-service)#

Syntax

accounting { cdr-types { mcdr | scdr | sms { mo-cdr | mt-cdr } | lcs { mt-cdr | mo-cdr } | smbmscdr }+ | context cntx_name }

default accounting cdr-types

no accounting ( cdr-types | context }

default

Returns the system to default CDR generation which includes:

• M-CDR
• S-CDR
• SMS CDRs
• LCS CDRs
• SMBMS CDR

no

Disables all CDR types.

cdr-types { mcdr | scdr | sms { mo-cdr | mt-cdr } | lcs { mt-cdr | mo-cdr } | smbmscdr }

Default: all types enabled.

Defines the types of CDRs to be generated within the specified GPRS service for accounting:

• mcdr: Enables generation of M-CDRs.
• scdr: Enables generation of S-CDRs.
• sms: Enables generation of SMS-type CDRs based on one of the following:
  • mo-cdr: SMS CDRs originates from the mobile.
GPRS Service Configuration Mode Commands

accounting

- **mt-cdr**: SMS CDRs terminates at the mobile.
- **smbmscdr**: This CDR type is currently under development and should not be included in configuration for this release.
- **lcs**: Enables the generation of LCS CDRs, based on:
  - **mt-cdr**: Mobile terminated location request CDR
  - **mo-cdr**: Mobile originated location request CDR

This symbol indicates that more than one keyword can be used and repeated. This enables you to include more than one type of CDR selection in a single command.

```
context cntx_name
```

Specifies an accounting context to be associated with the GPRS service.

*cntx_name*: Define a string of 1 to 79 alphanumeric characters.

Usage

Use this command to define the type of CDRs to generate for GPRS service. By default all types of CDRs are generated. Note that change of this configuration will be applied to new calls and/or to new PDP contexts only.

By default, the generation of all CDR types is enabled.

Example

The following command configures the system to generate only M-CDRs for accounting in the current GPRS service:

```
accounting cdr-types mcdr
```
**admin-disconnect-behavior**

This command defines some of the actions the SGSN will take during an Admin-Disconnect procedure.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
admin-disconnect-behavior { clear-subscription | detach-type { reattach-not-required | reattach-required } }

default admin-disconnect-behavior { clear-subscription | detach-type }
```

**clear-subscription**
Including this keyword in the configuration instructs the SGSN to clear subscriber contexts and the subscription data database whenever the **clear subscribers all** command is issued (from the Exec mode) for attached subscribers. As well, the SGSN will issue an appropriate Map-Purge-MS-Req to the HLR if needed.
Default: disabled

**detach-type**
Including this keyword defines which type of detach instruction to include in the Detach-Request message during an Admin-Disconnect procedure. One of the following options must be included when this command is entered:

- **reattach-not-required**
- **reattach-required**

Default: reattach-required

**default**
Including the **default** keyword in the command, instructs the SGSN to use the default value for the specified parameter.

**no**
Returns the SGSN to the default where this clear function is disabled
Usage
Using the clear subscribers all command (in the Exec Mode) will clear subscriber contexts and the subscription data database, and if needed, issue an appropriate Map-Purge-MS-Req to the HLR. Include the clear-subscription keyword with this command configuration to ensure that more than attached MM-context and active PDP-contexts are cleared when the clear subscribers all command is issued for attached subscribers.
To clear subscription data for detached subscribers, refer to the sgsn clear-detached-subscriptions command described in the Exec mode chapter.
Including the detach-type keyword with this command instructs the SGSN to include either a ‘reattach-required’ or a ‘reattach-no-required’ instruction in the Detach-Request message.

Example
Enable the clearing function so that subscription data is cleared from the HLR database:

```
admin-disconnect-behavior clear-subscription
```
associate

Associates or disassociates supportive services and policies, such as an Evolved GPRS Tunnelling Protocol (eGTP) service or a DSCP marking template with this GPRS service configuration.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service) #
```

**Syntax**

```
associate { { camel-service service_name [ context context_name ] | dscp-template downlink dscp_template_name | egtp-service egtp_svc_name [ context context_name ] | gs-service gs_svc_name [ context context_name ] | location-service loc_name | map-service map_svc_name [ context context_name ] | network-global-mme-id-mgmt-db | sgtp-service sgtp_svc_name [ context context_name ] | tai-mgmt-db database_name }

no associate { camel-service | dscp-template downlink | egtp-service | gs-service | hss-peer-service | location-service | map-service | network-global-mme-id-mgmt-db | sgtp-service | tai-mgmt-db }
```

**no**
Disassociates a previously associated service, DSCP marking template or management database with this GPRS service.

```
context ctx_name
```

Identifies an existing context name in which the named service is configured. If this keyword is omitted, the named service must exist in the same context as the GPRS service.

**camel-service camel_svc_name**
Associates a CAMEL service with this GPRS service.

**dscp-template downlink template_name**
Associates a DSCP template with the GPRS service.
### GPRS Service Configuration Mode Commands

#### egtp-service egtp_svc_name

 Associates an eGTP service with GPRS service.

- **egtp_svc_name** specifies the name for a configured eGTP service to associate with this GPRS service. Enter an alphanumeric string of 1 to 63 characters.

The eGTP service is created with the `egtp-service` command in the *Context Configuration Mode Commands* chapter. The eGTP service provides eGTP-C protocol interface support between the SGSN and EPS nodes. For more information on the eGTP service and the supported interface type(s), refer to the *eGTP Service Configuration Mode Commands* chapter.

**Important:** Only one eGTP service can be associated with a GPRS service. The eGTP service should be configured prior to issuing this command.

#### gs-service gs_svc_name

 Associates a Gs service with this GPRS service.

- **gs_svc_name** specifies the name for a configured Gs service to associate with the GPRS service. Enter an alphanumeric string of 1 to 63 characters.

The Gs service is created with the `gs-service` command in the *Context Configuration Mode Commands* chapter. The Gs service provides Gs interface support between the SGSN and MSC/VLR nodes. For more information on the Gs service and the supported interface type, refer to the *Gs Service Configuration Mode Commands* chapter.

**Important:** Only one Gs service can be associated with a GPRS service. The Gs service should be configured prior to issuing this command.

#### hss-peer-service hss_svc_name

 Associates an HSS peer service with this GPRS service.

- **hss_svc_name** specifies the name for a configured HSS peer service to associate with this GPRS service. Enter an alphanumeric string of 1 to 63 characters.

The HSS peer service provides S6d and S13-prime interface support via the Diameter protocol between the GPRS and an HSS (S6d) or EIR (S13-prime). For more information about the HSS peer service, refer to the `hss-peer-service` command in the *Context Configuration Mode Commands* chapter and the *HSS Peer Service Configuration Mode Commands* chapter.

**Important:** Only one HSS peer service can be associated to a service in this release. The HSS peer service should be configured prior to issuing this command.

#### location-service loc_svc_name

#### map-service map_svc_name

 Associates a location service with this GPRS service.

- **loc_svc_name** specifies the name for a pre-configured location service to associate with the GPRS service. Enter an alphanumeric string of 1 to 63 characters.

The location service is created with the `location-service` command in the *Context Configuration Mode Commands* chapter. For more information on the location services, refer to the *Location Services Configuration Mode Commands* section.
**Important:** Only one MAP service can be associated with a GPRS service. The MAP service should be configured prior to issuing this command.

```
network-global-mme-id-mgmt-db
```

Associates the configured global MME ID management database with the GPRS service. This enables operators to associate a single custom list of MME Group IDs for use in GPRS to E-UTRAN handovers on the S4-SGSN. The global MME ID management database is configured in the LTE Policy Configuration Mode using the `network-global-mme-id-mgmt-db` command. This command is available only if the SGSN S4 Interface license is enabled on the SGSN.

```
sgtp-service sgtp_svc_name
```

Associates an SGTP service with this GPRS service. `sgtp_svc_name` specifies the name for a configured SGTP service to associate with the GPRS service. Enter an alphanumeric string of 1 to 63 characters. The SGSN GPRS Tunneling Protocol (SGTP) service manages the configuration of the GTP-C and GTP-U related parameters. For more information on the SGTP service, refer to the `sgtp-service` command in the Context Configuration Mode Commands chapter and/or the SGTP Service Configuration Mode Commands chapter.

**Important:** Only one SGTP service can be associated with a GPRS service. The SGTP service should be configured prior to issuing this command. When co-locating an SGSN and MME, the GPRS Service cannot be associated with the same SGTP service that is used by the MME.

```
tai-mgmt-db database_name
```

Associates this GPRS service with a pre-configured TAI Management Database. `database_name` specifies the name of a pre-configured TAI Management Database to associate with the SGSN service as alphanumeric string of 1 through 64 characters. For more information on subscriber maps, refer to the `tai-mgmt-db` command in the LTE Policy Configuration Mode Commands chapter and the LTE TAI Management Database Configuration Mode Commands chapter. This command is available only if the SGSN S4 Interface license is enabled on the SGSN.

**Usage**

Use this command to associate a pre-configured service and/or DSCP marking template and/or management database with this GPRS service. The command can be repeated as necessary to configure associations for all desired services/templates/databases.

**Caution:** This is a critical configuration. The GPRS service cannot be started without this configuration. Any change to this configuration would lead to restarting the GPRS service. Removing or disabling this configuration will stop the GPRS service.

**Example**

The following command associates a previously-configured eGTP service called `egtp1` in the `dst_ctx` context to this GPRS service:

```
associate egtp-service egtp1 context dst_ctx
```
The following command disassociates a MAP service called map1 that was previously associated with this GPRS service:

```
no associate map-service egtp1
``` 

The following command associates an HSS peer service called hss1, previously-configured in the same context as the GPRS service, to this GPRS service:

```
associate hss-peer-service hss1
``` 

The following command associates a previously-configured DSCP marking template called dscp-temp1 to this GPRS service:

```
associate dscp-template downlink dscp-temp1
```
associate-dscp-template

Identifies a DSCP template to be associated with the GPRS service.

**Important:** This command is used only in Releases 12.0 and 12.2. For Release 14.0 refer to the `associate` command.

**Important:** This command can be used before the associated DSCP template instance is created and configured but care should be used to match the template names.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
associate-dscp-template downlink template_name

no associate-dscp-template downlink
```

**Usage**

Use this command to associate DSCP templates with this GPRS service. A single template can be associated with multiple GPRS services.

**Related commands:**

- The dscp-template command in the SGSN Global configuration mode creates / deletes an instance of a template. This command also provides access to the mode containing all the configuration commands used to define DSCP settings for the control packets for the Iu interface and the control and data packets for the Gb interface (see the DSCP Template Configuration Mode Commands section).
To check the list of DSCP templates configured, use the `show sgsn-mode` command documented in the *Exec Mode Commands* section.

**Example**

The following command associates the template with DSCP settings for traffic going through one of the SGSNs located in Paris mobile network:

```
associate-dscp-template dscp-template-paris3
```
**associate-service**

Identifies services to be associated with the GPRS Service.

**Important:** This command is used only in Releases 12.0 and 12.2. For Release 14.0 refer to the `associate` command.

**Important:** This command can be used before the associated service instance is created and configured but care should be used to match the service names.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

`configure > context context_name > gprs-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
[ no ] associate-service { gs name | map name | sgtp name } [ context ctxt_name ]
```

- **no**
  Removes the service association definition from the configuration.

- **gs name**
  Specifies the Gs service configuration to associate with this GPRS service. `name` must be a string of 1 to 63 alphanumeric characters with no spaces.

- **map name**
  Specifies the MAP service configuration to associate with this GPRS service. `name` must be a string of 1 to 63 alphanumeric characters with no spaces.

- **sgtp name**
  Specifies the SGTP service configuration to associate with this GPRS service. `name` must be a string of 1 to 63 alphanumeric characters with no spaces.

- **context ctxt_name**
  Defines the context in which the service was created. `ctxt_name` must be a string of 1 to 63 alphanumeric characters with no spaces.
Usage

Use this command to associate other services, that have been or will be configured, to this GPRS service.

Example

The following command associates Gs service gs1 with this GPRS service.

```
associate-service gs gs1 context sgsn2
```
## cc profile

Configures the charging characteristic (CC) profile index properties.

### Product
SGSN

### Privilege
Security Administrator, Administrator

### Mode
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

### Syntax

```
[ no ] cc profile index { buckets number | interval time | tariff time1 mins hours [ time2 mins hours [ time3 mins hours [ time4 mins hours ] ] ] | volume { downlink octets uplink octets | total octets } }
```

**default cc profile index**

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
<tbody>
<tr>
<td>Removes the a specific charging characteristics configuration definition.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resets the charging characteristics to system defaults.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>index</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configures a profile index for the parameter to be specified. index can be configured to any integer value from 0 to 15.</td>
</tr>
</tbody>
</table>

**Important:** 3GPP standards suggest that profile index values of 1, 2, 4, and 8 be used for hot billing, flat rate billing, prepaid billing and normal billing, respectively. A single charging characteristics profile can contain multiple behavior settings.

<table>
<thead>
<tr>
<th>buckets number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 4</td>
</tr>
<tr>
<td>Specifies the number of statistics container changes due to QoS changes or tariff time that can occur before an accounting record should be closed.</td>
</tr>
</tbody>
</table>

| number can be configured to any integer value from 1 through 4. |

<table>
<thead>
<tr>
<th>interval time</th>
</tr>
</thead>
<tbody>
<tr>
<td>time is measured in seconds and can be configured to any integer value from 60 to 40,000,000.</td>
</tr>
</tbody>
</table>
GPRS Service Configuration Mode Commands

**cc profile**

```
tariff time1 mins hours time2 mins hours time3 mins hours time4 mins hours
```

Specifies time-of-day time values to close the current statistics container (but not necessarily the accounting record). Six different tariff times may be specified. If less than six times are required, the same time can be specified multiple times.

**Important:** The system assumes that the billing system uses the day/date to determine if the statistics container represents an actual tariff period.

For each of the different tariff times, the following parameters must be configured:

- **mins:** The minutes of the hour, an integer value from 0 to 59.
- **hours:** The hour of the day, an integer value from 0 to 23.

```
volume { downlink vol_down_octets uplink vol_up_octets | total total_octets }
```

Specifies the downlink, uplink, and total volumes that must be met before closing a CDR.

- **vol_down_octets:** Measured in octets; can be configured to any integer value from 100,000 to 4,000,000,000.
- **vol_up_octets:** Measured in octets; can be configured to any integer value from 100,000 to 4,000,000,000.
- **total_octets:** The total traffic volume (up and downlink) measured in octets; can be configured to any integer value from 100,000 to 4,000,000,000.

**Usage**

Charging characteristics consist of a profile index and behavior settings. This command configures profile indexes for the SGSN’s charging characteristics. The SGSN supports up to 16 profile indexes. This command works in conjunction with the cc-sgsn command located in the APN configuration mode that dictates which CCs should be used for subscriber PDP contexts.

**Example**

The following command configures a profile index of 10 for tariff times of 7:00 AM and 7:30 PM:

```
cc profile 10 tariff time1 0 7 time2 30 19
```
checkimei

This command configures the action the SGSN will take if the route towards the EIR is down.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gprs-service)#

Syntax

checkimei { gf-failure-action | gf-timeout-action } { continue | reject }

default checkimei { gf-failure-action | gf-timeout-action }

default
Resets the default function to reject the Attach.

gf-failure-action
Coupled with either continue or reject, this keyword instructs the SGSN to take action if a valid EIR configuration exists under the MAP service and if the EIR is temporarily unreachable due to associated DPC/SSN inaccessible/out-of-service.

gf-timeout-action
Coupled with either continue or reject, this keyword instructs the SGSN to take action if a valid EIR configuration exists under the MAP service and the route to the EIR is available, but no response is received from the EIR.

continue
Instructs the SGSN to continue the Attach process.

reject
Instructs the SGSN to reject the Attach process.

Usage

Typically, the Attach process will be continued when there is an IMEI check timeout based on the configuration under the SGSN service configuration and/or the GPRS service configuration. But this works only if the route towards the EIR is UP and the IMEI request timer expires. This command configures the SGSN to allow the Attach process to continue in the case the route towards the EIR is down, that is the DPC/SSN is out-of-service.
Example

Use the following command to reset the default and reject Attach:

```
default check-imei gf-failure-action
```
check-imei-timeout-action

This command has been deprecated.
ciphering-algorithm

This command configures the priority, ordering, for the use of the GPRS encryption ciphering algorithms.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```bash
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```bash
ciphering-algorithm { negotiation-failure-action { reject [ failure-code cause_code ] | use-geo0 } priority priority [ algorithm ] } 
default ciphering-algorithm priority priority
```

**default**

Returns the system ciphering-algorithm priority to the default of GEA0 - which means that no ciphering will be done.

**negotiation-failure-action { reject [ failure-code cause_code ] | use-geo0 }**

This set of keywords configure the SGSN's action if there is not a match between the MS and SGSN ciphering algorithm configurations.

*reject:* Instructs the SGSN to reject a call when the ciphering algorithms do not match.

*failure-code cause_code:* Instructs the SGSN to include a GMM cause code in the Reject message. Enter an integer from 2 to 111; default code is 14 (GPRS services not allowed in this PLMN). Refer to the GMM failure cause codes listed below (information has been taken from section 10.5.5.14 of the 3GPP TS 124.008 v7.2.0 R7):

- 2 - IMSI unknown in HLR
- 3 - Illegal MS
- 6 - Illegal ME
- 7 - GPRS services not allowed
- 8 - GPRS services and non-GPRS services not allowed
- 9 - MSID cannot be derived by the network
- 10 - Implicitly detached
- 11 - PLMN not allowed
- 12 - Location Area not allowed
- 13 - Roaming not allowed in this location area
• 14 - GPRS services not allowed in this PLMN
• 15 - No Suitable Cells In Location Area
• 16 - MSC temporarily not reachable
• 17 - Network failure
• 20 - MAC failure
• 21 - Synch failure
• 22 - Congestion
• 23 - GSM authentication unacceptable
• 40 - No PDP context activated
• 48 to 63 - retry upon entry into a new cell
• 95 - Semantically incorrect message
• 96 - Invalid mandatory information
• 97 - Message type non-existent or not implemented
• 98 - Message type not compatible with state
• 99 - Information element non-existent or not implemented
• 100 - Conditional IE error
• 101 - Message not compatible with the protocol state
• 111 - Protocol error, unspecified

- **use-geo0**: Instructs the SGSN to honor the Attach/RAU Request without ciphering (geo0). This is the default action for negotiation failure.

### priority priority algorithm

Defines the priority, order of use, for the ciphering algorithm. **priority**: Must be an integer from 1 to 4.

### algorithm

Identifies the algorithm to be matched to the priority. Options include:

- **geo0**: No ciphering
- **geo1**: GPRS Encryption Algorithm - GEA1
- **geo2**: GPRS Encryption Algorithm - GEA2
- **geo3**: GPRS Encryption Algorithm - GEA3

### Usage

Use this command to specify the order (priority) of usage for the GPRS encryption algorithms. All of the GPRS encapsulation algorithms use a 64-bit key derived from a common mechanism: the mobile receives a random challenge, then the SIM calculates an authentication signature and an encryption key.

Also use this command to define the action to be taken if there is not a match between the MS and the SGSN ciphering algorithm configurations.

### Example

The following command sets no ciphering to be used after two encryption algorithms have been used:
The following command configures the SGSN to reject calls if the ciphering algorithm configurations don’t match:

```
ciphering-algorithm priority 3 gea0
ciphering-algorithm negotiation-failure-action reject
```
dns mcc-mnc-encoding

Configures the encoding format for the MCC and MNC values in the DNS query.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
dns mcc-mnc-encoding { apn-fqdn | mmec-fqdn | rai-fqdn | rnc-fqdn | tai-fqdn }* { a-query | snaptr-query }* { decimal | hexadecimal }
```

```
default dns mcc-mnc-encoding
```

- **default**
  Resets the SGSN to send the MCC and MNC values in decimal format for DNS queries.

- **apn-fqdn**
  This keyword is used for PGW/GGSN selection during PDP activation.

- **mmec-fqdn**
  This keyword is used for Peer MME selection during MME to SGSN ATTACH/RAU procedure and Suspend procedure.

- **rai-fqdn**
  This keyword is used for SGW selection, Peer SGSN selection during RAU/Attach procedure, Suspend procedure and RIM procedure.

- **rnc-fqdn**
  This keyword is used for Peer SGSN selection during SRNS re-location.

- **tai-fqdn**
  This keyword is used for Peer MME selection during SGSN to MME SRNS re-location and RIM procedure.

- **a-query**
  This keyword is used to control the DNS A/AAAA query MCC/MNC encoding format.
**snaptr-query**

This keyword is used to control the DNS SNAPTR query MCC/MNC encoding format.

---

**decimal**

Default

Instructs the SGSN to send the MCC and MNC in decimal format in the DNS query.

---

**hexadecimal**

Instructs the SGSN to send the MCC and MNC in hexadecimal format in the DNS query.

---

**Usage**

In order to provide effective control on DNS queries for particular type of procedures, existing CLI commands in GPRS and SGSN services have been deprecated and replaced with new enhanced commands. The command `dns israu-mcc-mnc-encoding [hexadecimal | decimal]` has been deprecated and this new CLI command is introduced. New keyword options `snaptr-query` and `a-Query` are provided to control different types of queries.

---

**Example**

Use the following command to configure hexadecimal encoding in the DNS query:

```
dns mcc-mnc-encoding rai-fqdn apn-fqdn mmec-fqdn rnc-fqdn tai-fqdn a-query hexadecimal
```
dns israu-mcc-mnc-encoding

Configures either decimal or hexadecimal format for the MCC and MNC values in the DNS query. This command is deprecated from release 16.0 onwards, it is replaced by the dns mcc-mnc-encoding command. See the dns mcc-mnc-encoding command for more information.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gprs-service)#

Syntax

dns israu-mcc-mnc-encoding ( decimal | hexadecimal )

default dns israu-mcc-mnc-encoding

default

Resets the SGSN to send the MCC and MNC values in decimal format for DNS queries.

default

decimal

Default.
Instructs the SGSN to send the MCC and MNC in decimal format in the DNS query.

hexadecimal

Instructs the SGSN to send the MCC and MNC in hexadecimal format in the DNS query.

Usage

Use this command to determine the type of encoding for the MCC and MNC to be included in the DNS query. For example:

In decimal, the MNC/MCC in a DNS query would appear like:

rac0017.lac42e3.mnc310.mcc722.gprs

In hexadecimal, the MNC/MCC in a DNS query would appear like:

rac0017.lac42e3.mnc0136.mcc02d2.gprs

Example

Use hexadecimal values for the MCC/MNC in the DNS query.
dns israu-mcc-mnc-encoding hexadecimal
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the previous configuration mode.

Security Administrator, Administrator

Syntax

```
exit
```

Usage
Return to the context configuration mode.
GPRS Service Configuration Mode Commands

**gmm**

`gmm` actually provides a set of commands used to define the GPRS mobility management parameters for the SGSN service.

![Important:](image) The `gmm` commands can be repeated as needed to set each timer.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

`configure > context context_name > gprs-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```

default gmm { attach ptmsi-signature-mismatch | ciph-gmm-msg-from-unknown-ms | mobile-reachable-timeout | implicit-detach-timeout secs | negotiate-t3314-timeout | purge-timeout | T3302-timeout | T3312-timeout | T3313-timeout | T3350-timeout | T3360-timeout | T3370-timeout | trau-timeout }

no gmm { Extended-T3312-timeout | negotiate-t3314-timeout

default

Disables the specified function or resets the specified timer to system defaults.

no

Removes the specified GMM definition from the configuration.

accept-procedure [ new-tlli | old-tlli ]

Default: new-tlli
This keyword enables the use of either a new TLLI (temporary logical link identifier) or an old TLLI for attach-accept or RAU-accept messages sent by the SGSN to the MS during related procedures.
attach ptmsi-signature-mismatch send-reject failure-code cause_code

Default: disabled
This keyword enables the SGSN to validate the P-TMSI signature, present in the Attach Request, against the PTMSI-SIGNATURE stored at the SGSN. The SGSN then sends an Attach Reject to the MS if the PTMSI-SIGNATURE does not match.
The P-TMSI signature validation functionality only works if the feature is enabled. But even if it is enabled, the feature does not validate in the following situations:

• when the PTMSI-SIGNATURE is absent from the 2G Attach Request.
• if the first subscriber being in DETACHED state or is purged with FREEZE-PTMSI. In both the scenarios PTMSI-SIGNATURE cannot be validated.
• when the 2G subscriber(MS2) attaches with the same P-TMSI and a different P-TMSI_Signature as previously attached 2G subscriber (MS1), both the subscriber profiles are cleared from the system.
  This is relevant where the old RAI for MS-2 is the same as the current RAI for MS-1.

Optionally, a GMM failure cause_code can be configured to include in the Attach Reject if one is sent.
Refer to the GMM failure cause codes listed below (information has been taken from section 10.5.5.14 of the 3GPP TS 124.008 v7.2.0 R7):

• 2 - IMSI unknown in HLR
• 3 - Illegal MS
• 6 - Illegal ME
• 7 - GPRS services not allowed
• 8 - GPRS services and non-GPRS services not allowed
• 9 - MSID cannot be derived by the network
• 10 - Implicitly detached
• 11 - PLMN not allowed
• 12 - Location Area not allowed
• 13 - Roaming not allowed in this location area
• 14 - GPRS services not allowed in this PLMN
• 15 - No Suitable Cells In Location Area
• 16 -MSC temporarily not reachable
• 17 - Network failure
• 20 - MAC failure
• 21 - Synch failure
• 22 - Congestion
• 23 - GSM authentication unacceptable
• 40 - No PDP context activated
• 48 to 63 - retry upon entry into a new cell
• 95 - Semantically incorrect message
• 96 - Invalid mandatory information
• 97 - Message type non-existent or not implemented
• 98 - Message type not compatible with state
● 99 - Information element non-existent or not implemented
● 100 - Conditional IE error
● 101 - Message not compatible with the protocol state
● 111 - Protocol error, unspecified

ciph-gmm-msg-from-unknown-ms { detach | ignore }

Configures how the SGSN will behave when it receives a ciphered GMM message from an unknown MS.
detach - Instructs the SGSN to send a Detach message to the MS.
ignore - Instructs the SGSN to send an Ignore (drop) message to the MS.
Default: ignore

implicit-detach-timeout secs

Specifies the implicit detach timer (IDT) value for the 2G ISR implicit detach procedure on the network side (see ISR -- Idle Mode Signaling Reduction on the S4-SGSN feature chapter in the SGSN Administration Guide for additional timer usage details).
The IDT is configurable from release 15.0 onwards and it is only applicable to 2G ISR activated calls. If ISR is not activated on a 2G call then the subscriber is detached soon after expiry of the mobile reachability timer (MNR) timer.
secs must be an integer from 240 to 86400 and the default value is 3600.

mobile-reachable-timeout mins

Default: 58 minutes
Specifies the timeout value for the mobile reachability timer (MNR). This timer is used with the IDT timer described above.
mins must be an integer from 4 to 1440.

negotiate-T3314-timeout secs

Set the number of seconds for the T3314-timeout ready timer value. Value sent out from SGSN so MS can negotiate ready timer.
secs must be an integer from 0 to 11160. Default is 44 seconds.
● If the MS does not send the ready timer in the Attach/RAU request, then the SGSN sends this T3314-timeout (ready timer) value.
● If the MS sends the requested value of the ready timer in the Attach/RAU Request, and if the requested value is less than or equal to the value of the negotiate-T3314-timeout timer, then the SGSN sends Att/RAU Accept with the requested T3314 value.
● If the MS sends the requested value of the ready timer in the Attach/RAU Request, and if the requested value is greater than the value of the negotiate-T3314-timeout timer, then the SGSN sends Att/RAU Accept with the negotiate-T3314-timeout value.

Important: This is the only GMM timer that can be disabled by entering no at the beginning of the command syntax: no gmm negotiate-t3314-timeout By disabling negotiation of the T3314-timeout value, if the MS sends the requested value of the ready timer in the Att/RAU Request, then the SGSN sends the T3314-timeout value in the Att/RAU Accept.
**paging-failure-action downlink-data-lockout-timer**  
Default: 1000 seconds.  
Enables and configures the downlink data lockout timer, for the SGSN services, to reduce the frequency of mobile-initiated keep alive messages.  
*seconds* set the number of seconds before timer expire, range of 0 to 10000.  
*repeat number_repeats* optionally sets the number of times (1 to 10) that the timer restarts after paging failure. **Note:** If repeat is not configured then paging proceeds endlessly until the MR timer expires.  
[ default | no ] **gmm paging-failure-action** disables the downlink data lockout timer.

**purge-timeout**  
Default: 10080 minutes  
The purge timer defines the MM-context lifetime, part of the MM-context procedure on the network side. The configured value sets the duration (number of minutes) the SGSN holds the detached subscriber’s MM-context profile. If the subscriber does not reattach to the SGSN during this time, then the SGSN purges this detached subscriber’s MM-context information from its database and sends a MAP purge request towards the HLR to indicate that the subscribers profile is gracefully purged from SGSN’s database.  
*mins* must be an integer from 1 to 20160.

**T3302-timeout**  
Default: 12 minutes  
Defines the number of minutes for timer to send to MS.  
*mins* is an integer from 1 to 186.

**T3312-timeout**  
Default: 54 minutes  
Periodic RAU update timer to send to MS.  
*mins* is an integer from 0 to 186.

**T3313-timeout**  
Default: 5 seconds  
Initial page timeout timer for retransmission for Paging Requests.  
*secs* is an integer from 1 to 60.

**T3314-timeout**  
Default: 44 seconds  
Ready Timer for controlling Cell Update Procedure.  
*secs* must be an integer from 0 to 11519.

**T3350-timeout**  
Default: 6 seconds  
Retransmission timer for Attach Accept/RAU Accept/P-TMSI Realloc Command.  
*secs* must be an integer from 1 to 20.

**T3360-timeout**  
Default: 6 seconds  
Retransmission timer for Authentication Request.  
*secs* must be an integer from 1 to 20.
**T3370-timeout**  
Default: 6 seconds  
Retransmission timer for Identity Request.  
*secs* must be an integer from 1 to 20.

**trau-timeout**  
This timer is available in releases 9.0 and higher.  
Default: 30  
Specifies the number of seconds the “old” 3G SGSN waits to purge the MS’s data. This timer is started by the “old” SGSN after completion of the inter-SGSN RAU.  
*secs*: Must be an integer from 5 to 60.

**Usage**
Use this command to set GMM timers.

**Example**
Set the t3370 timer expiration for 15 seconds:

```
gmm t3370-timeout 15
```
llc

Configures the timers that control the data flow for the logical link control (LLC) sub-layer.

**Important:** This command may be repeated as often as necessary to define the needed timers.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
llc { iov-ui-in-xid-reset | n201u-max { sapi11 pkt-size | sapi3 pkt-size | sapi5 pkt-size | sapi9 pkt-size } | nu-overflow-detection high-watermark high_num low-watermark low_num increment-oc| pdu-lifetime secs | random-value-in iov-ui | negotiation-failure-action { fallback-to-default iovui | reject } | reset-vur | t200 sapi1 time | t200 [ sapi11 time | sapi3 time | sapi5 time | sapi7 time | sapi9 time ] | uplink-pdu-len-validation }

default llc { iov-ui-in-xid-reset | n201u-max { sapi11 | sapi3 | sapi5 | sapi9 } | nu-overflow-detection | pdu-lifetime | random-value-in iov-ui | reset-vur | T200 [ sapi1 | sapi11 | sapi3 | sapi5 | sapi7 | sapi9 ] | uplink-pdu-len-validation }

no llc { iov-ui-in-xid-reset | nu-overflow-detection | random-value-in iov-ui | reset-vur | uplink-pdu-len-validation }
```

**default**

Resets the configuration parameter to the default values.

**no**

Disables a defined configuration parameter and returns to the SGSN default.

**iov-ui-in-xid-reset**

This keyword makes it possible for the operator to configure whether or not to send IOV-UI in an XID-RESET. This is useful when the MS is not setup to accept IOV-UI (for example, MS sends Attach/RAU Requests with cksn=7) and including IOV-UI in the XID-Reset would result in Attach/RAU failure.

Default: Enabled
**n20lu-max sapi n pkt_size**

This keyword sets the maximum number of octets, per service access point identifier (SAPI), for the downlink data packets. This is the upper limit that the SGSN will negotiate with the subscriber for packets sent from the SGSN to the BSC.

**sapi n**: Command must identify one of the following SAPI: sapi11, sapi3, sapi5, or sapi9.

**pkt_size**: Must be an integer from 140 to 1520. Default size is 1520 octets.

**nu-overflow-detection high-watermark high_num low-watermark low_num increment-oc**

Enables/disables overflow detection for the N(u) counter and setting overflow high/low thresholds facilitates ciphering synchronization between the MS and SGSN.

**high_num**: Enter an integer between 1 and 511.

**low_num**: Enter an integer between 0 and 510.

If the expected value of nu(Vur) is greater than or equal to the configured high-watermark, and the received nu(LFN) is less than or equal to the configured low-watermark, the SGSN increments the overflow counter (VurOC).

The recommended overflow settings are as follows:

```plaintext
llc nu-overflow-detection high-watermark 496 low-watermark 15 increment-oc
```

While expecting a packet with 496 < nu < 511 and a packet with 0 < nu < 15 is received, overflow is detected and VurOC is incremented.

**pdu-lifetime secs**

Defines LLC layer PDU lifetime at the BSC.

**secs** must be an integer from 0 to 90.

Default: 6

**random-value-in iov-ui [ negotiation-failure-action { fallback-to-default iovui | reject } ]**

Including this keyword enables the SGSN to negotiate the sending of a random value for the IOV/UI in the XID Request sent to the MS. If this keyword is not included, then by default the SGSN sends a zero (0) as the value of the IOV/UI in the XID message.

Including **default** in a command with the **negotiation-failure-action** keyword resets the SGSN configuration so that all calls are rejected whenever the deciphering fails due to failure of the XID negotiation for random IOV/UI

If the **negotiation-failure-action fallback-to-default iovui** option is included in the configuration, then the SGSN will fall back to unencrypted mode whenever the deciphering fails due to failure of the XID negotiation for random IOV/UI negotiation fails.

If the **negotiation-failure-action reject** option is included in the configuration to return the SGSN to the default functionality and reject all calls when random IOV/UI negotiation fails. This option is typically used only if the **negotiation-failure-action fallback-to-default iovui** option has previously been part of the configuration.

The **reject** option conditionally causes the SGSN to reject calls, for example, when XID for random IOV/UI negotiation failure occurs during intra-RAU or standalone authentication for SMS, the SGSN moves the subscriber to STANDBY and marks the XID negotiation as a failure.

OR

Despite the **reject** configuration, the SGSN may respond to XID negotiation failure in one of the following manners according to associated circumstances:

- Initiates XID for new random IOV/UI negotiation:

  - with the MS is in STANDBY state, any uplink packet (in either ciphered or unciphered mode, except Attach / Intra-RAU) from the MS which results in CELL-UPDATE, READY
TIMER START and RADIO STATUS READY causes an event indication to the application.

• Initiates Detach:
  • with the MS is in STANDBY state, any uplink activity causes the SGSN to initiate a new XID exchange, which if it fails or aborts due to the reception of SUSPEND, RADIO-STATUS and READY-TIMER expiry, results in the SGSN initiating Detach.
  • when PAGING is ongoing, any Page response from the MS results in the SGSN initiating Detach.
  • during OLD_SGSN ISRAU, when any uplink data comes before T3 tunnel timer expiry then the SGSN initiates Detach.

• Handles Messages:
  • Attach and intra-RAU (from both local and non-local TLLI or from both the same and different RA) will be processed in any state.

• Moves to STANDBY state:
  • MS is moved to STANDBY state if the XID exchange failed due to any of the following cases suspend, radio status, BVC block, BVC reset, ready timer expiry, no response received for XID exchange during INTRA-RAU/Standalone Authentication for SMS.
  • XID is ongoing in READY state and if the MS moves to either 3G or to the peer-SGSN then the subscriber is moved to STANDBY state.

reset-vur
Enables/disables the mechanism to reset the Vur value maintained at LLC if the intra RAU request is received with N(U) = 0
Default: Disabled

T200 sapi1 time
Sets the retransmission timer (in seconds) for sapi1.
time must be an integer of 1 to 10.
Default: 5

T200 sapi11 time
Sets the retransmission timer (in seconds) for sapi11.
time must be an integer of 1 to 50.
Default: 40

T200 sapi3 time
Sets the retransmission timer (in seconds) for sapi3.
time must be an integer of 1 to 10.
Default: 5

T200 sapi5 time
Sets the retransmission timer (in seconds) for sapi5.
time must be an integer of 1 to 20.
Default: 10
**GPRS Service Configuration Mode Commands**

**llc**

**Command Line Interface Reference, StarOS Release 16**

---

**T200 sapi7 time**

Sets the retransmission timer (in seconds) for sapi7.

*time* must be an integer of 1 to 40.

Default: 20

**T200 sapi9 time**

Sets the retransmission timer (in seconds) for sapi9.

*time* must be an integer of 1 to 40.

Default: 20

**uplink-pdu-len-validation**

Available in releases 8.1 and higher.

This feature enables validation of the size of the uplink LLC packets. With validation enabled, the SGSN will drop any uplinked packets that are larger than the negotiated limit.

If the no form of the command is used, then this feature is disabled. The SGSN will be more flexible with uplink packet sizes. So if the SGSN and MS have a mismatch and the MS sends packets that are larger than expected, then the SGSN will not drop the packets.

Default: Enabled.

**Usage**

Use the command repeatedly to configure additional timers and features for the LLC sub-layer.

**Example**

Set the T200 retransmission timer to timeout at 12 seconds for SAPI5:

```
llc t200 sapi5 12
```

Use the following command to instruct the SGSN to ignore the N201_U packet size limits for uplink packets from an MS:

```
no uplink-pdu-len-validation
```
network-sharing

This command enables or disables CS-PS coordination checking for homers (UEs in their home network) or roamers (UEs from outside the home network). The command also sets the failure code that will be sent for GPRS MOCN.

**Product**
SGSN

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```shell
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```shell
network-sharing { cs-ps-coordination { failure-code <gmm-cause> | homer | roammer } |
failure-code <gmm-cause>

no network-sharing cs-ps-coordination { homer | roammer }

default network-sharing cs-ps-coordination
```

---

**no**

Disables CS-PS coordination check for either homers or roamers.

---

**default**

Set the CS-PS coordination parameters to default values.

---

**failure-code <gmm-cause>**

This keyword has two optional functions:

- When used with the `cs-ps-coordination` keyword, it sets the GMM cause code that is to be included in the message when the SGSN requests the BSC to provide CS-PS coordination. Default value is 14.

- When used as an independent keyword with the `network-sharing` command, it sets the failure cause that is used by GPRS MOCN if no failure cause is available when the SGSN sends a Reject message. Default value is 7.

`<gmm-cause>` is an integer from 2-111. Valid options include:

- 2 - IMSI unknown in HLR
- 3 - Illegal MS
- 6 - Illegal ME
- 7 - GPRS services not allowed
- 8 - GPRS services and non-GPRS services not allowed
• 9 - MSID cannot be derived by the network
• 10 - Implicitly detached
• 11 - PLMN not allowed
• 12 - Location Area not allowed
• 13 - Roaming not allowed in this location area
• 14 - GPRS services not allowed in this PLMN
• 15 - No Suitable Cells In Location Area
• 16 - MSC temporarily not reachable
• 17 - Network failure
• 20 - MAC failure
• 21 - Synch failure
• 22 - Congestion
• 23 - GSM authentication unacceptable
• 40 - No PDP context activated
• 48 to 63 - retry upon entry into a new cell
• 95 - Semantically incorrect message
• 96 - Invalid mandatory information
• 97 - Message type non-existent or not implemented
• 98 - Message type not compatible with state
• 99 - Information element non-existent or not implemented
• 100 - Conditional IE error
• 101 - Message not compatible with the protocol state
• 111 - Protocol error, unspecified

**homer**
Enables checking for CS-PS coordination for UEs from inside the home network (homers) only.

**roamers**
Enables checking for CS-PS coordination for UEs from another network (roamers) only.

**Usage**
The operator can use this command to configure CS-PS coordination checking explicitly for homer or roamers subscribers and for the failure-code to be sent when the SGSN asks the BSC to perform CS-PS coordination.

**Example**
Use a command similar to the following to have the SGSN perform CS-PS coordination checking only for all UEs from outside of the home network. `network-sharing cs-ps-coordination homer`
nri

This command configures the network resource identifier (NRI) to identify a specific SGSN. The NRI information is stored in the P-TMSI. The SGSN uses a portion of this NRI to set the parameters for Gb flex (SGSN pooling) functionality.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
nri length nri_length  { nri-value nri_value  | null-nri-value null_nri_value non-broadcast-lac lac_id rac rac_id [ nri-value value ] }

default nri

no nri
```

---

**Important:** Behavior change in Release 14.0 -- it is no longer necessary to configure NRI as default values have been enabled.

---

**Important:** no nri command form is deprecated in Release 14.0. To ensure backward compatibility with configuration files created with pre-Release 14.0 builds, the no nri configuration will be automatically converted to the Release 14.0 default values of nri 6 and 0.

This command removes the configured NRI value and location information in the P-TMSI that would be retrieved by this SGSN.
**length nri_length**

Specifies the number of bits to be used in the P-TMSI, bits 23 to 18 are used to define the network resource identifier (NRI). The NRI length configuration also sets the maximum size of the pool. If not configured, the NRI length will be of zero length.

*nri_length*: Must be an integer from 1 to 6 to identify the number of bits.

**null-nri-value null_nri_value**

Configures the null NRI value which must be unique across the pool areas. This keyword is used for the offloading procedure for SGSN pooling (enabled with the `sgsn offloading` command, see the Exec Mode chapter).

*null_nri_value* is an integer from 0 (zero) to 63 used to identify the SGSN to be used for the offloading procedure for SGSN pooling. There is no default value for this parameter.

**non-broadcast lac lac_id rac rac_id**

Defines the non-broadcast LAC/RAC to be used in combination with the null-NRI for the offloading procedure.

*lac_id* defines a location area code associated with a BSS. Must be an integer between 1 and 65535.

*rac_id* defines the remote area code to be associated with a BSS. Must be an integer between 1 and 255.

**nri-value nri_value**

Specifies the MS-assigned value of the NRI to retrieve from the P-TMSI. This value must not exceed the maximum possible value specified by the NRI length. The NRI value must be unique across the pool or across all overlapping pools.

*nri_value* must be an integer from 1 to 63 to identify a specific SGSN in a pool. Use of 0 (zero) value is not recommended.

Multiple NRI values can be identified by providing multiple nri-values separated by a blank space for example: `nri length 6 nri-value 29 43 61`

**Usage**

Use this command to add or remove the Gb flex pool configuration for this GPRS service. The command can be repeated to specify different values for any of the keyword parameters. If more than one NRI is configured, the GPRS service will round-robin between the available NRIs when new subscribers (re)connect.

Use this command to retrieve the NRI (identity of an SGSN) stored in in bits 23 to 18 of the packet-temporary mobile subscriber identity (P-TMSI). If more than one NRI value is configured, the GPRS service will round-robin between the available NRIs when new subscribers (re)connect.

**Example**

The following command specifies the the NRI length as 5 bits, identifies SGSN 23 with LAC 222 and RAC 12 for offloading procedure with NRIs 6 and 41:

```
nri length 5 null-nri-value 34 non-broadcast lac 222 rac 12 nri-value 6 41
```
paging-policy

Configures the paging parameters for the GPRS service.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

Syntax

```
paging-policy { last-known-area { all | bsc | cell | location-area | routing-area } + |
  max-retransmissions retran_num }

no paging-policy last-known-area { bsc | cell | location-area | routing-area }

default paging-policy { last-known-area | max-retransmissions }
```

**no**
Disables the paging-policy definition for this GPRS service configuration.

**default**
Resets the defaults for parameters managed by this paging policy.

**last-known-area**
Select one or more paging areas and enter them in preferred paging order:
- **all**: Pages in the last known BSC.
- **bsc**: Pages in last known BSC.
- **cell**: Pages in last known cell.
- **location-area**: Pages in last known location area.
- **routing-area**: Pages in last known routing area.

By default, paging occurs in the following order:
cell, BSC, routing area, location area.

**max-retransmission retran_num**

Configures the maximum number of retries for a page request per paging area.

*retran_num*: Enter an integer from 0 to 5.
- **2**: default.
• 0: disables retransmission for paging request so that the SGSN only sends a single 2G PS-paging request to the BSC with no retransmissions.

Keywords can be repeated or combined as needed to complete the paging policy configuration.

Usage
Use this command to configure the order of preference for retransmitting into specified paging-areas.

Example
Use the following command to instruct the SGSN to page the cell and BSC as the last-known areas:

```
paging-policy last-known-area cell bsc
```
peer-nsei

This command associates a peer (remote) network service entity (NSEI) for a BSS with this GPRS service.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
peer-nsei nse_id { associate dscp-template downlink template_name | lac lac_id rac rac_id | name peer_nsei_name | pooled }
```

```
no peer-nsei nse_id [ associate dscp-template downlink | lac lac_id rac rac_id | name | pooled ]
```

```
no
```

Removes the specified configuration from this peer-nsei configuration.

---

**Important:** Deleting the LAC/RAC portion of the configuration will probably result in the loss of subscriber connections.

---

**nse_id**

Defines a specific peer NSEI configuration for this GPRS service.

**lac**

Defines a location area code associated with the NSE BSS.

**Template Configuration Mode Commands**

**associate dscp-template downlink template_name**

Identifies a specific DSCP marking template to associate with the peer-NSE. The DSCP template must first be created with SGSN Global configuration mode and then defined with the commands in the DSCP Template configuration mode. The template provides a mechanism for differentiated services code point (DSCP) marking of control packets and LLC signaling messages on Gb interfaces. This DSCP marking feature enables the SGSN to perform classifying and managing of network traffic and to determine quality of service (QoS) for the interfaces to an IP network.

**template_name** - enter an alphanumeric string of 1 to 64 characters.
GPRS Service Configuration Mode Commands

### rac rac_id
Defines the remote area code to be associated with the NSE BSS

`rac_id` must be an integer between 1 and 255.

### name peer_nsei_name
Enables identifying a BSC by a name which is stored in SCT.

`peer_nsei_name` - enter an alphanumeric string of 1 to 64 characters.

### pooled
Enables pooling with non-pooled BSCs within the pool area.

---

**Usage**

Use this command repeatedly to associate one or more LAC/RAC combinations and/or pooling with this peer-GPRS service configuration. Also repeat the command as needed to create an association with a DSCP marking template, to define a name for a BSC, and to enable pooling with non-pooled BSCs.

The Network Service Entity (NSE) at the BSS and the SGSN provides the network management functionality required for the operation of the Gb interface. Each NSE is identified by means of NSE identifier (NSEI).

**Example**

The following command configures the NSE with identifier as `4114` having location area code `234` and routing area code as `22`:

```
peer-nsei 4114 lac 234 rac 22
```

The following command enables Gb flex (pooling) functionality for NSEI `4414` for this GPRS service:

```
peer-nsei 4414 pooled
```
plmn

This command identifies the Public Land Mobile Network (PLMN) for the GPRS service. It also configures the common PLMN-Id and an optional list of dedicated PLMN-Ids in support of Multi-Operator Core Network (MOCN) operation.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

```
configure > context context_name > gprs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
plmn id mcc mcc_num mnc mnc_num [ network-sharing common-plmn mcc mcc_num mnc mnc_num [ plmn-list mcc mcc_num mnc mnc_num [ mcc mcc_num mnc mnc_num ] + ] ]
no plmn id
```

**no**

Removes the PLMN information from the configuration for the current SGSN service.

**mcc mcc_num**

Define the mobile country code (MCC) portion of the PLMN Id.

`mnc_num` must be a 3 digit integer from 100 to 999. MCC values of 000-099 are Reserved codes.

**mnc mnc_num**

Define the mobile network code (MNC) portion of the PLMN Id.

`mnc_num` must be a 2 or 3 digit integer from 00 to 999. MNC value of 000 is reserved.

**network-sharing common-plmn**

Configures the common PLMN-Id broadcast by a radio network. An MS that does not support network sharing will only see this PLMN-Id. An MS that supports network sharing (MOCN) will see this PLMN-Id and the list of PLMN-Ids configured using the `plmn-id` keyword.

**plmn-list**

Configures a list of PLMN-Ids that an MS will see when network sharing is enabled.

**+**

The plus symbol indicates that indicates that more than one more than one set of the keywords, for PLMN-Id, can be entered within a single command.
Usage
Use this command to set PLMN parameters for the current SGSN service. This command also sets the common PLMN-Id and a list of PLMN-Ids employed in network sharing (MOCN) deployments. There is no limit to the number of PLMN-Ids that can be included in the list.

Example
The following command identifies the PLMN MCC as 200 and the MNC as 10:

```
plmn id mcc 200 mnc 10
```
**reporting-action event-record**

This command enables the SGSN to log GMM/SM events in EDR files for 2G services.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration  
configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
reporting-action event-record

[ default | no ] reporting-action event-record
```

**default**
Disables the logging function.

**no**
Removes the logging function from the configuration file.

**Usage**

This command is one of the steps needed to enable the SGSN to create a log for events such as Attach, RAU, and Activations. The log is an EDR (event data record) in CSV format. For details about how this feature works, refer to the *GMM-SM Event Logging* chapter in the *SGSN Administration Guide*.

**Related Commands:**
- To enable GMM/SM event logging for 2G services, the `reporting-action event-record` command must be configured in the SGSN service configuration.
- To enable a log to be generated in an EDR file, the `edr-module active-charging-service` command must be enabled in the Context configuration mode.
- To configure parameters for the logging file characteristics and for file transfer, use the commands in the EDR Module Configuration Mode.

**Example**

Enable GMM/SM event logging for 3G services:

```
reporting-action event-record
```
setup-timeout

This command configures the maximum number of seconds allowed for session setup.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration
configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

```bash
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
setup-timeout seconds

default setup-timeout
```

---

**Usage**

Use this command to set the time allowed for session setup.

**Example**

The following command sets the maximum session setup time to 300 seconds:

```
setup-timeout 300
```
sgsn-context-request

This command specifies whether or not the PTMSI signature check should be skipped if the PTMSI signature is not included in the SGSN context request.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
sgsn-context-request ptmsi-signature-absence allowed
default sgsn-context-request ptmsi-signature-absence
no sgsn-context-request ptmsi-signature-absence allowed
```

---

**Usage**

Returns the configuration to the default action to perform the PTMSI signature check.

**no**

Removes this definition from the system configuration.

---

**Example**

Use this command to skip the PTMSI signature check.

The following command instructs the system to perform the PTMSI signature check.

```
default sgsn-context-request ptmsi-signature-absence
```
sgsn-number

Define the SGSN E.164 number to be used when interacting via MAP protocol for this GPRS service.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GPRS Service Configuration
configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gprs-service)#

Syntax

sgsn-number  sgsn_number

no sgsn-number

no

Disables the use of this definition in the system configuration.

sgsn-number

Enter a string of 1 to 16 digits to identify the SGSN’s E.164 identification.

Usage

Use this command to identify the ISDN number for the SGSN associated with this GPRS service. The SGSN supports multiple SGSN numbers – different numbers in the 2G GPRS service configuration and the 3G SGSN service configuration. If an HLR-initiated dialog is received, the SGSN will perform a lookup based on the IMSI and find the correct SGSN number with which the MS is associated. Subsequent messaging will use this address.

Example

Disable the E.164 number for this GPRS service.

no sgsn-number
**sm**

This command configures the session management (SM) parameters associated with this particular GPRS service context.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gprs-service)#
```

**Syntax**

```
sm { activate-max-retransmissions num_retries | deactivate-max-retransmissions num_retries | guard-timer guard_seconds | ignore-pco-decode-error | modify-max-retransmissions num_retries | partial-apn-match | radio-priority from-arp arp rp_prof_name | requested-apn-from-first-subrec | t3385-timeout secs | t3386-timeout secs | t3395-timeout secs | t3396 min minimum max maximum cause cause_code | trim-trailing-spaces-in-apn }

default sm { activate-max-retransmissions | deactivate-max-retransmissions | ignore-pco-decode-error | modify-max-retransmissions | t3385-timeout | t3386-timeout | t3395-timeout | trim-trailing-spaces-in-apn }

no sm { ignore-pco-decode-error | radio-priority from-arp | partial-apn-match | radio-priority | requested-apn-from-first-subrec | t3396 | trim-trailing-spaces-in-apn }
```

**default**

Resets the SM parameters to their defaults.

**no**

Removes the identified parameter configuration from the GPRS Service configuration.

**activate-max-retransmissions num_retries**

Defines the maximum number of retries to transmit ‘activate PDP context request’.

*num_retries*: Must be an integer from 1 to 10.

Default: 4

**deactivate-max-retransmissions num_retries**

Defines the maximum number of retries to transmit ‘deactivate PDP context request’.

*num_retries*: Must be an integer from 1 to 10.

Default: 4
### GPRS Service Configuration Mode Commands

**guard-timer guard_seconds**
Sets the number of seconds before the session manager resources are cleared.
*guard_seconds* is an integer from 30 to 150.
Default: 80 seconds

**ignore-pco-decode-error**
Enables the SGSN to ignore received decode errors that are due to incorrectly encoded PCO IE length in SM Requests.
Default: disabled

**modify-max-retransmissions num_retries**
Defines the maximum number of retries to transmit ‘modify PDP context request’.
*num_retries*: integer from 1 to 10.
Default: 4

**partial-apn-match**
Enables partial matching of requested APN during APN selection.
Partial APN or APN with trailing spaces may be present in an Activate Request because incorrect information was keyed in by the user. Though it is valid to reject such Activation Requests, it increases the signaling between the MS and the SGSN. This has an impact on the radio resources.

**radio-priority from-arp**
This keyword associates an ARP-RP Mapping Profile with the GPRS service. The profile is created and configured via the ARP-RP Mapping Profile configuration mode under the SGSN-Global configuration mode.
*arp-rp_prof_name*: Enter a string of 1 to 64 alphanumeric characters to identify the mapping profile and moves into the ARP-RP mapping profile configuration mode.
Use the *show configuration* command to display the association.

**requested-apn-from-first-subrec**
Enables use of a ‘requested APN’ from the first subscription record. When this feature is enabled, the PDP Activation is not rejected during APN Selection; instead, the APN from the first subscription record is used as the requested APN and the SGSN continues with the rest of the APN Selection process.
A requested APN is an optional IE in an Activate PDP Request. To get the requested PDP type, if multiple PDP subscription records exist for the subscriber, then the MS has to include the APN information to choose the PDP subscription record during APN selection. Otherwise, such activations will be rejected during APN selection (per TS 23.060 Appendix A). Though it is valid to reject such activation requests, it increases the signaling between the MS and the SGSN, which impacts the radio resources.

**t3385-timeout secs**
Defines the maximum amount of time for retransmission of ‘activate request’ messages.
*secs*: Must be an integer from 1 to 60.
Default: 8

**t3386-timeout secs**
Defines the maximum amount of time for retransmission of ‘modify request’ messages.
*secs*: Must be an integer from 1 to 60.
Default: 8 seconds.
**t3395-timeout secs**
Defines the maximum amount of time for retransmission of ‘deactivate request’ messages.
*secs*: Must be an integer from 1 to 60.  
Default: 8

**trim-trailing-spaces-in-apn**
Enables SGSN to strip off any trailing space(s) in requested APN.  
If a requested APN in an Activate PDP Context Request has any trailing spaces, then those trailing spaces will be removed and the length field will be updated.

**Usage**
Repeat this command with different keywords (parameters) to configure the SM (session management) as needed for this GPRS service. Keywords can be used to optimize signaling between the MS and the SGSN to reduce the impact on the radio resources.

**Example**
Reset the number of retransmission messages for deactivate PDP context request to 5.

```
sm deactivate-max-retransmissions 5
```
sndcp

Define the sub-network dependent convergence protocol (SNDCP) network packet data unit (N-PDU) reassembly timeout interval associated with this GPRS service.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GPRS Service Configuration

configure > context context_name > gprs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gprs-service)#

Syntax

sndcp reassembly-timeout seconds

default sndcp reassembly-timeout

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resets the timer configuration to the default value of 30 seconds.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>seconds</th>
</tr>
</thead>
<tbody>
<tr>
<td>Defines the number of seconds the SGSN waits for all the SNDCP segments to arrive before dropping all the disassembled segments.</td>
</tr>
<tr>
<td>seconds: Must be an integer from 1 to 300.</td>
</tr>
</tbody>
</table>

Usage

Use this command to modify the SNDCP reassembly timer. This timer starts as soon as the first N-PDU segment is received (either in-order or out-of-order). If all the segments belong to the N-PDU arrive before the timer expires then the segments are reassembled. If all the segments do not arrive before the timer expires, then the stored segments are discarded.

Example

Reset the default for the timer.

default sndcp reassembly-timeout
Chapter 148
GRE Tunnel Interface Configuration Mode Commands

The Generic Routing Encapsulation (GRE) Tunnel Interface Configuration Mode is used to create and manage the GRE tunneling interfaces for addresses, address resolution options, etc.

Mode

Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > GRE Tunnel Interface Configuration

configure > context context_name > interface interface_name tunnel > tunnel-mode gre

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-if-tunnel-mode)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**destination**

This command configures the destination IP address of the tunnel by specifying the destination end address. This is a mandatory configuration for a GRE tunnel interface.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > GRE Tunnel Interface Configuration

```
configure > context context_name > interface interface_name tunnel > tunnel-mode gre
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-if-tunnel-mode)#
```

**Syntax**

```
[ no ] destination address ip_address
```

- **no**
  Removes or disassociates the configured destination IP address from a specific GRE tunnel interface configuration.

- **address ip_address**
  Configures the IP address for the interface. `ip_address` must be specified using the IPv4 dotted-decimal notation.

**Usage**

Use this command to configure the destination IP address of the tunnel by specifying the IP address of destination tunnel end for GRE tunnel interface.

**Important:** State of source address will affect the operational state of the tunnel.

**Example**

The following command sets the 10.2.3.4 as destination IP address of the GRE tunnel interface:

```
destination address 10.2.3.4
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Use this command to return to the Exec mode.
**exit**

Exits the current mode and returns to the parent configuration mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
keepalive

This command configures various parameters for sending Keepalive messages to the remote end-point in GRE tunnel interface configuration. By default sending keepalives is disabled.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > GRE Tunnel Interface Configuration

configure > context context_name > interface interface_name tunnel > tunnel-mode gre

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-if-tunnel-mode)#

Syntax

keepalive [ interval time_interval num-retry retry ]
[ default | no ] keepalive

---

default

Sets the sending of Keepalives with default parameters.
interval: 10 seconds
num-retry: 3 retries

---

no

Disables the keepalive and turns off the sending of Keepalives messages.

---

interval time_interval

Default: 10
Specifies the time interval (in seconds) between two Keepalives sent to remote ends of GRE tunnel interface configuration.
time_interval must be an integer from 5 through 3600.

---

num-retry retry

Default: 3
Specifies number of retransmission of keepalives to remote node without getting any response before the remote node is marked as dead/down.
retry must be an integer between 0 through 10.

---

Usage

Use this command to configure the parameters for sending Keepalives to the remote end-point of GRE tunnel. It also configures the interval at which GRE Keepalives are sent on the interface and number of retries.
without getting a response from the remote end-point before the tunnel is shutdown. By default, Keepalives will not be sent.

**Example**

The following command enables the keepalive and sets the other parameters to defaults:

```
default keepalive
```
source

This command configures the source IP address of the tunnel either by specifying the IP address (host address) or by specifying another configured non-tunnel IP interface. This is a mandatory configuration for GRE tunnel interface.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > GRE Tunnel Interface Configuration

```
configure > context context_name > interface interface_name tunnel > tunnel-mode gre
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-if-tunnel-mode)#
```

Syntax

```
[ no ] source { address ip_address | interface interface_name }
```

- **no**: Removes/disassociates the configured source IP address or host interface from a specific GRE tunnel interface configuration.

- **address ip_address**

  Configures the IP address for the interface specifying the IP address.

  *ip_address* must be specified using IPv4 dotted-decimal notation.

- **interface interface_name**

  Specifies the name of the preconfigured non-tunnel IP interface, whose address is used as the source address of the GRE tunnel.

Usage

Use this command to configure the source IP address of the tunnel either by specifying the IP address (host address) or by specifying another configured non-tunnel IP interface for GRE tunnel interface.

**Important**: State of source address will affect the operational state of the tunnel.

Example

The following command sets the 10.2.3.4 as source IP address of the GRE tunnel interface:

```
source address 10.2.3.4
```
tos

This command configures the parameters/action for the type of Service (ToS) parameter in the IP tunnel transport protocol header.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > GRE Tunnel Interface Configuration

```bash
configure > context context_name > interface interface_name tunnel > tunnel-mode gre
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-if-tunnel-mode)#
```

**Syntax**

```
tos { value [ af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | ef | lower-bits tos_value ] | copy } 
[ default | no ] tos
```

- **default**
  
  Sets the IP TOS to lower bits value of 0.

- **value [ tos_value ]**
  
  Default: af11
  
  Specifies the IP QoS DSCP per-hop behavior to be marked on the outer header of signalling packets originating from the Access Gateway. This is a standards-based feature (RFC 2597). The following forwarding types are supported:
  
  - af11: Assured Forwarding 11 per-hop behavior
  - af12: Assured Forwarding 12 per-hop behavior
  - af13: Assured Forwarding 13 per-hop behavior
  - af21: Assured Forwarding 21 per-hop behavior
  - af22: Assured Forwarding 22 per-hop behavior
  - af23: Assured Forwarding 23 per-hop behavior
  - af31: Assured Forwarding 31 per-hop behavior
  - af32: Assured Forwarding 32 per-hop behavior
  - af33: Assured Forwarding 33 per-hop behavior
  - af41: Assured Forwarding 41 per-hop behavior
  - af42: Assured Forwarding 42 per-hop behavior
  - af43: Assured Forwarding 43 per-hop behavior
• be: Best Effort forwarding per-hop behavior
• ef: Expedited Forwarding per-hop behavior typically dedicated to low-loss, low-latency traffic.

The assured forwarding behavior groups are listed in the table below.

<table>
<thead>
<tr>
<th>Class 1</th>
<th>Class 2</th>
<th>Class 3</th>
<th>Class 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low Drop</td>
<td>AF11</td>
<td>AF21</td>
<td>AF31</td>
</tr>
<tr>
<td>Medium Drop</td>
<td>AF12</td>
<td>AF22</td>
<td>AF32</td>
</tr>
<tr>
<td>High Drop</td>
<td>AF13</td>
<td>AF23</td>
<td>AF33</td>
</tr>
</tbody>
</table>

Traffic marked with a higher class is given priority during congestion periods. If congestion occurs to traffic with the same class, the packets with the higher AF value are dropped first.

**lower-bits tos_value**
Default: 0
Sets the least-significant 6 bits in the ToS byte with the specified numeric value.
*tos_value* must be an integer from 0 through 255.

**copy**
This keyword instructs the system to copy the ToS value from the passenger IPv4 packet or Traffic class value from the passenger IPv6 packet to the ToS value of the IPv4 tunnel transport protocol header.

**Usage**
Use this command either to set the ToS parameter in the IPv4 tunnel transport protocol header to the specified value or instructs to copy the ToS value from the passenger IPv4 packet or Traffic class value from the passenger IPv6 packet to the ToS value of the IPv4 tunnel transport protocol header. If one of the enumerated values is set, the DSCP bits which are the six most-significant bits in the ToS byte are marked. If the integer value is set, it will be written into the six least-significant bits of the ToS byte.

**Example**
The following command instructs the system to copy the ToS value from the passenger IPv4 packet or Traffic class value from the passenger IPv6 packet to the ToS value of the IPv4 tunnel transport protocol header:

```
tos copy
```
**ttl**

This command configures the Time to live (TTL) parameter to be used in the tunnel transport protocol header for the current GRE tunnel interface.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > GRE Tunnel Interface Configuration

```bash
configure > context context_name > interface interface_name tunnel > tunnel-mode gre
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-if-tunnel-mode)#
```

**Syntax**

```bash
ttl ttl_value

default ttl
```

**default ttl**

Sets the TTL value to system default value.

**ttl_value**

Default: 15

Specifies the maximum time to live to be used in the tunnel transport protocol header

The time to live (TTL) is not a measure of time but the number of hops through the network.

**Usage**

Use this command to set the TTL parameter to be used in the tunnel transport protocol header for the GRE tunnel configuration.

**Example**

The following configures the TTL to a value of 10:

```
ttl 10
```
Chapter 149
Gs Service Configuration Mode Commands

The Gs Service configuration mode configures the parameters used to setup and maintain a Gs interface for a connection between the SGSN and an MSC/VLR.

Mode

Exec > Global Configuration > Context Configuration > Gs Service Configuration

configure > context context_name > gs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gs-service)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
associate-sccp-network

This command associates a previously defined Signaling Connection Control Part (SCCP) network instance with the Gs service. This association is required to access Visitor Location Register(s) (VLRs).

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Gs Service Configuration
configure > context context_name > gs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gs-service)#

**Syntax**

```
associate-sccp-network sccp_net_id
```

```
no associate-sccp-network
```

**Usage**
Use this command to associate the SCCP network configuration instance with the Gs interface in this service.

**Important:**
A single SCCP network configuration instance can not be shared with multiple Gs services.

**Important:**
To enable a Gs service, the user needs to configure ssn with the bssap+ command.

**Example**

Following command associates SCCP network 2 with this Gs service.

```
associate-sccp-network 2
```
**bssap+**

This command defines the Base Station System Application Part Plus configuration parameters for the Gs service to enable the SGSN to access a Visitor Location Register(s) (VLRs).

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Gs Service Configuration

configure > context context_name > gs-service service_name

Entering the above command sequence results in the following prompt:

\[\text{[context_name]host_name(config-gs-service)}#\]

**Syntax**

```
bssap+ ssn ss_num

no bssap+ ssn ss_num
```

- **no**
  Removes the configured BSSAP+ subsystem number from this Gs service.

- **ssn ss_num**
  Specifies the subsystem number to configure in this Gs interface to use BSSAP+.
  `ss_num` must be an integer from 1 through 255.

**Usage**

Use this command to configure the BSSAP+ subsystem with Gs interface in this service to communicate with VLR(s).

**Important:** A single SCCP network configuration instance can not be shared with multiple Gs services.

**Important:** To start a Gs service, the user needs to configure the `go` command parameter.

**Example**

Following command configures subsystem 101 with BSSAP+ in this Gs service.

```
bssap+ ssn 101
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
end

**Usage**
Return to the Exec mode.
**exit**

Exits the current configuration mode and returns to the previous configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the previous configuration mode.
max-retransmission

This command configures the retransmission values for different procedure counters in Gs service as described in TS 29.018.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Gs Service Configuration

configure > context context_name > gs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gs-service)#

**Syntax**

```
max-retransmissions { n8 | n9 | n10 | n12 } retrans_num
default max-retransmissions { n8 | n9 | n10 | n12 }
```

**no**
Removes the configured Gs procedures from this Gs service.

```
{ n8 | n9 | n10 | n12 }
```

Specifies the various Gs service procedures that are available to be used to communicate with VLR(s).

- **n8**: Defines the maximum number of retries for explicit IMSI detach from a non-GPRS service. Default is 2.
- **n9**: Defines the maximum number of retries for explicit IMSI detach from a non-GPRS service. Default is 2.
- **n10**: Defines the maximum number of retries for implicit IMSI detach from the GPRS service. Default is 2.
- **n12**: Defines the maximum number of retries for BSSAP+ to send Reset Indication messages. Default is 2.

**retrans_num**
Default: 2
Specifies the number of re-transmission of message for specified procedures.

**Usage**
Use this command to configure the retransmission values for specific procedure counters in Gs service. counters are based on TS 29.018.

This command can be entered for each procedure counter separately.
Example

Following command configure retransmission value as 3 for counter for procedure to send BSSAP+ Reset Indication messages in this Gs service.

```
max-retransmissions n12 3
```
non-pool-area

This command creates a non-pool area for a set of subscriber location area code (LAC) values that can be used with a specific VLR for the Gs service.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Gs Service Configuration
configure > context context_name > gs-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gs-service)#
```

**Syntax**

```
non-pool-area non_pool_name { use-vlr vlr_name lac lac_num } +
no non-pool-area non_pool_name { lac lac_num }
```

- **no**
  Removes the configured non-pool area from this Gs service.

- **non_pool_name**
  Specifies the name of the non-pool area to configure with this command.
  *non_pool_name* must be an alpha and/or numeric string of 1 to 63 characters.

- **use-vlr vlr_name**
  Specifies the name of the VLR to be associated with this non-pool area.
  *vlr_name* is the name of VLR and must be an alpha and/or numeric string of 1 to 63 characters.

- **lac lac_num**
  Specifies the subscribers’ location area code to be attached with this non-pool area and specific VLR. This LAC of subscriber is obtained from the radio area indicator (RAI).
  Including this keyword with the **no** form of the command enables the operator to remove a specific LAC from the non-pool area configuration.
  *lac_num* is the LAC value and must be an integer value from 1 through 65535.

- **+**
  More than one *lac_num*, separated by a space, can be entered within a single command.

**Usage**

This command can be repeated as necessary to define a total of 32 configured LACs for the combined **non-pool-area** and **pool-area** configurations per Gs service.
Example

Following command configure a non-pool area `starpool1` to use VLR named `starvlr1` for LAC 101 in a Gs service.

```
non-pool-area starpool1 use-vlr starvlr1 lac 101
```
pool-area

This command creates a pool area configuration instance. This command also enters the Pool Area configuration mode to define the set of VLRs to use for a pool area for a set of subscriber location area code (LAC) values in the Gs service.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Gs Service Configuration
configure > context context_name > gs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gs-service)#

Syntax

pool-area pool_name [ -noconfirm ]

no pool-area non_pool_name

no
Removes the configured pool area from this Gs service.

pool_name
Specifies the name of the pool area to configure with this command for VLR pooling and association of a LAC.

pool_name: Must be an alpha and/or numeric string of 1 to 63 characters.

-noconfirm
Indicates that the command is to execute without any additional prompt and confirmation from the user.

Usage
Use this command to create/enter the pool area configuration mode. This mode is used configue the set of VLRs to be used for a set of subscriber LAC.

This command can be used multiple times, subject to a limit of 128 LAC values (the total number of non-pool-area and pool-area configurations) per Gs service.

Example
The following command configures a pool area named starpool in a Gs service without any confirmation prompt.

    pool-area starpool -noconfirm
sbox-number

Define the SGSN’s E164 number to associate an SGSN with this Gs Service.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Gs Service Configuration

```bash
configure > context context_name > gs-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gs-service)#
```

**Syntax**

```bash
sgsn-number E.164_number
```

Where:

- **E.164_number**
  Defines the SGSN’s ‘telephone’ number, the ISDN number for per ITU-T E.164 numbering plan. The number must be a numerical string of 1 to 15 digits.

**Usage**

For releases 8.1 or higher, use this command to define the SGSN’s E.164 ISDN number. This value should match the `sgsn-number` defined for SGSN Service or GPRS Service.

**Important:** Note: the Gs Service will not start unless the SGSN’s E.164 number is configured.

**Example**

```bash
sgsn-number 12345678901234
```
timeout

This command configures various timers defining the wait before retransmitting a specific message for Gs service procedures.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Gs Service Configuration

configure > context context_name > gs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gs-service)#

Syntax

timeout { t6-1-timer t6_1_dur | t8-timer t8_dur | t9-timer t9_dur | t10-timer t10_dur |
t12-1-timer minute t12_1_dur | t12-2-timer t12_2_dur }

[ default ] timeout { t6-1-timer | t8-timer | t9-timer | t10-timer | t12-1-timer | t12-2-
timer }

default

Sets the timer value to wait in seconds/minutes to default values. Default values for timers are:
* t6-1-timer: 10 seconds
* t8-timer: 4 seconds
* t9-timer: 4 seconds
* t10-timer: 4
* t12-1-timer: 54 mins (+ 8 seconds)
* t12-2-timer: 4 seconds

t6-1-timer t6_1_dur

Default: 10
Specifies the retransmission timer value to guard the location update.
t6_1_dur is the waiting duration in seconds before retransmitting the specific message and must be an integer from 10 through 90.

t8-timer t8_dur

Default: 4
Specifies the retransmission timer value to guard the explicit IMSI detach from the GPRS service procedure.
t8_dur is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 30.
**t9-timer t9_dur**

Default: 4
Specifies the retransmission timer value to guard the explicit IMSI detach from the non-GPRS service procedure. 
*t9_dur* is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 30.

**t10-timer t10_dur**

Default: 4
Specifies the retransmission timer value to guard the implicit IMSI detach from the GPRS service procedure. 
*t10_dur* is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 30.

**t12-1-timer minute t12_1_dur**

Default: 54 minutes (plus 8 seconds for transmission delay)
Specifies the retransmission timer value to control the resetting of SGSN-Reset variable procedure. 
*t12_1_dur* is the waiting duration in minutes before retransmitting reset message for the SGSN Reset variable and must be an integer from 0 through 384.

**t12-2-timer t12_2_dur**

Default: 4
Specifies the retransmission timer value to guard the SGSN reset procedure. 
*t12_2_dur* is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 120.

**Usage**

Use this command to configure the time, for different procedure timers, to wait before retransmitting a procedure message. 
This command can be repeated for each timer to configure multiple timers.

**Example**

Following command sets the timeout duration of 4 seconds for t8 timer to wait before retransmitting the procedure message to explicitly do the IMSI detach from GPRS service:

```
default timeout t8-timer
```
vlr

This command defines a VLR configuration for use with this Gs service.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Gs Service Configuration

configure > context context_name > gs-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gs-service)#

Syntax

vlr vlr_name isdn-number E164_num [ bssap+ ssn ssn ] [ point-code pt_code ]

no vlr vlr_name

no

Removes the configured VLR from the Gs service.

vlr_name

Specifies the name of the VLR to configure in this Gs mode with ISDN number.
vlr_name must be an alpha and/or numeric string of 1 to 63 characters.

isdn-number E164_num

Specifies the VLR number to configure with this command.
E164_num: The ISDN number for the target VLR. Value must be defined according to the E.164 numbering plan and must be a numeric string of 1 to 15 digits.

bssap+ ssn ssn

Specifies the subsystem number to configure with this VLR to use BSSAP+.
ssn: Must be an integer from 1 through 255. Default value is 252.

point-code pt_code

Specifies SS7 address of VLR in point code value to this configured VLR name.
pt_code: Must be in SS7 point code dotted-decimal ###.###.### format or decimal ####### format.

Usage

Use this command to define VLR configuration instances to be associated with the Gs service.
A maximum of 32 VLRs can be configured per Gs service.

Example
Following command configures the VLR named `starvlr1` with an ISDN number 1234567, a subsystem number of 252, and a point code value of 123.345.567:

```plaintext
vlr starvlr1 isdn-number 1234567 point-code 123.345.567
```
Chapter 150
GT-Format1 Configuration Mode Commands

The GT-Format1 configuration mode is a sub-mode for either the Global Title Translation Association configuration mode or the Global Title Translation Address-Map configuration mode. This sub-mode configures a set of rules used in the global title translation (GTT) process.

Mode

Exec > Global Configuration > GTT Association Configuration > GT-Format1 Configuration

configure > global title translation association instance instance_number > gt-format format_number

Entering the above command sequence results in the following prompt:

[local]host_name(config-gtt-instance-format1)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the configuration mode and returns to the Exec mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
end

**Usage**
Change the mode back to the Exec mode.
**exit**

Exits the configuration mode and returns to the Global configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**
Return to the Global configuration mode.
nature-of-address

Configures the indicator to identify the nature of the address.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > GTT Association Configuration > GT-Format1 Configuration

```
configure > global title translation association instance instance_number > gt-format format_number
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-gtt-instance-format1)#
```

**Syntax**

```
nature-of-address { international | national | subscriber }
```

- **international**
  Identifies the numbers as international.

- **national**
  Identifies the numbers as matching the national configuration.

- **subscriber**
  Identifies the numbers as subscriber numbers.

**Usage**

Configure the identify of the GT format as national.

**Example**

```
nature-of-address national
```
odd-even-indicator

Configures the bits for matching the global title translation.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > GTT Association Configuration > GT-Format1 Configuration

`configure > global title translation association instance instance_number > gt-format format_number`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-gtt-instance-format1)#
```

**Syntax**

```
odd-even-indicator type
```

- **type**
  - `odd`: Sets the odd bit for matching the GTT.
  - `even`: Sets the even bit for matching the GTT.
Chapter 151
GT-Format2 Configuration Mode Commands

The GT-Format2 configuration mode is a sub-mode for either the Global Title Translation Association configuration mode or the Global Title Translation Address-Map configuration mode. This sub-mode configures a set of rules used in the global title translation (GTT) process.

Mode

Exec > Global Configuration > GTT Association Configuration > GT-Format2 Configuration

configure > global title translation association instance instance_number > gt-format format_number

Entering the above command sequence results in the following prompt:

[local]host_name(config-gtt-instance-format2)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Change the mode back to the Exec mode.
**exit**

Exits the configuration mode and returns to the Global configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Return to the Global configuration mode.
translation-type

Configures the translation type to be applied during the translation process.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > GTT Association Configuration > GT-Format2 Configuration

configure > global title translation association instance instance_number > gt-format format_number

Entering the above command sequence results in the following prompt:

[local]host_name(config-gtt-instance-format2)#

Syntax

translation-type number

number
Must be an integer between 0 and 255.
Default is 0

Usage
Use this command to configure the GTT translation type to be applied during global title translation process.

Example

translation-type 232
Chapter 152
GT-Format3 Configuration Mode Commands

The GT-Format3 configuration mode is a sub-mode for either the Global Title Translation Association configuration mode or the Global Title Translation Address-Map configuration mode. This sub-mode configures a set of rules used in the global title translation (GTT) process.

Mode
Exec > Global Configuration > GTT Association Configuration > GT-Format3 Configuration

configure > global title translation association instance instance_number > gt-format format_number

Entering the above command sequence results in the following prompt:

[local]host_name(config-gtt-instance-format3)#

⚠️ **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
encoding-scheme

Configures the encoding-scheme to use during global title translation (GTT).

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > GTT Association Configuration > GT-Format3 Configuration

configure > global title translation association instance instance_number > gt-format format_number

Entering the above command sequence results in the following prompt:

[local]host_name(config-gtt-instance-format3)#

Syntax

```plaintext
classify scheme scheme_type

scheme_type

Select one of the following encoding scheme types to determine the encoding type to be used during GTT:

- **bcd-even**: BCD even encoding scheme
- **bcd-odd**: BCD odd encoding scheme
- **nw-specific**: Network specific encoding scheme
- **unknown**: Unknown encoding scheme
```

Usage
Select BCD even encoding for GTT

Example

```plaintext
classify scheme bcd-even
```
end

Exits the configuration mode and returns to the Exec mode.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
end
```

**Usage**

Change the mode back to the Exec mode.
exit

Exits the configuration mode and returns to the Global configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
exit

**Usage**
Return to the Global configuration mode.
numbering-plan

Configures the GTT process to apply one of the numbering-plans during the GT translation process.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > GTT Association Configuration > GT-Format3 Configuration

```
configure > global title translation association instance instance_number > gt-format
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-gtt-instance-format3)#
```

**Syntax**

```
numbering-plan plan_type
```

`plan_type`
Select one of the following numbering plans be employed during GTT:
- `data`: Data numbering plan
- `generic`: Generic number plan
- `isdn` : ISDN tel numbering plan
- `isdn-mobile` : ISDN mobile numbering plan
- `land-mobile` : Land mobile numbering plan
- `maritime-mobile` : Maritime mobile numbering plan
- `nw-specific` : Private network / network-specific numbering plan
- `telex`: Telex numbering plan
- `unknown`: Unknown numbering plan

**Usage**

Select ISN telephone number plan for GTT process.

**Example**
The following command sets the numbering plan to use during GTT processing to isdn

```
numbering-plan isdn
```
**translation-type**

Configures the global title translation (GTT) process to apply a specific number for translation during the GTT process.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > GTT Association Configuration > GT-Format3 Configuration

```
configure > global title translation association instance instance_number > gt-format format_number
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-gtt-instance-format3)#
```

**Syntax**

```
translation-type number
```

- **number**
  - Must be an integer between 0 and 255.
  - Default is 0

**Usage**
Use this command to define the translation-type to be used during the global title translation process.

**Example**

```
translation-type 233
```
Chapter 153
GT-Format4 Configuration Mode Commands

The GT-Format4 configuration mode is a sub-mode for either the Global Title Translation Association configuration mode or the Global Title Translation Address-Map configuration mode. This sub-mode configures a set of rules used in the global title translation (GTT) process.

**Mode**

Exec > Global Configuration > GTT Association Configuration > GT-Format4 Configuration

configure > global title translation association instance instance_number > gt-format format_number

Entering the above command sequence results in the following prompt:

[local]host_name(config-gtt-instance-format4)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
encoding-scheme

Configures the encoding-scheme to use during GTT.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > GTT Association Configuration > GT-Format4 Configuration

```
 configure > global title translation association instance instance_number > gt-format
 format_number
```

Entering the above command sequence results in the following prompt:

```
 [local]host_name(config-gtt-instance-format4)#
```

**Syntax**
```
encoding scheme scheme_type
```

- **scheme_type**
  - Select one of the following encoding scheme types to determine the encoding type to be used during GTT:
    - **bcd-even**: BCD even encoding scheme
    - **bcd-odd**: BCD odd encoding scheme
    - **nw-specific**: Network-specific encoding scheme
    - **unknown**: Unknown encoding scheme

**Usage**
Select BCD even encoding for GTT

**Example**
```
 encoding scheme bcd-even
```
end

Exits the configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Change the mode back to the Exec mode.
exit

Exits the configuration mode and returns to the Global configuration mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
exit
```

Usage

Return to the Global configuration mode.
nature-of-address

Configures the indicator to identify the nature of the address.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > GTT Association Configuration > GT-Format4 Configuration

configure > global title translation association instance instance_number > gt-format format_number

Entering the above command sequence results in the following prompt:

[local] host_name(config-gtt-instance-format4)#

Syntax
	nature-of-address { international | national | subscriber }

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>international</td>
<td>Identifies the numbers as international.</td>
</tr>
<tr>
<td>national</td>
<td>Identifies the numbers as matching the national configuration.</td>
</tr>
<tr>
<td>subscriber</td>
<td>Identifies the numbers as subscriber numbers.</td>
</tr>
</tbody>
</table>

Usage
Configure the identify of the GT format as national.

Example

nature-of-address national
numbering-plan

Configures the GTT process to apply one of the numbering-plans during the GT translation process.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > GTT Association Configuration > GT-Format4 Configuration

```
configure > global title translation association instance instance_number > gt-format format_number
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-gtt-instance-format4)#
```

**Syntax**

```
numbering-plan plan_type
```

*plan_type*

Select one of the following numbering plans be employed during GTT:

- **data**: Data numbering plan
- **generic**: Generic number plan
- **isdn**: ISDN tel numbering plan
- **isdn-mobile**: ISDN mobile numbering plan
- **land-mobile**: Land mobile numbering plan
- **maritime-mobile**: Maritime mobile numbering plan
- **nw-specific**: Private network/ network-specific numbering plan
- **telex**: Telex numbering plan
- **unknown**: Unknown numbering plan

**Usage**

Select ISN telephone number plan for GTT process.

**Example**

```
numbering-plan isdn
```
translation-type

Configures the GTT process to apply a specific number for translation during the GTT process.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > GTT Association Configuration > GT-Format4 Configuration
```
configure > global title translation association instance instance_number > gt-format format_number
```

Entering the above command sequence results in the following prompt:
```
[local]host_name(config-gtt-instance-format4)#
```

**Syntax**
```
translation-type number
```

- `number`
  
  Must be an integer between 0 and 255.
  
  Default is 0.

**Usage**
Use this command to configure the translation-type to be implemented during the global title translation process.

**Example**
```
translation-type 231
```
Chapter 154
GTPP Server Group Configuration Mode Commands

The GTPP Server Group Configuration Mode is used to create and manage the GTPP server groups within the context or system.

GTPP server group commands facilitate the setup of the hard disk for CDR storage. They also support accounting and charging functionality within a context, and configuration of a group (list) of charging gateway function (CGF) servers on a per subscriber or per GGSN/P-GW APN level.

Mode

Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**
Use this command to return to the parent configuration mode.
gtpp attribute

Enables the specification of some of the optional fields in the CDRs that the GSN (GGSN or SGSN) generates and/or how the information is to be presented. Many keywords are also applicable to S-GW and P-GW CDRs.

Product

GGSN
P-GW
SAEGW
SaMOG
SGSN

**default**
Resets the default attribute values for this GTPP group configuration.

**no**
Disables the specified optional field so that the information will not be present in generated CDRs.

**apn-ambr [ include-for-all-bearers | include-for-default-bearer | include-for-non-gbr-bearers ]**

Default: Disabled
This keyword controls the inclusion of the optional field “apn-ambr” in the PGW-CDRs in the custom24 GTPP dictionary.

**Important:** This keyword option will be available only if a valid license is installed. For more information, contact your Cisco account representative.

The APN Aggregate Maximum Bit Rate (AMBR) is a subscription parameter stored per APN. It limits the aggregate bit rate that can be expected to be provided across all non-GBR bearers and across all PDN connections of the same APN. Each of these non-GBR bearers potentially utilize the entire APN AMBR, e.g. when the other non-GBR bearers do not carry any traffic. The APN AMBR is present as part of QoS information.

In 15.0 and later releases, this CLI command should be configured along with the following additional options to support APN-AMBR reporting in SGW-CDRs in all GTPP dictionaries.

- **include-for-all-bearers**: Includes the APN-AMBR information in SGW-CDRs for all bearers (GBR and NON-GBR)
- **include-for-default-bearer**: Includes APN-AMBR information in SGW-CDRs only for default bearer.
- **include-for-non-gbr-bearers**: Includes APN-AMBR information for non-gbr-bearers.

This feature is required to enable post-processing of CDRs to verify MVNO subscribers actual QoS against invoicing systems.

**Important:** This CLI command and the associated options are not available for products other than S-GW and P-GW. The option “non-gbr-bearers-only” is available in S-GW and P-GW but the other options are available in S-GW only.
In the P-GW implementation, if the CLI command “gtpp attribute apn-ambr” is configured, it will be treated as “gtpp attribute apn-ambr non-gbr-bearers-only”. In case of S-GW/P-GW combo if any of the options is configured, it will be considered that the attribute is available.

**apn-ni**
Default: Enabled
This keyword controls the inclusion of the optional field “APN” in the x-CDRs.

**apn-selection-mode**
Default: Enabled
This keyword controls the inclusion of the optional field “APN Selection Mode” in the x-CDRs.

**camel-info**
SGSN only
Enter this keyword to include CAMEL-specific fields in SGSN CDRs. Default: Disabled

**cell-plmn-id**
SGSN only
Enter this keyword to enable the system to include the Cell PLMN ID field in the M-CDR. Default: Disabled

**charging-characteristic-selection-mode**
Default: Enabled
This keyword controls the inclusion of the optional field “Charging Characteristic Selection Mode” in the x-CDRs.

**diagnostics**
Default: Disabled
Enables the system to include the Diagnostic field in the CDR that is created when PDP contexts are released. The field will include one of the following values:

- **26** - For GGSN: if the GGSN sends “delete PDP context request” for any other reason (e.g., the operator types “clear subscribers” on the GGSN). For SGSN: The SGSN includes this cause code in the S-CDR to indicate that a secondary PDP context activation request or a PDP context modification request has been rejected due to insufficient resources.

- **36** - For GGSN: this cause code is sent in the G-CDR to indicate the PDP context has been deactivated in the GGSN due to the SGSN having sent a “delete PDP context request” to the GGSN. For SGSN, this cause code is used to indicate a regular MS or network-initiated PDP context deactivation.

- **37** - when the network initiates a QoS modification, the SGSN sends in the S-CDR to indicate that the MS initiation deactivate request message has been rejected with QoS not accepted as the cause.

- **38** - if the GGSN sends “delete PDP context request” due to GTP-C/GTP-U echo timeout with SGSN. If the SGSN sends this cause code, it indicates PDP context has been deactivated due to path failure, specifically GTP-C/GTP-U echo timeout.

- **39** - SGSN only - this code indicates the network (GGSN) has requested a PDP context reactivation after a GGSN restart.

- **40** - if the GGSN sends “delete PDP context request” due to receiving a RADIUS Disconnect-Request message.
**duration-ms**

Specifies that the information contained in the mandatory Duration field be reported in milliseconds instead of seconds (as the standards require). Default: Disabled

**dynamic-flag**

Default: Enabled

This keyword controls the inclusion of the optional field “Dynamic Flag” in the x-CDRs.

**dynamic-flag-extension**

Default: Enabled

This keyword controls the inclusion of the optional field “Dynamic Address Flag Extension” in the x-CDRs. This field is seen in the CDR when the IPv4 address is dynamically assigned for a dual PDP context. This extension field is required in the 3GPP Release 10 compliant CDRs so that the Dual Stack Bearer support is available.

**furnish-charging-information**

Default: Disabled

This keyword controls the inclusion of the optional field “pSFurnishChargingInformation” in the eG-CDRs and PGW-CDRs.

---

**Important:** The Furnish Charging Information (FCI) feature is applicable to all GTPP dictionaries compliant to 3GPP Rel.7 and 3GPP Rel.8 except custom43 dictionary. This keyword option will be available only if a valid license is installed. For more information, contact your Cisco account representative.

PGW-CDR and eG-CDR will contain FCI only if it is enabled at command level, i.e. using the `gtpp attribute furnish-charging-information` command in GTPP Server Group Configuration mode. Whenever FCI changes, a new Free-Format-Data (FFD) value is either appended to existing FFD or overwritten on the existing FDD depending on Append-Free-Format-Data (AFFD) flag. CDR is not generated upon FCI change.

FCI is supported in main CDR as well as in LOSDV. Whenever a trigger (volume, time, RAT, etc.) happens current available FFD at command level is added to the main body of the CDR. The same FFD at command level is added to the main body of the next CDRs until it is not appended or overwritten by next Credit-Control-Answer message at command level.

In the case of custom43 dictionary, the FCI implementation will be as follows:

- Whenever FCI changes PGW-CDR will generate CDR i.e close old bucket and will have old FCI details in the generated CDR.
- Translation for the PS-Free-Format-Data in CDR will be conversion of hexadecimal values in ASCII format (for numbers 0 to 9) to decimal values as integers.
- PS-Append-Free-Format-Data always OVERWRITE.

**imei**

Default: Disabled

For SGSN: includes the IMEI value in the S-CDR.
For GGSN: includes the IMEISV value in the G-CDR.

**imsi-unauthenticated-flag**

Default: Enabled
This keyword controls the inclusion of the optional field “IMSI Unauthenticated Flag” in the x-CDRs. When the served IMSI is not authenticated, this field “IMSI Unauthenticated Flag” if configured, will be present in the P-GW CDR record for custom35 dictionary. This field is added per 3GPP TS 32.298 v10.7.

**local-record-sequence-number**

Default: Disabled
This keyword provides both the local record sequence number and the Node ID. In the x-CDRs, this field indicates the number of CDRs generated by the node and is unique within the session manager. The Node ID field is included in the x-CDR for any of several reasons, such as when PDP contexts are released or if partial-CDR is generated based on configuration. The field will consist of a AAA Manager identifier automatically appended to the name of the SGSN or GGSN service. The name of the SGSN or GGSN service may be truncated, because the maximum length of the Node ID field is 20 bytes. Since each AAA Manager generates CDRs independently, this allows the Local Record Sequence Number and Node ID fields to uniquely identify a CDR.

**losdv**

Default: Enabled
This keyword controls the inclusion of the optional field “List of Service Data” in the x-CDRs.

**ms-timezone**

Default: Enabled
This keyword controls the inclusion of the optional field “MS-Timezone” in the x-CDRs.

**msisdn**

Default: Enabled
This keyword controls the inclusion of the optional field “MSISDN” in the x-CDRs.

**node-id**

Default: Enabled
This keyword controls the inclusion of the optional field “Node ID” in the x-CDRs.

**node-id-suffix**  

Default: Disabled
Specifies the configured Node-ID-Suffix to use in the NodeID field of GTPP CDRs as an alphanumeric string of 1 through 16 characters. Each Session Manager task generates a unique NodeID string per GTPP context.

**Important:** The NodeID field is a printable string of the ndddSTRING format:  
n: The first digit is the Sessmgr restart counter having a value between 0 and 7.  
ddd: The number of sessmgr instances. Uses the specified NodeID-suffix in all CDRs. The “Node-ID” field consists of sessMgr Recovery counter (1 digit) n + AAA Manager identifier (3
digits) \( ddd + \) the configured Node-Id-suffix (1 to 16 characters) \( STRING \). If the centralized LRSN feature is enabled, the “Node-ID” field will consist of only the specified NodeID-suffix (NodeID-prefix is not included). If this option is not configured, then GTPP group name will be used instead (For default GTPP groups, context-name will be used).

**Important:** If this **node-id-suffix** is not configured, the GGSN uses the GTPP context name as the Node-id-suffix (truncated to 16 characters) and the SGSN uses the GTPP group name as the node-id-suffix.

---

<table>
<thead>
<tr>
<th><strong>Command</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
</table>
| **pdn-connection-id** | Default: Enabled  
This keyword controls the inclusion of the optional field “PDN Connection ID” in the x-CDRs. |
| **pdp-address** | Default: Enabled  
This keyword controls the inclusion of the optional field “PDP Address” in the x-CDRs. |
| **pdp-type** | Default: Enabled  
This keyword controls the inclusion of the optional field “PDP Type” in the x-CDRs. |
| **pgw-ipv6-addr** | Default: Disabled  
Specifying this option allows to configure the P-GW IPv6 address. |

**Important:** This attribute can be controllably configured in custom24 and custom35 SGW-CDR dictionaries.

---

<table>
<thead>
<tr>
<th><strong>Command</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
</table>
| **pgw-plmn-id** | Default: Enabled  
This keyword controls the inclusion of the optional field “PGW PLMN-ID” in the x-CDRs. |
| **plmn-id [ unknown-use ]** | Default: Enabled  
For SGSN, reports the SGSN PLMN Identifier value (the RAI) in the S-CDR provided if the dictionary supports it.  
For GGSN, reports the SGSN PLMN Identifier value (the RAI) in the G-CDR if it was originally provided by the SGSN in the GTP create PDP context request. It is omitted if the SGSN does not supply one.  
Normally when SGSN PLMN-id information is not available, the attribute sgsnPLMNIdentifier is not included in the CDR. This keyword enables the inclusion of the sgsnPLMNIdentifier with a specific value when the SGSN PLMN-id is not available.  
**unknown-use hex_num:** is aa hexadecimal number from 0x0 through 0xFFFFFFFF that identifies a foreign SGSN that has not provided a PLMN-id. For GGSN only. |
| **qos max-length** | Default: Disabled  
Specifying this option will change the parameters related to QoS sent in S-CDR and SaMOG CDR. The **max-length** option is used to modify the length of QoS sent in CDR. The **qos_value** must be an integer from 4 through 24. |
This feature is introduced to support Rel.7+ QoS formats.

rat
Default: Enabled
For SGSN: includes the RAT (identifies the radio access technology type) value in the S-CDR.
For GGSN: includes the RAT (identifies the radio access technology type) value in the G-CDR.

recordextension
Default: Disabled
This keyword controls the inclusion of the optional field “RecordExtension” in the x-CDRs.

record-extensions rat
Default: Disabled
Enables network operators and/or manufacturers to add their own recommended extensions to the CDRs according to the standard record definitions from 3GPP TS 32.298 Release 7 or higher.

record-type { sgsnpdprecord | sgwrecord }

**Important**: This keyword is available only when the SaMOG Mixed Mode license (supporting both 3G and 4G) is configured.

Default: sgwrecord
Specifies the SaMOG CDR type to use.
For an SaMOG 3G license, this keyword will not be available. However, sgsnpdprecord type will be used as the default record type.

served-mnai
Default: Disabled
This keyword controls the inclusion of the optional field “Served MNAI” in the x-CDRs.

served-pdp-pdn-address-extension
Default: Disabled
In support of IPv4v6 dual-stack PDP address types, this keyword causes the service to include IPv4v6 address information in the CDR. The IPv4 address goes in the Served PDP PDN Address Extension field and the IPv6 address goes in the Served PDP Address or Served PDP PDN Address field.

**Important**: This attribute will not be displayed if the GTPP dictionary is set to custom34.

served-pdp-pdn-address-prefix-length
Default: Enabled
In support of IPv6 prefix delegation, this keyword causes the service to include this field “Served PDP PDN Address” in the x-CDRs.
If this field is configured, the servedPDPPDNAddress field will support reporting the IPv6 prefix length as outlined in 3GPP 32.298. The prefix length will only be reported if:

- it is configured
- it is not the default length of 64
it is an IPv6 or IPv4v6 call

sgsn-change
Default: Enabled
This keyword is specific to SGSN and is license restricted.
This keyword controls the inclusion of the S-CDR attribute “SGSN Change” in the S-CDRs. It is enabled by default and the attribute “SGSN Change” is included in the S-CDRs by default.

sgw-ipv6-addr
Default: Disabled
Specifying this option allows to configure the S-GW IPv6 address.

Important: This attribute can be controllably configured in custom24 and custom35 SGW-CDR dictionaries.

sms { destination-number | recording-entity | service-centre }
This keyword is specific to the SGSN.
Entering this keyword causes the inclusion of an SMS-related field in the SMS-MO-CDR or SMS-MT-CDR.
destination-number: Includes the “destinationNumber” field in the SMS-MO-CDR or SMS-MT-CDR.
recording-entity: Includes the “recordingEntity” field in the SMS-MO-CDR or SMS-MT-CDR.
service-centre: Includes the “serviceCentre” field in the SMS-MO-CDR or SMS-MT-CDR.

Important: This attribute can be controllably configured in custom24 and custom35 SGW-CDR dictionaries.

sna-ipv6-addr
Default: Disabled
Specifying this option allows to configure the Serving Node IPv6 Address (SNAv6).

Important: This attribute can be controllably configured in custom24 and custom35 SGW-CDR dictionaries.

start-time
Default: Enabled
This keyword controls the inclusion of the optional field “Start-Time” in the x-CDRs.

stop-time
Default: Enabled
This keyword controls the inclusion of the optional field “Stop-Time” in the x-CDRs.

uli
Default: Enabled
This keyword controls the inclusion of the optional field “User Location Information” in the x-CDRs.

user-csg-information
Default: Disabled
This keyword controls the inclusion of the optional field “User CSG Information” in the x-CDRs.
**Important:** Currently, UCI values are only supported for SGW-CDRs. This attribute will not be displayed if the GTPP dictionary is set to custom11, custom34, or custom35.

+ Indicates that this command can be entered multiple times to configure multiple attributes.

**Usage**

This command dictates some of the optional information fields that should be reported in CDRs generated by the GGSN. In addition, it controls how the information for some of the mandatory fields are reported. Fields described as optional by the standards but not listed above will always be present in the CDRs, except for Record Extensions (which will never be present).

**Example**

The following command disables the inclusion of the field “SGSN Change” in the S-CDR:

```
no gtpp attribute sgsn-change
```

**Example**

The following command dictates that the time provided in the Duration field of the CDR is reported in milliseconds:

```
 gtpp attribute duration-ms
```
gtpp charging-agent

Configures the IP address and port of the system interface within the current context used to communicate with the CGF or the GSS.

Product
GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

\[
\text{[context_name]\_host_name(config-gtpp-group)#}
\]

Syntax

\[
\text{gtpp charging-agent address ip_address [ port port ]}
\]

\[
\text{no gtpp charging-agent}
\]

no

Removes a previously configured charging agent address.

address ip_address

Specifies the IP address of the interface configured within the current context that is used to transmit G-CDR records to the CGF or the GSS.

ip_address is expressed in IPv4 dotted-decimal notation.

port port

Specifies the Charging Agent UDP port as an integer from 1 through 65535. If the port is not defined, the default port number 49999 will be used.

Important: Configuring GTPP charging-agent on port 3386 may interfere with ggsn-service configured with the same ip address.
Usage
This command can be used to establish a UDP interface to connect to the GSS or this command can establish a Ga interface to connect to the CFG. These interfaces must exist in the same context in which GTPP functionality is configured (refer to the gtp commands in this chapter).
This command instructs the system as to what interface to use. The IP address supplied is also the address by which the GGSN/SGSN is known to the CGF or the GSS. Therefore, the IP address used for the Ga or UDP interface could be identical to one bound to a GGSN/SGSN service (a Gn interface).
If no GGSN/SGSN services are configured in the same context as the Ga/UDP interface, the address configured by this command is used to receive unsolicited GTPP packets.

Example
The following command configures the system to use the interface with an IP address of 192.168.13.10 as the accounting interface with port 20000 to the CGF:

```
gtp charging-agent address 192.168.13.10

gtp charging-agent address 192.168.13.10 port 20000
```
gtpp data-record-format-version

Encodes the data record format version. The version indicates the 3GPP release version.

**Important:** This CLI command is applicable only to custom24 standard and custom35 GTPP dictionaries for S-GW.

**Product**
S-GW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration

`configure > context` `context_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx)#
```

**Syntax**

```
[ no ] gtpp data-record-format-version string
```

- **no**
  Specifies that the default data record format will be encoded based on the GTPP dictionary being used.

- **gtpp data-record-format-version** `string`
  Specifies the 3GPP release version to be encoded. `string` must be in the format a.b (for example 10.10). This is applicable only for custom24 and custom35 GTPP dictionaries for S-GW. The entry can be from 1 to 1023 alphanumeric characters.

**Usage**

Use this command to support a configurable multiple data record format version only for Custom24 and Custom35 dictionaries. The entry can be from 1 to 1023 alphanumeric characters. This is useful when the value of the data record format version is taken according to the dictionary being used. If only the default configuration is used, a version mismatch causes the GTPP request to be discarded while using R10 attributes.

**Example**

This example configures the data record format version 10.10 to be encoded.

```
gtpp data-record-format-version 10.10
```
gtpp data-request sequence-numbers

Configures the range of sequence numbers to be used in the GTPP data record transfer record (DRT). Use this command to set the start value for the sequence number.

Product
GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

```
gtpp data-request sequence-numbers start { 0 | 1 }
```

default gtpp data-request sequence-numbers start

```
default
Default is 0 (zero).
```

```
start { 0 | 1 }
```

Specifies the value of the start sequence number for the GTPP Data Record Transfer Request. Default: 0

- 0: Designates the start sequence number as 0.
- 1: Designates the start sequence number as 1.

Usage
When the GGSN/P-GW/SGSN is configured to send GTPP echo request packets, the SGSN always uses 0 as the sequence number in those packets. Re-using 0 as a sequence number in the DRT packets is allowed by the 3GPP standards; however, this CLI command ensures the possibility of inter-operating with CGFs that cannot properly handle the re-use of sequence number 0 in the echo request packets.

Example
The following command sets the sequence to start at 1.

```
gtpp data-request sequence-numbers start 1
```
gtpp deadtime

Configures the amount of time the GGSN/SGSN waits before attempting to communicate with a CGF that was previously marked as unreachable (non-responsive).

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
- `configure > context context_name > gtpp group group_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
gtpp deadtime time

default gtpp deadtime
```

```
default

Resets the deadtime to the default of 120 seconds.
```

```
time

Specifies the amount of time (in seconds) that must elapse before the system attempts to communicate with a CGF that was previously unreachable.
time is an integer from 1 to 65535. Default: 120
```

**Usage**

If the system is unable to communicate with a configured CGF, after a pre-configured number of failures the system marks the CGF as being down. This command specifies the amount of time that the system waits prior to attempting to communicate with the downed CGF.

Refer to the `gtpp detect-dead-server` and `gtpp max-retries` commands for additional information on the process the system uses to mark a CGF as down.

**Example**

The following command configures the system to wait 60 seconds before attempting to re-communicate with a CGF that was marked as down:

```
gtpp deadtime 60
```
gtpp dead-server suppress-cdrs

Configures the action the GGSN or the SGSN will take on CDRs generated during a communication failure between the GGSN or the SGSN and the GTPP servers.

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
- configure > context context_name > gtp group group_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
[ no | default ] gtpp dead-server suppress-cdrs
```

- **no**
  - Removes the suppression instruction from the configuration and sets the CDR suppression mode as disabled.

- **default**
  - Resets to the default mode: disable suppression of CDRs when GTPP server detected as “dead” or unreachable.

**Usage**

**For the GGSN/P-GW:** This command works in conjunction with the `gtpp detect-dead-server` to set an action when a communication failure is detected between the GGSN and a configured GTPP server. It disables the archiving of CDRs on the system when the GTPP server is unreachable or dead.

**For the GGSN, P-GW, and SGSN:** During a communication or server failure, the GGSN, P-GW, or SGSN typically retains the GTPP requests until the system buffer runs out of resources. This command enables suppression of the CDRs, so with this command the GGSN, P-GW, or the SGSN will start purging all CDRs associated with this GTPP group as soon as the GGSN/P-GW/SGSN detects that the GTPP server is down or that a communication failure has occurred. The CDRs generated, for the period while the server is down/unreachable, will also be purged.

**Example**

The following command configures the system to start purging CDRs when a communication failure with a server is detected:

```
gtpp dead-server suppress-cdrs
```
**gtpp detect-dead-server**

Configures the number of consecutive communication failures that could occur before the system marks a CGF as “dead” (unreachable).

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
  - configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
gtpp detect-dead-server consecutive-failures max_number
```

```
default gtpp detect-dead-server consecutive-failures
```

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Resets the system to the default number of consecutive failures.</td>
</tr>
<tr>
<td>consecutive-failures max_number</td>
<td>Specifies the number of failures that could occur before marking a CGF as down as an integer from 0 through 1000. If 0 (zero) is the value entered, the system will mark the CGF as dead after a single instance of max-retries has been attempted with no success, regardless of configured deadtime.</td>
</tr>
</tbody>
</table>

**Usage**

This command works in conjunction with the **gtpp max-retries** parameter to set a limit to the number of communication failures that can occur with a configured CGF.

The **gtpp max-retries** parameter limits the number of attempts to communicate with a CGF. Once that limit is reached, the system treats it as a single failure. The **gtpp detect-dead-server** parameter limits the number of consecutive failures that can occur before the system marks the CGF as down and communicate with the CGF of next highest priority.

If all of the configured CGFs are down, the system ignores the detect-dead-server configuration and attempt to communicate with highest priority CGF again.

If the system receives a GTPP Node Alive Request, Echo Request, or Echo Response message from a CGF that was previously marked as down, the system immediately treats it as being active.
Refer to the `gtp max-retries` command for additional information.

**Example**

The following command configures the system to allow 8 consecutive communication failures with a CGF before it marks it as down:

```
gtp detect-dead-server consecutive-failures 8
```
**gtpp dictionary**

Designates specific dictionary used by GTTP for specific context.

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > GTTP Server Group Configuration
  - configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:
```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
gtpp dictionary { custom1 | custom10 | custom11 | custom12 | custom13 | custom14 |
custom15 | custom16 | custom17 | custom18 | custom19 | custom2 | custom20 | custom21 |
custom22 | custom23 | custom24 | custom25 | custom26 | custom27 | custom28 | custom29 |
custom30 | custom31 | custom32 | custom33 | custom34 | custom35 | custom36 |
custom37 | custom38 | custom39 | custom4 | custom40 | custom41 | custom42 | custom43 |
custom44 | custom45 | custom46 | custom47 | custom48 | custom49 | custom50 |
custom51 | custom52 | custom53 | custom54 | custom55 | custom56 | custom57 | custom58 |
custom59 | custom6 | custom60 | custom7 | custom8 | custom9 | standard }
```

**default gtpp dictionary**

- **default**
  - Configures the default dictionary.

- **custom1**
  - Custom-defined dictionary. It conforms to TS 32.015 v 3.6.0 for R99. It supports the encoding of IP addresses in text format for G-CDRs.

- **custom2**
  - Custom-defined dictionary.

- **custom3**
  - Custom-defined dictionary. It conforms to TS 32.015 v 3.6.0 for R99 but it does support the encoding of IP addresses in binary format for CDRs.
**custom4**
Custom-defined dictionary. It conforms to TS 32.015 v 3.6.0 for R99 except that:
- the Data Record Format Version information element contains 0x1307 instead of 0x1308
- “QoSRequested” is not present in the LoTV containers
- “QoSnegotiated” is added only for the first container and the container after a QoS change

**custom5 ... custom20**
Custom-defined dictionaries.

**custom21 ... custom25**
Custom-defined dictionaries for GGSN only.

**custom26**
Custom-defined dictionary for customization of G-CDR records for GGSN only. This is compliant to 3GPP TS 32.298 (R6 v 6.5.0) for proprietary fields and encoding.

**custom27**
Custom-defined dictionary for customization of S-CDR records for SGSN only. This is compliant to 3GPP TS 32.298 (R6 v 6.6.0) for proprietary fields and encoding.

**custom28 ... custom30**
Custom-defined dictionaries for GGSN only.

**custom31 ... custom40**
Custom-defined dictionaries based on 3GPP 32.298 v6.4.1 for SGSN only.
- **custom31**: Custom-defined dictionary for S-CDR encoding. Includes a field appended for PLMN-ID.
- **custom33**: Custom-defined dictionary for S-CDR encoding. Includes a field appended for PLMN-ID and does not support diagnostic or SGSN-change fields.

**standard**
Default: Enabled
A dictionary conforming to TS 32.215 v 4.6.0 for R4 (and also R5 - extended QoS format).

**Usage**
Use this command to designate specific dictionary used by GTPP for specific context.

**Important**: Note that the following warning message will be displayed whenever an existing GTPP dictionary is being changed or a new GTPP dictionary is configured irrespective of whether or not the calls are active on the system.

**Warning**: It is not recommended to change the dictionary when the system has active calls.

Are you sure? [Yes|No]: n

**Important**: This change will require user's input on the CLI console for GTPP dictionary configuration / change.

**Example**
The following command configures the system to use custom3 dictionary to encode IP address in Binary format in G-CDRs:

```
gtpdictionary custom3
```
gtpp duplicate-hold-time

Configures the number of minutes to hold onto CDRs that are possibly duplicates while waiting for the primary CGF to come back up.

Product
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

    configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

    [context_name]host_name(config-gtpp-group)#

Syntax

    gtpp duplicate-hold-time minutes minutes

    default gtpp duplicate-hold-time

    default

    Resets the configuration to the default value of 60 minutes for the duplicate hold time.

    minutes

    When the primary CGF is down, the number of minutes to hold onto CDRs that may be duplicates. minutes must be an integer from 1 to 10080. Default is 60.

Usage

Use this command to configure how long to hold onto CDRs, that are possibly duplicates, while waiting for the primary CGF to come back up. If the GGSN determines that the primary CGF is down, CDRs that were sent to the primary CGF, but not acknowledged, are sent by the GGSN to the secondary CGF as “possibly duplicates”. When the primary CGF comes back up, the GGSN uses GTPP to determine whether the possibly duplicate CDRs were received by the primary CGF. Then the secondary CGF is told whether to release or cancel those CDRs. This command configures how long the system should wait for the primary CGF to come back up. As soon as the configured time expires, the secondary CGF is told to release all of the possibly duplicate CDRs.

Example

Use the following command to set the amount of time to hold onto CDRs to 2 hours (120 minutes):

    gtpp duplicate-hold-time minutes 120
gtpp echo-interval

Configures the frequency at which the system sends GTPP echo packets to configured CGFs.

Product
GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

gtpp echo-interval time

{ default | no } gtpp echo-interval

default
Resets the configuration to the default echo-interval of 60 seconds.

no
Disables the use of the echo protocol except for the scenarios described in the Usage section for this command.

time
Specifies the number of seconds for sending GTPP echo packets as an integer from 60 to 3600. Default: 60.

Usage

The GTPP echo protocol is used by the system to ensure that it can communicate with configured CGFs. The system initiates this protocol for each of the following scenarios:

• Upon system boot
• Upon the configuration of a new CGF server on the system using the gtpp server command as described in this chapter
• Upon the execution of the gtpp test accounting command as described in the Exec Mode Commands chapter of this reference
Upon the execution of the `gtp sequencenumber`, `privateextensions` command as described in this chapter.

The echo-interval command is used in conjunction with the `gtp max-retries` and `gtp timeout` commands as described in this chapter.

In addition to receiving an echo response for this echo protocol, if we receive a GTPP Node Alive Request message or a GTPP Echo Request message from a presumed dead CGF server, we will immediately assume the server is active again.

The alive/dead status of the CGFs is used by the AAA Managers to affect the sending of CDRs to the CGFs. If all CGFs are dead, the AAA Managers will still send CDRs, (refer to the `gtp deadtime` command), albeit at a slower rate than if a CGF were alive. Also, AAA Managers independently determine if CGFs are alive/dead.

Example

The following command configures an echo interval of 120 seconds:

```
gtp echo-interval 120
```
gtpp egcdr

Configures the eG-CDR and P-CDR (P-GW CDR) parameters and triggers.

Product
GGSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

```
gtpp egcdr { closure-reason admin-disconnect [ management-intervention | normal-release ]
| final-record [ [ include-content-ids [ all | only-with-traffic ] ] ]
| closing-cause { same-in-all-partially | unique ] ]
| losdv-max-containers max_losdv_containers | lotdv-
max-containers max_lottv_containers | rulebase-max-length rulebase_name_max_length
| service-data-flow threshold { interval interval | volume { downlink bytes [ uplink bytes
| total bytes [ uplink bytes [ downlink bytes ] ] } ]
| service-idle-timeout { 0 | service_idle_timeout ] }
}
```

default gtpp egcdr { closure-reason admin-disconnect | final-record include-content-ids
| only-with-traffic closing-cause same-in-all-partially | losdv-max-containers | lotdv-max-
containers | service-idle-timeout 0 }

no gtpp egcdr { rulebase-max-length | service-data-flow threshold { interval | volume { downlink [ uplink ] | total | uplink [ downlink ] } ] }

```
closure-reason admin-disconnect [ management-intervention | normal-release ]
```

Controls the configuration of “causeForRecordClosing” in PGW-CDR when a call is cleared from the chassis.
Releases prior to 14.1, when a call is cleared from the chassis the field “causeForRecordClosing” in a PGW-
CDR shows “Normal Release”. In 15.0 and later releases, the behavior has changed to comply with the 3GPP
specifications. That is, the default “causeForRecordClosing” in PGW-CDR will be “Management Intervention”.

**Important:** This behavioral change is limited to PGW-CDR Release 8 dictionaries only.

```
closing-reason: Configures the record closing reason for PGW-CDR.
```

```
*management-intervention:* Specifies to send Management-Intervention as causeForRecordClosing
in PGW-CDRs. By default, Management-Intervention will be sent as the record closure reason for
PGW-CDRs.
• **normal-release**: Specifies to send Normal Release as causeForRecordClosing in PGW-CDRs.

```plaintext
final-record [ [ include-content-ids { all | only-with-traffic } ] [ closing-cause { same-in-all-partial | unique } ] ]
```

Enables configuration of the final eG-CDR/P-CDR.

- **include-content-ids**: Controls which content-ids are being included in the final eG-CDR/P-CDR.
  - **all**: Specifies that all content-ids be included in the final eG-CDR/P-CDR.
  - **only-with-traffic**: Specifies that only content-ids with traffic be included in the final eG-CDR/P-CDRs.

- **closing-cause**: Configures closing cause for the final eG-CDR/P-CDR.
  - **same-in-all-partial**: Specifies that the same closing cause is to be included for multiple final eG-CDR/P-CDRs.
  - **unique**: Specifies that the closing cause for final eG-CDR/P-CDRs is to be unique.

```plaintext
losdv-max-containers max_losdv_containers
```

Specifies the maximum number of List of Service Data Volume (LoSDV) containers in one eG-CDR/P-CDR. `max_losdv_containers` must be an integer from 1 through 255. Default: 10

```plaintext
lotdv-max-containers max_lotdv_containers
```

Specifies the maximum number of List of Traffic Data Volume (LoTDV) containers in one eG-CDR/P-CDR. `max_lotdv_containers` must be an integer from 1 through 8. Default: 8

```plaintext
rulebase-max-length rulebase_name_max_length
```

Specifies the maximum character length of charging rulebase name in LOSDVs of eG-CDR/P-GW-CDR. `rulebase_name_max_length` must be an integer from 0 through 63. Zero (0) means the rulebase name is added as-is. Default: None. That is, full (un-truncated) charging rulebase name will go in LOSDVs of eG-CDR/P-GW-CDR.

```plaintext
service-data-flow-threshold { interval interval | volume { downlink bytes | uplink bytes | total bytes | uplink bytes [ downlink bytes ] } }
```

Configures the thresholds for closing a service data flow container within an eG-CDR/P-CDR.

- **interval**: Specifies the time interval (in seconds) to close the eG-CDR/P-CDR if the minimum time duration thresholds for service data flow containers satisfied in flow-based charging. The interval is an integer from 60 through 40000000. Default: Disabled

- **volume**: Specifies the volume octet counts for the generation of the interim eG-CDR/P-CDRs to the service data flow container in FBC.
  - **downlink bytes**: Specifies the limit for the number of downlink octets after which the eG-CDR/P-CDR is closed.
  - **total bytes**: Specifies the limit for the total number of octets (uplink+downlink) after which the eG-CDR/P-CDR is closed.
  - **uplink bytes**: Specifies the limit for the number of uplink octets after which the eG-CDR/P-CDR is closed.
A service data flow container has statistics for an individual content ID. When the threshold is reached, the service data flow container is closed.

In 12.3 and earlier releases, when the CLI command `gtpp egcdr service-data-flow threshold interval` was configured to 'n' seconds, the difference between “timeOfFirstUsage” and “timeOfReport” of LOSDV was always 'n' seconds for the LOSDVs closed due to “service-data-flow” threshold. Here, changeTime of LOSDV was reported incorrectly. It was always timeOfFirstUsage + ‘n’. This does not hold true when the traffic for a particular content ID was not continuous.

In StarOS release 14.0 and later, when the command `gtpp egcdr service-data-flow threshold interval` is configured to ‘n’ seconds, the difference between “timeOfFirstUsage” and “timeOfReport” of LOSDV can be any value between 1 and ‘n’ seconds depending on the continuity of traffic. If the traffic is not continuous, the difference is less than ‘n’ seconds. And if the traffic is continuous the difference will be ‘n’ seconds. When this CLI command is configured in the GTPP Server Group Configuration mode, each LOSDV will be closed at configured regular interval after the arrival of first packet.

**service-idle-timeout**

```
{ 0 | service_idle_timeout}
```

Specifies a time period during which if no data is reported for a service flow, the service container is closed and added to eG-CDR/P-CDR (as part of LOSDV container list) with service condition change as ServiceIdleOut.

0: Specifies there is no service-idle-timeout trigger.

*service_idle_timeout* is an integer from 10 through 86,400. Default: 0

### Usage

Use this command to configure individual triggers for eG-CDR/P-CDR generation.

### Example

Use the following command to set the maximum number of LoSDV containers to 7:

```
gtpp egcdr losdv-max-containers 7
```
gtpp error-response

Configures the response when the system receives an error response after transmitting a DRT (data record transfer) request.

Product
GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

/context_name/host_name(config-gtpp-group)#

Syntax

gtpp error-response { discard-cdr | retry-request }

default gtpp error-response

default

Resets the system’s configuration to the default value for error-response. Default is retry-request.

discard-cdr

Purges the request upon receipt of an error response and not to retry.

retry-request

Retries sending a DRT after receiving an error response. This is the default behavior.

Usage

This command configures the system’s response to receiving an error message after sending a DRT request.

Example

gtpp error-response discard-cdr
gtpp max-cdrs

Configures the maximum number of charging data records (CDRs) to be included in a packet.

Product
GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

gtpp max-cdrs max_cdrs [ wait-time wait_time ]

default gtpp max-cdrs

default
Sets the default configuration.

max_cdrs
Specifies the maximum number of CDRs to insert in a single packet as an integer from 1 through 255. Default: 1

wait-time wait_time
Specifies the number of seconds the GSN waits to send the packet while accumulating CDRs as defined by max-cdrs. If the wait-time interval expires before max-cdrs is reached, this keyword over-rides and the packet is sent. Default: Disabled
wait_time is an integer from 1 through 300.

Important: The wait-time interval can only be enabled if the value for max-cdrs is greater than 1.

Usage

The system places CDRs into a packet until either max-cdrs is met, wait-time times out, or the maximum PDU size, configured by the gtpp max-pdu-size command, is met.
The gtpp max-pdu-size and the wait-time parameters take priority over max-cdrs.
**Important:** This command’s configuration is ignored if CDRs are stored on an SMC hard disk.

**Example**

The following command configures the system to place a maximum of 10 CDRs in a single GTPP packet with a wait-time of 30 seconds:

```
gtp max-cdr 10 wait-time 30
```
gtpp max-pdu-size

Configures the maximum payload size of a single GTTP packet that could be sent by the system.

Product
GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTTP Server Group Configuration
configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

**gtpp max-pdu-size pdu_size**

**default gtpp max-pdu-size**

default

Resets the default max-pdu-size of 65400.

pdu_size

Specifies the maximum payload size (in bytes) of the GTTP packet as an integer from 1024 to 65400. The payload includes the CDR and the GTTP header. Default: 65400

Usage

The GTTP packet contains headers (layer 2, IP, UDP, and GTTP) followed by the CDR. Each CDR contains one or more volume containers. If a packet containing one CDR exceeds the configured maximum payload size, the system creates and send the packet containing the one CDR regardless. The larger the packet data unit (PDU) size allowed, the more volume containers that can be fit into the CDR. The system performs standard IP fragmentation for packets that exceed the system’s maximum transmission unit (MTU).

**Important:** The maximum size of an IPv4 PDU (including the IPv4 and subsequent headers) is 65,535. However, a slightly smaller limit is imposed by this command because the system’s max-pdu-size doesn't include the IPv4 and UDP headers, and because the system may need to encapsulate GTTP packets in a different/larger IP packet (for sending to a backup device).
Example

The following command configures a maximum PDU size of 2048 octets:

```
gtp max-pdu-size 2048
```

**gtpp max-retries**

Configures the maximum number of times the system attempts to communicate with an unresponsive CGF.

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

```
configure > context context_name > gtpp group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
gtpp max-retries max_attempts
```

**default gtpp max-retries**

```
default
```

Resets the maximum number of to the default of 4.

```
max_attempts
```

Specifies the number of times the system attempts to communicate with a CGF that is not responding as an integer from 1 to 15. Default: 4

**Usage**

This command works in conjunction with the **gtpp detect-dead-server** and **gtpp timeout** parameters to set a limit to the number of communication failures that can occur with a configured CGF. When the value specified by this parameter is met, a failure is logged. The **gtpp detect-dead-server** parameter specifies the number of consecutive failures that could occur before the server is marked as down. In addition, the **gtpp timeout** command controls the amount of time between re-tries.

If the value for the max-retries is met, the system begins storing CDRs in Random Access Memory (RAM). The system allocates memory as a buffer, enough to store one million CDRs for a fully loaded chassis (a maximum of one outstanding CDR per PDP context). Archived CDRs are re-transmitted to the CGF until they are acknowledged or the system’s memory buffer is exceeded.

Refer to the **gtpp detect-dead-server** and **gtpp timeout** commands for additional information.

**Example**

The following command configures the maximum number of re-tries to be 8.
gtpp max-retries 8
**gtpp mbms bucket**

Configures the traffic data volume (bucket) limit of charging buckets due to QoS changes of tariff time that can occur before a G-MBMS-CDR should be closed.

**Product**

GGSN

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

`configure > context context_name > gtpp group group_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
gtpp mbms buckets number
[ no ] gtpp mbms buckets
```

- **no**
  
  Disables the configured traffic data volume bucket limits trigger for G-MBMS-CDR generation for MBMS user service data.

- **number**
  
  Specifies the number of statistics container changes due to QoS changes or tariff time that can occur before a G-MBMS-CDR should be closed as an integer from 1 through 4. Default: 4

**Usage**

Use this command to configure the traffic data volume (bucket) based G-MBMS-CDR generation triggers for MBMS user data service.

**Example**

The following command configures the bucket-based trigger to generate G-MBMS-CDRs after changes in 2 container:

```
gtpp mbms buckets 2
```
**gtpp mbms interval**

Configures the interval duration for interval-based triggers for GTPP MBMS Charging Data Record (G-MBMS-CDR) generation.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

```plaintext
configure > context context_name > gtpp group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```plaintext
gtpp mbms interval duration_sec
```

```plaintext
no gtpp mbms interval
```

**no**

Disables the interval-based trigger for G-MBMS-CDR generation for MBMs user service data.

**duration_sec**

Specifies the normal time duration (in seconds) that must elapse before closing an accounting record provided that any or all of the following conditions occur:

- Downlink traffic volume is reached within the time interval
- Tariff time based trigger occurred within the time interval
- Data volume (up and downlink) bucket trigger occurred within the time interval

`duration_sec` is an integer from 60 through 40,000,000. Default: Disabled

**Usage**

Use this command to configure the G-MBMS-CDR generation triggers for MBMS user data service.

**Example**

The following command configures the interval-based trigger to generate G-MBMS-CDRs in every 60 seconds:

```plaintext
gtpp mbms interval 60
```
gtp mbms tariff

Configures the tariff slots for tariff-based triggers for GTPP MBMS Charging Data Record (G-MBMS-CDR) generation.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

gtpp mbms tariff time1 mins hours [ time2 mins hours [ time3 mins hours [ time4 mins hours ] ] ]

no gtp mbms tariff

no
disables the tariff-based triggers for GTPP MBMS Charging Data Record (G-MBMS-CDR) generation.

tariff time1 mins hours [ time2 mins hours [ time3 mins hours [ time4 mins hours ] ] ]

Specifies time-of-day time values to close the current statistics container (but not necessarily the accounting record). Default: Disabled

Important: The system assumes that the billing system uses the day/date to determine if the statistics container represents an actual tariff period.

For each of the different tariff times, the following parameters must be configured:

• mins: Minute of the hour, an integer from 0 through 59.
• hours: Hour of the day, an integer from 0 through 23.

Usage

Use this command to configure the tariff-time-based triggers for G-MBMS-CDR generation in MBMS user data service.

Example

The following command configures the tariff-time-based trigger to generate G-MBMS-CDRs every day at 11 hours and 30 min:

    gtp mbms tariff time1 30 11
gtpp mbms volume

Configures the download traffic data volume based trigger for GTPP MBMS Charging Data Record (G-MBMS-CDR) generation.

Product
GGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

```
gtpp mbms volume download_bytes

no gtpp mbms volume

---

no

Disables the configured download traffic data volume based trigger for G-MBMS-CDR generation for MBMs user service data.

---

volume download_bytes

Specifies the threshold of downlink data volumes that (in bytes) must be met before a G-MBMS-CDR should be closed as an integer from 100000 through 4000000000. Default: Disabled

---

Usage

Use this command to configure the traffic data volume (download) based G-MBMS-CDR generation triggers for MBMS user data service.

Example

The following command configures the traffic data volume (download) limit to trigger to generate G-MBMS-CDRs after reaching 150,000 octets:

```
gtpp mbms volume download_bytes
```
gtpp redirection.allowed

Configures the system to allow/disallow the redirection of CDRs when the primary CGF is unavailable.

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

```
configure > context context_name > gtpp group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
[ default | no ] gtpp redirection-allowed
```

- **default**
  - Resets the system to allow redirection of CDRs.

- **no**
  - Removes the redirection definition from the configuration.

**Usage**

This command allows operators to better handle erratic network links, without having to remove the configuration of the backup server(s) via the `no gtpp server` command.

This functionality is enabled by default.

If the `no gtpp redirection-allowed` command is executed, the system only sends CDRs to the primary CGF. If that CGF goes down, the system will buffer the CDRs in memory until the CGF comes back or until the system runs out of buffer memory. In addition, if the primary CGF announces its intent to go down (with a GTPP Redirection Request message), the system responds to that request with an error response.

**Example**

The following command configures the system to allow the redirection of CDRs when the primary CGF is unavailable:

```
default gtpp redirection-allowed
```
gtpp redirection-disallowed

This command has been obsoleted and is replaced by the `gtpp redirection-allowed` command.
gtpp server

Configures the charging gateway function (CGF) accounting server(s) with in GTPP server group that the system is to communicate with.

Product

Entering the above command sequence results in the following prompt:

[cxtextht thư name(config-gtpp-group)#

Syntax

```
gtpp server ip_address [ max msgs ] [ priority priority ] [ udp-port port ] [ node-alive { enable | disable } ] [ -noconfirm ]
```

```
no gtpp server ip_address [ udp-port port ]
```

no

Deletes a previously configured CGF.

```
config
```

Specifies the IP address of the CGF in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

```
max msgs
```

Specifies the maximum number of outstanding or unacknowledged GTPP packets (from any one AAA Manager task) allowed for this CGF before the system begins buffering the packets.

msgs can be configured to an integer from 1 to 256. Default: 256

**Important:** In release 16.0, a warning message is displayed if the user tries to configure a value greater than 100 and the max-outstanding is configured as 100. This is because there is an internal limit of up to 100 max outstanding requests that can be configured.

```
priority priority
```

Default: 1000
Specifies the relative priority of this CGF as an integer from 1 through 1000. When multiple CGFs are configured, the priority is used to determine which CGF server to send accounting data to. When configuring two or more servers with the same priority you will be asked to confirm that you want to do this.

If you use the **-noconfirm** option, you are not asked for confirmation and multiple servers could be assigned the same priority.

**udp-port port**

Specifies the UDP port over which the GGSN communicates with the CGF. as an integer from 1 through 65535. Default: 3386

**node-alive { enable | disable }**

Enable or disables GGSN sending Node Alive Request to a GTPP Server (such as CGF). This configuration can be done per GTPP Server. Default: Disable.

**-noconfirm**

Executes this command without any additional prompt and confirmation from the user.

**Usage**

Use this command to configure the CGF(s) that the system sends CDR accounting data to. Multiple CGFs can be configured using multiple instances of this command subject to the following limits:

- Up to 4 CGFs can be configured in one GTPP server group
- Total of 32 CGFs can be configured per context.

Each configured CGF can be assigned a priority. The priority is used to determine which server to use for any given subscriber based on the routing algorithm that has been implemented. A CGF with a priority of “1” has the highest priority.

**Important:** The configuration of multiple CGFs with the same IP address but different port numbers is not supported.

Each CGF can also be configured with the maximum allowable number of unacknowledged GTPP packets. Since multiple AAA Manager tasks could be communicating with the same CGF, the maximum is based on any one AAA Manager instance. If the maximum is reached, the system buffers the packets Random Access Memory (RAM). The system allocates memory as a buffer, enough to store one million CDRs for a fully loaded chassis (a maximum of one outstanding CDR per PDP context).

**Example**

The following command configures a CGF with an IP address of 192.168.2.2 and a priority of 5.

```
gtp server 192.168.2.2 priority 5
```

The following command deletes a previously configured CGF with an IP address of 100.10.35.7:

```
no gtp server 100.10.35.7
```
**gtpp source-port-validation**

Configures whether the system validates the UDP source port in received GTPP messages.

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

```
configure > context context_name > gtpp group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
[ default | no ] gtpp source-port-validation
```

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Restores this parameter to its default setting of enabled.</td>
</tr>
<tr>
<td>no</td>
<td>Validates the IP source address but not the UDP source port.</td>
</tr>
</tbody>
</table>

**Usage**

This command configures whether the system validates the UDP source port in received GTPP messages.

**Example**

The following command disables UDP port validation:

```
no gtpp source-port-validation
```
**gtpp storage-server**

Configures information for the GTPP back-up storage server.

**Product**

GGSN
P-GW
SAEGW
SGSN
S-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

```
configure > context context_name > gtpp group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
[ no ] gtpp storage-server ip_address port port_num
```

- **no**
  
  Removes a previously configured back-up storage server.

- **ip_address**
  
  The IP address of the back-up storage server expressed in IPv4 dotted-decimal notation.

- **port port_num**
  
  Specifies the UDP port number over which the GGSN communicates with the back-up storage server. Default: 3386

**Usage**

This command identifies the connection to the GSS. One backup storage server can be configured per GTPP group.

**Example**

The following command configures a GSS with an IP address of 192.168.1.2:

```
gtpp storage-server 192.168.1.2
```
gtpp storage-server local file

Configures the parameters for GTPP files stored locally on the GTPP storage server.

Product
- GGSN
- IPSG
- PDG/TTG
- P-GW
- SAEGW
- SGSN
- S-GW

Privilege
- Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

```

default gtpp storage-server local file { compression | format | name { format | prefix } | purge-processed-files | rotation { cdr-count | time-interval | volume } start-file-seq-num }

no gtpp storage-server local file { purge-processed-files | push | rotation { cdr-count | time-interval } }
```

no

Removes a previously configured parameters for local storage of CDR files on HDD on SMC card.

```
compression { gzip | none }
```

Configures the type of compression to be used on the files stored locally.
- gzip – Enables Gzip file compression.
- none – Disables Gzip file compression -this is the default value.
format custom1 .. 8

Configures the file format to be used to format files to be stored locally.

- **custom1** – File format custom1 - this is the default file format.
- **custom2 to custom5** Customer specific CDR file formats.
- **custom6** – File format custom6 with a block size of 8K for CDR files.
- **custom7** – File format custom7 is a customer specific CDR file format.
- **custom8** – File format custom8 is a customer specific CDR file format. It uses `node-id-suffix_date_time_fixed-length-seq-num.u` format for file naming where:
  
  - **date** is date in MMDDYYYY (01312010) for mat
  - **time** is time in HHMMSS (023508) format
  - **fixed-length-seq-num** is the fixed length of the sequence number for specific file having a 6-digit counter starting from 000001 and ending at 999999. When file sequence reaches 999999, the sequence is reset to 000001.

name format string

Allows the format of the CDR filenames to be configured independently so that the name format contains the file name with conversion specifications.

- **string** – is an alphanumeric string of 1 through 127 characters. It must begin with the % (percent sign).
  
  - **%y** = year as a decimal number without century (range 00 to 99).
  - **%Y** = year as a decimal number with century.
  - **%m** = month as a decimal number (range 01 to 12).
  - **%d** = day of the month as a decimal number (range 01 to 31).
  - **%H** = hour as a decimal number 24-hour format (range 00 to 23).
  - **%h** = hour as a decimal number 12-hour format (range 01 to 12).
  - **%M** = minute as a decimal number (range 00 to 59).
  - **%S** = second as a decimal number (range 00 to 60). (The range is up to 60 to allow occasional leap seconds.)
  - **%Q** = file sequence number. Field width may be specified between the % and the Q. If the natural size of the field is smaller than this width, then the result string is padded (on the left) to the specified width with 0s
  - **%N** = No of CDRs in the file. Field width may be specified between the % and the N. If the natural size of the field is smaller than this width, then the result string is padded (on the left) to the specified width with 0s
  - **%%** = This field is used to add % to the CDR file name.

- **max-file-seq-no**: This can be configured optionally. It indicates the maximum value of sequence number in file name (starts from 1). Once the configured max-file-seq-no limit is reached, the sequence number will restart from 1. If no max-file-seq-no is specified then file sequence number ranges from 1- 4294967295.

By default the above keyword is not configured (default gtpp storage-server local file name format). In which case the CDR filenames are generated based on the file format as before (maintains backward compatibility).
**name prefix prefix**

Defines the prefix to be used for the file name. By default the file name prefix would be “GTPP-group-name + VPN-ID”. It is possible to have a NULL value prefix where the system would enter a default, which would be `group+vpn`, `prefix` - is an alphanumeric string of 1 through 64 characters, Do not enter a value (NULL).

**purge-processed-files [ file-name-pattern file_pattern | purge-interval purge_dur ]**

Enables the GSN to periodically (every 4 minutes) delete locally processed (*.p) CDR files from the HDD on the SMC card. Default: Disabled

This keyword also deletes the processed push files (tx.*,under $CDR_PATH/tx/*) a well when purging is enabled instead of "}*.p:*.*".

**Important:** This option is available only when GTPP server storage mode is configured for local storage of CDRs with the `gtpp storage-server mode local` command.

Optional keyword `file-name-pattern file_pattern` provides an option for user to control the pattern of files. `file_pattern` must be mentioned in "*.p:*.*:*" format in a string of size 1 through 127, which is also the default format. Wildcards * and: (synonymous to |) are allowed.

Optional keyword `purge-interval purge_dur` provides an option for user to control the purge interval duration (in minutes). `purge_dur` must be an integer from 1 through 259200. Default value 60.

**push { encrypted-url encrypted_url | url url } [ encrypted-secondary-url encrypted_url | secondary-url url ] [ via-local-context ]**

Enables push method to transfer local CDR files to remote system.

`encrypted-url`: Defines use of an encrypted url.

`encrypted_url` must be an alphanumeric string of 1 through 8192 characters in SFTP format.

`url`: Location where the CDR files are to be transferred.

`url` must be an alphanumeric string of 1 through 1024 characters in the format: `scheme://user:password@host`

`encrypted-secondary-url`: Defines use of an encrypted secondary url.

`encrypted_url` must be an alphanumeric string of 1 through 8192 characters in SFTP format.

`secondary-url`: Secondary location where the CDR files are to be transferred, in case primary is unreachable.

`url` must be an alphanumeric string of 1 through 1024 characters in the format: `scheme://user:password@host`

**Important:** When a file transfer to primary fails four times, the transfer of files will automatically be failed over to the secondary server. The transfer will switch back to the original primary after 30 minutes, or if there are four transfer failures to the secondary server.

`via-local-context`: Pushes the CDR files via SPIO in the local context.

Default: Pushes via the group's context.

**Important:** If the push is done through gtpp context, then the push rate is lesser compared to via local context as the HDD is attached to the local context.
rotation { cdr-count count | time-interval time [ force-rotation ] | volume size }

Specifies rotation related configuration for GTPP files stored locally.

cdr-count count: Configures the CDR count for the file rotation as an integer from 1000 through 65000. Default value 10000.
time-interval time: Configures the time interval for file rotation (in seconds) as an integer from 30 through 86400. Default: 3600 (1 hour).
force-file-rotation: Forces CDR file-rotation at a specified interval configured via the time-interval keyword, even if no CDRs were generated. By default this keyword is Disabled.
volume size: Configures the file volume (in megabytes) for file rotation as an integer from 2 through 40. This trigger can not be disabled. Default: 10

start-file-seq-num seq_num [ recover-file-seq-num ]

Default: disabled
 Enables the continuous file sequence number function. start-file-seq-num specifies the lowest number to be used as a file sequence number in the case of an aaaproxy or a chassis restart/reboot.

seq_num is an integer from 1 to 4294967295. Entering a value of 1 disables the recover file sequence number function. Entering any other number, for example 10, would instruct the system to always start from 10 as the file sequence number in the event of an aaaproxy or chassis reload.

When files are moved, the file sequence numbers are synced and stored in both RAM and the hard disk drive (HDD). recover-file-seq-num instructs the system to recover the last (largest) stored file sequence number, in the event of an aaaproxy/chassis restart/reboot, to continue file sequence numbering rather than resetting the file sequence numbering to the lowest start file sequence number.

Usage

This command configures the parameters for storage of GTPP packets as files on the local server - meaning the hard disk drive (HDD).

Example

The following command configures rotation for every 1.5 hours for locally stored files.

    gtpp storage-server local file rotation time-interval 5400

Configuring file name format along with max-file-seq-no:

    gtpp storage-server local file name format processed_2g_%Y%m%d_%5Q_%N.cdr
    max-file-seq-no 2345

Configuring file name prefix with a NULL value:

    gtpp storage-server local file name prefix NULL

Configure the file name pattern and purge interval to setup file purging from the HDD:

    gtpp storage-server local file purge-processed-files file-name-pattern *
               .z purge-interval 4
gtpp storage-server max-retries

Configures the maximum number of times the system attempts to communicate with an unresponsive GTPP back-up storage server.

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
[ default ] gtpp storage-server max-retries max_attempts
```

- **default**
  Restores the system to the default value of 2 retry attempts.

- **max_attempts**
  Specifies the number of times the system attempts to communicate with a GTPP back-up storage server that is not responding as an integer from 1 to 15. Default: 2

**Usage**

This command works in conjunction with the `gtpp storage-server timeout` parameters to set a limit to the number of communication failures that can occur with a configured GTPP back-up storage server. The `gtpp storage-server timeout` command controls the amount of time between retries. Refer to the description of this command for additional information.

**Example**

The following command configures the maximum number of re-tries to be 8.

```
gtpp storage-server max-retries 8
```
gtpp storage-server mode

Configures the storage mode (local, remote or streaming for CDRs) to be used. Local storage mode is available with ASR 5000 platforms only.

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

```bash
configure > context context_name > gtpp group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```bash
gtpp storage-server mode { local | remote | streaming [ parallel ] }
default gtpp storage-server mode
```

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Returns the GTPP group configuration to the default “remote” value for the GTPP storage server mode.</td>
</tr>
<tr>
<td>local</td>
<td>Specifies the use of the hard disk for storing CDRs. Default: Disabled</td>
</tr>
</tbody>
</table>

**Important:** This option is available with ASR 5000 platforms only.

- remote

  Specifies the use of an external server for storing CDRs. This is the default value.

**Important:** When the external server is down, the Session Managers will start buffering up to a maximum of 26400 CDRs or a total of 120 MB worth of CDRs, whichever limit reaches first. The maximum CDR limit specified is per the session manager. The chassis level limit varies depending on the number of session manager instances and number of active cards.
streaming [ parallel ]

Specifies the use of HDD to store CDRs in case if CGF fails and then stream the CDRs to the CGF when CGF is up. Streaming can be done in a First-In-First-Out (FIFO) or parallel mode. Default: streaming (FIFO)

**streaming**: This keyword allows the operator to configure “streaming” mode of operation for GTPP group. When this keyword is supplied the CDRs will be stored in following fashion:

- When GTPP link is active with CGF, CDRs are sent to a CGF via GTPP and local hard disk is NOT used as long as every record is acknowledged in time.

- If the GTPP connection is considered to be down, all streaming CDRs will be saved temporarily on the local hard disk and once the connection is restored, unacknowledged records will be retrieved from the hard disk and sent to the CGF.

In the streaming mode, when the CGF becomes active, CDRs in HDD are streamed in a First-In-First-Out order. In this mode, newly generated CDRs are routed to CGF via HDD.

**parallel**: In this mode, when the CGF becomes active, CDRs in HDD are streamed at slower pace. Newly generated CDRs are sent directly to CGF servers along with CDRs streamed from HDD.

In PARALLEL mode, rate of streaming from HDD will be slow. The maximum requests that can be streamed from HDD will be either set to 1 or 25% of the available bandwidth (i.e. max outstanding - outstanding req) if it is greater than 1. It is expected that the billing domain should be capable of handling Out-Of-Order CDRs in parallel streaming mode.

**Usage**

This command configures whether the CDRs should be stored on the hard disk of the SMC or remotely, on an external server.

**Example**

The following command configures use of a hard disk for storing CDRs.

```
  gtpp storage-server mode local
```
**gtpp storage-server timeout**

Configures the amount of time that must pass with no response before the system re-attempts to communicate with the GTPP back-up storage server.

**Product**
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration
- `configure > context context_name > gtpp group group_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
[ default ] gtpp storage-server timeout duration
```

- **default**
  - Restores the timeout duration to the default of 30 seconds.

- **duration**
  - Specifies the maximum amount of time (in seconds) that the system waits for a response from the GTPP back-up storage server before assuming the packet is lost.
  - `duration` is an integer from 30 through 120. Default: 30

**Usage**

This command works in conjunction with the `gtpp storage-server max-retries` command to establish a limit on the number of times that communication with a GTPP back-up storage server is attempted before a failure is logged.

This parameter specifies the time between retries.

**Example**

The following command configures a retry timeout of 60 seconds:

```
gtpp storage-server timeout 60
```
gtp suppress-cdrs zero-volume

Suppresses the CDRs with zero byte data count, so that the OCG node is not overloaded with a flood of CDRs. By default this mode is “disabled”.

Important: The Zero Volume CDR Suppression is a license-controlled feature. For more information, contact your Cisco account representative.

Product
GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

```
gtpp suppress-cdrs zero-volume { final-cdr | internal-trigger-cdr | external-trigger-cdr } +
{ default | no } gtpp suppress-cdrs zero-volume
```

**default | no**
Disables the CDR suppression mode. By default this command is disabled and system will not suppress any CDR.

**final-cdr**
Suppresses only the Final Zero Volume CDRs i.e. the CDRs that are generated when the session ends.

**internal-trigger-cdr**
Supresses Zero Volume interim CDRs that are generated due to internal triggers such as volume limit, time limit, tariff change or user generated interims through the CLI commands.

**external-trigger-cdr**
Supresses Zero Volume interim CDRs that are generated due to external triggers such as QoS Change, RAT change and so on.
GTPP Server Group Configuration Mode Commands

Usage
Use this command to suppress the CDRs (G-CDRs, eG-CDR, PGW-CDRs, SGW-CDRs, SGSN CDRs) with zero-volume session due to any reason.
This feature allows the customers to suppress the CDRs with zero byte data count, so that the OCG node is not overloaded with a flood of CDRs.
The CDRs can be categorized as follows:

- final-cdr: These CDRs are generated when the session ends.
- internal-trigger-cdr: These CDRs are generated due to internal triggers such as volume limit, time limit, tariff change or user generated interim through the CLI commands.
- external-trigger-cdr: These CDRs are generated due to external triggers such as QoS Change, RAT change and so on. All triggers which are not considered as final-cdrs or internal-trigger-cdrs are considered as external-trigger-cdrs.

Customers can select the CDRs they want to suppress. This feature is disabled by default to ensure backward compatibility.

Example
The following command configures the system to suppress Zero Volume Final CDRs, interim CDRs due to internal and external triggers:

```
gtpp suppress-cdrs zero-volume final-cdr internal-trigger-cdr external-trigger-cdr
```
gtpp suppress-cdrs zero-volume-and-duration

Suppresses the CDRs created by session having zero duration and/or zero volume. By default this mode is “disabled”.

**Product**
- GGSN
- P-GW
- SAEGW
- S-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

```
configure > context context_name > gtpp group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
gtpp suppress-cdrs zero-volume-and-duration { gcdrs [ egcdrs ] | egcdrs [ gcdrs ] }
```

**Usage**
Use this command to suppress the CDRs (G-CDRs and eG-CDR/P-CDRs) which were created due with zero-duration session and zero-volume session due to any reason. By default this command is disabled and system will not suppress any CDR.

**Example**
The following command configures the system to suppression the eG-CDR/P-CDRs created for a zero duration session or zero volume session:

```
gtpp suppress-cdrs zero-volume-and-duration egcdrs gcdrs
```
gtpp timeout

Configures the amount of time that must pass with no response before the system re-attempts to communicate with the CGF.

Product
GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

configure > context context_name > gtpp group group_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpp-group)#

Syntax

[ default ] gtpp timeout time

default
 Resets the systems GTPP timeout value to 20 seconds.

time
 Specifies the maximum amount of time (in seconds) the system waits for a response from the CGF before assuming the packet is lost.

$time$ is an integer from 1 through 60. Default: 20

Usage

This command works in conjunction with the gtpp max-retries command to establish a limit on the number of times that communication with a CGF is attempted before a failure is logged.

This parameter specifies the time between retries.

Example

The following command configures a retry timeout of 30 seconds:

    gtpp timeout 30
**gtpp transport-layer**

Selects the transport layer protocol for Ga interface for communication between AGW (GSNs) and GTPP servers.

**Product**

- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

```
configure > context context_name > gtpp group group_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

**Syntax**

```
gtpp transport-layer { tcp | udp }
```

```
default gtpp transport-layer
```

- **default**
  
  Resets the transport layer protocol to GTPP servers to the default of UDP.

- **tcp**
  
  Enables the system to implement TCP as transport layer protocol for communication with GTPP server. Default: Disabled

- **udp**
  
  Enables the system to implement UDP as transport layer protocol for communication with GTPP server. Default: Enabled

**Usage**

Use this command to select the TCP or UDP as the transport layer protocol for Ga interface communication between GTPP servers and AGWs (GSNs).

**Example**

The following command enables TCP as the transport layer protocol for the GSN’s Ga interface.

```
gtpp transport-layer tcp
```
gtpp trigger

Disables GTPP trigger conditions that cause either partial CDR record closure or opening of a new CDR record container. GTPP Triggers are specified in 3GPP TS 32.251 v6.6.0. All GTPP trigger changes take effect immediately, except volume-limit.

Product
- ECS
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration > Context Configuration > GTPP Server Group Configuration

`configure > context context_name > gtpp group group_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpp-group)#
```

Syntax

```

default gtpp trigger

default

Sets the specified trigger condition back to the default setting. All trigger conditions are enabled by default.

no

Disables the specified trigger condition.
**apn-ambr-change** [ default-bearer-only | all-non-gbr-bearers | all-bearers ]

Default: Disabled
Enables APN AMBR trigger only for default-bearer or for all bearers for that PDN or selectively for apn-non-gbr bearers.

**Important:** This keyword option will be available only if a valid license is installed. For more information, contact your Cisco account representative.

The APN Aggregate Maximum Bit Rate (AMBR) is a subscription parameter stored per APN. It limits the aggregate bit rate that can be expected to be provided across all non-GRB bearers and across all PDN connections of the same APN. Each of these non-GRB bearers potentially utilize the entire APN AMBR, e.g., when the other non-GRB bearers do not carry any traffic.

In 15.0 and later releases, this CLI command should be configured along with the following additional options to enable APN-AMBR trigger for SGW-CDRs in all GTPP dictionaries:

- **default-bearer-only:** Adds container only to default bearer.
- **all-non-gbr-bearers:** Adds container to all non-gbr-bearers.
- **all-bearers:** Adds containers for all bearers.

**Important:** This CLI command and the associated options are not available for products other than S-GW and P-GW.

The first container of each CDR includes apn-ambr fields along with QoS. In the following containers this field is present if previous change condition is "QoS change" or "APN AMBR Change".

**cell-update**

Enables the cell update trigger for S-CDRs, if the dictionary specified in the **gtp trigger** configuration includes support for cell update. This trigger is available only for 2G. Currently, custom18 dictionary supports the cell update trigger.

**dcca**

This keyword enables or disables the addition of LOSDV in PGW-CDR for the following DCCA generated triggers.

- Time Threshold Reached
- Volume Threshold Reached
- Service Specific Unit Threshold Reached
- Time Exhausted
- Volume Exhausted
- Validity Timeout
- Reauthorization Request
- Continue Ongoing Session
- Retry And Terminate Ongoing Session
- Terminate Ongoing Session
- Service Specific Unit Exhausted
- Envelope Closure

direct-tunnel
Enables the direct tunnel trigger for CDRs.

eycdr max-losdv
Enables the trigger for an eG-CDR/P-CDR if the List of Service Data Volume (LoSDV) containers crosses the configured limit for LOSDV containers. Default: Disabled

ggsn-preservation-mode-change
This keyword is for GGSN only.
This trigger enables the preservation-mode-change trigger for G-CDR.

inter-plmn-sgsn-change
This keyword is for GGSN only.
Disabling this trigger ignores an Inter-PLMN SGSN change and doesn't release a G-CDR. Default: Enabled

ms-timezone-change
This keyword is specific to GGSN.
No partial record closure for a time zone change occurs when this trigger is disabled. MS time zone change should be applicable only for 3GPP R6 based GTPP dictionaries. Default: Enabled

plmn-id-change
This trigger keyword is specific to the 2G SGSN and is proprietary (non-standard).
Enables the PLMNID change trigger for S-CDRs if the dictionary specified in the gtpp dictionary configuration supports the PLMNID change. If enabled, the SGSN generates a partial S-CDR when the MS changes the PLMN while under the same SGSN (intra-system intra-SGSN PLMN-ID handover). Currently, custom18 dictionary supports this trigger. Default: Disabled

qos-change
Enables the QoS-change trigger for CDRs. Disabling this trigger ignores a QoS-change and does not open a new CDR for it. Default: Enabled
When QoS changes are observed, the system generates only containers. However when the max-container condition is reached, an interim CDR is generated.

rat-change [ generate { cdr | container } ]
Enables or disables the partial record closure for a RAT change. If disabled, no partial record closure for a RAT change occurs. RAT change should be applicable only for 3GPP R6 based GTPP dictionaries. Default: Enabled
In SGSN, RAT change trigger (2G<->3G) means inter-service handoff (SGSN service <-> GPRS service). If this trigger is enabled, after the RAT change interim CDR is generated. After this RAT change CDR, CDR thresholds such as volume/time etc. and GTPP Group are applicable from new service. If RAT change trigger is disabled, the CDR thresholds and GTPP group etc. will not change and will continue to use from old service.
After the RAT change, the System Type field in CDR changes to indicate the new system type. If this trigger is disabled, then the next CDR generated will indicate System Type, but the data count in the CDR does not
necessarily belong to the system type indicated in CDR; instead, it may belong to both 2G and 3G as CDR is not closing when handover takes place.

**Important:** The System Type field in CDR-related change is not applicable to customized CDR formats, which does not use the System Type field.

\[ \text{generate } \{ \text{cdr | container} \} : \text{Sets generation of CDR or just a Container on a RAT change.} \]

\[ \text{cdr}: \text{Generates a CDR on a RAT-change.} \]

\[ \text{container}: \text{Generates a container only on a RAT-change.} \]

**routing-area-update**

Enables the routing-area-update trigger for CDRs.

**service-idle-out**

This keyword enables or disables the addition of LOSDV in PGW-CDR when a service idles out. Note that the CDR module receives service idle out trigger from DCCA module when the quota hold timer expires, or from ACS manager when rulebase has a service idle out configuration.

**serving-node-change-limit \[ \text{also-intra-sgsn-multiple-address-group-change} \]**

This keyword is enabled for P-GW, S-GW, and GGSN. However, the **also-intra-sgsn-multiple-address-group-change** is enabled only for GGSN. Default: Enabled

Disabling this trigger ignores an SGSN change and does not add the SGSN IP address into the SGSN address list of the CDR. This helps to reduce the release of CDRs due to SGSN changes crossing the configured limit.

**also-intra-sgsn-multiple-address-group-change**: This keyword includes Intra-SGSN group changes as an SGSN change.

**sgsn-change-limit \[ \text{also-intra-sgsn-multiple-address-group-change} \]**

This keyword is obsolete and is available to maintain the backward compatibility for existing customers. The new keyword for **sgsn-change-limit** is **serving-node-change-limit**. Default: Enabled

Disabling this trigger ignores an SGSN change and does not add the SGSN IP address into the SGSN address list of the CDR. This helps to reduce the release of CDRs due to SGSN changes crossing the configured limit.

**also-intra-sgsn-multiple-address-group-change**: This keyword includes Intra-SGSN group changes as an SGSN change.

**tariff-time-change**

When this trigger is disabled, container closure does not happen for a tariff-time change. Default: Enabled

This trigger is applicable for G-MB-CDRs for MBMS session too.

**time-limit**

When this trigger is disabled, no partial record closure occurs when the configured time limit is reached. Default: Enabled

This trigger is applicable for G-MB-CDRs for MBMS session too.

**uli-change**

Enables the user location update trigger for eG-CDRs/PGW-CDRs/SGW-CDRs, if the dictionary specified in the GTPP dictionary configuration includes support for user location update trigger. Default: Enabled
volume-limit

When this trigger is disabled no partial record closure occurs when volume limit is reached. Default: Enabled
This trigger is applicable for G-MB-CDRs for MBMS session too.

Usage

Use this command to disable or enable GTTP triggers that can cause partial CDR record closure or cause a new CDR to be created.

Example

The following command disables partial record closure when a configured time limit is reached:

```
gtp trigger time-limit
```

The following command re-enables partial record closure when a configured time limit is reached:

```
no gtp trigger time-limit
```
Chapter 155
GTP-U Service Configuration Mode Commands

The GTP-U Service Configuration Mode is used to manage parameters applied to incoming GTP-U packets.

Mode
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration
configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpu-service)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
bind

Configures the IP address to use for GTP-U data packets.

Product

ePDG
GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege

Administrator

Mode

Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

command > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpu-service)#

Syntax

[ no ] bind { ipv4-address ipv4_address [ crypto-template crypto_template ] [ ike-bind-address { ipv4-address } ] [ ipv6-address ipv6_address [ bearer-type { non-ims-media | ims-media | all } ] [ ipv6-address ipv6_address [ crypto-template crypto_template ] [ ike-bind-address { ipv6-address } ] [ ipv4-address ipv4_address [ bearer-type { non-ims-media | ims-media | all } ] ]

no

removes a configured IP address from this service.

ipv4-address ipv4_address

Binds this service to the IPv4 address of a configured interface.

ipv4_address must be entered using IPv4 dotted-decimal notation.

bearer-type non-ims-media | ims-media | all

Specifies the type of bearer to be associated with the bind address. Default behavior is for that the address will be used for all bearer types.

non-ims-media Configures bind address for non-ims media only.

ims-media Configures bind address for ims-media traffic only.

all configures bind address to handle all types of bearer traffic. This is the default setting.

ipv6-address ipv6_address

Binds this service to the IPv6 address of a configured interface.

ipv6_address must be entered using IPv6 colon-separated-hexadecimal notation.
**crypto-template crypto_template**

Configures crypto template for IPSec, which enables IPSec tunneling for this GTP-U address. Must be followed by the name of an existing crypto template.

crypto_template must be an alphanumeric string of 1 through 127 characters.

**ike-bind-address ip_address**

Configures an IKE bind address. Must be followed by IPv4 or IPv6 address; IP address type must be the same as the GTP-U address type.

ipv4_address must be entered using IPv4 dotted-decimal notation.

ipv6_address must be entered using IPv6 colon-separated-hexadecimal notation.

**bearer-type non-ims-media | ims-media | all**

Specifies the type of bearer to be associated with the bind address. Default behavior is for that the address will be used for all bearer types.

**non-ims-media** configures bind address for non-ims media only.

**ims-media** configures bind address for ims-media traffic only.

**all** configures bind address to handle all types of bearer traffic. This is the default setting.

**Usage**

Use this command to bind the service to an interface for sending/receiving GTP-U packets.

**Important:** A GTP-U service can support a maximum of 12 GTP-U endpoints/interfaces.

**Example**

The following command configures the IPv4 address for this GTP-U service as $10.2.3.4$:

```
bind ipv4-address 10.2.3.4
```
echo-interval

Configures the rate at which GPRS Tunneling Protocol (GTP) v1-U echo packets are sent.

**Product**
- ePDG
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration
`configure > context context_name > gtpu-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpu-service)#
```

**Syntax**

```
echo-interval seconds [ dynamic [ smooth-factor multiplier ] ]
{ default | no } echo-interval
```

**default**
Disables the configured echo-interval setting.

**no**
Removes the configured echo-interval setting.

**seconds**
Specifies the number of seconds between the sending of a GTP-Uv1 echo packet. `seconds` must be an integer from 60 through 3600. Default: 60

**dynamic [ smooth-factor multiplier ]**
Enables the dynamic echo timer for the GTP-U service.
`smooth-factor multiplier`: Introduces a multiplier into the dynamic echo timer as an integer from 1 through 5. Default: 2

**Usage**
Use this command to configure the rate at which GTP-Uv1 echo packets are sent.

**Example**

Use this command to configure the rate at which GTP-Uv1 echo packets are sent.
The following command sets the rate between the sending of echo packets at 120 seconds:

```
echo-interval 120
```
echo-retransmission-timeout

Configures the timeout for GTP-U echo message retransmissions for this service.

Product

ePDG
GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege

Administrator

Mode

Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpu-service)#

Syntax

echo-retransmission-timeout seconds

default echo-retransmission-timeout

default
Returns the command to its default setting of 5.

seconds
Default: 5
Configures the echo retransmission timeout, in seconds, for the GTP-U service as an integer ranging from 1 to 20.

Usage

Use this command to configure the amount of time, in seconds, before the GTP-U service transmits another echo request message. The value set in this command is used, as is, for the default echo. If dynamic echo is enabled (echo-interval dynamic) the value set in this command serves as the dynamic minimum (if the RTT multiplied by the smooth factor is less than the value set in this command, the service uses this value).

Example

The following command sets the retransmission timeout for echo messages to 2 seconds:

    echo-retransmission-timeout 2
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
extension-header

Configures the addition of an extension header in the GTP-U packet header, allowing for error indication messages.

Product
GGSN
P-GW
SAEGW
SGSN
S-GW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration
configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpu-service)#

Syntax

[ default | no ] extension-header source-udp-port

default
Returns the command to its default setting of disabled.

no
Disables the feature.

source-udp-port
Configures extension header type UDP Port support in GTP-U header for GTP-U Error Indication messages.

Usage
Use this command to configure the addition of an extension header in the GTP-U packet to allow for error indication messages

Example
The following command enables the inclusion of an extension header to allow for error indication messages:

extension-header source-udp-port
ip qos-dscp

Configures the quality of service (QoS) differentiated service code point (DSCP) per-hop behavior (PHB) to be marked on the outer header of signalling packets originating from the LTE component.

**Product**
- ePDG
- P-GW
- SAEGW
- S-GW

**Privilege**
- Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > GTP-U Service Configuration
- configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpu-service)#
```

**Syntax**

```
ip qos-dscp { af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | cs1 | cs2 | cs3 | cs4 | cs5 | cs6 | cs7 | ef }
[ default | no ] ip qos-dscp
```

- **default**
  - Sets/restores default value.

- **no**
  - Disables DSCP marking.

```
af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | cs1 | cs2 | cs3 | cs4 | cs5 | cs6 | cs7 | ef
```

Specifies the IP QoS DSCP PHB to be marked on the outer header of signalling packets originating from the LTE component. This is a standards-based feature (RFC 2597 and RFC 2474).

Note that CS (class selector) mode options below are provided to support backward compatibility with the IP precedence field used by some network devices. CS maps one-to-one to IP precedence, where CS1 is IP precedence value 1. If a packet is received from a non-DSCP aware router that used IP precedence markings, then the DSCP router can still understand the encoding as a Class Selector code point.

The following forwarding types are supported:

- **af11**: Designates the use of Assured Forwarding 11 PHB.
  - This is the default setting.
- **af12**: Designates the use of Assured Forwarding 12 PHB.
- **af13**: Designates the use of Assured Forwarding 13 PHB.
- **af21**: Designates the use of Assured Forwarding 21 PHB.
- **af22**: Designates the use of Assured Forwarding 22 PHB.
- **af23**: Designates the use of Assured Forwarding 23 PHB.
- **af31**: Designates the use of Assured Forwarding 31 PHB.
- **af32**: Designates the use of Assured Forwarding 32 PHB.
- **af33**: Designates the use of Assured Forwarding 33 PHB.
- **af41**: Designates the use of Assured Forwarding 41 PHB.
- **af42**: Designates the use of Assured Forwarding 42 PHB.
- **af43**: Designates the use of Assured Forwarding 43 PHB.
- **be**: Designates the use of Best Effort forwarding PHB.
- **cs1**: Designates the use of Class Selector code point “CS1”.
- **cs2**: Designates the use of Class Selector code point “CS2”.
- **cs3**: Designates the use of Class Selector code point “CS3”.
- **cs4**: Designates the use of Class Selector code point “CS4”.
- **cs5**: Designates the use of Class Selector code point “CS5”.
- **cs6**: Designates the use of Class Selector code point “CS6”.
- **cs7**: Designates the use of Class Selector code point “CS7”.
- **ef**: Designates the use of Expedited Forwarding PHB typically dedicated to low-loss, low-latency traffic.

The assured forwarding behavior groups are listed in the table below.

<table>
<thead>
<tr>
<th></th>
<th>Class 1</th>
<th>Class 2</th>
<th>Class 3</th>
<th>Class 4</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Low Drop</strong></td>
<td>AF11</td>
<td>AF21</td>
<td>AF31</td>
<td>AF41</td>
</tr>
<tr>
<td><strong>Medium Drop</strong></td>
<td>AF12</td>
<td>AF22</td>
<td>AF32</td>
<td>AF42</td>
</tr>
<tr>
<td><strong>High Drop</strong></td>
<td>AF13</td>
<td>AF23</td>
<td>AF33</td>
<td>AF43</td>
</tr>
</tbody>
</table>

Traffic marked with a higher class is given priority during congestion periods. If congestion occurs to traffic with the same class, the packets with the higher AF value are dropped first.

**Usage**

Use this command to implement DSCP marking only for GTP-U ECHO Request and Response messages.

**Example**

Use the following command to set the use of Best Effort forwarding PHB:

```
ip qos-dscp be
```
ipsec-allow-error-ind-in-clear

Configures whether error-indication is dropped or sent without IPSec tunnel.

Product
S-GW
SAEGW
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration
   configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:
   [context_name] host_name(config-gtpu-service)#

Syntax
[ default | no ] ipsec-allow-error-ind-in-clear

   default
   Error-indication is dropped if no IPSec tunnel is present for that peer.

   no
   Disables the feature.

Usage
Use this command to determine whether error-indication is dropped or sent without an IPSec tunnel. On receiving data packets for a session that does not exist, error-indication needs to be sent back to the peer. If there is no IPSec tunnel present with that peer, error-indication may be either dropped or sent without any IPSec tunnel.

Example
The following command allows error-indication to be sent without any IPSec tunnel:
   ipsec-allow-error-ind-in-clear
ipsec-tunnel-idle-timeout

Configures the IPSec tunnel idle timeout after which IPSec tunnel deletion is triggered.

Product
S-GW
SAEGW
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration
configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpu-service)#

Syntax

ipsec-tunnel-idle-timeout seconds

default ipsec-tunnel-idle-timeout

seconds

Default: 60
Specifies the number of seconds an IPSec tunnel is idle before tunnel deletion is triggered. seconds must be an integer from 10 through 600.

default

Returns the command to its default setting of 60.

Usage

When there are no bearers on a particular IPSec tunnel, GTPUMGR initiates the delete for that tunnel. This timer helps to avoid unnecessary IPSec tunnel deletions for an idle tunnel.

Example

The following command sets the IPsec tunnel idle timeout to 100 seconds:

ipsec-tunnel-idle-timeout 100
max-retransmissions

Configures the maximum retry limit for GTP-U echo retransmissions.

Product
- ePDG
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

Privilege
- Administrator

Mode
- Exec > Global Configuration > Context Configuration > GTP-U Service Configuration
- configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpu-service)#

Syntax

max-retransmissions num

no max-retransmissions

num

Default: 4
Specifies the number of GTP-U echo message retransmissions allowed before triggering a path failure error condition. num must be an integer from 0 through 15.

no

Disables the feature.

Usage

Use this command to set the maximum number of GTP-U echo message retransmissions in order to define a limit that triggers a path failure error.

Example

The following command sets the maximum GTP-U echo message retransmissions for this service to 10:

    max-retransmissions 10
**path-failure clear-trap**

Configures a trigger for clearing the path failure trap.

**Product**
- ePDG
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

`configure > context context_name > gtpu-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpu-service)#
```

**Syntax**

```
path-failure clear-trap gtp echo
[ default | no ] path-failure clear-trap
```

---

**gtp echo**
Sets the clearing trigger/trap to detect a failure upon reaching the maximum number of GTP-U echo message retransmissions.

---

**default**
Resets the command to its default setting of enabled.

---

**no**
Disables the feature.

---

**Usage**
Use this command to set the detection policy for path failures. By default, path failure trap is cleared on receiving first control plane message for that GTP-U peer allocation.

**Example**
The following command sets the clearing trigger to detect failures upon reaching the maximum number of GTP-U echo message retries:

```
path-failure clear-trap gtp echo
```
path-failure detection-policy

Configures a path failure detection policy on GTP-U echo messages that have been retransmitted the maximum number of retry times.

**Product**
- ePDG
- GGSN
- P-GW
- SAEGW
- SGSN
- S-GW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

```plaintext
configure > context context_name > gtpu-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpu-service)#
```

**Syntax**

```plaintext
path-failure detection-policy gtp echo

[ default | no ] path-failure detection-policy
```

- **gtp echo**
  Sets the detection policy to detect a failure upon reaching the maximum number of GTP-U echo message retransmissions.

- **default**
  Resets the command to its default setting of enabled.

- **no**
  Disables the feature.

**Usage**

Use this command to set the detection policy for path failures.

**Example**

The following command sets the path failure detection policy to detect failures upon reaching the maximum number of GTP-U echo message retries:

```plaintext
path-failure detection-policy gtp echo
```
retransmission-timeout

Configures retransmission timeout for GTPU echo message retransmissions for this service.

**Important:** In release 14.0 and later versions, this command is replaced by the `echo-retransmission-timeout` command.

**Product**
- ePDG
- GGSN
- P-GW
- SAEGW
- S-GW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration
configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpu-service)#
```

**Syntax**

```
retransmission-timeout seconds
```

```
default retransmission-timeout
```

**default**

Returns the command to its default setting of 5.

**seconds**

Default: 5
Specifies the number of seconds between the re-sending of GTP-U echo messages. `seconds` must be an integer from 1 through 20.

**Usage**

Use this command to set the number of seconds between the retransmission of GTP-U echo messages.

The following command sets the number of seconds between the sending of GTP-U echo messages to 7:

```
retransmission-timeout 7
```
sequence-number

Enables addition of the sequence number to every GTP-U packet. Default is disabled.

**Product**

GGSN
HSGW
P-GW
SAEGW
SGSN
S-GW

**Privilege**

Administrator

**Mode**

Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

```
configure > context context_name > gtpu-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-gtpu-service)#
```

**Syntax**

```
[ no ] sequence-number
```

- **no**
  
  Disables addition of the sequence number to every GTP-U packet.

**Usage**

Use this command to enable/disable addition of the sequence number to every GTP-U packet coming from Gi interface and going towards Gn/Gp interface. If GTP-U packets are received out of sequence, sequence numbers would allow the packets to be reordered.

**Example**

The following command enables addition of the sequence number to every GTP-U packet:

```
sequence-number
```
source-port

Configures GTP-U data packet source port related parameters.

Product

P-GW
SAEGW
S-GW

Privilege

Administrator

Mode

Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpu-service)#

Syntax

source-port { non-standard | standard }

default source-port

default

Configures GTP-U service to use standard port 2152 as source port for all GTP-U data packets. By default, standard port 2152 will be configured as GTP-U data packet source port (same as existing behavior).

non-standard

Configures GTP-U service to use multiple non-standard ports defined by system as a source port for GTP-U data packets. Starting port is 25500. Non-standard port number is unique per session manager instance.

standard

Configures GTP-U service to use standard port 2152 as source port for all GTP-U data packets.

Usage

Currently, for forwarding GTP-U data packets, standard UDP port (2152) as source and destination port are used for outgoing GTP-U packet. This creates hardship to balance traffic properly over the LAG interfaces between the different L2/L3 elements in the network. Some routers use source UDP port to do load balancing of packets towards destination. This command allows the source port outgoing GTP-U packet to be different for each SESSMGR. The destination port should remain as 2152, as per protocol.

Example

The following command configures GTP-U service to use standard port 2152 as source port for all GTP-U data packets.:
source-port standard
udp-checksum

Inserts UDP-checksum in the UDP header of GTP-U packet.

Product
GGSN
HNB-GW
P-GW
SGSN
S-GW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > GTP-U Service Configuration

configure > context context_name > gtpu-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-gtpu-service)#

Syntax
udp-checksum { no-optimize | optimize }
[ default | no ] udp-checksum

default
Through releases 14.0: Enables the UDP checksum, but no optimization is attempted. Releases 15.0 and later: Enables the UDP checksum, and attempts optimization of the UDP checksum in UDP header of GTPU packet using the inner payload transport checksum.

no
Outer UDP checksum is marked as 'ZERO,' effectively disabling UDP checksum. Applicable only for IPv4 data.

no-optimize
No optimization attempt over UDP checksum in UDP header of GTP-U packet.

optimize
Attempts optimization of UDP checksum in UDP header of GTP-U packet using inner payload transport checksum.

Usage
This command is used for enabling optimization of UDP checksum in UDP header of the GTP-U packet. An option to completely disable the UDP checksum of GTP-U packet is also introduced.

Example
The following command enables the optimization of UDP checksum in UDP header of the GTP-U packet:

\texttt{udp-checksum optimize}
Chapter 156
HA Proxy DNS Configuration Mode Commands

The HA Proxy DNS Configuration Mode is used to create rules for Home Agent (HA) proxy DNS intercept lists that redirect packets with unknown foreign DNS addresses to a home network DNS server.

**Important:** HA Proxy DNS Intercept is a license-enabled feature.

**Mode**

Exec > Global Configuration > Context Configuration > Proxy DNS Configuration

`configure > context context_name > proxy-dns intercept-list list_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-proxy-dns-intercept-list)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
description

Sets the descriptive text for the object.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
description text
no description
```

- **description**
  Specifies the descriptive text as an alphanumeric string of 1 to 79 characters. If you include spaces between words in the description, you must enclose the text within double quotation marks (" "), for example, “AAA BBBB”.

- **no**
  Clears the description for the object.

**Usage**
The description should provide useful information on the object’s primary function, services, endusers, etc.
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
pass-thru

Sets IP addresses that should be allowed through the proxy DNS intercept feature.

configure > context context_name > proxy-dns intercept-list list_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-proxy-dns-intercept-list)#

Syntax

[ no ] pass-thru ip_address [ /ip_mask ]

no

Removes the DNS IP address from the pass-thru rule.

pass-thru ip_address [ /ip_mask ]

Specifies an DNS IP address that is allowed through the intercept feature.

ip_address[/ip_mask]: Specifies the IP address and network mask bits. ip_address[/ip_mask] is specified using IPv4 dotted decimal or IPv6 colon-separated-hexadecimal notation. The mask bits are a numeric value which is the number of bits in the subnet mask (CIDR notation).

Usage

Use this command to identify DNS IP addresses that should be allowed through the intercept feature. For a more detailed explanation of the proxy DNS intercept feature, see the proxy-dns intercept-list command in the Context Configuration Mode Commands chapter. A maximum of 16 intercept rules (either redirect or pass-thru) are allow for each intercept list.

Important: To allow packets through that do not match either the pass-thru or redirect rules, set a pass-thru rule address as: 0.0.0.0/0. If a packet does not match either the pass-thru or redirect rule, the packet is dropped.

Example

The following command allows a foreign network’s DNS with an IP address of 10.2.55.12 to avoid being redirected:

pass-thru 10.2.55.12
**redirect**

Redirects DNS IP addresses from foreign networks matching an IP address in this command to a home network DNS.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Proxy DNS Configuration

```sh
configure > context context_name > proxy-dns intercept-list list_name
```

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-proxy-dns-intercept-list)#
```

**Syntax**

```
[ no ] redirect any [ primary-dns ip_address [ secondary-dns ip_address ] ]
```

- **no**
  Removes the DNS IP address from the redirect rule.

- **primary-dns ip_address**
  Specifies the IP address of the primary home network DNS.
  *ip_address* is specified using IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

- **secondary-dns ip_address**
  Specifies the IP address of the secondary home network DNS.
  *ip_address* is specified using IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

**Usage**

Use this command to identify DNS IP addresses from foreign networks that are to be redirected to the home DNS. For a more detailed explanation of the Proxy DNS feature, see the proxy-dns intercept-list command in the *Context Configuration Mode Commands* chapter. A maximum of 16 intercept rules (either redirect or `pass-thru`) are allowed for each intercept list.

Since this command is configured in the source context, the destination context containing the path to the home network DNS is identified using the Context Configuration Mode command `ip dns-proxy source-address`.

**Important:** If a packet does not match the `pass-thru` or `redirect` rule, the packet is dropped. If `primary-dns` or `secondary-dns` is not configured, DNS messages are redirected to the primary-dns-server (or the secondary-dns-server) configured for the subscriber OR inside the context.

**Example**

The following command identifies a foreign network DNS with an IP address of 10.2.55.12 and redirects it to a primary home network DNS with an IP address of 10.3.4.5:
predirect 10.2.55.12 primary-dns 10.3.4.5
Chapter 157
HA Service Configuration Mode Commands

The HA Service Configuration Mode is used to create and manage the Home Agent (HA) services within the current context.

Mode

Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
a11-signalling-packets

Applies Differentiated Services Code Point (DSCP) marking for IP headers carrying outgoing signalling packets.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

a11-signalling-packets ip-header-dscp ip-header-dscp{ default | no } a11-signalling-packets ip-header-dscp

no

Disables DSCP marking for IP header encapsulation for the HA service.

default

Configures DSCP marking for IP header encapsulation for a specific HA service.

ip-header-dscp

Is a hexadecimal number between 0x0 and 0x3F.

Usage

The following command is used to apply DSCP marking for IP header carrying outgoing signalling packets.

Example

The following command applies DSCP marking for IP header carrying outgoing signalling packets.

a11-signalling-packets ip-header-dscp 0x2f
aaa

Configures the sending of subscriber session AAA accounting by the HA service.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration
configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

aaa { accounting [ roaming ] | group string }

no aaa { accounting | group }

default aaa accounting

no

Disables AAA accounting for the HA service.

default

Configures AAA parameters for specific HA service

accounting

accounting Enables the sending of AAA accounting information for subscriber sessions by the Home Agent (HA), by default is enabled.
roaming Enables the sending of AAA accounting information for subscriber sessions by the Home Agent (HA) only for roaming subscribers.

group

group configures aaa group for ha-service, group has lower priority than subscriber/apn config.

string: size ranges between 1 and 63.

Usage

Enabling the HA service will send all accounting data (start, stop, and interim) to the configured AAA servers.
The chassis is shipped from the factory with the AAA accounting enabled.
**Important:** In order for this command to function properly, AAA accounting must be enabled for the context in which the HA service is configured using the `aaa accounting subscriber radius` command.

**Example**

The following command disables AAA accounting for the HA service:

```
no aaa accounting
```
**access-network**

Configures a specific access network configuration.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration
```
configure > context context_name > ha-service service_name
```
Entering the above command sequence results in the following prompt:
```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
access-network accounting identifier access_network_accounting_identifier
no
```

**no**
Disables a specific access network configuration.

**accounting**
Specifies an access network configuration for accounting

**identifier**
Specifies an access network accounting identifier

*access_network_accounting_identifier*
This is an alphanumeric string of 1 through 128 characters.

**Usage**
This command is used to configure an access network for accounting.

**Example**
The following command configures an access network for accounting with the identifier *idnt*:
```
access-network accounting identifier idnt
```
associate

Associates an HA-service with a QoS policy.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

associate qci-qos-mapping string

no associate qci-qos-mapping

no

Disables the association of an HA-service with a QoS policy.

qci-qos-mapping string
Maps a QoS Class Identifier (QCI) for this HA service.

string is an alphanumeric string of 1 through 63 characters.

Usage
This command associates an HA-service with a QoS policy.

Example
The following command associates an HA-service with a QCI map01.

associate qci-qos-mapping map01
authentication

Configures authentication parameters for a specific HA service within a context.

Product
HA
ASN-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

authentication { aaa-distributed-mip-keys [ disabled | optional | required ] | dmu-refresh-key | imsi-auth| mn-aaa { allow-noauth | always| dereg-noauth | noauth | renew-reg-noauth | renew-and-dereg-noauth } | mn-ha { allow-noauth | always } | pmip-auth | stale-key-disconnect }

no authentication { imsi-auth | pmip-auth }

default authentication { aaa-distributed-mip-keys | dmu-refresh-key | imsi-auth | mn-aaa | mn-ha | pmip-auth | stale-key-disconnect }

no
Disable the parameter.

default
Resets the specified option to its default setting.

aaa-distributed-mip-keys [ disabled | optional | required ]

Configures use of AAA distributed MIP keys for authenticating RRQ for WiMAX HA calls. Default is disabled.

disabled: Disables using AAA distributed WiMAX Mobile IP (MIP) keys for authenticating MIP RRQ.
optional: Uses AAA distributed WiMAX MIP keys for authenticating RRQ with fallback option to use static/3GPP2 based MIP keys.
required: AAA distributed WiMAX MIP keys for authenticating MIP RRQ are mandatory

dmu-refresh-key

Typically, when a Dynamic Mobile IP Update (DMU) resets, the next MIP re-registration causes MN-HA authorization failure and the HA rejects the MIP RRQ. This parameter enables the HA to retrieve the MN-HA key again from the AAA during the call and to use the freshly retrieved key value to recheck authentication. Default is disabled.
**imsi-auth**
Enable uses the International Subscriber Mobile identity (IMSI) to determine if MN-AAA or MN-FAC extensions are not present in the RRQ.
Default is disabled.

**mn-aaa**
Specifies how mobile node-to-AAA authentication extension in registration requests from the mobile node should be handled by the HA service.
Default is always.
- **allow-noauth**: Specifies that the HA service does not require authentication for every mobile node registration request. However, if the mn-aaa extension is received, the HA service will authenticate it.
- **always**: Specifies that the HA service will perform authentication each time a mobile node registers.
- **dereg-noauth**: Disables authentication request upon de-registration.
- **noauth**: Specifies that the HA service will not look for mn-aaa extension and will not authenticate it.
- **renew-reg-noauth**: Specifies that the HA service will not perform authentication for mobile node re-registrations. Initial registration and de-registration will be handled normally.
- **renew-and-dereg-noauth**: Disables authentication request upon re-registration and de-registration.

**mn-ha**
Specifies whether the HA service looks for an MN-HA authentication extension in the RRQ.
Default is always.
- **allow-noauth**: Allows a request that does not contain the auth extension.
- **always**: A request should always contain the auth extension to be accepted.

**pmip-auth**
Specifies whether the HA service looks for an MN-HA authentication extension in the RRQ.
Default is always.
- **allow-noauth**: Allows a request that does not contain the auth extension.
- **always**: A request should always contain the auth extension to be accepted.

**stale-key-disconnect**
If MN-HA auth fails for MIP renew and dereg, disconnects the call immediately.
Disabled by default.

**Usage**
The **authentication** command, combined with a keyword, can be used to specify how the system will perform authentication of registration request messages.

**Example**
The following command configures the HA service to always perform mobile node authentication for every registration request.

```
authentication mn-aaa always
```

The following command configures the HA service to always look for an MN-HA authentication extension in the RRQ.

```
authentication mn-ha always
```
bind

Binds the HA service to a logical IP interface serving as the Pi interface and specifies the maximum number of subscribers that can access this service over the interface.

**Product**

HA

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
bind address address|range_address ip_mask | range_address/bitmask [ max-subscribers count ]
```

```
no bind address
```

---

**address**

Specifies the IP address (address) of the interface configured as the Pi interface. *address* is specified in IPv4 dotted-decimal notation.

---

**range_address ip_mask | range_address/bitmask**

Specifies the pool of IP addresses (IPv4) of the interface configured as the Pi interface with an enterprise HA (EHA). *ip_mask* and *bit_mask* specify the number of subnet bits, representing the subnet mask in CIDR notation and must be a value between 1 to 32. *range_address* is a preconfigured range of IPv4 addresses in Loopback Interface Configuration Mode to enable the Enterprise HA support with enhanced capacity and configured

---

**max-subscribers count**

Default: 2500000

Specifies the maximum number of subscribers that can access this service on this interface. *count* can be configured to an integer from 0 through 4000000.

---

**Important:** The maximum number of subscribers supported is dependant on the license key installed and the number of active packet processing cards installed in the system.
**Usage**

Associate the HA service to a specific logical IP address. The logical IP address or interface takes on the characteristics of a Pi interface. Only one interface can be bound to a service. The interface should be configured prior to issuing this command.

This command also sets a limit as to the number of simultaneous subscribers sessions that can be facilitated by the service/interface at any given time.

When configuring the `max-subscribers` option, be sure to consider the following:

- The total number of interfaces that you will configuring for use as Pi interfaces
- The maximum number of subscriber sessions that all of these interfaces may handle during peak busy hours
- The average bandwidth for each of the sessions
- The type of physical port to which these interfaces will be bound

Taking these factors into account and distributing your subscriber session across all available interfaces will allow you to configure your interfaces to optimally handle sessions without degraded performance.

IP range support is provided through `ranged_address` value. This value enables the pool of IPv4 addresses to support Enterprise HA on HA service to connect enhanced number of enterprise nodes. Refer *HA Administration Guide* for more information.

Use the `no bind address` command to delete a previously configured binding.

**Example**

The following command would bind the logical IP interface with the address of 192.168.3.1 to the HA service and specifies that a maximum of 600 simultaneous subscriber sessions can be facilitated by the interface/service at any given time:

```
bind address 192.168.3.1 max-subscribers 600
```

The following command disables a binding that was previously configured:

```
no bind address
```

The following command binds the range of IP addresses with HA service to be used with Enterprise HA support:

```
bind address 10.2.3.0/24
```
description

Sets the descriptive text for the object.

Product
All

Privilege
Security Administrator, Administrator

Syntax

description text

no description

no

Clears the description for the object.

text

Specifies the descriptive text as an alphanumeric string of 1 to 79 characters.
If you include spaces between words in the description, you must enclose the text within double quotation marks (" "), for example, “AAA BBBB”.

Usage

The description should provide useful information on the object’s primary function, services, endusers, etc.
encapsulation

Configures Mobile IP (MIP) encapsulation types supported for a specific HA service.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

Syntax

```
[ no ] encapsulation allow { gre | keyless-gre }
```

no

Disables MIP encapsulation types supported for specific HA service

allow

Allows encapsulation type for MIP data.

```
  gre
  Default: Enabled.
  Specifies the use of Generic Routing Encapsulation (GRE) for MIP data.

  keyless-gre
  Default: Disabled.
  Specifies the use of GRE without exchanging keys for MIP data.
```

Usage

Use to disable or re-enable the use of GRE encapsulation or Key-less encapsulation for MIP sessions. In case of chassis HA operating with other vendor equipment, which does not support the 3GPP2 to exchange key, this command with keyless-gre keyword will make the chassis HA to accept MIP data with legacy GRE.

Example

To disable GRE for MIP sessions, enter the following command:

```
no encapsulation allow gre
```

To re-enable GRE for MIP sessions, enter the following command:

```
encapsulation allow gre
```
To enable key-less GRE for MIP sessions, enter the following command:

```
encapsulation allow keyless-gre
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

exit

Usage
Use this command to return to the parent configuration mode.
fa-ha-spi

Configures the security parameter index (SPI) for specific HA service parameters.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)>
```

**Syntax**

```
fa-ha-spi remote-address { fa_ip_address | fa_ip_address_mask } spi-number number {
encrypted secret enc_secret | secret secret } [ allow-fa-ha-auth-extension ] [ 
description string ] [ disallow-fa-ha-auth-extension ] [ hash-algorithm { hmac-md5 | md5 |
rfc2002-md5 } ] [ replay-protection { nonce | timestamp [ timestamp-tolerance tolerance ] } ] [ timestamp-tolerance tolerance ]

no fa-ha-spi remote-address { fa_ip_address | fa_ip_address_mask } spi-number number
```

Disables the security parameter index (SPI) for specific HA service parameters.

```
remote-address { fa_ip_address | fa_ip_address_mask }
```

Specifies the IP address of the FA. `fa_ip_address` is entered using IPv4 dotted-decimal notation with CIDR for the subnet mask.

**Important:** The system supports unlimited peer FA addresses per HA but only maintains statistics for a maximum of 8,192 peer FAs. If more than 8,192 FAs are attached, older statistics are overwritten.

```
spi-number number
```

Specifies the SPI (number) which indicates a security context between the FA and the HA in accordance with RFC 2002.

`number` is an integer value from 256 through 4294967295.

```
encrypted secret enc_secret | secret secret
```

Configures the shared-secret between the HA service and the FA. The secret can be either encrypted or non-encrypted.

`encrypted secret enc_secret`: Specifies the encrypted shared key between the HA service and the FA.

`enc_secret` must be an alphanumeric string of 1 through 236 characters that is case sensitive.
**secret** *secret*: Specifies the shared key between the HA service and the FA. *secret* must be an alphanumeric string of 1 through 236 characters that is case sensitive.

**allow-fa-ha-auth-extension**
Allows validation of FA HA Authentication extension.

**description** *string*
This is a description for the SPI. *string* must be an alphanumeric string of 0 through 31 characters.

**hash-algorithm** { hmac-md5 | md5 | rfc2002-md5 }  
Default: hmac-md5  
Specifies the hash-algorithm used between the HA service and the FA.  
**hmac-md5**: Configures the hash-algorithm to implement HMAC-MD5 per RFC 2002bis.  
**md5**: Configures the hash-algorithm to implement MD5 per RFC 1321.  
**rfc2002-md5**: Configures the hash-algorithm to implement keyed-MD5 per RFC 2002.

**replay-protection** { timestamp [ timestamp-tolerance tolerance ] | nonce }  
Specifies the replay-protection scheme that should be implemented by the FA service for this SPI.  
**nonce**: Configures replay protection to be implemented using NONCE per RFC 2002.  
**timestamp**: Configures replay protection to be implemented using timestamps per RFC 2002.  
**timestamp-tolerance**: Specifies the allowable difference (tolerance) in timestamps that is acceptable. If the difference is exceeded, then the session will be rejected. *tolerance* is measured in seconds and can be configured to an integer from 1 and 65535. The default is 60.

**Usage**
An SPI is a security mechanism configured and shared by the HA service and the FA. Please refer to RFC 2002 for additional information.

Though it is possible for FAs and HAs to communicate without SPIs being configured, the use of them is recommended for security purposes. It is also recommended that a "default" SPI with a remote address of 0.0.0.0/0 be configured on both the HA and FA to prevent hackers from spoofing addresses.

**Important**: The SPI configuration on the HA must match the SPI configuration for the FA service on the system in order for the two devices to communicate properly.

A maximum of 2,048 SPIs can be configured per HA service.  
Use the no version of this command to delete a previously configured SPI.

**Example**

The following command configures the FA service to use an SPI of 512 when communicating with an HA with the IP address 192.168.0.2. The key that would be shared between the HA and the FA service is q397F65. When communicating with this HA, the FA service will also be configured to use the rfc2002-md5 hash-algorithm.

```
fa-ha-spi remote-address 192.168.0.2 spi-number 512 secret q397F65 hash-algorithm rfc2002-md5
```

The following command deletes the configured SPI of 400 for an HA with an IP address of 172.100.3.200:

```
no fa-ha-spi remote-address 172.100.3.200 spi-number 400
```
gre

Configures Generic Routing Encapsulation (GRE) parameters.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
gre { checksum | checksum-verify | reorder-timeout timeout | sequence-mode { none | reorder } | sequence-numbers }
```

```
default gre { checksum | checksum-verify | reorder-timeout | sequence-mode | sequence-numbers }no gre { checksum | checksum-verify | sequence-numbers }
```

**no**

Disables the specified functionality.

**default**

Sets or restores default value assigned for specified parameter.

---

**checksum**

Default: disabled
Enables the introduction of the checksum field in outgoing GRE packets.

**checksum-verify**

Default: disabled
Enables verification of the GRE checksum (if present) in incoming GRE packets.

**reorder-timeout timeout**

Default: 100
Configures the maximum number of milliseconds to wait before processing reordered out-of-sequence GRE packets. `timeout` must be an integer from 0 through 5000.

**sequence-mode { none | reorder }**

Default: none
Configures how incoming out-of-sequence GRE packets should be handled.

- **none**: Disables reordering of incoming out-of-sequence GRE packets.
- **reorder**: Enables reordering of incoming out-of-sequence GRE packets.
sequence-numbers
Default: Disabled
Enables the insertion of sequence numbers into the GRE packets.

Usage
Use this command to configure how the HA service handles GRE packets.

Example
To set the maximum number of milliseconds to wait before processing reordered out-of-sequence GRE packets to 500 milliseconds, enter the following command:

  gre reorder-timeout 500

To enable the reordering of incoming out of sequence GRE packets, enter the following command:

  gre sequence-mode reorder

To enable the insertion or removal of GRE sequence numbers in GRE packets, enter the following command:

  gre sequence-numbers
idle-timeout-mode

Configures the sessions idle-timer reset behavior.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration
configure > context context_name > ha-service service_name
Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax
idle-timeout-mode { aggressive | handoff | normal } [ upstream-only ]
default idle-timeout-mode
default
Resets the idle timeout mode to the default settings.

aggressive
Resets the session idle timer only when MIP user data is detected. This is the default behavior.

handoff
Resets the session idle timer when MIP user data is detected and an inter-Access Gateway/FA handoff occurs.

normal
Resets the session idle timer when MIP user data is detected and any MIP control signaling occurs.

upstream-only
Only upstream user data (data from the mobile node) resets the idle timer for the session. This is disabled by default.

Usage
Use this command to set how the current HA service resets the idle timer for a session.

Example
To reset the idle timer whenever user data is detected or whenever an inter-Access Gateway/FA occurs, use the following command:
idle-timeout-mode handoff
ikev1

Configures IPSec Internet Key Exchange (IKE) parameters.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service) #
```

**Syntax**

```
ikev1 { aaa-context aaa_context_string | peer-fa IPAddress crypto-map crypto_map_string
[ encrypted ] [ secret secret_string ] | skew-lifetime seconds }no ikev1 { aaa-context | peer-fa IPAddress | skew-lifetime }
```

**no**

Disables IPSec IKE parameters.

**aaa-context aaa_context_string**
Configures AAA context from which to retrieve IKE keys. Must be followed by the context name.

`aaa_context_string` is an alphanumeric string of 1 through 63 characters.

**peer-fa IPAddress**
Sets the IKE crypto-map for a peer Foreign Agent (FA).

`IPAddress` is IP address entered using IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

**crypto-map crypto_map_string**
Configures IKE crypto-map. Must be followed by the crypto-map name.

`crypto_map_string` is an alphanumeric string of 1 through 63 characters.

**encrypted** designates use of encryption

**secret secret_string** uses a secret that is shared between FA and HA. `secret_string` is an alphanumeric string of 1 through 256 characters.

**skew-lifetime seconds**
Configures the “S” lifetime Skew (in seconds). `seconds` is an integer from 1 through 65534. Default is 10.

**Usage**

Use this command to configure IPSec IKE parameters.

**Example**

Use this command to configure IPSec IKE parameters.
ikev1 peer-fa 11.22.33.44 crypto-map er encrypted secret ert
**ip context-name**

Specifies name of the destination context to be applied to the subscribers.

This configuration overrides the local subscriber configuration as well as the return attributes sent by RADIUS. All calls coming to this HA service are assigned this destination context; the IP address is allocated from the specified IP pool or group that is configured in the context specified in the service.

**Product**

HA

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HA Service Configuration

```bash
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```bash
ip context-name name
{ default | no } ip context-name
```

- `name`
  
  Specifies the name of the context to assign the subscriber to once authenticated. `name` must be an alphanumeric string from 1 through 79 characters.

- `no`
  
  Removes the current assigned context from the subscriber’s data. Set the name of the destination context to be applied to the subscribers.

**Usage**

- Removes the current assigned context from the subscriber’s data. Set the name of the destination context to be applied to the subscribers.

**Example**

```bash
ip context-name sampleName
no ip context-name
```
ip local-port

Configures the local User Datagram Protocol (UDP) port for the Pi interface’s IP socket on which to listen for Mobile IP Registration messages.

**Product**

HA

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
ip local-port number
```

```
default ip local-port
```

**Default**

Sets or restores the default value assigned for the IP local port.

```
number
```

Specifies the UDP port number.

`number` is an integer from 1 through 65535. Default is 434.

**Usage**

Specify the UDP port that should be used for communications between the FA service and the HA.

**Example**

The following command specifies a UDP port of 3950 for the HA service to use to communicate with the HA on the Pi interface:

```
ip local-port 3950
```
ip pool

Specifies name of the IP address pool or group to use for subscriber IP address allocation.
This configuration overrides the local subscriber configuration, as well as the return attributes sent by RADIUS. All
calls coming to this HA service are assigned this destination context and an IP address is allocated from the specified IP
pool or group that is configured in the context specified in the service.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

ip pool name

{ default | no } ip pool

name

Specifies the logical name of the IP address pool. name must be an alphanumeric string of 1 through 31
caracters.

no

Removes the specified IP address pool specified from the current context or disables the option for an IP
pool.

default

Clears the IP address pool or group setting.

Usage

Define a pool of IP addresses for the context to use in assigning IPs for this service.

Example

The specifies name of the IP address pool or group to use for subscriber IP address allocation:

    ip pool pool1

The following command removes the specified IP address pool:

    no ip pool pool1
min-reg-lifetime

Configures Mobile IP session minimum registration lifetime, in seconds.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

[ no | default ] min-reg-lifetime min_reg_lifetime_seconds

no

Disables the min registered lifetime.

default

Configures Mobile IP session minimum registration lifetime to default which is 0.

min-reg-lifetime

Configures Mobile IP session minimum registration lifetime.

min_reg_lifetime_seconds

Variable in the range between 1 and 65534.

Usage

Use this command to configure Mobile IP session minimum registration lifetime, in seconds, between 1 and 65534. Default is 0 seconds.

Example

Use the following command to configure mobile IP session to minimum registered lifetime to 100 seconds:

min-reg-lifetime 100
**mn-ha-spi**

Configures the security parameter index (SPI) between the HA service and the mobile node (MN).

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

`configure > context context_name > ha-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
mn-ha-spi spi-number number [ description string ] [ encrypted secret enc_secret ] [ hash-algorithm { hmac-md5 | md5 | rfc2002-md5 } ] [ permit-any-hash-algorithm ] [ replay-protection { nonce | timestamp } ] [ secret secret ] [ timestamp-tolerance tolerance ]
```

```
nomn-ha-spi spi-number number
```

---

**spi-number number**

Specifies the SPI (number) which indicates a security context between the mobile node and the HA service in accordance with RFC 2002. `number` can be configured to an integer from 256 through 4294967295.

---

**description string**

This is a description for the SPI. `string` is an alphanumeric string of 1 through 31 characters.

---

**encrypted secret enc_secret | secret secret**

Configures the shared-secret between the HA service and the mobile node. The secret can be either encrypted or non-encrypted.

- **encrypted secret enc_secret**: Specifies the encrypted shared key between the HA service and the mobile node. `enc_secret` must be an alphanumeric string of 1 through 254 characters that is case sensitive.
- **secret secret**: Specifies the shared key between the HA service and the mobile node. `secret` must be an alphanumeric string of 1 through 127 characters that is case sensitive.

The `encrypted` keyword is intended only for use by the chassis while saving configuration scripts. The system displays the `encrypted` keyword in the configuration file as a flag that the variable following the `secret` keyword is the encrypted version of the plain text secret key. Only the encrypted secret key is saved as part of the configuration file.

---

**hash-algorithm { hmac-md5 | md5 | rfc2002-md5 }**

Default: hmac-md5

Specifies the hash-algorithm used between the HA service and the mobile node.

- **hmac-md5**: Configures the hash-algorithm to implement HMAC-MD5 per RFC 2002bis.
- **md5**: Configures the hash-algorithm to implement MD5 per RFC 1321.
- **rfc2002-md5**: Configures the hash-algorithm to implement keyed-MD5 per RFC 2002.
**permit-any-hash-algorithm**

Default: disabled
Allows verification of the MN-HA authenticator using all other hash-algorithms after failure with configured hash-algorithm. The successful algorithm is logged to aid in troubleshooting and used to create the MN-HA authenticator in the Registration Reply message.

**replay-protection { nonce | timestamp }**

Default: timestamp
Specifies the replay-protection scheme that should be implemented by the HA service for this SPI.
- **nonce**: configures replay protection to be implemented using NONCE per RFC 2002.
- **timestamp**: configures replay protection to be implemented using timestamps per RFC 2002.

**timestamp-tolerance tolerance**

Default: 60
Specifies the allowable difference (tolerance) in timestamps that is acceptable. If the difference is exceeded, then the session will be rejected. If this is set to 0, timestamp tolerance checking is disabled at the receiving end.
Tolerance is measured in seconds and can be configured to an integer from 0 through 65535.

**Usage**

An SPI is a security mechanism configured and shared by the HA service and the mobile node. Please refer to RFC 2002 for additional information.
Use the **no** version of this command to delete a previously configured SPI.

**Example**

The following command configures the HA service to use an SPI of 640 when communicating with a mobile node. The key that would be shared between the mobile node and the HA service is q397F65.

```
  mn-ha-spi spi-number 640 secret q397F65
```

The following command deletes the configured SPI of 400:

```
  no mn-ha-spi spi-number 400
```
nat-traversal

This command enables NAT traversal and also configures the forcing of UDP tunnels for NAT traversal.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

`configure > context context_name > ha-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
[ default | no ] nat-traversal [ force-accept ]
```

- **no**
  Disables NAT traversal or disables forcing the acceptance of UDP tunnels for NAT traversal.

- **default**
  Reset the defaults for this command.
  Default: NAT traversal disabled, force-accept disabled.

- **force-accept**
  This keyword configures the HA to accept requests when NAT is not detected but the Force (F) bit is set in the RRQ with the UDP Tunnel Request. By default this type of request is rejected if NAT is not detected.

**Usage**

Use this command to enable NAT traversal and enable the forcing of UDP tunnels for NAT traversal.

**Example**

The following command enables NAT traversal for the current HA service and forces the HA to accept UDP tunnels for NAT traversal:

```
nat-traversal force-accept
```
**optimize tunnel-reassembly**

Designates that tunnel reassembly optimization will be used for fragmented large packets passed between HA and FA. Default is disabled.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```bash
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```bash
[context_name] host_name(config-ha-service)#
```

**Syntax**

```
[ default | no ] optimize tunnel-reassembly
```

**Usage**

Enabling this functionality fragments large packets prior to encapsulation for easier processing. Tunnel reassembly optimization is disabled by default.

**Important:** You should not use this command without first consulting Cisco Systems Technical Support. This command applies to very specific scenarios where packet reassembly is not supported at the far end of the tunnel. There are cases where the destination network may either discard the data, or be unable to reassemble the packets.

**Important:** This functionality works best when the HA service is communicating with an FA service running in a system. However, an HA service running in the system communicating with an FA from a different manufacturer will operate correctly even if this parameter is enabled.

**Example**

Use the `no` version of this command to disable tunnel optimization if enabled.

The following command enables tunnel reassembly optimization:

```
optimize tunnel-reassembly
```
per-domain statistics-collection

Enables per-domain statistics collection.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
[ no ] per-domain statistics-collection
```

**Usage**

Use this command to enable per-domain statistics collection.

**Example**

The following command enables per-domain statistics collection.

```
per-domain statistics-collection
```
policy bc-query-result

Configure the binding cache (BC) query Response Result code.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration
configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

policy bc-query-result network-failure code

default policy bc-query-result network-failure

network-failure code
Default: 0xFFFF
Specify the response code for BC responses sent on network failures.
code must be either 0xFFFF or 0xFFFE.

Usage
Use this command to specify the type of response code to send in a P-MIP BC query result.

Example
The following command sets the P-MIP BC query result response code to 0xFFFE:

    policy bc-query-result network-failure 0xFFFE
policy nw-reachability-fail

Specifies the action to take upon detection of an up-stream network-reachability failure.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration
configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:
context_name host_name(config-ha-service)#

Syntax

policy nw-reachability-fail { redirect ip_addr1 [ weight value ] [ ip_addr2 [ weight value ] ... ip_addr16 [ weight value ] ] | reject [ use-reject-code { admin-prohibited | insufficient-resources } ] }

no policy nw-reachability-fail [ redirect ip_addr1 ... ip_addr16 ]

no

Deletes the network reachability policy completely or deletes the specified redirect addresses from the policy.

reject [ use-reject-code { admin-prohibited | insufficient-resources } ]

upon network reachability failure, reject all new calls for this context.

use-reject-code { admin-prohibited | insufficient-resources }: When rejecting calls send the specified reject code. If this keyword is not specified the admin-prohibited reject code is sent by default.

reject [ use-reject-code { admin-prohibited | insufficient-resources } ]

upon network reachability failure reject all new calls for this context. If no reject code is specified, the HA sends a registration reply code of 81H (admin-prohibited).

use-reject-code { admin-prohibited | insufficient-resources }: Use the specified reject code when rejecting traffic.

admin-prohibited: When this keyword is specified and traffic is rejected, the error code 81H (admin-prohibited) is returned.

insufficient-resources: When this keyword is specified and traffic is rejected, the error code 82H (insufficient resources) is returned.

redirect ip_addr1 [ weight value ] [ ip_addr2 [ weight value ] ... ip_addr16 [ weight value ] ]

upon network reachability failure redirect all calls to the specified IP address.

ip_addr1: This must entered using IPv4 dotted-decimal notation. Up to 16 IP addresses and optional weight values can be entered on one command line.
**weight value:** When multiple addresses are specified, they are selected in a weighted round-robin scheme. If a weight is not specified the entry is automatically assigned a weight of 1. value must be an integer from 1 through 10.

**Usage**

Use this command to set the action for the HA service to take upon a network reachability failure.

**Important:** Refer to the Context Configuration mode command `nw-reachability server` to configure network reachability servers.

**Important:** Refer to the Subscriber Configuration mode command `nw-reachability-server` to bind the network reachability to a specific subscriber.

**Important:** Refer to the `nw-reachability server server_name` keyword of the Context Configuration mode `ip pool` command to bind the network reachability server to an IP pool.

**Example**

To set the HA service to reject all new calls on a network reachability failure, enter the following command:

```
policy nw-reachability-fail reject
```

Use the following command to set the HA service to redirect all calls to the HA at IP address 192.168.100.10 and 192.168.200.10 on a network reachability failure:

```
policy nw-reachability-fail redirect 192.168.100.10 192.168.200.10
```
policy overload

Configures the overload policy within the HA service.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
policyoverload { redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ] | reject [ use-reject-code { admin-prohibited | insufficient-resources } ] }

no policyoverload [ redirect address [ address2...address16 ] ]
```

- **no policy overload [ redirect address [ address2...address16 ] ]**
  Deletes a previously set policy or removes a redirect IP address.
  - **overload**: Without any options deletes the complete overload policy from the PDSN service.
  - **overload redirect address [ address2 ... address16 ]**: deletes up to 16 IP addresses from the overload redirect policy. The IP addresses must be expressed in IP v4 dotted-decimal notation.

```
redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ]
```

This option enables a redirect policy for overloading conditions. When a redirect policy is invoked, the HA service rejects new sessions with a Registration Reply Code of 136H (unknown home agent address) and provides the IP address of an alternate HA. This command can be issued multiple times.
  - **address**: The IP address of an alternate HA expressed in IP v4 dotted-decimal notation. Up to 16 IP addresses can be specified either in one command or by issuing the redirect command multiple times. If you try to add more than 16 IP addresses to the redirect policy, the CLI issues an error message. If you specify an IP address and weight that already exists in the redirect policy the new values override the existing values.
  - **weight weight_num**: When multiple addresses are specified, they are selected in a weighted round-robin scheme. Entries with higher weights are more likely to be chosen. If a weight is not specified the entry is automatically assigned a weight of 1. *weight_num* must be an integer from 1 through 10.

```
reject [ use-reject-code { admin-prohibited | insufficient-resources } ]
```

This option causes any overload traffic to be rejected. If no reject code is specified, the HA sends a registration reply code of 81H (admin-prohibited).
  - **use-reject-code { admin-prohibited | insufficient-resources }**: Use the specified reject code when rejecting traffic.
admin-prohibited: When this keyword is specified and traffic is rejected, the error code 81H (admin-prohibited) is returned.
insufficient-resources: When this keyword is specified and traffic is rejected, the error code 82H (insufficient resources) is returned.

Usage
The system invokes the overload policy if the number of calls currently being processed exceeds the licensed limit for the maximum number of sessions supported by the system.
The system automatically invokes the overload policy when an on-line software upgrade is started.
Use the no version of this command to restore the default policy.
The setting for overload policy is reject.

Example
The following command enables an overload redirect policy for the HA service that will send overload calls to either of two destinations with weights of 1 and 10 respectively:

```
policy overload redirect 192.168.100.10 weight 1 192.168.100.20 weight 10
```
**reg-lifetime**

Configures Mobile IP session registration lifetime.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
reg-lifetime time

{ default | no } reg-lifetime
```

- **no**
  
  Sets the registration lifetime to infinite.
  
- **default**
  
  Sets the registration lifetime to default value, 600.
  
- **time**
  
  Specifies the registration lifetime in seconds.
  
  `time` is an integer from 1 through 65534.

**Usage**

Use this command to limit a mobile node's lifetime. If the mobile node requests a shorter lifetime than what is specified, it is granted. However, Per RFC 2002, should a mobile node request a lifetime that is longer than the maximum allowed by this parameter, the HA service will respond with the value configured by this command as part of the Registration Reply. The default is 600 seconds.

**Example**

The following command configures the registration lifetime for the HA service to be 2400 seconds:

```
reg-lifetime 2400
```

The following command configures an infinite registration lifetime for MIP calls:

```
no reg-lifetime
```
reverse-tunnel

Enables use of reverse tunneling for Mobile IP session. Use no reverse-tunnel command to disable. If disabled, mobile node (MN) packets are not tunneled to the HA in the reverse direction.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration
configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

reverse-tunnel

{ default | no } reverse-tunnel

no
Indicates the reverse tunnel option is to be disabled. When omitted, the reverse tunnel option is enabled.

default
Indicates the reverse tunnel option is to be set to the default. When omitted, the reverse tunnel option is enabled.

Usage

Reverse tunneling involves tunneling datagrams originated by the mobile node to the HA service via the FA. When an MN arrives at a foreign network, it listens for agent advertisements and selects an FA that supports reverse tunnels. The MN requests this service when it registers through the selected FA. At this time, the MN may also specify a delivery technique such as Direct or the Encapsulating Delivery Style. Among the advantages of using reverse-tunneling are that:

• All datagrams from the mobile node seem to originate from its home network
• The FA can keep track of the HA to which the mobile node is registered and tunnel all datagrams from the mobile node to its HA

Use the no version of this command to disable reverse tunneling. If reverse tunneling is disabled, and the mobile node does not request it, triangular routing will be performed. Routing will be used.

The default setting is reverse tunnel enabled.

Important: If reverse tunneling is disabled on the system and a mobile node requests it, the call will be rejected with a reply code of 74H (reverse-tunneling unavailable).
Example

The following command disables reverse-tunneling support for the HA service:

```
no reverse-tunnel
```
revocation

Configures the Registration Revocation feature for a specific HA service.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

revocation { enable | max-retransmission number | negotiate-i-bit | retransmission-timeout secs | send-nai-ext | trigger { handoff | idle-timeout } }

no revocation { enable | negotiate-i-bit | send-nai-ext | trigger { handoff | idle-timeout } }

default revocation [ enable ] [ max-retransmission ] [ negotiate-i-bit ] [ retransmission-timeout ] [ send-nai-ext ] [ trigger { handoff | idle-timeout } ]

no

Completely disables registration revocation on the HA, disables trigger handoff, or disables revocation on idle timer expiration.

default

Sets or restores the default value assigned for specified parameter.

enable

Enables the MIP registration revocation feature on the HA. When enabled, if revocation is negotiated with an FA and a MIP binding is terminated, the HA can send a Revocation message to the FA. This feature is disabled by default.

max-retransmission number

Default: 3
The maximum number of retransmissions of a Revocation message before the revocation fails. number must be an integer from 0 through 10.

negotiate-i-bit

Default: disabled
Enables the HA to negotiate the i-bit via PRQ/RRP messages and processes the i-bit revocation messages.
retransmission-timeout \textit{secs}

Default: 3
The number of seconds to wait for a Revocation Acknowledgement from the FA before retransmitting the
Revocation message. \textit{secs} must be an integer from 1 through 10.

\texttt{send-nai-ext}

Default: off
Enables sending the NAI extension in the revocation message.

\texttt{trigger \{ handoff | idle-timeout \}}

\texttt{handoff}: Default: Enabled
Triggers the HA to send a Revocation message to the FA when an inter-Access Gateway/FA handoff of the
MIP session occurs. If this is disabled, the HA is never triggered to send a Revocation message.
\texttt{idle-timeout}: Default: Enabled
Triggers the HA to send a Revocation message to the FA when a session idle timer expires.

\textbf{Usage}

Use this command to enable or disable the MIP revocation feature on the HA or to change settings for this
feature. Both the HA and the FA must have Registration Revocation enabled and FA/HA authorization must
be in use for Registration Revocation to be negotiated successfully.

\textbf{Example}

The following command enables Registration Revocation on the HA:

\begin{verbatim}
revocation enable
\end{verbatim}

The following command sets the maximum number of retries for a Revocation message to 10:

\begin{verbatim}
revocation max-retransmission 10
\end{verbatim}

The following command sets the timeout between retransmissions to 3:

\begin{verbatim}
revocation retransmission-timeout 3
\end{verbatim}

The behavior of send MIP revocation to FA is as follows:

\begin{itemize}
  \item 1st retry: Retransmit in 3 seconds after previous MIP revocation send.
  \item 2nd retry: Retransmit in 6 seconds after previous MIP revocation send (9 seconds after sending initial
  MIP revocation).
  \item 3rd retry: Retransmit in 12 seconds after previous MIP revocation send (21 seconds after sending initial
  MIP revocation).
  \item 4th retry: Retransmit in 24 seconds after previous MIP revocation send (45 seconds after sending initial
  MIP revocation).
  \item 5th retry: Retransmit in 48 seconds after previous MIP revocation send (93 seconds after sending initial
  MIP revocation).
\end{itemize}

\textbf{Important}: The value of retransmission-timeout doubles. HA disconnects the session forcibly in 120 seconds
after sending initial MIP revocation.
**setup-timeout**

The maximum time allowed for session setup in seconds. Default is 60 seconds.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration
configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
setup-timeout seconds

default setup-timeout
```

**Usage**
Use this command to set the maximum amount of time allowed for setting up a session.

**Example**
To set the maximum time allowed for setting up a session to 5 minutes (300 seconds), enter the following command:

```
setup-timeout 300
```
**simul-bindings**

Specifies the maximum number of “care-of” addresses that can simultaneously be bound for the same user as identified by NAI and Home address.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration
configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
simul-bindings number
default simul-bindings
```

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>default</strong></td>
<td>Sets or restores the default value.</td>
</tr>
<tr>
<td><strong>number</strong></td>
<td>Configures the maximum number of simultaneous “care-of” bindings that the HA service will maintain for any given subscriber. is an integer from 1 through 3.</td>
</tr>
</tbody>
</table>

**Usage**
Per RFC 2002, the HA service creates a mobile binding record (MBR) for each subscriber session it is facilitating. Each MBR is associated with a care-of address. As the mobile node roams, it is possible that the session will be associated with a new care of address. Typically, the HA service will delete an old binding and create a new one when the information in the Registration Request changes. However, the mobile could request that the HA maintain previously stored MBRs. This command allows you to configure the maximum number of MBRs that can be stored per subscriber if the requested. The default value is 3.

**Example**
The following command configures the HA service to support up to 4 MBRs per subscriber:

```
simul-bindings 4
```
threshold dereg-reply-error

Sets an alarm or alert based on the number of de-registration reply errors per HA service.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

threshold dereg-reply-error high_thresh [ clear low_thresh ]

no threshold dereg-reply-error

no

Deletes the alert or alarm.

high_thresh

Default: 0
Specifies the high threshold number of de-registration reply errors that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to an integer from 0 through 100000.

clear low_thresh

Default: 0
The low threshold number of de-registration reply errors that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to an integer from 0 through 100000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of de-registration reply errors is equal to or greater than a specified number of calls per second.

Alerts or alarms are triggered for the number of de-registration reply errors on the following rules:

• Enter condition: Actual number of de-registration reply errors > High Threshold

• Clear condition: Actual number of de-registration reply errors < Low Threshold

Example
The following command configures a de-registration reply error threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```
threshold reg-reply-error 1000 clear 500
```
threshold init-rrq-rcvd-rate

Sets an alarm or alert based on the average number of calls setup per second for the context.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
threshold init-rrq-rcvd-rate high_thresh [ clear low_thresh ]

no threshold init-rrq-rcvd-rate
```

**Usage**

Use this command to set an alert or an alarm when the average number of calls setup per second is equal to or greater than a specified number of calls per second.

Alerts or alarms are triggered for the number of calls setup per second based on the following rules:

- **Enter condition:** Actual number of calls setup per second is greater than the high threshold.
- **Clear condition:** Actual number of calls setup per second is less than the low threshold.

**Example**

```
threshold init-rrq-rcvd-rate 100 [ clear 90 ]
```

---

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.
The following command configures a number of calls setup per second threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```plaintext
threshold init-rrq-rcvd-rate 1000 clear 500
```
threshold ipsec-call-req-rej

Configures a threshold for the total IPSec calls request rejected.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration
configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

threshold ipsec-call-req-rej high_thresh [ clear low_thresh ]

no threshold ipsec-call-req-rej

no

Deletes the alert or alarm.

high_thres

Default: 0
Specifies the high threshold number of IPSec call requests rejected per second that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thres is an integer from 0 through 1000000.

clear low_thres

Default: 0
Specifies the low threshold number of IPSec call requests rejected per second that must be met or exceeded within the polling interval to clear an alert or alarm.

low_thres is an integer from 0 through 1000000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of IPSec call requests rejected is equal to or greater than a specified number per second.
Alerts or alarms are triggered for the number of IPSec IKE requests on the following rules:
• Enter condition: Actual number of IPSec IKE requests is greater than the high threshold.
• Clear condition: Actual number of IPSec IKE requests is less than the low threshold.
Example

The following command configures a number of IPSec call requests rejected threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-call-rej 1000 clear 800
```
threshold ipsec-ike-failrate

Configures a threshold for the percentage of IPSec IKE failures.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration
configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

threshold ipsec-ike-failrate high_thresh [ clear low_thresh ]

no threshold ipsec-ike-failrate

no
Deletes the alert or alarm.

high_thresh
Default: 0
Specifies the high threshold percentage of IPSec IKE failures per second that must be met or exceeded within the polling interval to generate an alert or alarm. 
high_thresh is an integer from 0 through 100.

clear low_thresh
Default: 0
Specifies the low threshold percentage of IPSec IKE failures per second that must be met or exceeded within the polling interval to clear an alert or alarm.
low_thresh is an integer from 0 through 100.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
Use this command to set an alert or an alarm when the percentage of IPSec IKE failures is equal to or greater than a specified number per second.
Alerts or alarms are triggered for the percentage of IPSec IKE failures on the following rules:

- Enter condition: Percentage of IPSec IKE failures is greater than the high threshold.
- Clear condition: Percentage of IPSec IKE failures is less than the low threshold.
Example

The following command configures a percentage of IPSec IKE failures threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-ike-failrate 90 clear 80
```
threshold ipsec-ike-failures

Configures a threshold for the total IPSec IKE failures.

```

**Syntax**

```
threshold ipsec-tunnels-established high_thresh [ clear low_thresh ]
```

```
no threshold ipsec-tunnels-established
```

- **no**
  Deletes the alert or alarm.

  - **high_thresh**
    Default: 0
    Specifies the high threshold number of IPSec tunnels established per second that must be met or exceeded within the polling interval to generate an alert or alarm.
    `high_thresh` is an integer from 0 through 1000000.

  - **clear low_thresh**
    Default:0
    Specifies the low threshold number of call IPSec tunnels established per second that must be met or exceeded within the polling interval to clear an alert or alarm.
    `low_thresh` is an integer from 0 through 1000000.

  - **Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to set an alert or an alarm when the number of IPSec tunnels established is equal to or greater than a specified number per second.

Alerts or alarms are triggered for the number of IPSec tunnels established on the following rules:

- **Enter condition:** Actual number of IPSec tunnels established is greater than the high threshold.
- **Clear condition:** Actual number of IPSec tunnels established is less than the low threshold.
Example

The following command configures a number of IPSec tunnels established threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-tunnels-established 1000 clear 800
```
threshold ipsec-tunnels-setup

Configures a threshold for the total IPSec tunnels setup.

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

threshold ipsec-tunnels-setup high_thresh [ clear low_thresh ]

no threshold ipsec-tunnels-setup

no
Deletes the alert or alarm.

high_thresh
Default: 0
Specifies the high threshold number of IPSec tunnels setup per second that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh is an integer from 0 through 1000000.

clear low_thresh
Default: 0
Specifies the low threshold number of call IPSec tunnels setup per second that must be met or exceeded within the polling interval to clear an alert or alarm.

low_thresh is an integer from 0 through 1000000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of IPSec tunnels setup is equal to or greater than a specified number per second.

Alerts or alarms are triggered for the number of IPSec tunnels setup on the following rules:

- **Enter condition:** Actual number of IPSec tunnels setup is greater than the high threshold.
- **Clear condition:** Actual number of IPSec tunnels setup is less than the low threshold.
Example

The following command configures a number of IPSec tunnels setup threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-tunnels-setup 1000 clear 800
```
threshold reg-reply-error

Set an alarm or alert based on the number of registration reply errors per HA service.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

threshold reg-reply-error high_thresh [ clear low_thresh ]

no threshold reg-reply-error

no
Delete the alert or alarm.

high_thresh
Default: 0
Specifies the high threshold number of registration reply errors that must be met or exceeded within the polling interval to generate an alert or alarm. high_thresh is an integer from 0 through 100000.

clear low_thresh
Default: 0
Specifies the low threshold number of registration reply errors that must be met or exceeded within the polling interval to clear an alert or alarm. low_thresh is an integer from 0 through 100000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
Use this command to set an alert or an alarm when the number of registration reply errors is equal to or greater than a specified number of calls per second. Alerts or alarms are triggered for the number of registration reply errors on the following rules:

• Enter condition: Actual number of registration reply errors is greater than the high threshold.
• Clear condition: Actual number of registration reply errors is less than the low threshold.

Example
The following command configures a registration reply error threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```
threshold reg-reply-error 1000 clear 500
```
threshold rereg-reply-error

Set an alarm or alert based on the number of re-registration reply errors per HA service.

Product
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HA Service Configuration

configure > context context_name > ha-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ha-service)#

Syntax

threshold rereg-reply-error high_thresh [ clear low_thresh ]

no threshold rereg-reply-error

no
Deletes the alert or alarm.

high_thresh
Default: 0
Specifies the high threshold number of re-registration reply errors that must be met or exceeded within the polling interval to generate an alert or alarm. high_thresh is an integer from 0 through 100000.

clear low_thresh
Default: 0
Specifies the low threshold number of re-registration reply errors that must be met or exceeded within the polling interval to clear an alert or alarm. low_thresh is an integer from 0 through 100000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of re-registration reply errors is equal to or greater than a specified number of calls per second. Alerts or alarms are triggered for the number of re-registration reply errors on the following rules:

- Enter condition: Actual number of re-registration reply errors is greater than the high threshold.
  - Clear condition: Actual number of re-registration reply errors is less than the low threshold.

Example
The following command configures a reregistration reply error threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```
threshold dereg-reply-error 1000 clear 500
```
**wimax-3gpp2 interworking**

Configures the interworking between WiMAX and 3GPP2 network at HA. This support provides handoff capabilities from 4G to 3G (PDSN) network access and vice-versa.

**Product**

HA

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HA Service Configuration

```
configure > context context_name > ha-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ha-service)#
```

**Syntax**

```
[ no | default ] wimax-3gpp2 interworking
```

- **no**
  
  Disables the pre-configured interworking between WiMAX and 3GPP2 networks at HA level.

- **default**
  
  Configures the **WiMAX-3GPP2 interworking** to default setting: disabled.

**Usage**

Use this command to enable/disable the interworking between WiMAX and 3GPP2 network for seamless session continuity.

This functionality provides HA support for both 4G and 3G technology HA (WiMAX HA and PDSN/HA) for handoff from 4G and 3G network access (ASN GW/FA and PDSN/FA) and vice-versa.

**Important:** Use this command in conjunction with the **authentication aaa-distributed-mip-keys required** command.

**Example**

The following command enables the interworking for a subscriber between WiMAX and 3GPP2 network.

```
wimax-3gpp2 interworking
```
The HD Storage Policy Configuration Mode is used to configure directory name and file parameters for Diameter record files being stored on the HD storage device.

**Mode**

Exec > Global Configuration > HD Storage Policy Configuration

`configure > hd storage-policy policy_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hd-storage-policy)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
directory

Configures the name of the directory on the HD storage drive where Diameter records are stored.

**Product**
- HSGW
- P-GW
- SAEGW
- S-GW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > HD Storage Policy Configuration

```
configure > hd storage-policy policy_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hd-storage-policy)#
```

**Syntax**

```
directory name dir_name

default directory name

default

Returns the command to its default setting of using the policy name as the directory name.

name dir_name

Specifies the name to be applied to the directory. *dir_name* must be an alphanumeric string of 1 through 63 characters.

When configured, the actual directory path is:

```
/hd-raid/records/<record-type>/<dir_name>/
```

So if the directory name variable is entered as "sgwpgw", the path is:

```
/hd-raid/records/acr/sgwpgw
```

**Usage**

Use this command to name a directory on the HD storage drive where Diameter records are to be stored.

**Example**

The following command configures a directory named cdr1:

```
directory name cdr1
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**
Use this command to return to the parent configuration mode.
**file**

Configures file parameters for Diameter records being stored on the HD storage device.

**Product**
- HSGW
- P-GW
- SAEGW
- S-GW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > HD Storage Policy Configuration

`configure > hd storage-policy policy_name`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hd-storage-policy)#
```

**Syntax**

```
file { format acr { custom1...custom10 } | name { extension string | prefix string } | rotation { record-count num | time-interval sec | volume mb mbytes } }

default file { format acr | name prefix | rotation { record-count | time-interval | volume } }

no file { extension | rotation { record-count | time-interval } }
```

**default**

Returns the command to the default settings for the specified keywords.

**no**

Removes the configuration for the specified parameters.

**format acr { custom1...custom10 }**

Default: `custom1`

Specifies the file format used when storing records on the HD storage device. `custom1` is a vendor-specific file format.

**name { extension string | prefix string }**

Specifies a string to be pre-pended or appended to the filenames. By default, the policy name is used for the prefix.

- `extension string`: Specifies a file extension to append to the filename. `string` must be an alphanumeric string of 1 through 10 characters.
- `prefix string`: Specifies a file prefix to append to the filename. `string` must be an alphanumeric string of 1 through 63 characters. This parameter replaces the policy name used by default.
rotation { record-count num | time-interval sec | volume mb mbytes }

Specifies the triggers that prompt file rotation on the HD storage drive. All options can be configured and upon reaching any of the thresholds, file rotation is initiated.

- **record-count num**: File rotation occurs when the number of records reaches the number configured in this keyword. `num` must be an integer from 1000 through 65000. Default = 10000
- **time-interval sec**: File rotation occurs at time intervals (in seconds) configured by this keyword. `sec` must be an integer from 30 through 86400. Default = 3600 (1 hour)
- **volume mb mbytes**: File rotation occurs when the record volume exceeds the value (in megabytes) configured by this keyword. `mbytes` must be an integer from 2 through 40. Default = 4

**Usage**

Use this command to configure file parameters for Diameter records being stored on the HD storage device.

**Example**

The following command sets the file rotation thresholds for files being stored on the HD storage device:

```
file rotation volume mb 4
file rotation record-count 15000
file rotation time-interval 7200
```

The following command replaces the policy name as the prefix of all files being stored through this policy with the prefix `sgw`:

```
file name prefix sgw
```
Chapter 159
HeNB-GW Access Service Configuration Mode Commands

A new service “henbgw-access-service” is defined under Context Configuration Mode to initialize HeNB-GW functionality. This service configuration controls the S1-MME interface for communication between HeNB-GW to HeNB(s). HeNBs connect to the S1-MME bind address configured in this service.

Mode

Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

configure > context context_name > henbgw-access-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-access-service)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
associate henbgw-network-service

Associates a previously configured HeNB-GW Network service to the this HeNB-GW Access service. An HeNB-GW Network service must be configured in Context Configuration mode before using this configuration.

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

configure > context context_name > henbgw-access-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-access-service)#

**Syntax**

```plaintext
associate henbgw-network-service svc_name [ context contxt_name ]

no associate henbgw-network-service
```

- **no**
  Removes the associated HeNB-GW Network service from this HeNB-GW Access service configuration.

- **svc_name**
  Identifies the name of the pre-configured HeNB-GW Network service to associate with this HeNB-GW Access service.
  `svc_name` is an alphanumeric string of 1 through 63 characters.

- **context contxt_name**
  Identifies the name of the context to which the HeNBGW service belongs.
  `contxt_name` is an alphanumeric string of 1 through 79 characters.

**Usage**

Use this command to bind/associate a pre-configured HeNB-GW Network service to the this HeNB-GW Access service. The HeNB-GW Network service can be configured in Context configuration mode. The associate configuration is used to establish associations with other helper services in general.

**Example**

Following command associates an HeNB-GW Network service named `henb-network` with specific HeNB-GW Access service.

```plaintext
associate henbgw-network-service henb-network
```
associate sctp-param-template

Associates a previously configured SCTP Parameter Template to the this HeNB-GW Access service. A SCTP Parameter Template must be configured globally before using this configuration.

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
associate sctp-param-template template_name

no associate sctp-param-template
```

- **no**
  Removes the associated SCTP Parameter Template from this HeNB-GW Access service configuration.

- **template_name**
  Identifies the name of the pre-configured SCTP Parameter Template to associate with this HeNB-GW Access service.

  *template_name* is an alphanumeric string of 1 through 63 characters.

**Usage**

Use this command to bind/associate a pre-configured SCTP Parameter Template to the this HeNB-GW Access service. The SCTP Parameter Template can be configured global mode. The associate configuration is used to establish associations with other helper services in general.

**Example**

Following command associates an SCTP Parameter Template named *sctp_tmpl* with specific HeNB-GW Access service.

```
associate sctp-param-template sctp_tmpl
```
associate x2gw-service

This command Configures x2gw-service for this HENBGW ACCESS service.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

configure > context context_name > hembgw-access-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hembgw-access-service)#

Syntax

associate x2gw-service  associate_x2gw-service_name context context_name

no associate x2gw-service

no
Removes the association of x2gw-service interface from this HeNB-GW Access service configuration.

associate_x2gw-service_name
Name of the service that will be used by this HENBGW ACCESS service to associate with. Name of the string is an alphanumeric, 1 through 63 characters.

context_name
Name of the context that will be used by this HENBGW ACCESS service to associate with. Name of the string is an alphanumeric, 1 through 79 characters.

Usage
Use this command to associate x2gw-service with HENBGW Access service.

Example
Following command associates an x2gw-service with specific HeNB-GW Access service with name gate123:

associate x2gw-service  gate123
**bind s1-mme**

Binds the pre configured HeNB-GW Access Service to the IP address of the S1-MME interface.

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

configure > context context_name > henhbgw-access-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henhbgw-access-service)#

**Syntax**

```
bind s1-mme { ipv4-address | ipv6-address } ip_addr max-subscribers max_sub
no bind s1-mme
```

**Usage**

Use this command to bind the pre configured IPv4 address of the S1-MME interface to the HeNB-GW Access Service.

**Example**

Following command binds the S1-MME interface having 192.68.111.61 IP address with specific HeNB-GW Access service.

```
bind s1-mme ipv4-address 192.68.111.61
```
csg-optimized-paging

Configures the support for Paging Optimization Function on this HeNB-GW Access service based on the CSG-ID in the Paging message

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

configure > context context_name > henbgw-access-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-access-service)#

Syntax

[ no ] csg-optimized-paging

no

Removes the paging optimization function from this HeNB-GW Access service configuration.

Usage
Use this command to enable the CSG-ID based paging optimization function to the HeNB-GW Access Service.

Example
Following command enables the CSG-ID based paging optimization on a specific HeNB-GW Access service.

    csg-optimized-paging
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
mme-id

Configures the MME ID for this HeNB-GW Access service. For this configuration, MME Group ID and MME Code has to be configured.

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

```
configure > context context_name > henbgw-access-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-henbgw-access-service)#
```

**Syntax**

```
mme-id group-id mme_group_id mme-code mme_code

no mme-id
```

- **no**
  - Removes the configured MME ID from this HeNB-GW Access service configuration.

- **mme_group_id**
  - Identifies the MME Group ID which must be entered as an integer between 32768 and 65535.

- **mme_code**
  - Identifies the MME code which is again an integer value between 0 and 255.

**Usage**

Use this command to configure the MME Identifier which includes the MME Group ID and MME Code for this HeNB-GW Access service. MME ID configuration is required, because it is the same ID which HeNB-GW sends in response messages to HeNBs.

⚠️ **Caution:** Changing the MME ID is a disruptive operation. HeNB-GW service is restarted on any change.

**Example**

Following command configures 32770 as the MME Group ID and 105 as MME code on a specific HeNB-GW Access service.

```
mme-id group-id 32770 mme-code 105
```
plmn

Configures the PLMN identifier for this HeNB-GW Access service. Other identifiers that are configured along with the PLMN include the MCC and MNC values too.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

configure > context context_name > hnbgw-access-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-access-service)#

Syntax

[ no ] plmn id mcc mcc_val mnc mnc_val

no
Removes the existing PLMN configuration from this HeNB-GW Access service configuration.

mcc_val
Identifies the mobile country code for the IMSI which must be entered between 100 and 999 as a string of size 3.

mnc_val
Identifies the Mobile Network Code which is a value between 00 and 999, as a string of size 2 to 3.

Usage
Use this command to configure the PLMN related configuration for this HeNB-GW Access service.

Example
Following command configures 123 as the MCC value and 456 as the MNC value as part of the PLMN configuration for this HeNB-GW Access service.

plmn id mcc 123 mnc 456
s1-mme ip qos-dscp

This command configures the quality of service (QoS) differentiated service code point (DSCP) marking for IP packets sent out on the S1-MME interface, from the HeNB-GW to the HeNB(s).

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

```
configure > context context_name > hnbgw-access-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-henbgw-access-service)#
```

Syntax
```
s1-mme ip qos-dscp { af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 |
    af42 | af43 | be | cs0 | cs1 | cs2 | cs3 | cs4 | cs5 | cs6 | cs7 | ef }
```

```
default s1-mme ip qos-dscp
```

```
qos-dscp { af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 |
    af42 | af43 | be | cs0 | cs1 | cs2 | cs3 | cs4 | cs5 | cs6 | cs7 | ef }
```

Default: af11
Specifies the DSCP for the specified QoS traffic pattern. qos-dscp can be configured to any one of the following:

- **af11**: Assured Forwarding 11 per-hop-behavior (PHB)
- **af12**: Assured Forwarding 12 PHB
- **af13**: Assured Forwarding 13 PHB
- **af21**: Assured Forwarding 21 PHB
- **af22**: Assured Forwarding 22 PHB
- **af23**: Assured Forwarding 23 PHB
- **af31**: Assured Forwarding 31 PHB
- **af32**: Assured Forwarding 32 PHB
- **af33**: Assured Forwarding 33 PHB
- **af41**: Assured Forwarding 41 PHB
- **af42**: Assured Forwarding 42 PHB
- **af43**: Assured Forwarding 43 PHB
- **be**: Best effort forwarding PHB
- **cs0**: Designates use of Class Selector 0 PHB. This is same as DSCP Value BE
- **cs1**: Designates use of Class Selector 1 PHB
- **cs2**: Designates use of Class Selector 2 PHB
- **cs3**: Designates use of Class Selector 3 PHB
- **cs4**: Designates use of Class Selector 4 PHB
- **cs5**: Designates use of Class Selector 5 PHB
- **cs6**: Designates use of Class Selector 6 PHB
- **cs7**: Designates use of Class Selector 7 PHB
**Usage**

DSCP levels can be assigned to specific traffic patterns to ensure that data packets are delivered according to the precedence with which they are tagged. The diffserv markings are applied to the IP header of every subscriber data packet transmitted over the S1-MME interface(s).

**Example**

The following command sets the DSCP-level for data traffic sent over the S1-MME interface to **af12**:

```
s1-mme ip qos-dscp af12
```
s1-mme sctp port

This command configures the local Stream Control Transmission Protocol (SCTP) port used for binding the SCTP socket to communicate with the HeNBs over S1-MME interface.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

configure > context context_name > hnbw-access-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hnbw-access-service)#

Syntax

s1-mme sctp port port_num

default s1-mme sctp port

---

default

Sets the SCTP port to the default value of 36412 to communicate with the HeNBs using S1-MME interface.

---

port_num

Specifies the SCTP port number to communicate with the HeNBs using S1-MME interface as an integer from 1 through 65535. Default: 36412

---

Usage

Use this command to assign the SCTP port with SCTP socket to communicate with the HeNB using S1AP. Only one SCTP port can be associated with one MME service.

Example

The following command sets the default SCTP port number 699 for to interact with Home eNodeB using S1AP on S1-MME interface:

   default s1-mme sctp port
s1u-relay

This command configures the S1-U Relay service for the HeNB-GW Access service. The user enters in the S1-U Relay configuration mode using this command.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

configure > context context_name > henbgw-access-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-access-service)#

Syntax

[ no ]s1u-relay

no

Removes the S1-U Relay service function from this HeNB-GW Access service configuration.

Usage

Use this command to enable the S1-U Relay service function to the HeNB-GW Access Service. S1-U relay service is disabled by default.

Example

Following command enables the S-U Relay service on a specific HeNB-GW Access service.

s1u-relay
security-gateway

This command configuration defines the IPv4 address to be used as the connection point for establishing IKEv2 sessions and specify the crypto template to use for the security gateway (SeGW) for the HeNB-GW Access service.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

configure > context context_name > henbgw-access-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-access-service)#

Syntax

security gateway bind ipv4-address ip_addr crypto-template template_name [ context ctxt_name ]

no security gateway bind

no
Removes the security gateway related configuration associated with this HeNB-GW Access service configuration.

ip_addr
Identifies the security gateway address used for this HeNB-GW Access service. It must be entered in dotted decimal notation.

template_name
Identifies the crypto template name for security gateway for this HeNB-GW Access service. It must be entered a string of size 0 to 127.

ctxt_name
Identifies the context name where crypto template is defined for this HeNB-GW Access service. It must be entered a string of size 1 to 79.

Usage
Use this command to configure the security gateway (SeGW) related configuration for this HeNB-GW Access service. SeGW configuration includes crypto template configuration as part of IPSec settings, therefore if the crypto-template is defined in a different context than the current HeNB-GW Access service, the context name has to be specified.

Example
Following command configures 192.68.111.15 as the SeGW address and crypto-temp as the crypto template name on a specific HeNB-GW Access service.

```
security gateway bind ipv4-address 192.68.111.15 crypto-template crypto-temp
```
timeout

Configures the maximum duration of the session for this HeNB-GW Access service, in seconds, before system automatically reports/terminates the session.

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-ACCESS Service Configuration

```
configure > context context_name > henbgw-access-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-henbgw-access-service)#
```

**Syntax**

```
timeout long-duration dur action { detection | disconnect }
no timeout long-duration
```

- **no**
  - Removes the currently setup maximum duration of session.

- **dur**
  - Specifies the number of seconds for the session’s timeout duration, before system automatically terminates the session or a defined action is to be taken.
  - `dur` is an integer from 1 through 2147483647. Default: 0

**Usage**

Use this command to configure the maximum duration of the session, in seconds, before system automatically reports/terminates the session of this HeNB-GW Access service.

**Example**

The following command sets the timeout duration of 60 seconds for a particular HeNB-GW Access service and disconnect the session:

```
timeout long-duration 60 action disconnect
```
Chapter 160
HeNB-GW Network Service Configuration Mode
Commands

A new service "henbgw-network-service" is defined under the Context configuration mode in order to support HeNB-GW functionality. This service configuration controls the S1-MME interface functionality between HeNB-GW and MME node.

**Mode**

Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

```plaintext
configure > context context_name > henbgw-network-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-henbgw-network-service)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
anr-info-retrieval

This command enables the HeNB-GW to intercept and respond to the Automatic Neighbor Relation (ANR) related SON messages with the requested information.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

    configure > context context_name > henbgw-network-service service_name

Entering the above command sequence results in the following prompt:

    [context_name] host_name(config-henbgw-network-service)#

Syntax

    [ no | default ] anr-info-retrieval

    no
    Removes the ANR information retrieval related function from this HeNB-GW Network service configuration.

    default
    Sets/Restores the default value assigned for the ANR information retrieval related function from the configured HeNB-GW Network service.

Usage
Use this command to enable the ANR information retrieval function to the HeNB-GW Network Service.

Example
Following command enables the ANR information retrieval function on a specific HeNB-GW Network service.

    anr-info-retrieval
associate sctp-param-template

Associates a previously configured SCTP Parameter Template to the this HeNB-GW Network service. A SCTP Parameter Template must be configured globally before using this configuration.

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
associate sctp-param-template template_name

no associate sctp-param-template
```

**Usage**

Use this command to bind/associate a pre-configured SCTP Parameter Template to the this HeNB-GW Network service. The SCTP Parameter Template can be configured global mode. The associate configuration is used to establish associations with other helper services in general.

**Example**

Following command associates an SCTP Parameter Template named `sctp_tmpl` with specific HeNB-GW Network service.

```
associate sctp-param-template sctp_tmpl
```
default-paging-drx

This command is used to configure the Default paging DRX value that is sent to the MME(s) in the S1 SETUP request message.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

configure > context context_name > hnbw-network-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-network-service)#

Syntax

default-paging-drx { v128 | v256 | v32 | v64 }

default default-paging-drx

default

Sets/Restores the default value assigned for Default-Paging-DRX for the configured HeNB-GW Network service.

default-paging-drx { v128 | v256 | v32 | v64 }

Any one of the following DRX values can be configured:

- v128: Designates use of Paging DRX v128.
- v256: Designates use of Paging DRX v256.
- v32: Designates use of Paging DRX v32.
- v64: Designates use of Paging DRX v64.

Usage
Use this command to configure the Default Paging DRX value for this HeNB-GW Network service.

Example
Following command configures v256 as the Default Paging DRX value on a specific HeNB-GW Network service.

default-paging-drx v256
end

Exits the current configuration mode and returns to the Exec mode.

All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

configure > context context_name > henbgw-network-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-network-service)#

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

`configure > context context_name > henbgw-network-service service_name`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-henbgw-network-service)#`

**Syntax**

`exit`

**Usage**

Use this command to return to the parent configuration mode.
**logical-enb**

This command enables the configuration of one or more logical eNodeBs within the HeNB-GW.

**Product**

HeNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

configure > context context_name > henbgw-network-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-henbgw-network-service)#

**Syntax**

```plaintext
logical-enb global-enb-id plmn id mcc  mcc_val mnc  mnc_val { home-enb-id henb_id | macro-enb-id menb_id [ -noconfirm ] }

[ no ] logical-enb global-enb-id plmn id mcc  mcc_val mnc  mnc_val { home-enb-id henb_id | macro-enb-id menb_id }
```

- `no`
  Removes the configured logical eNodeB from this HeNB-GW Network service configuration.

- `mcc  mcc_val`
  Identifies the mobile country code for the IMSI which must be entered between 100 and 999, as a string of size 3.

- `mnc  mnc_val`
  Identifies the Mobile Network Code which is a value between 00 and 999, as a string of size 2 to 3.

- `home-enb-id henb_id`
  Identifies the Home eNodeB ID which is an integer from 1 to 268435455.

- `macro-enb-id menb_id`
  Identifies the Macro eNodeB ID which is again an integer value between 1 and 1048575.

- `-noconfirm`
  Creates a new HeNB-GW network service without prompting for confirmation.
Usage

Use this command for the configuration of one or more logical eNodeBs within the HeNB-GW. The Logical eNodeB configuration can be used to support load balancing within a pool of TAIs (i.e. Multiple logical eNodeBs can service calls connecting from a specific set of TAIs). It can also be used to create and support disjoint serving areas, that is each logical eNodeB will serve a different set of TAIs.

At least one logical eNodeB configuration is required to START an HeNB-GW Network service.

⚠️ Caution: Deleting or modifying any of the parameters for a fully configured logical eNodeB is a disruptive operation. It will result in the termination of SCTP connections to MMEs from that logical eNodeb.

Example

Following command configures a logical eNodeB having Home eNodeB ID as 1000 on a specific HeNB-GW Network service.

```bash
logical-enb global-enb-id plmn id mcc 123 mnc 456 home-enb-id 1000
```
paging-rate-control

This command is used to configure the Paging-Rate-Control which determines the maximum number of paging messages per second which an HeNB-GW can handle received from the MME(s).

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

```
configure > context context_name > hengw-network-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hengw-network-service)#
```

**Syntax**

```
paging-rate-control number_of_msg
```

```
no paging-rate-control
```

- **no**

  Removes the configured rate of paging messages from this HeNB-GW Network service configuration.

- **number_of_msg**

  Identifies the number of paging messages to be handled by the HeNBGW service per second. This number must be entered as an integer between 1 and 65535 \((\text{min} \ 1 \ \text{and} \ \text{max} \ 65535)\).

**Usage**

Use this command to configure the number of paging messages per second to be handled by this HeNB-GW Network service. MME ID configuration is required, because it is the same ID which HeNB-GW sends in response messages to HeNBs. This parameter is not part of logical-enb configuration and therefore it would include paging messages received from all the MMEs to which this HeNB-GW is connected on the network side.

**Important**: Paging messages exceeding the configured rate are dropped. Total Paging and Dropped Statistics is updated in the logs.

**Example**

Following command configures 32770 as the number of paging messages per second to be handled on a specific HeNB-GW Network service.

```
paging-rate-control 32770
```
pws

This command sets values for parameters related to public warning system feature.

Product
HeNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration
configure > context context_name > hengw-network-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hengw-network-service)#

Syntax

pws { kill-request-timeout kill_req_timeout_seconds | restart-indication-timeout restart_ind_timeout_seconds | warning-request-timeout warn_req_timeout_seconds }

default pws { kill-request-timeout | restart-indication-timeout | warning-request-timeout }

default
Configures the default value to kill request timeout and warning request timeout of public warning system feature.

kill-request-timeout kill_req_timeout_seconds
Configures the Kill Request timeout value in seconds.
kill_req_timeout_seconds is an integer from 1 through 65535.

restart-indication-timeout restart_ind_timeout_seconds
Configures Restart Indication timeout value in seconds.
restart_ind_timeout_seconds is an integer from 1 through 65535.

warning-request-timeout warn_req_timeout_seconds
Configures the Warning request timeout value in seconds.
warn_req_timeout_seconds is an integer from 1 through 65535.

Usage
Use this command to set the values for parameters related to public warning system feature for this HeNB-GW Network service.

Example
Following command configures the Warning request timeout value to 100 seconds.

pws warning-request-timeout 100
s1ap-max-retransmissions

This command configures the number of times node level S1AP message is retransmitted towards MME.

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

configure > context context_name > henbgw-network-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-henbgw-network-service)#
```

**Syntax**

```
s1ap-max-retransmissions number_of_retries

default s1ap-max-retransmissions
```

**Usage**
Use this command to configure the maximum number of Node level S1AP retransmissions for this HeNB-GW Network service.

⚠️ **Caution:** Configuring s1ap-max-retransmissions to 0 will disable the S1AP retransmission support.

**Example**
Following command configures default (which is also 4) S1AP retransmission on a specific HeNB-GW Network service.

```
default s1ap-max-retransmissions
```
s1ap-retransmission-timeout

This command configures the timeout interval to support Node Level S1AP retransmissions if there in no response received from the peer (MME).

**Product**
HeNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HENBGW-NETWORK Service Configuration

```
configure > context context_name > henbgw-network-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-henbgw-network-service)#
```

**Syntax**

```
s1ap-retransmission-timeout number_of_secs

default s1ap-retransmission-timeout
```

**default s1ap-retransmission-timeout**

```
default
```

Configures the default S1AP retransmission timeout for this HeNB-GW Network service configuration. Default retransmission timeout is 60 seconds.

```
number_of_secs
```

Identifies the number seconds as the S1AP retransmission timeout to be configured. This number must be entered as an integer between 1 and 600.

**Usage**

Use this command to configure the timeout interval to support Node Level S1ap retransmissions for this HeNB-GW Network service.

**Example**

Following command configures 100 as the S1AP retransmission timeout on a specific HeNB-GW Network service.

```
s1ap-retransmission-timeout 100
```
Chapter 161
HSGW Service Configuration Mode Commands

The HSGW Service Configuration Mode is used to create and manage a configuration allowing the HRPD Serving Gateway (HSGW) to communicate, send and receive call data, and session flows to/from an Access Network/evolved Packet Control Function (eAN/ePCF) in an eHRPD network.

Mode

Exec > Global Configuration > Context Configuration > HSGW Service Configuration

configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
a11-signalling-packets

Enables the DSCP marking feature for IP headers carrying outgoing A11-signalling A11 packets (such as RRP, RU, SU).

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
a11-signalling-packets ip-header-dscp value
```

- **default**
  Restores the specified parameter to its default setting of 0x0.

- **no**
  Disables the specified functionality.

- **ip-header-dscp value**
  Configures the QoS Differentiated Services Code Point (DSCP) marking for IP header encapsulation.

  - *value*: Represents the DSCP setting as the first six most-significant bits of the ToS field. It can be configured to any hex value from 0x0 through 0x3F. Default is 0x0.

**Usage**

Use this command to enable or disable the DSCP marking feature for IP headers carrying outgoing A11-signalling A11 packets. DSCP marking is disabled by default.

**Example**

The following command configures the HSGW service to support DSCP marking for IP headers on A11 packets in outgoing A11-signalling traffic:

```
a11-signalling-packets ip-header-dscp 0x21
```
associate

Associates accounting policies and QCI-QoS mapping parameters with this HSGW service.

**Product**

HSGW

**Privilege**

Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
associate { accounting-policy name | qci-qos-mapping name }
```

```
no associate { accounting-policy [ name ] | qci-qos-mapping }
```

**Usage**

Use this command to associate an accounting policy with the HSGW service.

**Example**

The following command associates an accounting policy named `acct2` to the HSGW service:

```
associate accounting-policy acct2
```
bind address

Binds the service to a logical IP interface serving as the A10 interface and specifies the maximum number of subscribers that can access this service over the configured interface.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

bind address ip_address [ max-subscribers num ]

no bind address

no

Removes the interface binding from this service.

address ip_address

Specifies the IP address of the A10/A11 interface in IPv4 dotted-decimal notation.

max-subscribers num

Specifies the maximum number of subscribers that can access this service on this interface as an integer from 0 through 2500000. Default: 2500000

Important: The maximum number of subscribers supported is dependant on the license key installed and the number of active PSCs in the system. A fully loaded system with 13 active PSCs can support 3,000,000 total subscribers. Refer to the license key command and the Usage section (below) for additional information.

Usage

Associate the HSGW service to a specific logical IP address. The logical IP address or interface takes on the characteristics of an A10/A11 interface that provides the session connectivity to/from an eAN/PCF. Only one interface can be bound to a service. The interface should be configured prior to issuing this command. This command also sets a limit as to the number of simultaneous subscribers sessions that can be facilitated by the service/interface at any given time.

When configuring the max-subscribers option, be sure to consider the following:

• The total number of A10/A11 interfaces you will configure

• The total number of subscriber sessions that all of the configured interfaces may handle during peak busy hours
• An average bandwidth per session multiplied by the total number of sessions
• The type of physical port (10/100Base-T or 1000Base-Tx) that these interfaces will be bound to

Taking these factors into account and distributing your subscriber session across all available interfaces will allow you to configure your interfaces to optimally handle sessions without degraded performance.

Example

The following command would bind the logical IP interface with the address of 112.334.556.778 to the HSGW service and specifies that a maximum of 200,000 simultaneous subscriber sessions can be facilitated by the interface/service at any given time:

    bind address 112.334.556.778 max-subscribers 200000
context-retention-timer

Configures the maximum number of consecutive seconds that a UE session context (which includes the LCP, authentication and A10 session context for a given UE) is maintained by the HSGW before it is torn down.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-hsgw-service)#
```

**Syntax**

```
context-retention-timer timeout [ sec ]
[ default | no ] context-retention-timer timeout
```

- **default**
  
  Disables the timer.

- **no**
  
  Disables the timer.

- **timeout [ sec ]**
  
  Specifies the amount of time (in seconds) that the session context is maintained before it is disassembled as an integer from 1 through 3600. Default: 60.
  
  In Release 15.0 and later, the maximum value has been increased to 86400 seconds (24 hours).

**Usage**

Use this command to configure a timer to retain session contexts for a specified amount of time before disassembling it.

**Example**

The following command allows the HSGW to maintain session contexts for 120 seconds before tearing them down:

```
context-retention-timer timeout 120
```
**data-available-indicator**

Enables sending the Data Available Indicator extension in A10/A11 Registration Reply messages.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
data-available-indicator
```

**Usage**

Use this command to enable the sending of the Data Available Indicator extension in A10/A11 Registration Reply messages.
data-over-signaling

Enables the data-over-signaling marking feature for A10 packets.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
[ default | no ] data-over-signaling
```

**default**

Enables the data-over-signaling feature for A10 packets.

**no**

Disables the data-over-signaling feature for A10 packets.

**Usage**

Use this command to enable or disable the data-over-signaling feature for A10 packets.
HSGW Service Configuration Mode Commands

dns-pgw

Identifies the location of the DNS client to the HSGW service and enables/disables P-GW load balancing using DNS SRV lookup.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

dns-pgw { context name | selection { topology [ weight ] | weight } }

[ default | no ] dns-pgw { context | selection { topology [ weight ] | weight } }

---

default

Returns the command to its default setting of the current context.
By default, topology will be enabled and weight will be disabled.

---

no

Removes the configured DNS client context name or P-GW DNS selection criteria from this service.

---

context name

Specifies an existing context in which the DNS client is configured as an alphanumeric string of 1 through 79 characters.

---

selection { topology [ weight ] | weight }

Specifies P-GW DNS selection criteria.
topology: Enables topology selection, which selects a P-GW topologically closer to the HSGW.
topology weight: Enables topology selection with weight.
weight: Enables selection with weight only when both preference values are the same; disables topology selection.

---

Usage

Use this command to identify to the HSGW service the context where the DNS client is configured. The DNS client is used to identify an FQDN for the peer P-GW. This command defaults to the same context as the HSGW service.
In addition, this command enables and disables P-GW load balancing using DNS SRV lookup by defining P-GW DNS selection criteria.
Example

The following command identifies the context where the DNS client is configured as `isp3`:

```sh
dns-pgw context isp3
```

The following command enables P-GW DNS topology selection with weight:

```sh
dns-pgw selection topology weight
```
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
fqdn

Configures the Fully Qualified Domain Name (FQDN) for this HSGW service.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration
configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax
fqdn domain_name
[ default | no ] fqdn

default
Returns the command to the default setting of “null”.

no
Removes the configured FQDN name from this service.

domain_name
Specifies an FQDN for the HSGW service as an alphanumeric string of 1 through 256 characters.

Important: In order to properly interact with other nodes in the network, the FQDN should be 96 alpha and/or numeric characters or less.

Usage
Use this command to configure an FQDN for this HSGW service. The FQDN is used when matching a P-GW with an HSGW.

Topology Matching
You may specify which P-GW you wish an HSGW interface to connect with by enabling topology matching within the FQDNs for both the HSGW service and P-GW service. Topology matching selects geographically closer nodes and reduces backhaul traffic for a specified interface.
The following optional keywords enable or disable topology matching when added to the beginning of an FQDN:
  • topon.<interface_name>.
Beginning an FQDN with `topon` initiates topology matching with available P-GWs in the network. Once this feature is enabled, the rest of the FQDN is processed from right to left until a matching regional designator is found on a corresponding P-GW FQDN.

• `topoff.<interface_name>`.

By default, topology matching is disabled. If you enable topology matching for any interfaces within a node, however, all interfaces not using this feature should be designated with `topoff`.

**Example**

The following command configures this HSGW service with an FQDN of `abc123.com`:

```
fqdn abc123.com
```

The following command configures this HSGW service with an FQDN that enables topology matching:

```
fqdn topon.<interface_name>.hsgw01.bos.ma.node.epc.mnc<value>.mcc<value>.3gppnetwork.org
```

**Important:** The associated P-GW service must have a corresponding FQDN similar to the following:

```
topon.<interface_name>.pgw01.bos.ma.node.epc.mnc<value>.mcc<value>.3gppnetwork.org
```
fragment

Enables or disables Point-to-Point Protocol (PPP) payload fragmentation.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```bash
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
[ default | no ] fragment ppp-data
```

- **default**
  - Returns the command to its default setting of enabled.

- **no**
  - Disables PPP payload fragmentation.

**Usage**

Use this command to enable or disable PPP payload fragmentation.
gre

Configures Generic Routing Encapsulation (GRE) parameters for the A10 protocol within the HSGW service.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

gre { checksum | checksum-verify | flow control [ action { disconnect-session | resume-session } ] [ timeout msecs ] + | ip-header-dscp value { all-control-packets | setup-packets-only } | reorder-timeout msecs | segmentation | sequence-mode { none | reorder } | sequence-numbers | threegppp2-ext-headers qos-marking }

default gre { checksum | checksum-verify | flow-control | ip-header-dscp | reorder-timeout | sequence-mode | sequence-numbers | threegppp2-ext-headers qos-marking }

no gre { checksum | checksum-verify | flow-control | ip-header-dscp | segmentation | sequence-numbers | threegppp2-ext-headers qos-marking }

default
Restores the specified parameter to its default setting.

no
Disables the specified functionality.

cHECKSUM
Enables the introduction of the checksum field in outgoing GRE packets. Default: disabled

CHECKSUM-VERIFY
Enables verification of the GRE checksum (if present) in incoming GRE packets. Default: disabled

flow-control [ action { disconnect-session | resume-session } ] [ timeout msecs ] +

Default: no GRE flow-control
Enables 3GPP2 GRE flow control which causes the HSGW to send flow control enabled Normal Vendor Specific Extensions (NVSE) in A11 RRs.

action { disconnect-session | resume-session }:
Default: disconnect-session
Specifies the action to be taken when timeout is reached:

- **disconnect-session**: Ends the session and releases the call.
- **resume-session**: Switches flow control to XON and resumes delivery of packets to the RAN.

**timeout msecs**

Specifies the amount of time (in milliseconds) to wait for an XON indicator from the RAN (after receiving an XOFF). Also sets the action to be taken if the timeout limit is reached.

*msecs* is an integer from 1 through 1000000. Default: 1000

**ip-header-dscp value { all-control-packets | setup-packets-only }**

Default: Disabled

Configures QoS Differentiated Services Code Point (DSCP) marking for GRE packets.

- **value**: Represents the DSCP setting as the first six most-significant bits of the ToS field. It can be configured to any hexadecimal value from 0x0 through 0x3F.
- **all-control-packets**: Dictates that the DSCP marking is to be provided in all GRE control packets.
- **setup-packets-only**: Dictates that the DSCP marking is to be provided only in GRE setup packets.

**reorder-timeout msecs**

Configures the maximum number of milliseconds to wait before processing reordered out-of-sequence GRE packets as an integer from 0 through 5000. Default: 100

**segmentation**

Enables GRE Segmentation for the HSGW service. Default: disabled

**sequence-mode { none | reorder }**

Default: none

Configures handling of incoming out-of-sequence GRE packets.

- **none**: Specifies that sequence numbers in packets are ignored and all arriving packets are processed in the order they arrive.
- **reorder**: Specifies that out of sequence packets are stored in a sequencing queue until one of the conditions is met:
  - The reorder timeout occurs: All queued packets are sent for processing and the accepted sequence number is updated to the highest number in the queue.
  - The queue is full (five packets): All packets in the queue are sent for processing, the reorder timer is stopped and the accepted sequence number is updated to the highest number in the queue.
  - An arriving packet has a sequence number such that the difference between this and the packet at the head of the queue is greater than five. All the packets in the queue are sent for processing, the reorder timer is stopped and the accepted sequence number is updated to the highest number that arrived.
  - A packet arrives that fills a gap in the sequenced numbers stored in the queue and creates a subset of packets whose sequence numbers are continuous with the current accepted sequence number. This subset of packets in the queue is sent for processing. The reorder timer continues to run and the accepted sequence number is updated to the highest number in the subset delivered.

**sequence-numbers**

Enables insertion of GRE sequence numbers in data that is about to be transmitted over the A10 interface. Data coming into the system containing sequence numbers but that is out of sequence is not re-sequenced.
threegpp2-ext-headers qos-marking

When threegpp2-ext-headers qos-marking is enabled and the PCF negotiates capability in the A11 RRQ, the HSGW will include the QoS optional data attribute in the GRE 3gpp2 extension header. The no keyword, enables qos-marking in the GRE header based on the tos value in the header.

Usage

Use this command to set GRE parameters for the A10 protocol within the HSGW service.

Example

The following command configures the HSGW service to support the inclusion of GRE sequence numbers in outgoing traffic:

```
gre sequence-numbers
```
ip

Enables the use of Robust Header Compression (RoHC) and enters the HSGW Service ROHC Configuration Mode where RoHC parameters are configured for the service.

Configures the local User Datagram Protocol (UDP) port for the A10/A11 interface IP socket.

Sets the parameters for IP source validation. Source validation is useful if packet spoofing is suspected or for verifying packet routing and labeling within the network. Source validation requires the source address of received packets to match the IP address assigned to the subscriber (either statically or dynamically) during the session.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration
configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

ip { header-compression rohc | local-port number | source-violation { clear-on-valid-packet | drop-limit num | period secs | reneg-limit num } }

default ip { header-compression rohc | local-port | source-violation { drop-limit | period | reneg-limit } }

no ip { header-compression rohc | source-violation clear-on-valid-packet }

default

 Resets the keyword to its default value.

do

header-compression rohc: Removes the RoHC configuration from this service.
ip source-violation clear-on-valid-packet: Disables the ability of the service to reset the reneg-limit and drop-limit counters after receipt of a properly addressed packet.

header-compression rohc

Specifies that Robust Header Compression will be applied to sessions using this service and enters the HSGW Service RoHC Configuration Mode where RoHC parameters are configured.

local-port number

Specifies the UDP port number as an integer from 1 through 65535. Default: 699
source-violation { clear-on-valid-packet | drop-limit num | period secs | reneg-limit num }

clear-on-valid-packet
Configures the service to reset the reneg-limit and drop-limit counters after receipt of a properly addressed packet. Default: disabled

drop-limit num
Specifies the number of allowed source violations within a detection period before forcing a call disconnect as an integer from 1 through 1000000. If num is not specified, the value is set to the default. Default: 10

period secs
Specifies the length of time (in seconds) for a source violation detection period to last; drop-limit and reneg-limit counters are decremented each time this value is reached.
The counters are decremented in this manner: reneg-limit counter is reduced by one (1) each time the period value is reached until the counter is zero (0); drop-limit counter is halved each time the period value is reached until the counter is zero (0). If secs is not specified, the value is set to the default.
secs is an integer from 1 through 1000000. Default: 120

reneg-limit num
Sets the number of allowed source violation s within a detection period before forcing a PPP renegotiation. If num is not specified, the value is set to the default.
num is an integer from 1 through 1000000. Default: 5

Usage

Header Compression RoHC: Use this command to specify that sessions using this service will have Robust Header Compression applied and configure parameters supporting RoHC.
Entering this command results in the following prompt:

[context_name]hostname(config-ip-header-compression-rohc)#

HSGW Service RoHC Configuration Mode commands are defined in the HSGW Service RoHC Configuration Mode Commands chapter.

Local Port: Specify the UDP port that should be used for communications between the Packet Control Function (PCF) and the HSGW.

Important: The UDP port setting on the PCF must match the local-port setting for the HSGW service on the system in order for the two devices to communicate.

Source Violation: This function is intended to allow the operator to configure a network to prevent problems such as when a user gets handed back and forth between two HSGWs a number of times during a handoff scenario.
This function operates in the following manner:
When a subscriber packet is received with a source address violation, the system increments both the IP source-violation reneg-limit and drop-limit counters and starts the timer for the IP-source violation period. Every subsequent packet received with a bad source address during the IP-source violation period causes the reneg-limit and drop-limit counters to increment.
For example, if reneg-limit is set to 5, then the system allows 5 packets with a bad source address (source violations), but on the 5th packet, it re-negotiates PPP.
If the drop-limit is set to 10, the above process of receiving 5 source violations and renegotiating PPP occurs only once. After the second 5 source violations, the call is dropped. The period timer continues to count throughout this process.
If the configured source-violation period is exceeded at any time before the call is dropped, the reneg-limit counter is checked. If the reneg-limit counter is greater than zero (0), the reneg-limit is decremented by 1. If the reneg-limit counter equals zero, the drop-limit is decremented by half.

**Example**

The following command specifies a UDP port of 3950 for the HSGW service to use to communicate with the PCF on the A10/A11 interface:

```
   ip local-port 3950
```

The following command sets the drop limit to 15 and leaves the other values at their defaults:

```
   ip source-violation drop-limit 15
```
lifetime

Specifies how long an A10 connection can exist before its registration is considered expired.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

class > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

lifetime time

[ default | no ] lifetime

---

default

Resets the lifetime value to the default setting of 1800 seconds.

---

no

Specifies that an A10 connection can exist for an infinite amount of time.

---

time

Specifies the time (in seconds) that an A10 connection can exist before its registration is considered expired as an integer from 1 through 65534. Default: 1800

Usage

Use this command to set a limit to the amount of time that a subscriber session can remain up whether or not the session is active or dormant. If the lifetime timer expires before the subscriber terminates the session, the connection is terminated automatically.

Example

The following command specifies a time of 3600 seconds (1 hour) for subscriber sessions on this HSGW service:

lifetime 3600
**max-retransmissions**

Configures the maximum number of times the HSGW service will attempt to communicate with an eAN/PCF before it marks it as unreachable.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
max-retransmissions count
```

```
default max-retransmissions
```

**Usage**
Use this command to limit the number of retransmissions to an eAN/PCF before marking it as unreachable. If the value configured is reached, the call is dropped.

**Example**

The following command configures the maximum number of retransmissions for the HSGW service to 3:

```
max-retransmissions 3
```
mobile-access-gateway

Identifies the mobile access gateway (MAG) context through which MIPv6 calls are to be routed.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

mobile-access-gateway context context_name [ mag-service service_name ]

no mobile-access-gateway context

no

Removes the configured MAG context route from this service.

context context_name [ mag-service service_name ]

Specifies the name of the context and, optionally, the service through which MIPv6 sessions are to be routed.
context_name is an existing context expressed as an alphanumeric string of 1 through 79 characters.
service_name is an existing MAG service expressed as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to specify where MIPv6 sessions are routed through this service.

Example

The following command identifies the MAG context MAG1 as the context through which MIPv6 sessions are to be routed and further narrows the route by specifying the service name (mag_serv3):

  mobile-access-gateway context MAG1 mag-service mag_serv3
**network-initiated-qos**

Enables the use of network initiated QoS functionality.

**Product**

HSGW

**Privilege**

Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HSGW Service Configuration

`configure > context context_name > hsgw-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
[ default | no ] network-initiated-qos
```

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Returns the command to its default setting of enabled.</td>
</tr>
<tr>
<td>no</td>
<td>Disables the ability to use network initiated QoS functionality.</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to enable or disable support for network initiated QoS functionality. Network initiated QoS is enabled by default. When network initiated QoS functionality is enabled, if the vendor specific network control protocol (VSNCP) protocol configuration options (PCO) arrive from the UE with the BCM set, the HSGW CCR-I includes the Network-Request-Support AVP. If the PCRF behavior returns a BCM of MS+NW when this AVP is received, then flows originating from the network (RSVP Resv) would be triggered upon a PCC-Rule install.
**plmn id**

Configures Public Land Mobile Network identifiers used to determine if a mobile station is visiting, roaming or belongs to this network.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

`configure > context context_name > hsgw-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
plmn id mcc number mnc number
```

- **mcc number**: Specifies the mobile country code (MCC) portion of the PLMN identifier as an integer from 100 through 999.
- **mnc number**: Specifies the mobile network code (MNC) portion of the PLMN identifier as a 2- or 3-digit integer from 00 through 999.

**Usage**

The PLMN identifier is used to aid the HSGW service in the determination of whether or not a mobile station is visiting, roaming, or home. Multiple P-GW services can be configured with the same PLMN identifier. Up to five PLMN IDs can be configured for each P-GW Service. The configured IDs are used in Diameter-EAP-Request messages (as a Visited-Network-Identifier AVP).

**Example**

The following command configures the PLMN identifier with an MCC of 462 and MNC of 02:

```
plmn id mcc 462 mnc 02
```
policy overload

Specifies how an HSGW service should handle overload conditions.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

policy overload { redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ] | reject [ use reject-code { admin-prohibite | insufficient-resources } ] }

default policy overload

no policy overload [ redirect address [ address2 ] ... [ address16 ]

---

default

Returns the command to it default setting of “reject” with the “admin-prohibited” code.

---

no

Removes a specified “redirect address” from this service.

---

redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ]

This option enables a redirect policy for overloading conditions. When a redirect policy is invoked, the HSGW service rejects new sessions with an A11 Registration Reply Code of 88H (unknown HSGW address) and provides the IP address of an alternate HSGW. This command can be issued multiple times.

address: The IP address of an alternate HSGW expressed in IPv4 dotted decimal notation. Up to 16 IP addresses can be specified either in one command or by issuing the redirect command multiple times. If you try to add more than 16 IP addresses to the redirect policy the CLI issues an error message. If you specify an IP address and weight that already exists in the redirect policy the new values override the existing values.

weight weight_num: When multiple addresses are specified, they are selected in a weighted round-robin scheme. Entries with higher weights are more likely to be chosen. If a weight is not specified, the entry is automatically assigned a weight of 1 (default). weight_num must be an integer value from 1 through 10.

---

reject [ use reject-code { admin-prohibite | insufficient-resources } ]

This option will cause any overload traffic to be rejected. The HSGW sends an A11 Registration Reply Code of 82H (insufficient resources).
**Policy Overload (policy overload)**

Use-override-code admin-prohibited: When this keyword is specified and traffic is rejected, the error code admin prohibited is returned instead of the error code “insufficient resources”. This is the default behavior.

Use-override-code insufficient-resources: When this keyword is specified and traffic is rejected, the error code “insufficient resources” is returned instead of the error code admin prohibited.

**Usage**

Policies can be implemented to dictate HSGW service behavior for overload conditions. The system invokes the overload policy if the number of calls currently being processed exceeds the licensed limit for the maximum number of sessions supported by the system. The system automatically invokes the overload policy when an on-line software upgrade is started. Use the `no policy overload` command to delete a previously configured policy. If after deleting the policy setting you desire to return the policy parameter to its default setting, use the `default policy` command.

The chassis is shipped from the factory with the policy options overload disabled.

**Example**

The following command configures the HSGW service to redirect overload traffic to two IPv4 addresses, one priority weighted 1 and the other priority weighted 5:

```
policy overload redirect 10.2.3.4 weight 1 10.2.3.5 weight 5
```
profile-id-qci-mapping

Associates a configured mapping table for RP QoS Profile ID to LTE QoS Class Index (QCI) mapping with this service.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
profile-id-qci-mapping name

no profile-id-qci-mapping [ name ]
```

**Usage**

Use this command to associate the HSGW service with a configured Profile ID - QCI Mapping table. The table is configured in the Global Configuration Mode using the `profile-id-qci-mapping-table` command.

**Example**

The following command associates a Profile ID - QCI Mapping table named `table3` with this service:

```
profile-id-qci-mapping table3
```
registration-deny

Configures parameters related to registration rejection.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```bash
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```bash
registration-deny { handoff connection-setup-record-absent | newcall connection-setup-record-absent } [ use-deny-code { poorly-formed-request | reason-unspecified } ]
```

```
[ default | no ] registration-deny { handoff connection-setup-record-absent | newcall connection-setup-record-absent }
```

---

**default | no**

Returns the command to its default settings.

---

**handoff connection-setup-record-absent**

When enabled, the HSGW denies or discards handoff R-P sessions that do not have an Airlink Connection Setup record in the A11 Registration Request. Default is disabled. Default HSGW behavior is to accept such requests.

---

**newcall connection-setup-record-absent**

When enabled, the HSGW denies or discards new R-P sessions that do not have the Airlink Connection Setup record in the A11 Registration Request. Default is disabled. Default HSGW behavior is to accept such requests.

---

**use-deny-code { poorly-formed-request | reason-unspecified }**

Sets the specified Registration Deny Code when denying a new call or handoff because of a missing connection setup record.

---

**Usage**

Use this command to configure parameters relating to the rejection of registration requests.

---

**Example**

The following command denies registration for registration requests missing the connection setup record and replies with a use deny code of “poorly formed request”:
registration-deny handoff connection-setup-record-absent use-deny-code poorly-formed-request
retransmission-timeout

Configures the maximum allowable time for the HSGW service to wait for a response from the eAN/PCF before it attempts to communicate with the eAN/PCF again (if the system is configured to retry the PCF), or marks the eAN/PCF as unreachable.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

retransmission-timeout time

[ default | no ] retransmission-timeout

---

**Default**

Resets the timeout setting to the default value of 3.

---

**No**

Deletes a previously configured timeout value.

---

**Time**

Specifies the maximum allowable time (in seconds) for the HSGW service to wait for a response from the eAN/PCF before it: a) attempts to communicate with the eAN/PCF again (if the system is configured to retry the PCF), or b) marks the eAN/PCF as unreachable.

time is an integer from 1 through 1000000. Default: 3

---

**Usage**

Use the retransmission timeout command in conjunction with the max-retransmissions command in order to configure the HSGW service’s behavior when it does not receive a response from a particular PCF.

---

**Example**

The following command configures a retransmission timeout value of 5 seconds:

retransmission-timeout 5
rsvp

Configures resource reservation protocol (RSVP) parameters for this HSGW service in support of the network initiated QoS feature.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
rsvp { max-retransmissions count | retransmission-timeout seconds }
[ default | no ] rsvp { max-retransmissions | retransmission-timeout }
```

- **default**
  Resets the maximum number of allowed retransmissions to the default value of 5 or the timeout setting to the default value of 3.

- **no**
  Disables the feature.

- **max-retransmissions count**
  Specifies the maximum retransmission count of RP control packets as an integer from 1 through 1000000. Default: 5

- **retransmission-timeout seconds**
  Specifies the maximum amount of time (in seconds) to allow for retransmission of RP control packets as an integer from 1 through 1000000. Default: 3

**Usage**

Use this command to set RSVP parameters for this HSGW service in support of the network initiated QoS feature.

**Example**

The following command configures the maximum number of retransmissions to 3:

```
rsvp max-retransmissions 3
```
setup-timeout

Specifies the maximum amount of time allowed for session setup.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

setup-timeout seconds

[ default| no ] setup-timeout

- **default**
  Resets the command to the default value of enabled with a timeout of 60 seconds.

- **no**
  Disables the feature.

- **seconds**
  Specifies the maximum amount of time (in seconds) to allow for setup of a session in this service as an integer from 1 though 1000000. Default: 60

Usage

Use this command to set the maximum amount of time allowed for setting up a session.

Example

The following command sets the maximum time allowed for setting up a session to 5 minutes (300 seconds):

setup-timeout 300
**spi remote-address**

Configures the security parameter index (SPI) between the HSGW service and the evolved Access Network/evolved Packet Control Function (eAN/ePCF). This command also configures the redirection of calls based on the PCF zone.

**Product**

HSGW

**Privilege**

Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```bash
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```bash
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```bash
spi remote-address { pcf_ip_address | ip_addr_mask_combo } spi-number number { encrypted secret enc_secret | secret secret } [ description string ] [ hash-algorithm { md5 | rfc2002-md5 } ] [ replay-protection { nonce | timestamp } ] [ timestamp-tolerance tolerance ] [ zone zone_id ]
```

```bash
no spi remote-address pcf_ip_address spi-number number
```

- **pcf_ip_address | ip_addr_mask_combo**
  - `pcf_ip_address`: Specifies the IP address of the ePCF. `pcf_ip_address` is an IP address expressed in IPv4 dotted decimal notation or IPv6 colon separated notation.
  - `ip_addr_mask_combo`: Specifies the IP address and mask bits of the PCF. `ip_addr_mask_combo` must be specified using the form “IP Address/Mask Bits” where the IP address must in IPv4 dotted-decimal or IPv6 colon-separated notation, and the mask bits are a numeric value corresponding to the number of bits in the subnet mask.

- **spi-number number**
  - Specifies the SPI which indicates a security context between the PCF and the HSGW as an integer from 256 through 4294967295.

- **encrypted secret enc_secret | secret secret**
  - Configures the shared-secret between the HSGW service and the PCF. The secret can be either encrypted or non-encrypted.
  - `encrypted secret enc_secret`: Specifies the encrypted shared key (`enc_secret`) between the PCF and the HSGW service. `enc_secret` must be between 1 and 236 alpha and/or numeric characters and is case sensitive.
  - `secret secret`: Specifies the shared key (secret) between the PCF and the HSGW services. `secret` must be between 1 and 127 alpha and/or numeric characters and is case sensitive.

The `encrypted` keyword is intended only for use by the chassis while saving configuration scripts. The system displays the `encrypted` keyword in the configuration file as a flag that the variable following the
**secret** keyword is the encrypted version of the plain text secret key. Only the encrypted secret key is saved as part of the configuration file.

**description** string

This is a description for the SPI expressed as an alphanumeric string of 1 through 31 characters.

**hash-algorithm** { md5 | rfc2002-md5 }

Specifies the hash-algorithm used between the HSGW service and the PCF. Default: md5
- md5: Configures the hash-algorithm to implement MD5.
- rfc2002-md5: Configures the hash-algorithm to implement keyed-MD5.

**replay-protection** { nonce | timestamp }

Specifies the replay-protection scheme that should be implemented by the HSGW service. Default: timestamp
- nonce: Configures replay protection to be implemented using NONCE (Number ONCE).
- timestamp: Configures replay protection to be implemented using timestamps.

**timestamp-tolerance** tolerance

Specifies the allowable difference (in seconds) between timestamps as an integer from 0 through 65535. If the difference is exceeded, the session will be rejected. If set to 0, timestamp tolerance checking is disabled at the receiving end. Default: 60

**zone** zone_id

Specifies the different PCF zones to configure in HSGW service. Mapping of a zone-number to a set of HSGWs can be done per HSGW service basis.
- zone_id is an integer value from 1 through 32. A maximum of 32 PCF zones can be configured for a HSGW service.

**Usage**

An SPI is a security mechanism configured and shared by the PCF and the HSGW service. Please refer to IETF RFC 2002: IP Mobility Support for additional information.

Multiple SPIs can be configured if the HSGW service is communicating with multiple eAN/ePCFs.

**Important:** The SPI configuration on the PCF must match the SPI configuration for the HSGW service on the system in order for the two devices to communicate properly.

**Example**

This command used with the **zone** keyword redirects all calls on the basis of PCF zone to the specific HSGW on the basis of parameters configured using the **policy pcf-zone-match** command.

The following command configures the HSGW service to use an SPI of 256 when communicating with a PCF with the IP address 192.168.0.2. The key that would be shared between the PCF and the HSGW service is q397F65.

```
spi remote-address 192.168.0.2 spi-number 256 secret q397F65
```

The following command creates the configured SPI of 400 for an PCF with an IP address of 172.100.3.200 and zone id as 11:

```
spi remote-address 172.100.3.200 spi-number 400 zone 11
```
ue-initiated-qos

Configures the HSGW behavior for UE initiated QoS requests.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration
configure > context context_name > hsgw-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hsgw-service)#

Syntax

[ default | no ] ue-initiated-qos

---

**default**

Returns the HSGW to the default behavior, where UE initiated QoS requests are accepted and forwarded to the PCRF via Gxa interface.

---

**no**

Enables rejection of UE initiated QoS request for dedicated bearer in HSGW service. HSGW does not forward the request to the PCRF over Gxa and instead rejects the UE initiated QoS immediately.

---

Usage

Use this command to enable or disable support for UE initiated QoS functionality.
By default, UE initiated QoS requests are accepted and forwarded to the PCRF via Gxa interface. If PCRF rejects the UE initiated QoS, UE request is rejected.
This command allows rejection of UE initiated QoS request for dedicated bearer in HSGW service. HSGW does not forward the request to the PCRF over Gxa and instead rejects the UE initiated QoS immediately.

---

Example

The following command rejects UE-initiated QoS request for dedicated bearer in HSGW service:

no ue-initiated-qos
**unauthorized-flows**

Configures the service to wait a specified number of seconds before triggering a QoS update to downgrade an unauthorized flow.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration

```
configure > context context_name > hsgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hsgw-service)#
```

**Syntax**

```
unauthorized-flows qos-update wait-timeout seconds
```

[ default | no ] unauthorized-flows qos-update wait-timeout

---

**default**
Returns the command to its default setting.

**no**
Removes the configure wait-timeout setting for this service.

**qos-update wait-timeout seconds**
Specifies the number of seconds to wait before triggering the QoS update to downgrade the unauthorized flow as an integer from 1 through 65534.

**Usage**
Use this command to specify a wait timeout trigger for flows that are unauthorized by policy rules received via the Gxa interface from the PCRF. When the wit timer expires, the HSGW triggers a QoS update to downgrade the unauthorized flow.

**Example**

The following command configures the HSGW service to apply the wait time of 30 seconds after receiving an flow unauthorized by the PCRF:

```
unauthorized-flow qos-update wait-timeout 30
```
Chapter 162
HSGW Service RoHC Configuration Mode Commands

The HSGW Service RoHC Configuration Mode is used to configure Robust Header Compression (RoHC) parameters for the service.

**Mode**

Exec > Global Configuration > Context Configuration > HSGW Service Configuration > HSGW Service RoHC Configuration

```bash
configure > context context_name > hsgw-service service_name > ip header-compression rohc
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ip-header-compression-rohc)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
cid-mode

This mode allows you to configure options that apply during RoHC compression for the service.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration > HSGW Service RoHC Configuration

`configure > context context_name > hsgw-service service_name > ip header-compression rohc`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ip-header-compression-rohc)#
```

Syntax

```
cid-mode { large | small } max-cid integer
```

**default cid-mode**

- **default**
  Reset all options in the RoHC Profile Compression Configuration mode to their default values.

- **large**
  Use large packets with optional information for RoHC

- **small**
  This is the default packet size.
  Use small RoHC packets.

- **max-cid integer**
  Specifies the highest context ID number to be used by the compressor as an integer from 0 through 15 when small packet size is selected, and 0 through 31 when large packet size is selected. Default: 15

Usage

Use this command to set the RoHC packet size and define the maximum

Example

The following command sets large RoHC packet size and sets the maximum CID to 100:

```
cid-mode large max-cid 100
```

The following command sets the cid-mode to the default settings of small packets and max-cid 0:

```
default cid-mode
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
mrru

Specifies the size of the largest reconstructed reception unit that the decompressor is expected to reassemble from segments. The size includes the CRC. If maximum received reconstructed unit (MRRU) is negotiated to be 0, no segment headers are allowed on the channel.

**Product**
HSGW

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSGW Service Configuration > HSGW Service RoHC Configuration

`configure > context context_name > hsgw-service service_name > ip header-compression rohc`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ip-header-compression-rohc)#
```

**Syntax**

```
mrru num_octets

default mrru
```

**default mrru**

```
default
Reset the value of this command to its default setting of 0.
```

```
num_octets
Specifies the number of allowed octets for the MRRU as an integer from 0 through 65535. Default: 0
```

**Usage**

Use this command to set the size, in octets, of the largest reconstructed reception unit that the decompressor is expected to reassemble from segments.

**Example**

The following command sets the largest reconstructed reception unit to 1024 octets:

```
mrru 1024
```

The following command resets the MRRU size to its default of 0 octets:

```
default mrru
```
profile

Specifies the header compression profiles to use. A header compression profile is a specification of how to compress the headers of a specific kind of packet stream over a specific kind of link. At least one profile must be specified.

Product
HSGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSGW Service Configuration > HSGW Service RoHC Configuration

configure > context context_name > hsgw-service service_name > ip header-compression rohc

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ip-header-compression-rohc)#

Syntax

profile { [ esp-ip ] [ rtp-udp ] [ udp-ip ] [ uncompressed-ip ] }

default profile

  default
  Default: esp-ip rtp-udp udp-ip uncompressed-ip
  Returns the RoHC profile configuration to its default setting.

  esp-ip
  Enables RoHC Profile 0x0003 which is for ESP/IP compression, compression of the header chain up to and including the first ESP header, but not subsequent subheaders.

  rtp-udp
  Enables RoHC Profile 0x0001 which is for RTP/UDP/IP compression

  udp-ip
  Enables RoHC Profile 0x0002 which is for UDP/IP compression; compression of the first 12 octets of the UDP payload is not attempted.

  uncompressed-ip
  Enables RoHC Profile 0x0000 which is for sending uncompressed IP packets.

Usage

Use this command to specify the RoHC header compression profiles.

Example

The following command sets the profiles to use as esp-ip and rtp-udp:
profile esp-ip rtp-udp
Chapter 163
HLR Configuration Mode Commands

The HLR Configuration Mode provides the commands and parameters to configure the home location register (HLR) node that is the database containing the subscriber profile and connection information for a specific GPRS/UMTS core network.

The HLR Configuration Mode is a sub-mode derived from the MAP Configuration Mode which controls the MAP service configuration. It is the MAP service that provides the application-layer protocol support used to connect the HLR to other nodes in the network such as the SGSN.

Mode

Exec > Global Configuration > Context Configuration > MAP Service Configuration > HLR Configuration

configure > context context_name > map-service service_name > hlr

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-map-service-service_name-hlr)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
acn-version-retention

This command configures the ACN version retention method.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > MAP Service Configuration > HLR Configuration

```config > context context_name > map-service service_name > hlr```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-map-service-service_name-hlr)#
```

**Syntax**

```acn-version-retention { per-imsi-prefix | per-subscriber }
```

**default acn-version-retention**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Returns the configuration to the default value: retains the version information per IMSI prefix.</td>
</tr>
<tr>
<td>per-imsi-prefix</td>
<td>Retain ACN version information, for communication with the HLR, on a per IMSI prefix basis.</td>
</tr>
<tr>
<td>per-subscriber</td>
<td>Retain ACN version information, for communication with the HLR, on a per buscriber basis.</td>
</tr>
</tbody>
</table>

**Usage**
By default, the SGSN sends ACN version 3 SAI (service area identity) to the HLR. If the SGSN receives an error message indicating that the HLR does not support that version, then the SGSN tries again with an ACN version 2 SAI. Next time the SGSN communicates with that HLR, it retains that version information and version persists based on the IMSI prefix.

Use this command to enable the SGSN to retain version according to subscriber.

**Example**

Configure the SGSN to retain version information according to the IMSI prefix:

```default acn-version-retention```
end

Exits the current configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the MAP Service configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Return to the MAP Service configuration mode.
**imsi**

This command sets up IMSI (International Mobile Subscriber Identity)-based configuration. The IMSI prefix includes the mobile country code (MCC) and the mobile network code (MNC).

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > MAP Service Configuration > HLR Configuration

configure > context context_name > map-service service_name > hlr

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-map-service-service_name-hlr)#
```

**Syntax**

```
[ no ] imsi { any | starts-with prefix_number } { imsi [ sgsn-source-address-format point-code-ssn [ source-ssn ssn ] | isdn isdn_number | mobile-global-title mgt_number [ max-gt-address-len max_gt_address ] | point-code pt-code ] }
```

- **no**
  Removes the imsi-prefix definition from the configuration.

- **any**
  Configures acceptance of any IMSI prefix.

- **starts-with prefix_number**
  Selects IMSI prefix-based routing.
  prefix_number is a string of up to 15 integers.

- **imsi**
  Enables configurable default behavior for routing.
  Entering imsi with the any keyword preserves the default behavior and the E.212 address is used as a destination address and the MAP request will be sent towards the HLR.
  If this keyword is not used with the any keyword, then the MAP request will be rejected.

- **isdn isdn_number**
  Defines the E.164 number of the HLR.
  isdn_number is a string of integers, up to 15.

- **mobile-global-title mgt_number [ max-gt-address-len max_gt_address_length ]**
  Defines the mobile global title address that the MCC/MNC portion of the IMSI will be converted to. If the maximum GT address length is specified (optional) and if the length of the MGT string is greater than defined, then the least significant digits will be omitted.
**mgt_number** is a string of digits, up to 18 digits in length.

**max_gt_address** is an integer from 1 to 32.

---

**point-code pt-code source-ssn ssn**

Defines the point code for the HLR.

*pt-code* is a string of digits, up to 11; SS7 format preferred.

---

**sgsn-source-address-format point-code-ssn**

Selects HLR call process according to SCCP calling party address of the SGSN. This will be filled at MAP level, including the ITU point code address.

---

**source-ssn ssn**

Defines the SSN of the source that will be used for the call filtering.

*ssn*: Must be an integer from 1 to 255.

---

**Usage**

Routing will be done according to IMSI parameters configured with this command or according to the mobile global title address (replacing the MCC/MNC portion of the IMSI) is so specified.

---

**Example**

```
imsi starts-with 3 isdn 123456789 sgsn-source-address-form at point-code-ssn
```
policy routing

This command configures the policy for the routing of MAP messages. If this command is not configured or disabled (with the default keyword), then routing is done according to the configuration of the IMSI parameters.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > MAP Service Configuration > HLR Configuration
configure > context context_name > map-service service_name > hlr

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-map-service-service_name-hlr)#
```

**Syntax**

```
policy routing { hlr-isdn | ms-isdn }
default policy routing
no policy routing
```

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Resets the policy routing to the system default, disabled.</td>
</tr>
<tr>
<td>no</td>
<td>Removes the policy routing configuration from the system.</td>
</tr>
<tr>
<td>hlr-isdn</td>
<td>Selects HLR-ISDN based routing.</td>
</tr>
<tr>
<td>ms-isdn</td>
<td>Selects mobile station (MS)-ISDN based routing.</td>
</tr>
</tbody>
</table>

**Usage**
Use this command to set the policy for routing MAP messages.

**Example**

```
policy routing hlr-isdn
```
release-compliance

Enables/disables the sending of EPS information in the Update GPRS Location Request message to the HLR.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > MAP Service Configuration > HLR Configuration

configure > context context_name > map-service service_name > hlr

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-map-service-service_name-hlr)#

Syntax

release-compliance release-8

no release-compliance

release-compliance release-8

Enables the sending of EPS information in the UGL Request message to the HLR. This setting sets the 3GPP release compliance to Release 8 and above.

no release-compliance

Disables the sending of EPS information in the UGL Request message to the HLR. This command sets the 3GPP release compliance setting to Pre-release 8. This is the default setting.

Usage

Use this command to enable or disable the sending of EPS information in the UGL Request message to the HLR.

Operators can use the show map-service all command to view the current 3GPP release compliance setting.

Example

This command enables the sending of EPS information in the UGL Request message to the HLR.

release-compliance release-8
Chapter 164
HNB-CS Network Configuration Mode Commands

The HNB-CS Network configuration mode provides the commands to create, provide, and manage the circuit switched (CS) network instance allowing the Home Evolved NodeB Gateway (HNB-GW) access with the CS core network in a 3G UMTS network.

Mode

Exec > Global Configuration > HNB-CS Network Configuration

configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
associate alcap-service

 Associates a previously defined Access Link Control Application Part (ALCAP) service with the CS network instance for multiplexing of different users onto one AAL2 transmission path using channel IDs (CIDs). This configuration is provided to support IuCS-over-ATM functionality

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-CS Network Configuration

`configure > cs-network cs_instance`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-cs-network-instance_id)#
```

**Syntax**

```
associate alcap-service svc_name context ctx_name

no associate alcap-service
```

**no**

Removes the associated ALCAP service from this HNB-CS network instance configuration.

**svc_name**

Identifies the name of the ALCAP service preconfigured in Context configuration mode to associate with an HNB-CS network instance for multiplexing of different users onto one AAL2 transmission path using channel IDs (CIDs).

**ctx_name** must be a preconfigured ALCAP service. Only one instance of this command can be configured.

⚠️ **Caution:** If this CLI is not configured any RAB-ASST-REQ requesting AAL2 connection setup shall be rejected with an appropriate cause.

**context ctx_name**

Specifies the name of the context in which ALCAP service is configured.

**ctx_name** must be an existing context name in which this ALCAP service is configured.

**Usage**

Use this command to configure IuCS-over-ATM support. This association of ALCAP protocol service configuration in HNB-CS network instance provides multiplexing of different users onto one AAL2 transmission path using channel IDs (CIDs).
**Caution:** If this CLI is not configured any RAB-ASST-REQ message requesting AAL2 connection setup shall be rejected with an appropriate cause.

**Important:** This command must not be used more than once to configure IuCS-over-ATM support.

Example

Following command associates ALCAP service `alcap_svc1` configured in context named `Ctx_alcap1` with specific HNB-CS network instance:

```
associate alcap-service alcap_svc1 context ctx_alcap1
```
associate rtp pool

Associates a previously defined RTP pool (IP pool) with the CS network instance to be used for assignment of IP address/port as RTP streams end point address over IuCS interface. This configuration support is provided for RTP stream management feature in an HNB-GW service.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-CS Network Configuration
configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

Syntax

associate rtp pool pool_name context ctx_name
no associate rtp pool

no

Removes the associated RTP pool (IP pool) from this HNB-CS network instance configuration.

pool_name

Identifies the name of the RTP IP pool preconfigured in Context configuration mode to associate with an HNB-CS network instance to be used for assignment of IP address/port over the IuCS interface RTP streams. pool_name must be an existing IP pool name configured in Context configuration mode.

**Important:** For IP pool (RTP pool) configuration, refer *Context Configuration Commands Mode* chapter.

context ctx_name

Specifies the name of the context in which RTP pool (IP pool) is configured. ctx_name must be an existing context name in which this IP pool is configured.

Usage

Use this command to associate RTP pool (IP Pool) with an HNB-CS network instance for allotment of IP address/port over IuCS interface for RTP streams across all sessions. A fixed range of RTP ports from 5000 through 65000 shall be used to allocate to RTP stream.

**Important:** This command must be used to provide IP address/port for RTP streams end point address over IuCS interface.
**Important:** This configuration support is provided for RTP stream management feature on an HNB-GW service.

**Example**

Following command associates RTP pool named `rtp_1` with specific HNB-CS network instance:

```plaintext
associate rtp pool rtp_1
```
associate sccp-network

Associates a predefined Signaling Connection Control Part (SCCP) network ID with the CS network instance in order to route the messages towards MSC/VLR over IuCS interface.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-CS Network Configuration

configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local] host_name(config-cs-network-instance_id)#

Syntax

associate-sccp-network sccp_net_id

no associate-sccp-network

---

no

Removes the associated SCCP network ID from this HNB-CS network instance configuration.

---

sccp_network_id

Identifies the predefined SCCP network ID to associate with an HNB-CS network instance over IuCS/IuFlex interface to enable connection with MSC/VLR(s).

sccp_network_id must be a predefined SCCP network ID in Global configuration mode.

---

Usage

Use this command to associate a preconfigured SCCP network ID over IuCS interface in HNB-GW service to connect with CS network elements; i.e. MSC.

---

Important: The SCCP network ID must be defined in Global Configuration mode before using it with this command.

---

Important: A single SCCP network configuration instance can not be shared with multiple HNB-CS network instances.

---

Example

Following command associates SCCP network 2 with specific HNB-CS network instance:

associate-sccp-network 2
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
**global-rnc-id**

Configures the Radio Network Concentrator (RNC) identifier in a Radio Network PLMN associated with HNB-CS network configuration instance. The RNC identifier is provided to the HNB during HNB-REGISTRATION.

**Product**

HNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > HNB-CS Network Configuration

configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

**Syntax**

```
[ no ] global-rnc-id mcc mcc_num mnc mnc_num id rnc_id
```

- **no**
  
  Deletes the RNC, MMC, and MNC information from the HNB-CS Network configuration instance.

- **mcc mcc_num**
  
  Specifies the mobile country code (MCC) part of radio network PLMN identifier as an integer value from 100 through 999.

- **mnc mnc_num**
  
  Specifies the mobile network code (MNC) part of radio network PLMN identifier as a 2- or 3-digit integer from 00 through 999.

**Usage**

Use this command to configure RNC id to associate Radio Network PLMN which will be sent to HNBs from HNB-GW during HNB-REGISTRATION procedure. Depending upon the requirement the RNC Identifier can be provided at the desired granularity.

**Example**

The following command configures the HNB-GW service to return an RNC identifier as 102 when an HNB-REGISTRATION request is received with LAC 1, and RAC 2:

```
  global rnc-id mcc 102 mnc 02 id 2
```
map core-network-id

Maps/associates the CS core network id to a default Mobile Switching Center (MSC) in network using MSC point code in HNB-CS network to allow HNBs to access UMTS network.

**Product**

HNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > HNB-CS Network Configuration

configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

**Syntax**

map core-network-id cn_id point-code msc_point_code

no map core-network-id cn_id

**no**

Removes the mapping of a CS core network id with particular MSC point code.

**cn_id**

Specifies the core network identifier configured to represent a UMTS CS core network as an integer from 0 through 4095.

Multiple instance of this command can be mapped with different MSC point code.

**point-code msc_point_code**

Specifies the SS7 address of the default MSC in the CS network in point code value to a configured HNB-CS network instance.

*point_code* is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ####### format.

Only one instance of this MSC point code can be mapped with one CS core network id.

**Usage**

Use this command to map a UMTS CS core network identifier with a particular MSC point code. This command can be entered multiple times with same MSC point code to map with one or more CS core network Id, but a particular core network identifier can be mapped to one MSC only.

This command is instrumental in Iu-Flex functionality, whenever HNB-GW receives RESET/RESET-RES messages from MSC with Global CN-ID information element, the response from HNB-GW is sent to the node configured for that particular Global CN-ID.

If the RESET/RESET-RES messages do not have Global CN-ID IE, then the response of those messages is directed to the default MSC which is configured using *msc point-code* command in this mode.

**Example**

The following command configures the CS core network identifier 101 with an MSC point code 1.2.3:
The following command configures the CS core network identifier 102 with the same MSC point code 1.2.3:

```bash
map core-network-id 102 point-code 1.2.3
```
map idnns

Configures the mapping of Intra-Domain NAS Node Selector (IDNNS) IE received from UE in RUA connect message towards HNB-GW to MSC point code. This is an important configuration for CS network resource sharing over Iu-Flex interface.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-CS Network Configuration

```
configure > cs-network cs_instance
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-cs-network-instance_instance_id)#
```

**Syntax**

```
map idnns range idnns_start to idnns_end point-code msc_point_code [ backup point-code bkup_msc_point_code]
no map idnns range idnns_start to idnns_end
```

`no`

Removes the entries of mapping of range of IDNNS received from UE with particular MSC point code.

```
range idnns_start to idnns_end
```

Specifies the range of IDNNS received from the UE to map with a particular MSC point code during initial CS core network node selection.

- `idnns_start` is an integer from 0 through 1023 that should be less than `idnns_end`.
- `idnns_end` must be an integer from 0 through 1023 that should be more than `idnns_start`.

The command can be entered more than once to map multiple IDNNS ranges to the same MSC, but overlapping and mapping of the same range to different MSC point codes is not allowed.

```
point-code msc_point_code
```

Specifies the SS7 address of the MSC in the CS network to map with a range of IDNNS values.

- `msc_point_code` is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ####### format.

```
backup point-code bkup_msc_point_code
```

Specifies the SS7 address of the MSC to be used as a backup in the CS network to map with a range of IDNNS values.

- `bkup_msc_point_code` is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ####### format.
Usage

Use this command to map a NRI received from UE during initial CS network node selection to MSC point code through NRI range mapping over Iu-Flex interface.

The IDNNS refers to the information element in RUA connect message from UE towards RAN (HNB-GW).

In IDNNS IE, if the choice of routing mentioned is other than local P-TMSI, then the value it provides is used against this configuration to map the MSC point code.

If backup MSC point-code is specified, then specified MSC works as backup for the IDNS range configured.

This Backup MSC is selected if the mapped MSC for a given IDNNS range is going for offloading using `offload-msc point-code` command.

The command can be entered more than once to map multiple IDNNS ranges to same MSC point code, but overlapping and mapping of same range to different MSC point code is not allowed.

Example

The following command maps the IDNNS range from 101 to 201 with MSC point code 1.2.3 and point code 7.8.9 as backup MSC point code:

```
map nri range 101 to 201 point-code 1.2.3 backup point-code 7.8.9
```

The following command removes all IDNNS range matching entries between 301 to 399 from the configuration:

```
no map idnns range 301 to 399
```
map lac

Configures the mapping of the Location Area Code (LAC) received from UE to an MSC point code. This is an important configuration for CS network resource sharing without Iu-Flex interface configuration.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-CS Network Configuration

configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

Syntax

map lac range lac_start to lac_end point-code msc_point_code

no map lac range lac_start to lac_end

go

Removes the entries of mapping of range of LACs received from UE with particular MSC point code.

range lac_start to lac_end

Specifies the range of LACs received from UE to map with particular MSC point code during initial CS core network node selection.

lac_start is an integer from 0 through 65535 that should be less than lac_end.
lac_end is an integer from 0 through 65535 that should be more than lac_start.
The command can be entered more than once to map multiple LAC ranges to same MSC, but overlapping is not allowed.

point-code msc_point_code

Specifies the SS7 address of the MSC in the CS network to map with a range of LAC values.

point_code is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ####### format.

Usage

Use this command to map a LAC, received from UE during HNB registration, for MSC selection over Iu-CS interface through LAC range mapping with MSC point code.
This configuration is used during initial CS core network node selection when the LAC from the UE is available. This configuration is used when the core network is not using Iu-Flex interface for MSC selection.
The command can be entered more than once to map multiple LAC ranges to same MSC point code.
**Important:** This command can be used together with Iu-Flex configuration, but MSC selection based on LAC takes place only if Iu-Flex is not configured. If both Iu-Flex and LAC are configured then selection of MSC is based on Iu-Flex configuration only.

**Example**

The following command maps the LAC range from 20 to 50 with MSC point code 1.2.3:

```
map lac range 20 to 50 point-code 1.2.3
```

The following command removes all LAC range matching entries between 20 to 50 from the configuration:

```
no map lac range 20 to 50
```
map nri

Configures the mapping of Network Resource Identifier (NRI) sent from UE to the MSC point code. This is an important configuration for CS network resource sharing over Iu-Flex interface.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-CS Network Configuration
configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

Syntax

map nri range nri_start to nri_end point-code msc_point_code

no map nri range nri_start to nri_end

no

Removes the entries of mapping of range of NRIs received from UE with particular MSC point code.

range nri_start to nri_end

Specifies the range of NRIs received from UE to map with particular MSC point code during initial CS core network node selection.

nri_start is an integer from 0 through 1023 that should be less than nri_end.
nri_end is an integer from 0 through 1023 that should be more than nri_start.

The command can be entered more than once to map multiple NRI ranges to same MSC, but overlapping is not allowed.

point-code msc_point_code

Specifies the SS7 address of the MSC in the CS network to map with a range of NRI values.

point_code is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ####### format.

Usage

Use this command to map a NRI received from UE during initial CS network node selection to MSC point code through NRI range mapping over Iu-Flex interface.

This configuration is used during initial CS core network node selection when the network resource identifier (NRI) from the UE is available. The NRI range is mapped to MSC point code. This configuration is used when the core network uses Iu-Flex interface.

The command can be entered more than once to map multiple NRI ranges to same MSC point code.

It is possible to configure multiple ranges to more than one MSC however this configuration is required only when the CS core network is configured as Multi-Operator Core Network (MOCN).
When the CS core network is not MOCN and one range is mapped to more than one MSC then MSC is selected randomly in a non-predictable manner.

**Example**

The following command maps the NRI range from 101 to 201 with MSC point code 1.2.3:

```
map nri range 101 to 201 point-code 1.2.3
```

The following command maps the NRI range from 301 to 399 with MSC point code 1.2.3:

```
map nri range 301 to 399 point-code 1.2.3
```

The following command removes all NRI range matching entries between 301 to 399 from the configuration:

```
no map nri range 301 to 399
```
**msc deadtime**

Configures a timer on the HNB-GW to manage MSC availability in a CS core network on receiving of a PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from an SCCP instance.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-CS Network Configuration

```bash
configure > cs-network cs_instance
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-cs-network-instance_id)#
```

**Syntax**

```bash
msc deadtime { immediate | dur }
```

```bash
[ no | default ] msc deadtime
```

---

**no**
Marks the peer node (MSC) as always available; it can never be marked down for a specific HNB-CS network instance.

---

**default**
Sets the default action for HNB-GW and provisions it as such that the peer node (MSC) is marked down as soon as HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP in a specific HNB-CS network instance. Default: Enabled

---

**immediate**
Sets the HNB-GW to mark the peer node (MSC) down immediately and clears all Iu-CS connections towards the MSC. Default: Disabled

---

**dur**
Sets the duration (in seconds) for a timer that starts when the HNB-GW receives a PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer MSC. On expiry of this timer the peer MSC is marked as dead and all Iu-CS connections towards that MSC are released.

dur is an integer from 1 through 30.
Only one instance of this command can be configured.

**Usage**
This command is used to configure a timer on HNB-GW to manage MSC availability in a CS core network on receiving of PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP. This configuration plays important role during RANAP reset procedure as well.
Timer value sets the duration in seconds for a timer which started once HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer MSC. On expiry of this timer the peer MSC is marked as dead and all Iu-CS connections towards that MSC shall be released.

**Important:** This command can be entered only once. Reentering this command overwrites the previous parameters.

**Example**

The following command configures the deadtime timer value for 10 seconds on HNB-GW. Once HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer MSC the HNB-GW waits for configured period and on expiry of timer it marks the specific MSC as dead:

```
msc deadtime 10
```
**msc point-code**

Configures the default MSC point-code within an HNB-CS network instance. This command is used when HNB-GW is to be connected to only one MSC with in a CS network or as default MSC for all HNBs connected through specific HNB-CS network instance.

**Product**

HNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > HNB-CS Network Configuration

`configure > cs-network cs_instance`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-cs-network-instance_id)#
```

**Syntax**

```
[ no ] msc point-code point_code
```

- **no**
  
  Removes the configured default MSC point code from a specific HNB-CS network instance.

**Caution:** Removing the MSC point code is a disruptive operation and affects all HNB sessions which are connected to particular MSC through an HNB-CS network instance.

```
msc point_code
```

Specifies the SS7 address of the default MSC in the CS network to this configured HNB-CS network instance.

*point_code* is an SS7 point code in dotted-decimal ####.#### or 8-digit decimal ####### format.

Only one instance of this command can be configured.

**Usage**

Use this command to configure a default MSC to which HNB connects for CS network access through HNB-GW service.

Point-code is an SS7 address for an element in the SS7 network. Point-codes must be defined in dotted-decimal format in a string of 1 to 11 digits. Format options include:

- 0.0.1 to 7.255.7 for point-code in the ITU range.
- 0.0.1 to 255.255.255 for point-code in the ANSI range.
- 0.0.1 to 15.31.255 for point-code in the TTC Range.
- a string of 1 to 11 digits in dotted-decimal to represent a point-code in a different range.
**Important:** This command can be entered only once. If entered again the previous value shall be overwritten.

**Example**

The following command configures a default MSC with point code `101.201.101` for HNBs to access CS network through HNB-GW service in this HNB-CS network instance:

```
msc point-code 101.201.101
```
nri length

Configures the network resource identifier (NRI) length in bits to identify a specific MSC serving in a pooled area. At least one NRI value has to be assigned to an MSC serving in a pool. The NRI is coded inside of the temporary mobile subscriber identity (TMSI), located within bits 14 to 23 with a variable length between 0 and 10 bits. Operator needs to set this NRI length to indicate the number of bits that shall be used for the NRI field to set the parameters for Iu-Flex (MSC pooling) functionality.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-CS Network Configuration
configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

Syntax

nri length nri_value

default nri length

default

Sets the NRI length to the default value of 0 and disables the Iu-Flex (MSC pooling) functionality.

Usage

Use this command to enable the Iu-Flex functionality on HNB-GW. This command identifies a unique MSC serving a pooled area for Iu-Flex functionality and at least one NRI value has to be assigned to an MSC serving in a pool. It performs MSC pooling/offloading scenario over Iu-Flex interface. The NRI is stored in the bits 14 to 23 of TMSI. The HNB-GW uses a portion of this NRI to set the parameters for Iu-Flex (MSC pooling) functionality.

If more than one NRI is configured, the HNB-GW service does round-robin between the available NRIs when new subscriber(s) (re)connect.

This command must be used in conjunction with null nri command to configure MSC pooling/offloading over Iu-Flex interface.

Example
The following command sets the HNB-GW to a bit length of 6 to derive the values from the NRI field (stored in bits 14 to 23 of TMSI) to set the parameters for Lu-Flex (MSC pooling) functionality:

```
nri length 6
```
null-nri

Configures the null NRI for load redistribution in support of Iu-Flex functionality. The NRI value defined with this command must be unique across the pool areas. This null-NRI is used by HNB-GW for load redistribution during MSC offloading.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-CS Network Configuration

```
configure > cs-network cs_instance
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-cs-network-instance_id)#
```

Syntax

```
null-nri null_nri_value
no null-nri null_nri_value
```

**null-nri null_nri_value**

Specifies the null-NRI value to be used by HNB-GW for load re-distribution during MSC offloading as an integer from 0 through 1023.

Without MOCN configuration this value can be entered only once.

For MOCN a unique null-NRI must be assigned to each MOCN operator identified by its PLMN-ID (MCC+MNC).

A 0 (zero) value configured as a null-NRI indicates the keyword is not to be used. There is no default value for this parameter.

**Usage**

Use this command to identify the MSC to be used by HNB-GW for load redistribution during MSC offloading over an Iu-Flex interface.

There is one unique null-NRI in a PLMN supporting pool functionality.

Without MOCN configuration this command can be entered only once. For MOCN a unique null-NRI must be assigned to each MOCN operator identified by its PLMN-ID (MCC+MNC).

**Example**

The following command sets the null-NRI as 1001 to be used by HNB-GW for load redistribution during MSC offloading:

```
null-nri 1001
```
offload-msc

Provisions the HNB-GW to enable or disable the exclusion of a particular primary MSC node during an NAS Node Selection Function (NNSF) procedure when it needs to be offloaded while using Iu-Flex functionality on the HNB-GW.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-CS Network Configuration
configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

Syntax

[ no ] offload-msc point-code msc_point_code

no

Removes the specified primary MSC point code from the exclusion list for NNSF function on HNB-GW and re-enables the inclusion of the primary MSC to be considered by HNB-GW.

point-code msc_point_code

Specifies the SS7 address of the primary MSC in the CS network to be excluded for NNSF function on HNB-GW when it needs to be offloaded via Iu-Flex functionality.

point_code is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ####### format. Only one instance of this primary MSC point code can be mapped with one CS core network id.

Usage

Use this command to provision the HNB-GW to enable or disable the exclusion of the primary MSC node when it needs to be offloaded.

When this command is enabled for exclusion of primary MSC node during NNSF function in HNB-GW, the HNB-GW excludes the particular node from being considered.

User can re-enable the inclusion of the primary MSC node to be considered for NNSF functionality by no offload-msc point-code command.

Important: Offload check is only for the primary point code and NOT for the backup point code.

Example

This command can be used for planned maintenance as well.

The following command configures the HNB-GW to exclude the primary MSC point code 1.2.3 from being considered in NSSF function for Iu-Flex support:

offload-msc point-code 1.2.3
The following command re-enables the inclusion of MSC point code 1.2.3 from being considered in NSSF function for Iu-Flex support:

```
no offload-msc point-code 1.2.3
```
ranap reset

Configures various Radio Access Network (RAN) Application Part reset procedure parameters for CS network association in an HNB access network.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-CS Network Configuration
  configure > cs-network cs_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-cs-network-instance_id)#

Syntax

ranap reset { ack-timeout timer_value | guard-timeout g_timer | hnbgw-initiated | max-retransmissions retries }

default ranap reset { ack-timeout | guard-timeout | hnbgw-initiated | max-retransmissions }

no ranap { hnbgw-initiated

---

default

Resets the RANAP RESET parameters in HNB-CS Network configuration instance.

---

no

Disables the RANAP RESET procedure related parameters in an HNB-CS Network configuration instance.

---

ack-timeout timer_value

Sets the timer value (in seconds) to wait for Reset Acknowledge from MSC. This is used during HNB-GW initiated RANAP RESET procedure in HNB-CS Network configuration instance.

*timer_value* is an integer value from 5 through 10. Default: 10

---

guard-timeout g_timer_value

Sets the timer value (in seconds) to send Reset Acknowledge to MSC. After this duration the HNB-GW sends RESET-ACK to MSC. This is used during MSC initiated RANAP RESET procedure in HNB-CS Network configuration instance.

*g_timer_value* is an integer value from 5 through 10. Default: 10

---

hnbgw-initiated

Enables the HNB-GW Initiated RANAP RESET procedures. Default: Disabled
max-retransmission retries

Sets the maximum number of retries allowed for transmission of RESET-ACK message to MSC. This is used during RANAP RESET procedure in HNB-CS Network configuration instance. retries is an integer value from 0 through 2. When 0 is used retransmission is disabled. Default: 1

use-actual-plmn

Actual PLMN will be sent in RANAP Reset/Reset Resource. By default, Common PLMN will be sent.

Usage

Use this command to configure the RANAP RESET procedure related parameters in HNB-CS Network configuration for multiple HNB-GW service support.

Example

The following command configures the HNB-GW initiated RANAP RESET Procedure for an HNB-CS Network configuration instance:

```
ranap reset hnbgw-initiated
```
Chapter 165
HNB-GW Global Configuration Mode Commands

The 3G UMTS Home-NodeB Gateway Global Configuration Mode provides the global configurations for multiple HNB-GW services on a chassis to manage the access to the UMTS core network in a 3G UMTS network through a Femto node. This configuration mode is supported from StarOS 14.0 onward.

Mode

Exec > Global Configuration > HNB-GW Global Configuration

```
configure > hnbGW-global
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnggw-global)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**access-control-db**

Configures the access control database parameters in HNB-GW Global configuration mode to control HNB and UE access to the HNB-GW node.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-GW Global Configuration

```
configure > hnb-gw-global
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-hnbgw-global)#
```

**Syntax**

```
access-control-db imsi-purge-timeout { immediate | dur }
```

```
default access-control-db imsi-purge-timeout
```

**default**

Sets the default value to HNB-UE access control database on a chassis for HNB-GW Global configuration instance.

The default timeout duration for purging the IMSI White List from the HNB-GW Access Control database is 24 hours. The HNB-GW service waits for 24 hours after all referenced HNBs have de-registered before purging the records.

**immediate**

Sets the HNB-GW Global configuration instance to purge the HNB-UE access control database immediately after all referenced HNBs have de-registered.

**imsi-purge-timeout dur**

Sets the timeout duration (in minutes) for the access control database to wait before purging the IMSI values received as a White List from HMS/BAC.

After all HNBs have de-registered, the Access Control database on HNB-GW maintains the IMSI White List received from HMS/BAC during HNB registration procedure for the configured durations before purging the list.

**dur** is an integer from 1 through 1440.

**Usage**

Use this command to configure the HNB-UE access control database parameters on a chassis for HNB-GW Global configuration instance.

This command sets the timeout duration to maintain the IMSI White List received from HMS/BAC during HNB registration procedure in HNB-GW Global configuration instance for the configured **dur** in minutes after de-registration of all referenced HNBs from HNB-GW node and then purge the database.
Example

Following command sets the HNB-GW Global configuration instance to purge all IMSI records from HNB-UE access control database immediately after all referenced HNBs de-registered from HNB-GW service instance.

```
access-control-db imsi-purge-timeout immediate
```
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Use this command to return to the parent configuration mode.
paging hybrid-hnb

Configures paging optimization parameters for hybrid HNBs connected through Hybrid Access mode in the HNB-GW Global parameter.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-GW Global Configuration

```bash
configure > hnbgw-global
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnggw-global)#
```

**Syntax**

```bash
paging hybrid-hnb always

paging hybrid-hnb hnb-where-ue-registered [hnbs-having-imsi-in-whitelist] fallback {always | never |only-if-with-paging-area}

paging hybrid-hnb hnbs-having-imsi-in-whitelist fallback {always | never |only-if-with-paging-area}

paging hybrid-hnb never

paging hybrid-hnb only-if-with-paging-area

default paging hybrid-hnb
```

```bash
default
```

Sets the default behavior of paging optimization configuration for a hybrid HNB while using Hybrid Access mode support.

By default the HNB-GW pages hybrid HNBs only if paging-area IE is received in the paging message.

```bash
{always | never | only-if-with-paging-area}
```

Sets the HNB-GW Global parameter to page hybrid HNB for a paging message.

- **always**: Sets the system to ALWAYS page the hybrid HNBs irrespective of `paging-area` IE is received in paging messages.
- **never**: Sets the system to NEVER page any hybrid HNB.
- **only-if-with-paging-area**: Sets the system to page the hybrid HNBs only when `paging-area` IE is received in paging messages.

```bash
hnb-where-ue-registered fallback {always | never |only-if-with-paging-area}
```

Sets the HNB-GW Global parameter to page hybrid HNB from where the UE is registered.
always: Sets the system to ALWAYS page the hybrid HNBs from where the UE is registered. If the UE is not registered then it pages the hybrid HNBs irrespective of `paging-area` IE is received in paging messages.

never: Sets the system to page the hybrid HNBs from where the UE is registered. If the UE is not registered then it NEVER pages any hybrid HNB.

only-if-with-paging-area: Sets the system to ALWAYS page the hybrid HNBs from where the UE is registered. If the UE is not registered then it pages the hybrid HNBs only when `paging-area` IE is received in paging messages.

hnbs-having-imsi-in-whitelist fallback {always | never | only-if-with-paging-area}

Sets the HNB-GW Global parameter to page hybrid HNB where HNB have IMSI in white-list.

always: Sets the system to ALWAYS page Hybrid HNB which have requested IMSI in whitelist. If no such Hybrid HNB is found, then system will page Hybrid HNBs irrespective of presence or absence of `paging-area` IE in paging messages.

never: Sets the system to ALWAYS page Hybrid HNB which have requested IMSI in whitelist. If no such Hybrid HNB is found, then system will NEVER page Hybrid HNBs irrespective of presence or absence of `paging-area` IE in paging messages.

only-if-with-paging-area: Sets the system to ALWAYS page Hybrid HNB which have requested IMSI in whitelist. If no such Hybrid HNB is found, then system will page hybrid HNB only when `paging-area` IE is found in paging messages.

Usage

Use this command to configure the paging optimization parameters for hybrid HNBs connected through Hybrid Access mode in HNB-GW Global parameter.

Example

The following command configures the HNB-GW Global parameter to page an hybrid HNB from where the UE is registered and `paging-area` IE is received in paging message:

```
  paging hybrid-hnb hnb-where-ue-registered fallback only-if-with-paging-area
```
paging open-hnb

Configures paging optimization parameters for open HNBs connected through Hybrid Access mode in the HNB-GW Global parameter.

> **Important:** This command is deprecated from release 16.0.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-GW Global Configuration

```
configure > hnb-gw-global
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnggw-global)#
```

**Syntax**

```
paging open-hnb [hnb-where-ue-registered fallback] {always | never | only-if-with-paging-area}
default paging open-hnb
```

**default**

Sets the default behavior of paging optimization configuration for an open HNB while using Open Access mode support.
By default the HNB-GW pages open HNBs only if paging-area IE is received in the paging message.

```
{always | never | only-if-with-paging-area}
```

Sets the HNB-GW Global configuration instance to page open HNB for a paging message.
```
always: Sets the system to ALWAYS page the open HNBs irrespective of paging-area IE is received in paging messages.
never: Sets the system to NEVER page any open HNB.
only-if-with-paging-area: Sets the system to page the open HNBs only when paging-area IE is received in paging messages.
```

```
hnb-where-ue-registered fallback {always | never | only-if-with-paging-area}
```

Sets the HNB-GW Global configuration instance to page open HNB from where the UE is registered.
```
always: Sets the system to ALWAYS page the open HNBs from where the UE is registered. If the UE is not registered then it pages the open HNBs irrespective of paging-area IE is received in paging messages.
never: Sets the system to page the open HNBs from where the UE is registered. If the UE is not registered then it NEVER pages any open HNB.
only-if-with-paging-area: Sets the system to ALWAYS page the open HNBs from where the UE is registered. If the UE is not registered then it pages the open HNBs only when paging-area IE is received in paging messages.
Usage

Use this command to configure the paging optimization parameters for open HNBs connected through Open Access mode in HNB-GW Global configuration instance.

Example

The following command configures the HNB-GW Global configuration instance to page an open HNB from where the UE is registered and paging-area IE is received in paging message:

```
paging open-hnb hnb-where-ue-registered fallback only-if-with-paging-area
```
sctp

Configures the SCTP-related parameters like timeout duration for various timers and cookie life over an IuH interface on a chassis for HNB-GW Global configuration instance.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-GW Global Configuration

configure > hnbgw-global

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnggw-global)#

Syntax

sctp { alpha-rto alpha_rto_dur | beta-rto beta_rto_dur | max-in-strms in_strms | max-out-strms out_strms | max-retx { assoc | init | path } max_retry }

default sctp { alpha-rto | beta-rto | max-in-strms | max-out-strms | max-retx { assoc | init | path } }

default

Restores the SCTP parameters to default value in HNB-GW Global configuration instance. Default values for all parameters are as follows:

• alpha-rto: 5 seconds
• beta-rto: 10 seconds
• max-in-strms: 4
• max-out-strms: 4
• max-retx assoc: 10 retries
• max-retx init: 5 retries
• max-retx path: 5 retries

alpha-rto alpha_rto_dur

Sets the alpha retransmission timeout duration (in seconds) for SCTP association between HNB and HNB-GW as an integer from 0 through 65535. A “zero” value disables the timer in this configuration. Default: 5

beta-rto beta_rto_dur

Sets the beta retransmission timeout duration (in seconds) for SCTP association between HNB and HNB-GW as an integer from 0 through 65535. A “zero” value disables the timer in this configuration. Default: 10
max-retx { assoc | init | path } max_retry

Sets the maximum number of retries allowed in SCTP states for SCTP association between HNB and HNB-GW.

- **assoc**: Sets the maximum number of consecutive retransmissions to its peer is allowed. If the value of this counter exceeds the limit configured with this keyword the HNB-GW considers the peer HNB unreachable and stop transmitting any more data to it. The SCTP association is automatically closed when the peer endpoint becomes unreachable. Default number of attempts max_retry for this state is 10.
- **init**: Sets the maximum attempts allowed after T1-init timer expires. If the T1-init timer expires then the HNB-GW retransmits INIT chunk and re-start the T1-init timer without changing state. This is repeated up to the configured times with this configuration. After that, the HNB-GW aborts the initialization process. Default number of attempts max_retry for this state is 5.
- **path**: Sets the maximum attempts allowed after T3-rtx timer expires. Each time the T3-rtx timer expires on any address, or when a HEARTBEAT sent to an idle address is not acknowledged within a RTO, the error counter of that destination address incremented. When the value in the error counter exceeds this protocol parameter of that HNB address, the HNB-GW marks the destination transport address as inactive. Default number of attempts max_retry for this state is 5.

- max_retry is an integer from 0 through 255.

max-in-strms in_strms

Sets the maximum number of inward SCTP streams allowed on HNB-GW for an associated HNB in an SCTP association as an integer from 1 through 16. Default: 4

max-out-strms out_strms

Sets the maximum number of outgoing SCTP streams allowed from HNB-GW for an associated HNB in an SCTP association as an integer from 1 through 16. Default: 4

**Usage**

Use this command to configure the SCTP protocol messaging and session management parameters in SCTP association between HNB and HNB-GW.

**Example**

The following command sets the maximum number of inward SCTP streams allowed to 4 on HNB-GW for the SCTP association:

default max-in-strms
**tnnsf-timer**

Configures the NAS Node Selection Function (NNSF) timer (T-NNSF) which is used by the HNB-GW to store the IMSI and the relevant Global-CN-ID in the short term after Paging. This timer is used for Iu-Flex feature support.

**Product**

HNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > HNB-GW Global Configuration

configure > hnbgw-global

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-hnbgw-global)#
```

**Syntax**

```
tnnsf-timer <dur>

[ no | default ] tnnsf-timer
```

**tnnsf-timer dur**

<table>
<thead>
<tr>
<th>no</th>
<th>Disables/removes the configured timer value of NNSF timer (T-NNSF) for HNB-GW Global configuration instance.</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Sets the timer value of NNSF timer (T-NNSF) for HNB-GW Global configuration instance to default value of 30 seconds.</td>
</tr>
</tbody>
</table>

```
tnnsf-timer <dur>
```

Configures the NNSF timer (in seconds) which is used by the HNB-GW to store the IMSI and the relevant Global-CN-ID as an integer from 10 through 60. Default: 30

**Usage**

Use this command to configure the NNSF timer value in seconds for Iu-Flex support. Whenever the MSC sends the paging request with IMSI, the HNB-GW stores the Global_CN_ID of the node which issued the paging request message for the given IMSI and HNB-GW starts the **tnnsf-timer**. HNB-GW stores the mapping of IMSI to Global_CN_ID until the **tnnsf-timer** expires.

**Example**

The following command sets the NNSF timer value to 30 seconds on a chassis for HNB-GW Global configuration instance:

```
default tnnsf-timer
```
The 3G UMTS Home-NodeB Gateway Service Configuration Mode manages access to the UMTS core network in a 3G UMTS network through a Femto node.

**Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration**

```bash
configure > context context_name > hnbgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbgw-service)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
access-control-db

Configures the access control database parameters in an HNB-GW service instance to control HNB and UE access to the HNB-GW node.

Platform
ASR 5000

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration
configure > context context_name > hnbw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbw-service)#

Syntax

access-control-db imsi-purge-timeout {immediate | dur }
default access-control-db imsi-purge-timeout

default
Sets the default value to HNB-UE access control database on HNB-GW service instance. The default timeout duration for purging of the IMSI White List from the HNB-GW Access Control database is 24 hours. The HNB-GW service waits for 24 hours after all referenced HNBs have de-registered before purging the records.

immediate
Sets the HNB-GW service to purge the HNB-UE access control database immediately after all referenced HNBs have de-registered.

imsi-purge-timeout dur
Sets the timeout duration (in minutes) for the access control database to wait before purging the IMSI values received as a White List from HMS/BAC. After all HNBs have de-registered, the Access Control database on HNB-GW maintains the IMSI White List received from HMS/BAC during HNB registration procedure for the configured durations before purging the list.

dur is an integer from 1 through 1440.

Usage
Use this command to configure the HNB-UE access control database parameters on HNB-GW service. This command sets the timeout duration to maintain the IMSI White List received from HMS/BAC during HNB registration procedure in HNB-GW service for the configured dur in minutes after de-registration of all referenced HNBs from HNB-GW node and then purge the database.
Example

Following command sets the HNB-GW service instance to purge all IMSI records from HNB-UE access control database immediately after all referenced HNBs de-registered from HNB-GW service instance.

```
access-control-db imsi-purge-timeout immediate
```
associate cbs-service

Associates a previously configured CBS service to bind the HNB-GW service with an HNB towards the HNB side. A CBS service must be configured in Context Configuration mode before using this configuration.

Platform
ASR 5000

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-service)#

Syntax

associate cbs-service svc_name

no associate cbs-service

no
Disables the cell broadcasting for all the connections/HNBs under this HNB-GW service.

svc_name
Identifies the name of the pre-configured CBS service to associate with an HNB-GW service towards the Home-NodeB side.

svc_name is an alphanumeric string of 1 through 63 characters.

Usage
Use this command to configure CBS service to HNB-GW service and Home-NodeB. The service defined for CBS can be configured in Context configuration mode.

Important: Multiple HNB-GW services can be used to bind to a CBS service at a time. A maximum of 16 HNB-GW services can be associated to a CBS service. For more information on CBS service configuration, refer CBS Service Configuration Mode Commands.

Example

Following command associates CBS service named cbs-hnb1 with specific HNB-GW service towards Home-NodeB side.

associate cbs-service cbs-hnb1
associate gtpu-service

Associates a previously configured GTP-U service to bind the HNB-GW service with an HNB towards the HNB side. A GTP-U service must be configured in Context Configuration mode before using this configuration.

Platform
ASR 5000

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-service)#

Syntax

associate gtpu-service svc_name

no associate gtpu-service

no

Removes the associated GTP-U service from this HNB-GW service configuration.

svc_name

Identifies the name of the pre-configured GTP-U service to associate with an HNB-GW service towards the Home-NodeB side.

svc_name is an alphanumeric string of 1 through 63 characters.

Usage

Use this command to configure GTP-U data plan between HNB-GW service and Home-NodeB. The service defined for GTP-U can be configured in Context configuration mode.

Important: Another GTP-U service can be used to bind the HNB-GW service towards the Core Network and can be configured in HNB-PS Configuration mode. For more information on GTP-U service configuration, refer GTP-U Service Configuration Mode Commands.

Example

Following command associates GTP-U service named gtpu-hnb1 with specific HNB-GW service towards Home-NodeB side.

associate gtpu-service gtpu-hnb1
**associate rtp pool**

Associates a previously defined RTP pool (IP pool) with the HNB-GW service. This pool is used by HNB-GW to send an IP address to HNB where HNB uses it to map the RTP streams over Iuh interface. This command is used for RTP stream management on HNB-GW.

**Platform**
ASR 5000

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

```
configure > context context_name > hnbgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-hnbgw-service)#
```

**Syntax**

```
associate rtp pool pool_name

no associate rtp pool

no
```

**no**
Removes the associated RTP pool (IP pool) from this HNB-GW service configuration.

```
pool_name
```

Specifies the name of the pre-configured RTP IP pool that the HNB-GW uses to assign IP addresses when mapping RTP streams over the Iuh interface.

`pool_name` is an alphanumeric string of 1 through 31 characters.

**Important:** For IP pool (RTP pool) configuration, refer `ip pool` command in *Context Configuration Mode Commands* chapter.

**Usage**

Use this command to associate an RTP pool (IP Pool) with an HNB-GW service for allotment of RTP IP address to HNB-GW node and send the same to HNB for RTP stream management support. The HNB maps the RTP streams with received IP address(es) while communicating with HNB-GW over Iuh interface where HNB-GW communicates with MSC/VLR through IuCS-over-IP tunnel.

This command is used for RTP stream management on HNB-GW.

**Important:** This command must be used to provide IP address for mapping of RTP streams on Iuh interface between HNB and HNB-GW.
Example

Following command associates RTP pool named _rtp_1 with HNB-GW service for RTP stream end point from Home-NodeB:

```
associate rtp pool rtp_1
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
end

**Usage**
Use this command to return to the Exec mode.
**exit**

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```bash
exit
```

**Usage**

Use this command to return to the parent configuration mode.
handin

Allows or disallows the incoming hand-over of an MS in HNB-GW via the Serving Radio Network Subsystem (SRNS) Relocation procedure for the specified packet switched/circuit switched (PS/CS) core network (CN) domain.

Platform
ASR 5000

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnbw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbw-service)#

Syntax
[no | default] handin cn-domain [cs | ps]

no
Disallows the incoming MS hand-over for the particular CN domain via SRNS Relocation procedure in an HNB-GW service instance.
If hand-over is restricted the relocation request will be rejected with rejection cause “Relocation Not Supported In Target RNC Or Target System”.

default
Sets the HNB-GW service instance to allow the incoming MS hand-over for the particular CN domain via SRNS Relocation procedure in an HNB-GW service instance.

cs
Sets the HNB-GW service instance to allow the incoming MS hand-over for the CS core network domain via SRNS Relocation procedure in an HNB-GW service instance.

ps
Sets the HNB-GW service instance to allow the incoming MS hand-over for the PS core network domain via SRNS Relocation procedure in an HNB-GW service instance.

Usage
Use this command to set HNB-GW service instance for allowing/disallowing incoming hand-over of an MS in HNB-GW via SRNS Relocation procedure for PS or CS core network domain.
If hand-over is restricted the Relocation Request message will be rejected with rejection cause “Relocation Not Supported In Target RNC Or Target System”.
Example

The following command configures the HNB-GW service instance to allow hand-over of an MS in HNB-W via SRNS Relocation procedure for PS core network domain:

```
handin ps
```
## hnb-access-mode hybrid

Configures the Hybrids HNB access mode in HNB-GW service instance and related parameters.

### Platform
- ASR 5000
- ASR 5500

### Product
- HNB-GW

### Privilege
- Security Administrator, Administrator

### Mode
- Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration
  ```
  configure > context context_name > hnbgw-service service_name
  ```
- Entering the above command sequence results in the following prompt:
  ```
  [local]host_name(config-hnbgw-service)#
  ```

### Syntax

```
  hnb-access-mode hybrid [ max-non-access-controlled-ue reg_ue_hyb ]
  [ no | default] hnb-access-mode hybrid
```

- **no**
  - Disables Hybrid Access mode support.
  - If disabled and a Hybrid HNB tries to register, the HNB-GW sends HNB-Registration-Reject message with “OAM Intervention” cause.

  **Important:** UE-Reg/CS-Call/PS-Call requests (both existing and future) is allowed from already registered Hybrid HNBs even after operator has disabled the Hybrid Access support. No new Hybrid HNB registration is allowed once operator disables the Hybrid Access support.

- **default**
  - Sets the default configuration of Hybrid Access mode support.
  - By default, HNB-GW allows registration of Hybrid HNBs and a maximum of 16 non-access-controlled UEs to register from a Hybrid HNB in an HNB-GW service instance.

- **max-non-access-controlled-ue reg_ue_hyb**
  - Sets the HNB-GW service instance to allow the maximum number of non-access-controlled UEs that can register from a Hybrid HNB under Hybrid Access mode support.
  - `reg_ue_hyb` defines the maximum number of UEs that can register from an Open HNB as an integer from 0 through 1000.
  - If a UE tries to register from a Hybrid HNB which has already reached to the limit configured, the HNB-GW sends HNB-Registration-Reject message with “ue not allowed in this hnb” cause in an HNB-GW service instance.
Value “0” disables the mode and refuses the any non-access-controlled UEs to register with a Hybrid HNB under Hybrid Access mode support. A maximum of 32 simultaneously registered non-access-controlled UEs from a Hybrid HNB is supported in this access-mode on HNB-GW.

Usage
Use this command to configure the HNB-GW service instance for Hybrid Access Mode support and related parameters. This command enable Hybrid Access mode support to allow the non-access-controlled UEs that can register from a Hybrid HNB. If a UE tries to register from a Hybrid HNB with an HNB-GW service instance, which is already reached to the limit configured through max-non-access-controlled-ue reg_ue_hyb the HNB-GW sends HNB-Registration-Reject message with “ue not allowed in this hnb” cause.

Important: If Operator has reduced the maximum number of non-access-controlled UEs allowed per Hybrid HNB during the session, this will not have any effect on already registered UEs/CS-Calls/PS-Calls even if previously configured reg_ue_hyb is beyond the newly configured reg_ue_hyb value. Limits is respected while handling new requests.

Example
The following command configures the HNB-GW service instance to allow 16 UEs to register through a Hybrid HNB:

default hnb-access-mode hybrid
hnb-access-mode mismatch-action

Configures the HNB-GW service instance to manage the access-mode where a mismatch in the access-mode sent by a HNB in the Registration Request message and the access-mode sent by the AAA in the Access-Accept message is found.

Platform
ASR 5000
ASR 5500

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

[local] host_name(config-hnbgw-service)#

Syntax

hnb-access-mode mismatch-action { accept-aaa-value | hnb-reg-rej }

default hnb-access-mode mismatch-action

---

default

Sets the default action of a HNB-GW service instance to manage the access-mode where a mismatch in the access-mode sent by a HNB in the Registration Request message and the access-mode sent by the AAA in the Access-Accept message is found.
By default, HNB-GW rejects the HNB registration and sends the HNB-Registration-Reject message to the HNB.

---

accept-aaa-value

Sets the HNB-GW service instance to accept the HNB registration where a mismatch in the access-mode sent by a HNB in the Registration Request message and the access-mode sent by the AAA in the Access-Accept message is found.
In this configuration HNBGW registers the HNB with the access-mode value sent by the AAA.

---

reject-hnb-reg

Sets the HNB-GW service instance to reject the HNB registration where a mismatch in the access-mode sent by a HNB in the Registration Request message and the access-mode sent by the AAA in the Access-Accept message is found.
In this mode, after rejecting the HNB registration, the HNB-GW sends the HNB-Registration-Reject message to the HNB.
Usage
Use this command to configure the HNB-GW service instance for Hybrid Access Mode support and related parameters.
This command enable Hybrid Access mode support to allow the non-access-controlled UEs that can register from a Hybrid HNB. If a UE tries to register from a hybrid HNB with an HNB-GW service instance, which is already reached to the limit configured through `max-non-access-controlled-ue reg_ue_hyb` the HNB-GW sends HNB-Registration-Reject message with “ue not allowed in this hnb” cause.

**Important:** If Operator has reduced the maximum number of non-access-controlled UEs allowed per Hybrid HNB during the session, this will not have any effect on already registered UEs/CS-Calls/PS-Calls even if previously configured `reg_ue_hyb` is beyond the newly configured `reg_ue_hyb` value. Limits is respected while handling new requests.

Example
The following command configures the HNB-GW service instance to allow 16 UEs to register through an open HNB:

```
default hnb-access-mode hybrid
```
**hnb-access-mode open**

Configures the Open HNB access mode in HNB-GW service instance and related parameters.

**Platform**
ASR 5000

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration
```
configure > context context_name > hnbgw-service service_name
```
Entering the above command sequence results in the following prompt:
```
[local]host_name(config-hnbgw-service)#
```

**Syntax**
```
hnb-access-mode open [ max-registered-ue reg_ue_open ]
[ no | default ] hnb-access-mode open
```

**no**
Disables Open Access mode support. If disabled and an Open HNB tries to register, the HNB-GW sends HNB-Registration-Reject message with “OAM Intervention” cause.

**default**
Sets the default configuration of Open Access mode support. By default, HNB-GW allows registration of Open HNBs and a maximum of 16 UEs can register from an open HNB in an HNB-GW service instance.

**max-registered-ue reg_ue_open**
Sets the HNB-GW service instance to allow the maximum number of UEs through an open HNB under Open Access mode support.
```
reg_ue_open defines the maximum number of UEs that can register from an Open HNB as an integer from 1 through 1000.
If a UE tries to register from an Open HNB which has already reached to the configured limit configured, the HNB-GW sends HNB-Registration-Reject message with “ue not allowed in this hnb” cause in an HNB-GW service instance.
Usage
Use this command to configure the HNB-GW service instance for Open Access Mode support and related parameters.
This command enable Open Access mode support to allow the UEs that can register from an Open HNB. If a UE tries to register from an Open HNB with an HNB-GW service instance, which is already reached to the limit configured through `max-registered-ue reg_ue_open` the HNB-GW sends HNB-Registration-Reject message with "ue not allowed in this hnb" cause.

**Important:** If Operator has reduced the maximum number of UEs allowed per Open HNB during the session, this will not have any effect on already registered UEs/CS-Calls/PS-Calls even if previously configured `reg_ue_open` is beyond the newly configured `reg_ue_open` value. Limits is respected while handling new requests.

Example
The following command configures the HNB-GW service instance to allow 16 UEs to register through an open HNB:
```
default hnb-access-mode open
```
**hnb-identity**

Configures and also allows modification to the HNB ID before it is sent to the AAA server for authentication in HNB-GW service instance.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

```
configure > context context_name > hnbgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbgw-service)#
```

**Syntax**

```
[ default | no ] hnb-identity oui discard-leading-char
```

- **no**
  Disables discarding of leading character of HNB-id if it contains Organizationally Unique Identifier

- **default**
  Enables the default behavior of discarding of leading character of HNB-id if it contains Organizationally Unique Identifier. By default this feature is deactivated.

- **oui discard-leading-char**
  This CLI allows to modify the HNB ID before it is sent to the AAA server for authentication. By using this CLI, first character of the HNB-id can be removed if the HNB-id follows the format: ‘1<OUI>-<SerialNumber>@<realm>’.

**Example**

The following command configures the discarding of leading character of HNB-id if it contains Organizationally Unique Identifier:

```
hnb-identity oui discard-leading-char
```
**ip iu-qos-dscp**

Enables or disables the DSCP marking parameter for data packets carried over an IuCS/IuPS interface towards MSC/SGSN. By default this command is **Disabled**.

**Platform**
ASR 5000

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

Configuration of Context context_name > hnbw-service service_name

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbw-service)#
```

**Syntax**

```
ip iu-qos-dscp protocol udp payload { gtpu | rtcp | rtp} dscp_code

[default | no] ip iu-qos-dscp protocol udp payload { gtpu | rtcp | rtp }
```

**no**

Use this keyword to place the configuration in **pass-through** mode (no marking of DSCP). Use of this keyword is allowed even when there is no previous DSCP parameter set.

**Important:** In this configuration the **no** keyword does not disable or remove a previous configuration.

**default**

Enables the DSCP marking on HNB-GW and set/restores the QoS parameters to their default setting.

```
udp payload { gtpu | rtcp | rtp} dscp_code
```

Specifies the QoS traffic pattern towards MSC/SGSN in UDP protocol association over IuCS/IuPS interface. By this keyword the Traffic classes specified by a user based on UDP protocol and GTPU, RTCP, and RTP type of payload identified based on the transport level port numbers.

Default DSCP code in UDP traffic are:

- **GTP-U:** cs1
- **RTCP:** ef
- **RTP:** af41
### dscp_code

Specifies the QoS DSCP codes supported for UDP traffic and its payloads towards MSC/SGSN over IuCS/IuPS interface.

The following type of DSCP codes `dscp_code` are supported over IuH interface:

- **af11**: Marks traffic as Assured Forwarding 11 PHB (high throughput data)
- **af12**: Marks traffic as Assured Forwarding 12 PHB (high throughput data)
- **af13**: Marks traffic as Assured Forwarding 13 PHB (high throughput data)
- **af21**: Marks traffic as Assured Forwarding 21 PHB (low latency data)
- **af22**: Marks traffic as Assured Forwarding 22 PHB (low latency data)
- **af23**: Marks traffic as Assured Forwarding 23 PHB (low latency data)
- **af31**: Marks traffic as Assured Forwarding 31 PHB (multimedia streaming)
- **af32**: Marks traffic as Assured Forwarding 32 PHB (multimedia streaming)
- **af33**: Marks traffic as Assured Forwarding 33 PHB (multimedia streaming)
- **af41**: Marks traffic as Assured Forwarding 41 PHB (multimedia conferencing). This is the default DSCP code for RTP payloads in UDP protocol.
- **af42**: Marks traffic as Assured Forwarding 42 PHB (multimedia conferencing)
- **af43**: Marks traffic as Assured Forwarding 43 PHB (multimedia conferencing)
- **cs1**: Marks traffic with Class Selector 1 (low priority data). This is the default DSCP code for GTP-U payloads in UDP protocol.
- **cs2**: Marks traffic with Class Selector 2 (OAM)
- **cs3**: Marks traffic with Class Selector 3 (broadcast video)
- **cs4**: Marks traffic with Class Selector 4 (real-time interactive)
- **cs5**: Marks traffic with Class Selector 5 (signaling). This is the default DSCP code for all SCTP payloads.
- **cs6**: Marks traffic with Class Selector 6 (network control)
- **df**: Marks traffic as Default Forwarding (best effort: DSCP = 0)
- **ef**: Marks traffic as Expedited Forwarding PHB (telephony). This is the default DSCP code for RTCP payloads in UDP protocol.

### Usage

Use this command to enable/disable the DSCP marking for data packets over IuCS/PS interface. This command assigns the DSCP levels to specific traffic patterns in order to ensure that the packets are delivered according to the precedence with which they are tagged. The DiffServ markings are applied to the IP header of every subscriber data packet transmitted over IuCS/IuPs interface(s) towards MSC/SGSN.

**Important:** SCTP payload option is removed in StarOS 14.0 and onward.
This command adds DSCP marking on egress traffic going towards CN (CS/PS). To make the configuration pass-through mode or not marking DSCP at all in the packets, no variant of command is used. Use of no is allowed even when there is no previous DSCP configuration done.

**Important:** By default this command is Disabled.

**Important:** When DSCP configuration is not specified, the system works in pass-through mode and DSCP values in the ingress (from CN) and egress (to HNB) data packets remain unchanged. Multiple traffic classes can share the same code point value.

Following type shown in following tables respectively:

**Table 32. Supported DSCP Codes and Service Class**

<table>
<thead>

</table>

The DSCP level can be configured for multiple traffic patterns within a single instance of this command.

**Example**

The following command configures the DSCP code for the UDP IuCS/IuPS streaming traffic pattern for all payloads to be af31:

```
ip iu-qos-dscp protocol udp payload rtp af31
```
ip iuh-qos-dscp

Enables or disables the DSCP marking parameter for control and data packets transmitted over an IuH interface towards HNB. By default this command is Disabled.

Platform
ASR 5000

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration
configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:
[local]host_name(config-hnbgw-service)#

Syntax

ip iuh-qos-dscp protocol { sctp payload all | udp payload { gtpu | rtcp | rtp } } dscp_code

[default | no] ip iuh-qos-dscp protocol { sctp payload all | udp payload { gtpu | rtcp | rtp } } dscp_code

no

Use this keyword to set the configuration in pass-through mode. Use of this keyword is allowed even when there is no previous DSCP parameter set.

---

**Important**: In this configuration the no keyword does not disable/remove a previous configuration.

---

default

Enables the DSCP marking on HNB-GW and set/restores the QoS parameters to its default setting.

---

sctp payload all dscp_code

Specifies the QOS traffic pattern towards HNB in SCTP protocol association over IuH interface.
By this keyword the Traffic classes specified by a user based on SCTP protocol and all type of payload identified based on the transport level port numbers.
By default DSCP codes cs5 is supported for all payloads in SCTP protocol.

---

udp payload { gtpu | rtcp | rtp } dscp_code

Specifies the QOS traffic pattern towards HNB in SCTP protocol association over IuH interface.
By this keyword the Traffic classes specified by a user based on UDP protocol and GTPU, RTCP, and RTP type of payload identified based on the transport level port numbers.
Default DSCP code in UDP traffic are:
HNB-GW Service Configuration Mode Commands

ip iuh-qos-dscp

- GTP-U: cs1
- RTCP: ef
- RTP: af41

dscp_code

Specifies the QoS DSCP codes supported for SCTP and UDP traffic and its payloads towards HNB over IuH interface.

The following type of DSCP codes dscp_code are supported over IuH interface:

- af11: Marks traffic as Assured Forwarding 11 PHB (high throughput data)
- af12: Marks traffic as Assured Forwarding 12 PHB (high throughput data)
- af13: Marks traffic as Assured Forwarding 13 PHB (high throughput data)
- af21: Marks traffic as Assured Forwarding 21 PHB (low latency data)
- af22: Marks traffic as Assured Forwarding 22 PHB (low latency data)
- af23: Marks traffic as Assured Forwarding 23 PHB (low latency data)
- af31: Marks traffic as Assured Forwarding 31 PHB (multimedia streaming)
- af32: Marks traffic as Assured Forwarding 32 PHB (multimedia streaming)
- af33: Marks traffic as Assured Forwarding 33 PHB (multimedia streaming)
- af41: Marks traffic as Assured Forwarding 41 PHB (multimedia conferencing). This is the default DSCP code for RTP payloads in UDP protocol.
- af42: Marks traffic as Assured Forwarding 42 PHB (multimedia conferencing)
- af43: Marks traffic as Assured Forwarding 43 PHB (multimedia conferencing)
- cs1: Marks traffic with Class Selector 1 (low priority data). This is the default DSCP code for GTP-U payloads in UDP protocol.
- cs2: Marks traffic with Class Selector 2 (OAM)
- cs3: Marks traffic with Class Selector 3 (broadcast video)
- cs4: Marks traffic with Class Selector 4 (real-time interactive)
- cs5: Marks traffic with Class Selector 5 (signaling). This is the default DSCP code for all SCTP payloads.
- cs6: Marks traffic with Class Selector 6 (network control)
- df: Marks traffic as Default Forwarding (best effort: DSCP = 0)
- ef: Marks traffic as Expedited Forwarding PHB (telephony). This is the default DSCP code for RTCP payloads in UDP protocol.

Usage

Use this command to enable/disable the DSCP marking for control and data packets carried by the IP protocols and their payloads on IuH. This command assigns the DSCP levels to specific traffic patterns in order to ensure that the packets are delivered according to the precedence with which they are tagged. The DiffServ markings are applied to the IP header of every subscriber data packet transmitted over IuH interface(s) towards HNB.
This command adds DSCP marking on egress traffic going towards HNB. To make the configuration **pass-through mode** or not marking DSCP at all in the packets, **no** variant of command is used. Use of **no** is allowed even when there is no previous DSCP configuration done.

**Important:** By default this command is **Disabled**.

**Important:** When DSCP configuration is not specified, system works in **pass-through** mode and DSCP value in the ingress (from CN) and egress (to HNB) control and data packets remain unchanged. Multiple traffic classes can share the same code point value.

Following type shown in following tables respectively:

<table>
<thead>
<tr>
<th>Service Class</th>
<th>DSCP Code</th>
<th>Service Class</th>
<th>DSCP Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>high throughput data</td>
<td>af11, af12, af13</td>

</tbody>
</table>

The DSCP level can be configured for multiple traffic patterns within a single instance of this command.

**Example**

The following command configures the DSCP code for the SCTP IuH streaming traffic pattern for all payloads to be **ef**:

```
ip iuh-qos-dscp protocol sctp payload all ef
```
paging open-hnb

From StarOS Release 14.0 and onward this command is part of *HNB-Global Configuration Mode*. 
radio-network-plmn

Creates, remove and enters the HNB-RN-PLMN Configuration mode. In this mode you can configure various parameters for radio network public mobile land networks (PLMNs). A maximum of 16 radio PLMN-IDs can be configured in an HNB-GW service.

Platform
ASR 5000

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-service)#

Syntax

radio-network-plmn mcc mcc_num mnc mnc_num [-noconfirm]

no radio-network-plmn mcc mcc_num mnc mnc_num

no

Removes the configured radio network PLMN identifier for an HNB-GW service.

⚠️ Caution: Removing the PLMN-ID is a disruptive operation; the HNB-GW service will be re-started.

mcc mcc_num

Specifies the mobile country code (MCC) part of radio network PLMN identifier as an integer value from 101 through 998.

mnc mnc_num

Specifies the mobile network code (MNC) part of radio network PLMN identifier as a 2- or 3-digit integer from 01 through 998.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use this command to configure the radio network PLMN identifier for an HNB-GW service. This command also creates a configuration mode to configure various parameters for defined radio network PLMN identifier in HNB-GW service.
Caution: Changing or removing the PLMN-ID is a disruptive operation; the HNB-GW service will be restarted.

Entering this command results in the following prompt:

```
[context_name]hostname(config-radio-network-plmn)#
```  

A maximum of 16 radio network PLMN identifiers are supported for an HNB-GW service.

Example

The following command configures the radio network PLMN identifier with MCC value as 102 and MNC value as 20 for an HNB-GW service:

```
radio-network-plmn mmc 102 mnc 20
```
**ranap reset**

From 14.0 onward this command is part of HNB-CS Network Configuration Mode and HNB-PS Network Configuration Mode.
rtcp report

Enables or disables the generation of RTP Control Protocol (RTCP) packet/report types on a per HNB-GW service instance basis. It also sets the time interval in seconds between two consecutive RTCP reports.

Platform
ASR 5000

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-service)#

Syntax

rtcp report interval dur

[no | default] rtcp report interval

no

Disables the RTCP report generation on HNB-GW service. When RTP configuration is not explicitly mentioned, this is the default behavior.

default

Restores the report interval value to its default value of 5 seconds.

interval dur

Sets the time interval (in seconds) between two consecutive RTCP reports as an integer from 5 through 30. Default: 5

Usage

Use this command to configure the enabling or disabling of the generation of RTCP packet/report types on a per HNB-GW service instance basis and sets the specified time interval in seconds between two consecutive RTCP reports.

RTCP enables the receiver to detect if there is any packet loss and needs to compensate for any delay jitter. RTP and RTCP protocols work independently of the underlying Transport layer and Network layer protocols. Whenever this command is disabled, RTCP report generation stops from the next expiry of the previously configured interval and after enabling, reports are generated only for the calls that established as new calls in the future. For existing calls reports generated as per configuration in place.

RTCP reports are generated for each RAB for RTP received from and sent to IuH interface.
**Important:** The same interval is applicable for all kinds of RTCP packets/reports across all sessions on an HNB-GW service.

**Example**

The following command configures the RTCP report generation interval to 15 seconds on an HNB-GW service for RTP stream:

```bash
rtcp report interval 15
```
**rtp mux**

Configures the HNB-GW service to allow an Home-NodeB to multiplex multiple RTP streams in one IP packet. This support is provided for RTP stream management feature on HNB-GW.

**Platform**
ASR 5000

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

```
cfg > context context_name > hnbgw-service service_name
```

Entering the above command sequence results in the following prompt:
```
[local]host_name(config-hnbgw-service)#
```

**Syntax**

```
[no | default]rtp mux
```

---

**default**
Sets the multiplexing option to default state of “disabled”.

---

**no**
Removes the configured option to multiplex multiple RTP stream in one packet by Home-NodeB in HNB-GW configuration.

**Usage**
Use this command to allow an Home-NodeB to multiplex multiple RTP streams in one IP packet. This configuration support is provided for RTP stream management feature on HNB-GW and it is disabled by default.

**Example**
The following command sets the HNB-GW to allow HNB to multiplex multiple RTP stream in one packet:
```
rtp mux
```
sctp

Configures the SCTP-related parameters like timeout duration for various timers and cookie life over an IuH interface in an HNB-GW service.

Platform
ASR 5000

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-service)#

Syntax

sctp alpha-rto alpha_rto_dur
sctp beta-rto beta_rto_dur
sctp checksum-type [ adler32 | crc32 ]
sctp cookie-life cookie_life
sctp max-retx [ init | path | assoc ] max_retry
sctp mtu-size [ start | min | max ] mtu_byte
sctp rto { initial init_rto_dur | min min_rto_dur | max max_rto_dur }
sctp sack-frequency sack_frq
sctp sack-period sack_dur
sctp max-in-strms in_strms
sctp max-out-strms out_strms

default sctp { alpha-rto | beta-rto | checksum-type | cookie-life | max-retx [ init | path | assoc] | mtu-size [start | min | max ] | rto { initial | min | max} | sack-frequency | sack-period | max-in-strms | max-out-strms }

default

Restores the SCTP parameters to default value in HNB-GW service instance. Default values for all parameters are as follows:

* alpha-rto: 5 seconds
• **beta-rto**: 10 seconds
• **checksum-type**: CRC32
• **cookie-life**: 600 ms
• **max-rex init**: 5 retries
• **max-rex path**: 5 retries
• **max-rex assoc**: 10 retries
• **mtu-size min**: 508 Bytes
• **mtu-size max**: 1500 Bytes
• **mtu-size start**: 508 Bytes
• **rto initial**: 30 seconds
• **rto min**: 10 seconds
• **rto max**: 600 seconds
• **sack-frequency**: 2
• **sack-period**: 2 ms
• **max-in-strms**: 4
• **max-out-strms**: 4

**alpha-rto alpha_rto_dur**
Sets the alpha retransmission timeout duration (in seconds) for SCTP association between HNB and HNB-GW as an integer from 0 through 65535. A “zero” value disables the timer in this configuration. Default: 5

**beta-rto beta_rto_dur**
Sets the beta retransmission timeout duration (in seconds) for SCTP association between HNB and HNB-GW as an integer from 0 through 65535. A “zero” value disables the timer in this configuration. Default: 10

**checksum-type** [ adler32 | crc32 ]
Sets the checksum algorithm type to be used in SCTP association between HNB and HNB-GW for packet validation. Default: CRC32
- **adler32**: Specifies the SCTP association to use Adler32 checksum algorithm for packet validation. By default this is disabled.
- **crc32**: Specifies the SCTP association to use 32-bit cyclic redundancy check (CRC) algorithm for packet validation. By default this is enabled.

**cookie-life cookie_life**
Sets the COOKIE life (in milliseconds) for SCTP association between HNB and HNB-GW as an integer from 500 through 120000. Default: 600

**max-rex [ init | path | assoc ] max_retry**
Sets the maximum number of retries allowed in SCTP states for SCTP association between HNB and HNB-GW.
HNB-GW Service Configuration Mode Commands

- **init**: Sets the maximum attempts allowed after T1-init timer expires. If the T1-init timer expires then the HNB-GW retransmits INIT chunk and re-start the T1-init timer without changing state. This is repeated up to the configured times with this configuration. After that, the HNB-GW aborts the initialization process. Default number of attempts `max_retry` for this state is 5.
- **path**: Sets the maximum attempts allowed after T3-rtx timer expires. Each time the T3-rtx timer expires on any address, or when a HEARTBEAT sent to an idle address is not acknowledged within a RTO, the error counter of that destination address incremented. When the value in the error counter exceeds this protocol parameter of that HNB address, the HNB-GW marks the destination transport address as inactive. Default number of attempts `max_retry` for this state is 5.
- **assoc**: Sets the maximum number of consecutive retransmissions to its peer is allowed. If the value of this counter exceeds the limit configured with this keyword the HNB-GW considers the peer HNB unreachable and stop transmitting any more data to it. The SCTP association is automatically closed when the peer endpoint becomes unreachable. Default number of attempts `max_retry` for this state is 10.

`max_retry` is an integer from 1 through 255.

```
mtu-size [ min | max | start ] mtu_byte
```

Sets the maximum transmission unit (MTU) size in Bytes for SCTP association between HNB and HNB-GW.
- **min**: Sets the minimum size of MTU for SCTP association between HNB and HNB-GW. Default minimum MTU size `mtu_byte` is 508 Bytes.
- **max**: Sets the maximum size of MTU for SCTP association between HNB and HNB-GW. Default maximum MTU size `mtu_byte` is 1500 Bytes.
- **start**: Sets the size of MTU for SCTP association at the start of session between HNB and HNB-GW. Default MTU size `mtu_byte` at initial sate is 508 Bytes.

`mtu_byte` is an integer from 508 to 65535.

```
rto { initial ini_rto_dur | min min_rto_dur | max max_rto_dur }
```

Sets the Retransmission TimeOut (RTO) duration parameters for SCTP association between HNB and HNB-GW.
- **initial ini_rto_dur**: Sets the initial retransmission timeout duration (in seconds) for SCTP association between HNB and HNB-GW as an integer from 1 through 1200. Default: 30.
- **min min_rto_dur**: Sets the minimal retransmission timeout duration (in seconds) for SCTP association between HNB and HNB-GW as an integer from 1 through 50. Default: 10
- **max max_rto_dur**: Sets the maximum retransmission timeout duration (in seconds) for SCTP association between HNB and HNB-GW as an integer from 5 through 1200. Default: 600.

```
sack-frequency sack_frq
```

Sets the number of chunks received before sending the Selective Acknowledgement chunk HNB from HNB-GW in SCTP association. the SACK chunk is sent to the HNB to acknowledge received DATA chunks and to inform the HNB of gaps in subsequently received DATA chunks.

`sack_frq` is the frequency after which SACK chunk is sent to HNB specified as an integer from 1 through 5. Default: 2

```
sack-period sack_dur
```

Sets the duration (in seconds) after which Selective Acknowledgement chunk is sent to HNB from HNB-GW in SCTP association. The SACK chunk is sent to the HNB to acknowledge received DATA chunks and to inform the HNB of gaps in subsequently received DATA chunks.

`sack_dur` is an integer from 0 through 5. A “zero” value disables the parameter.
max-in-strms \text{\textit{in\_strms}}

Sets the maximum number of inward SCTP streams allowed on HNB-GW for an associated HNB in an SCTP association as an integer from 1 through 16. Default: 4

max-out-strms \text{\textit{out\_strms}}

Sets the maximum number of outgoing SCTP streams allowed from HNB-GW for an associated HNB in an SCTP association as an integer from 1 through 16. Default: 4

Usage

Use this command to configure the SCTP protocol messaging and session management parameters in SCTP association between HNB and HNB-GW.

Example

The following command sets the SCTP COOKIE life to 600 milliseconds on HNB-GW for the SCTP association:

\begin{verbatim}
  default sctp cookie-life
\end{verbatim}
**sctp bind**

Configures the SCTP IP address and port that is used for binding the SCTP socket to communicate with the Home-NodeB over an Iuh interface within an HNB-GW service.

**Platform**
ASR 5000

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

```
configure > context context_name > hnbgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbgw-service)#
```

**Syntax**

```
sctp bind { address address | port port_num }
[ default | no ] sctp bind { address | port }
```

- **default**
  Sets the SCTP port to the default value of 600.

- **address address**
  Specifies the IP address of the HNB-GW Iuh interface in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

- **port port_num**
  Specifies the SCTP port number to communicate with the Home-NodeBs using Iuh interface as an integer form 1 through 65535.

**Usage**

Use this command to assign the SCTP IP address and port with SCTP socket on HNB-GW to communicate with the Home-NodeB using Iuh interface. This SCTP configuration provides the IP-address and listen port where HNB-GW service shall bind to listen for incoming SCTP associations from HNB.

**Example**

The following command sets the SCTP port number 999 on HNB-GW to listen from Home-NodeB over Iuh interface:

```
sctp bind port 999
```

The following command sets the SCTP address 10.2.3.4 of HNB-GW to use with Home-NodeB over Iuh interface:
sctp bind address 10.2.3.4
sctp connection-timeout

Configures the SCTP connection timeout duration to explicitly remove the SCTP association with a non-responsive HNB in an HNB-GW service.

Platform
ASR 5000

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-service)#

Syntax

sctp connection-timeout dur

[ default | no ] sctp connection-timeout

no

Disables the connection time out configuration on HNB-GW service.

default

Restores the connection timeout duration value to its default value of 10 seconds.

dur

Sets the connection timeout duration (in seconds) after which the association is explicitly removed. In case of an HNB de-registration scenario, the HNB-GW waits for configured amount of time before initiating the procedure to clear the SCTP association.

dur is an integer from 5 through 30. Default: 10

Usage

Use this command to configure the minimum duration value before removing the SCTP association between a non-responding HNB and HNB-GW. If HNB registration not happened within the configured period after the SCTP association is established then the SCTP association is explicitly removed. In a scenario where an HNB de-registered due to any reason, the HNB-GW waits for the configured amount of time before initiating the procedure to clear the SCTP association.

Example

The following command sets the SCTP connection timeout duration to 15 second on HNB-GW after expiry of which the SCTP association is removed:

sctp connection-timeout 15
sctp heart-beat-timeout

Configures the SCTP heartbeat timer parameters for SCTP connection over an IuH interface in an HNB-GW service instance.

**Platform**
ASR 5000

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration
configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-hnbgw-service)#
```

**Syntax**

```
sctp heart-beat-timeout dur
[ default | no ] sctp heart-beat-timeout
```

- **no**
  Disables the heartbeat timer configuration for SCTP over IuH in HNB-GW service instance.

- **default**
  Restores the default timeout value for heartbeat timer to 30 seconds.

- **dur**
  Sets the heartbeat timer timeout duration (in seconds) after which the next heartbeat command is sent to HNB from HNB-GW in SCTP over an IuH interface. In an HNB de-registration scenario, the HNB-GW waits for configured amount time before initiating the procedure to clear the SCTP association. 
  
  *dur* is an integer from 1 through 300. Default: 30

**Usage**

Use this command to configure the minimum duration value before retransmitting the HEARTBEAT chunk to HNB from HNB-GW in SCTP transmission. By default HNB-GW monitors the reachability of the idle HNBs by sending a HEARTBEAT chunk periodically to the HNB address. Each time the HEARTBEAT timer expires on any address, or when a HEARTBEAT sent to an idle address is not acknowledged within a Retransmission Timeout duration, the error counter of that HNB incremented. When the value in the error counter exceeds the protocol parameter for maximum retransmission for that destination address, the HNB-GW mark the destination HNB as inactive and a notification is sent to the upper layer.

**Example**
The following command sets the SCTP HEARTBEAT timeout duration to 15 seconds on HNB-GW after expiry of which the HNB-GW retransmits the HEARTBAT chunk to HNB over SCTP association:

```
 sctp heart-beat-timeout 15
```
security-gateway aaa

From StarOS Release 14.0 onward this command is deprecated.
security-gateway bind

Binds the SeGW in an HNB-GW service to a logical IP interface serving as an Iuh interface and associates an IPsec IKEv2 crypto-map template.

Platform
ASR 5000

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

configure > context context_name > hnbgw-service service_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-hnbgw-service)#

Syntax

security-gateway bind address address crypto-template cryp_name [ context ctxt_name]

no security-gateway bind

no

Removes a previously configured IPsec IP address use for binding the IKEv2 IPsec tunnel (local bind address) to communicate with the Home-NodeBs using Iuh interface.

bind address address

 Specifies the IP address for the Iuh interface for the IPsec tunnel. This is the IP address where the HNB-GW service is bound and that is provided to the Home-NodeB during HNB-GW discovery. The IP address is expressed in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

crypto-template cryp_name

 Specifies the Crypto-map template to be used for IPsec IKEv2 tunneling for the interface configured as an Iuh.

cryp_name specifies the name of the pre-configured Crypto-map template which is configured in Crypto-Map Template Configuration mode and associated with the HNB-GW service to create an IPsec tunnel with a Home-NodeB during HNB-GW discovery procedure over an Iuh interface.

context ctx_name

 Specifies the name of the pre-configured context in which the Security Gateway service is configured. By default this command uses the HNB-GW service context for the security Gateway configuration.
Usage

Use this command to associate or tie the HNB-GW service to a specific logical IP address that is used for binding the Iuh socket to communicate with the Home-NodeB using IPSec tunnel. A maximum of one IP address can be configured with this command for one HNB-GW service. The HNB-GW passes the IP address during setting up the HNB-GW discovery procedure with the Home-NodeB.

⚠️ Caution: This is a critical configuration. The HNB-GW service cannot be started without this configuration. Any change to this configuration would lead to restarting the HNB-GW service and removing or disabling this configuration stops the HNB-GW service.

Example

The following command binds the logical IP interface with the address of 10.2.3.4 to the HNB-GW service using existing IPsec Crypto-Map template crypto1 to establish IPSec tunnel with Home-NodeB:

```plaintext
security-gateway bind address 10.2.3.4 crypto-template crypto1
```

The following command disables a binding that was previously configured:

```plaintext
security-gateway bind address
```
security-gateway username

From StarOS Release 14.0 onward this command is deprecated.
tnnsf-timer

From StarOS Release14.0 onward this command is part of HNB-Global Configuration Mode.
**ue registration-timeout**

Configures the UE registration timeout duration to de-register the connected UE from an HNB-GW service.

**Platform**
ASR 5000

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration

```command
configure > context context_name > hnbgw-service service_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-hnbgw-service)#
```

**Syntax**

```command
ue registration-timeout dur
[ default | no ] ue registration-timeout
```

- **no**
  Disables the UE registration timeout duration and explicitly de-registers UE from the HNB-GW service.

- **default**
  Restores the UE registration timeout duration value to its default value of 120 seconds.

- **dur**
  Sets the UE registration timeout duration (in seconds) after which the UE is de-registered from HNB-GW. In a scenario when all Iu connections are released for a subscriber, the HNB-GW service de-registers the UE after the configured duration only.
  
  `dur` is an integer from 60 through 1800. Default: 120

**Usage**

Use this command to configure the minimum duration value before de-registering the UE when subscriber fails to establish the Iu connection. If subscriber’s Iu session does not established before configured period then UE is de-registered. Also in a scenario where all Iu connections are released for a subscriber, the HNB-GW service waits for configured period before starting UE deregistration procedure.

**Example**

The following command sets the UE registration timeout duration to 150 second on HNB-GW after expiry of which the UE is de-registered:

```
ue registration-timeout 150
```
Chapter 167
HNB-PS Network Configuration Mode Commands

The HNB-PS Network Configuration Mode is used to manage the packet switched (PS) network instance on HNB-GW service to provide HNB access with the PS core network in a 3G UMTS network.

**Mode**

Exec > Global Configuration > HNB-PS Network Configuration

`configure > ps-network ps_instance`

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-ps-network-instance_id)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
associate gtpu-service

Associates a previously configured GTP-U service to provide a GTP-U tunnel with an SGSN towards the core network side. A GTP-U service must be configured in Context Configuration mode before using this configuration.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-PS Network Configuration
configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-ps-network-instance_id)#

Syntax

associate gtpu-service svc_name context ctx_name

no associate gtpu-service

no

Removes the associated GTP-U service from this HNB-GW service configuration.

svc_name

Specifies the name of the preconfigured GTP-U service.

context ctx_name

Specifies the name of the context in which the GTP-U service is configured.

Usage

Use this command to configure GTP-U data plan tunnel between HNB-GW service and GSNs in core network. The service defined for GTP-U tunnel must be configured in Context configuration mode.

Important: Another GTP-U service can be used to bind the HNB-GW service to GTP-U tunnel with HNB in HNB access network and can be configured in HNB-GW Service Configuration mode. For more information on GTP-U service configuration, refer to GTP-U Service Configuration Mode Commands chapter.

Example

The following command associates GTP-U service gtpu_svc1 configured in context named Ctx_gtpu1 with specific HNB-PS network instance for GTP-U tunnel towards GSN in core network:

associate gtpu-service gtpu_svc1 context Ctx_gtpu1
**associate-sccp-network**

Associates a previously defined Signaling Connection Control Part (SCCP) network identifier with the PS network instance in order to route the messages towards the SGSN via the IuPS interface.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-PS Network Configuration

    configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

    [local]host_name(config-ps-network-instance_id)#

**Syntax**

```
associate-sccp-network sccp_net_id

no associate-sccp-network
```

- **no**
  - Removes the associated SCCP network configuration instance from this HNB-PS network instance configuration.

- **sccp_net_id**
  - Specifies a predefined SCCP network identifier.

**Usage**

Use this command to associate a predefined SCCP network ID with the IuPS interface in HNB-GW service to connect with PS network elements; i.e. SGSN.

**Important:** The SCCP network ID must be defined in Global Configuration mode before using it with this command.

**Important:** A single SCCP network ID can not be shared with multiple HNB-PS network instances.

**Example**

The following command associates SCCP network ID 2 with specific HNB-PS network instance:

```
associate-sccp-network 2
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
dend

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Use this command to return to the parent configuration mode.
global-rnc-id

Configures the Radio Network Concentrator (RNC) identifier in a Radio Network PLMN associated with HNB-PS network configuration instance. The RNC identifier is provided to the HNB during HNB-REGISTRATION.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-PS Network Configuration
configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-ps-network-instance_id)#

Syntax

[ no ] global-rnc-id mcc mcc_num mnc mnc_num id rnc_id [ common-plmn mcc mcc_num mnc mnc_num ]

- **no**
  Deletes the RNC, MMC, and MNC information from the HNB-PS Network configuration instance.

- **mcc mcc_num**
  Specifies the mobile country code (MCC) part of radio network PLMN identifier as an integer value from 100 through 999.

- **mnc mnc_num**
  Specifies the mobile network code (MNC) part of radio network PLMN identifier as a 2- or 3-digit integer from 00 through 999.

- **id rnc_id**
  Specifies the RNC identifier as an integer from 0 through 4095.

- **common-plmn mcc mcc_num mnc mnc_num**
  Configures the Common PLMN for this PS Network.

  - **mcc mcc_num** configures the MCC of Common PLMN for this PS Network as an integer value from 100 through 999.
  - **mnc mnc_num** configures the MNC of Common PLMN for this PS Network as a 2- or 3-digit integer from 00 through 999.
Usage

Use this command to configure RNC id to associate Radio Network PLMN which will be sent to HNBs from HNB-GW during HNB-REGISTRATION procedure. Depending upon the requirement the RNC Identifier can be provided at the desired granularity.

Example

The following command configures the HNB-GW service to return an RNC identifier as 102 when an HNB-REGISTRATION request is received with LAC 1, and RAC 2:

```
  global rnc-id mcc 102 mnc 02 id 2
```
map core-network-id

Maps/associates the PS core network identifier to a default SGSN in the network using an SGSN point code to allow HNBs to access the UMTS network.

**Product**

HNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > HNB-PS Network Configuration

**Syntax**

```plaintext
map core-network-id cn_id point-code sgsn_point_code
no map core-network-id cn_id
```

**Usage**

Use this command to map a UMTS PS core network identifier with a particular SGSN point code.

This command can be entered multiple times with same SGSN point code to map with one or more PS core network Id, but a particular core network identifier can be mapped to one SGSN only.

This command is instrumental in Iu-Flex functionality, whenever HNB-GW receives RESET/RESET-RES messages from SGSN with Global CN-ID information element, the response from HNB-GW is sent to the node configured for that particular Global CN-ID.

If the RESET/RESET-RES messages do not have Global CN-ID IE, then the response of those messages is directed to the default SGSN which is configured using sgsn point-code command in this mode.

**Example**

The following command configures the PS core network identifier 101 with an SGSN point code 1.2.3:
map core-network-id 101 point-code 1.2.3

The following command configures the PS core network identifier 102 with the same SGSN point code 1.2.3:

map core-network-id 102 point-code 1.2.3
**map idnns range**

Configures the mapping of an Intra-Domain NAS Node Selector (IDNNS) IE received from UE in an RUA connect message towards HNB-GW. This is an important configuration for PS network resource sharing over an Iu-Flex interface.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-PS Network Configuration

configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-ps-network-instance_id) #
```

**Syntax**

```
map idnns range idnns_start to idnns_end point-code sgsn_point_code [backup point-code bkup_sgsn_point_code]
```

```
no map idnns range idnns_start to idnns_end
```

Removes the entries of mapping of range of IDNNS received from UE with particular SGSN point code.

```
range idnns_start to idnns_end
```

Specifies the range of IDNNSs received from UE to map with particular SGSN point codes during the initial PS core network node selection.

- `idnns_start` is an integer from 0 through 1023 that should be less than `idnns_end`.
- `idnns_end` is an integer from 0 through 1023 that should be more than `idnns_start`.

The command can be entered more than once to map multiple IDNNS ranges to the same SGSN. However, overlapping and mapping of the same range to different SGSN point codes is not allowed.

```
point-code sgsn_point_code
```

Specifies the SS7 address of the SGSN in the PS network.

- `sgsn_point_code` is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ####### format.

```
backup point-code bkup_sgsn_point_code
```

Specifies the SS7 address of the SGSN to be used as the backup in the PS network.

- `bkup_sgsn_point_code` is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ####### format.
Usage

Use this command to map a NRI received from UE during initial PS network node selection to SGSN point code through NRI range mapping over Iu-Flex interface.

The IDNNS refers to the information element in RUA connect message from UE towards RAN (HNB-GW). In IDNNS IE, if the choice of routing mentioned is other than local P-TMSI, then the value it provides is used against this configuration to map the SGSN point code.

If backup SGSN point-code is specified, then specified SGSN works as backup for the IDNS range configured. This Backup SGSN is selected if the mapped SGSN for a given IDNNS range is going for offloading using `offload-sgsn point-code` command.

The command can be entered more than once to map multiple IDNNS ranges to same SGSN point code, but overlapping and mapping of same range to different SGSN point code is not allowed.

Example

The following command maps the IDNNS range from 101 to 201 with SGSN point code 1.2.3 and point code 7.8.9 as backup SGSN point code:

```
map nri range 101 to 201 point-code 1.2.3 backup point-code 7.8.9
```

The following command removes all IDNNS range matching entries between 301 to 399 from the configuration:

```
no map idnns range 301 to 399
```
map nri range

Configures the mapping of the Network Resource Identifier (NRI) received from UE to an SGSN point code. This is an important configuration for PS network resource sharing over Iu-Flex interface.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-PS Network Configuration

configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

[local] host_name (config-ps-network-instance_id) #

Syntax

map nri range nri_start to nri_end point-code sgsn_point_code

no map nri range nri_start to nri_end

no

Removes the entries of mapping of range of NRIs received from UE with a particular SGSN point code.

range nri_start to nri_end

Specifies the range of NRIs received from UE to map with a particular SGSN point code during initial PS core network node selection.

nri_start is an integer from 0 through 1023 that should be less than nri_end.

nri_end is an integer from 0 through 1023 that should be more than nri_start.

The command can be entered more than once to map multiple NRI ranges to the same SGSN, but overlapping is not allowed.

point-code sgsn_point_code

Specifies the SS7 address of the SGSN in the PS network to map with range of NRI values.

point_code is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ####### format.

Usage

Use this command to map a NRI received from UE during initial PS network node selection to SGSN point code through NRI range mapping over Iu-Flex interface.

This configuration is used during initial PS core network node selection when the network resource identifier (NRI) from the UE is available. The NRI range is mapped to SGSN point code. This configuration is used when the core network uses Iu-Flex interface.

The command can be entered more than once to map multiple NRI ranges to same SGSN point code.

It is possible to configure multiple ranges to more than one SGSN however this configuration is required only when the PS core network is configured as Multi-Operator Core Network (MOCN).
When the PS core network is not MOCN and one range is mapped to more than one SGSN then SGSN is selected randomly in a non-predictable manner.

**Example**

The following command maps the NRI range from 101 to 201 with SGSN point code 1.2.3:

```
map nri range 101 to 201 point-code 1.2.3
```

The following command maps the NRI range from 301 to 399 with SGSN point code 1.2.3:

```
map nri range 301 to 399 point-code 1.2.3
```

The following command removes all NRI range matching entries between 301 to 399 from the configuration:

```
no map nri range 301 to 399
```
nri length

Configures the network resource identifier (NRI) length in bits to identify a specific SGSN serving in a pooled area. At least one NRI value must be assigned to an SGSN serving in a pool. The NRI is coded inside of the temporary mobile subscriber identity (TMSI), located within bits 14 to 23 with a variable length between 0 and 10 bits. The operator must set this NRI length to indicate the number of bits that shall be used for the NRI field to set the parameters for Iu-Flex (SGSN pooling) functionality.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-PS Network Configuration
command > configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-ps-network-instance_id)#

Syntax

nri length nri_value

default nri length

default
Sets the NRI length to default value of 0 and disables the Iu-Flex (SGSN pooling) functionality.

nri length nri_length

Default: 0

Specifies the number of bits to be used in the P-TMS (bits 23 to 18) to define the network resource identifier (NRI). The NRI length configuration also sets the maximum size of the pool. If not configured, the NRI length is set to zero length.

length is an integer from 1 to 10. When a non-zero value is configured the PS network is considered to be a pool. Default: 0

Usage

Use this command to enable the Iu-Flex functionality on HNB-GW. This command identifies a unique SGSN serving a pooled area for Iu-Flex functionality and at least one NRI value has to assigned to an SGSN serving in a pool. It performs SGSN pooling/offloading scenario over Iu-Flex interface. The NRI is stored in the bits 14 to 23 of TMSI. The HNB-GW uses a portion of this NRI to set the parameters for Iu-Flex (SGSN pooling) functionality.

If more than one NRI is configured, the HNB-GW service does round-robin between the available NRIs when new subscriber(s) (re)connect.

This command must be used in conjunction with null nri command to configured SGSN pooling/offloading over Iu-Flex interface.

Example
The following command sets the HNB-GW to use bit length as 6 to derive the values from the NRI field (stored in the bits 14 to 23 of TMSI) to set the parameters for Iu-Flex (SGSN pooling) functionality:

```
nri length 6
```
null-nri

Configures the null network resource identifier (NRI) for load redistribution in support of Iu-Flex functionality. The NRI value defined with this command must be unique across the pool areas. This null-NRI is used by HNB-GW for load redistribution during SGSN offloading.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-PS Network Configuration
  configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-ps-network-instance_id)#

Syntax

null-nri null_nri_value

no null-nri null_nri_value

no

Disables/removes the configured null-NRI value used for SGSN offloading procedure.

onnull_nri_value

Indicates the null-NRI value to be used by HNB-GW for load re-distribution during SGSN offloading as an integer from 0 through 1023.
Without MOCN configuration this value can be entered only once. For MOCN a unique null-NRI must be assigned to each MOCN operator identify by its PLMN-ID (MCC+MNC).
A 0 (zero) value configured as null-NRI indicates the keyword is not to be used. There is no default value for this parameter.

Usage

Use this command to identify the SGSN by HNB-GW to be used for load redistribution during SGSN offloading over Iu-Flex interface.
There is one unique null-NRI in a PLMN supporting pool functionality.
Without MOCN configuration this command can be entered only once. In case of MOCN a unique null-NRI must be assigned to each MOCN operator identify by its PLMN-id (MCC+MNC).

Example

The following command sets the null-NRI as 1001 to be used by HNB-GW for load redistribution during SGSN offloading:

null-nri 1001
offload-sgsn

Enables or disables the exclusion of a specified primary SGSN node during the NAS Node Selection Function (NNSF) procedure when it needs to be offloaded using Iu-Flex functionality.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-PS Network Configuration
`configure > ps-network ps_instance`

Entering the above command sequence results in the following prompt:
`[local]host_name(config-ps-network-instance_id)#`

**Syntax**

`[ no ] offload-sgsn point-code sgsn_point_code`

- **no**
  Removes the specified primary SGSN point code from the exclusion list for NNSF function on HNB-GW and re-enables the inclusion of the primary SGSN node to be considered by HNB-GW.

- **point-code sgsn_point_code**
  Specifies SS7 address of primary SGSN in PS network having specific point code value to be excluded for NNSF function on HNB-GW when it needs to be offloaded in Iu-Flex functionality.
  *point_code* is an SS7 point code in dotted-decimal ####.####.#### or 8-digit decimal ####### format. Only one instance of this primary SGSN point code can be mapped with one PS core network id.

**Usage**

Use this command to provision the HNB-GW to enable or disable the exclusion of the SGSN node when it needs to be offloaded.

When this command is enabled for exclusion of SGSN node during NNSF function in HNB-GW, the HNB-GW excludes the particular node from being considered.

User can re-enable the inclusion of the SGSN node to be considered for NNSF functionality by `no offload-sgsn point-code` command.

**Important:** The offload check is only for the primary point code and NOT for the backup point code.

**Example**

This command can be used for planned maintenance as well.

The following command configures the HNB-GW to exclude the primary SGSN point code `1.2.3` from being considered in NSSF function for Iu-Flex support:

`offload-sgsn point-code 1.2.3`
The following command re-enables the inclusion of SGSN point code 1.2.3 from being considered in NSSF function for Iu-Flex support:

```
no offload-sgsn point-code 1.2.3
```
ranap reset

Configures various Radio Access Network (RAN) Application Part reset procedure parameters for PS network association in an HNB access network.

**Product**
HNB-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > HNB-PS Network Configuration

configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-ps-network-instance_id)#

**Syntax**

```
ranap reset { ack-timeout timer_value | guard-timeout g_timer | hnbgw-initiated | max-retransmissions retries }

default ranap reset { ack-timeout | guard-timeout | hnbgw-initiated | max-retransmissions }

no ranap { hnbgw-initiated }
```

---

**default**
Resets the RANAP RESET parameters in HNB-PS Network configuration instance.

---

**no**
Disables the RANAP RESET procedure related parameters in an HNB-PS Network configuration instance.

---

**ack-timeout timer_value**
Sets the timer value (in seconds) to wait for Reset Acknowledge from SGSN. This is used during HNB-GW initiated RANAP RESET procedure in HNB-PS Network configuration instance. 

*timer_value* is an integer value from 5 through 10. Default: 10

---

**guard-timeout g_timer_value**
Sets the timer value (in seconds) to send Reset Acknowledge to SGSN. After this duration the HNB-GW sends RESET-ACK to SGSN. This is used during SGSN initiated RANAP RESET procedure in HNB-PS Network configuration instance. 

*g_timer_value* is an integer value from 5 through 10. Default: 10

---

**hnbgw-initiated**
Enables the HNB-GW Initiated RANAP RESET procedures. Default: Disabled
ranap reset

max-retransmission retries

Sets the maximum number of retries allowed for transmission of RESET-ACK message to SGSN. This is used during RANAP RESET procedure in HNB-PS Network configuration instance. retries is an integer value from 0 through 2. When 0 is used retransmission is disabled. Default: 1

Usage

Use this command to configure the RANAP RESET procedure related parameters in HNB-PS Network configuration for multiple HNB-GW service support.

Example

The following command configures the HNB-GW initiated RANAP RESET Procedure for an HNB-PS Network configuration instance:

    ranap reset hnbgw-initiated
sgsn deadtime

Configures a timer on HNB-GW to manage SGSN availability in a PS core network on receiving of a PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-PS Network Configuration
configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:
[local]host_name(config-ps-network-instance_id)#

Syntax
sgsn deadtime { immediate | dur }
[ no | default ] sgsn deaddtime

---

no
Makes the peer node (SGSN) always available for all HNB-PS network instances.

default
Sets the default action for HNB-GW such that the peer node (SGSN) is marked down as soon as HNB-GW receives a PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP in a specific HNB-PS network instance. Default: Enabled

immediate
Sets the HNB-GW to mark the peer node (SGSN) down immediately and clears all Iu-PS connections towards the SGSN. Default: Disabled

dur
Sets the duration (in seconds) for a timer which starts once HNB-GW receives a PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer SGSN. On expiry of this timer the peer SGSN is marked as dead and all Iu-PS connections towards that SGSN are released.
dur is an integer from 1 through 30.
Only one instance of this command can be configured.

Usage
This command is used to configure a timer on HNB-GW to manage SGSN availability in a PS core network on receiving of PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP.
Timer value sets the duration in seconds for a timer which started once HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer SGSN. On expiry of this timer the peer SGSN is marked as dead and all Iu-PS connections towards that SGSN shall be released.

**Important:** This command can be entered only once. Reentering this command overwrites the previous parameters.

**Example**

The following command configures the deadtime timer value for 10 seconds on HNB-GW. Once HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer SGSN the HNB-GW waits for configured period and on expiry of timer it marks the specific SGSN as dead:

```
sgsn deadtime 10
```
sgsn point-code

Configures the default SGSN point-code with the HNB-PS network instance. This command is used when HNB-GW is to be connected to only one SGSN with in a PS network or as the default SGSN for all HNBs connected through specific HNB-PS network instance.

Product
HNB-GW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > HNB-PS Network Configuration

configure > ps-network ps_instance

Entering the above command sequence results in the following prompt:

[local]host_name(config-ps-network-instance_id)#

Syntax

[ no ] sgsn point-code point_code

no

Removes the configured default SGSN point code from specific HNB-PS network instance.

⚠️ **Caution:** Removing the SGSN point code is a disruptive operation and affects all HNB sessions which are connected to particular SGSN through an HNB-PS network instance.

point_code

Specifies the SS7 address of the default SGSN in a PS network.

point_code is an SS7 point code in dotted-decimal ###.###.### or 8-digit decimal ######## format. Only one instance of this command can be configured.

Usage

Use this command to configure a default SGSN to which HNB connects for PS network access through the HNB-GW service.

Point-code is an SS7 address for an element in the SS7 network. Point-codes must be defined in dotted-decimal format in a string of 1 to 11 digits. Format options include:

- 0.0.1 to 7.255.7 for point-code in the ITU range.
- 0.0.1 to 255.255.255 for point-code in the ANSI range.
- 0.0.1 to 15.31.255 for point-code in the TTC Range.
- a string of 1 to 11 digits in dotted-decimal to represent a point-code in a different range.

⚠️ **Important:** This command can be entered only once. If entered again the previous value shall be overwritten.

Example
The following command configures a default SGSN with point code 101.201.101 for HNBs to access PS network through HNB-GW service in this HNB-PS network instance:

\texttt{sgsn point-code 101.201.101}
Chapter 168
HNB-RN PLMN Configuration Mode Commands

This HNB Radio Network PLMN configuration mode defines the radio network PLMN parameters related to the HNB-GW connection with a UMTS Femto radio network.

Mode

Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration > HNB-RN PLMN Configuration

configure > context context_name > hnb-gw-service service_name > radio-network-plmn mcc mcc_number mnc mnc_number

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hnb-gw-radio-plmn)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
associate cs-network

From StarOS Release 14.0 onward this command is deprecated.
associate ps-network

From StarOS Release 14.0 onward this command is deprecated.
**authorised-macro-lai**

Configures the macro LAI based authorization parameters for this HNB-GW service.

**Product**

HNB-GW

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration > HNB-RN PLMN Configuration

```
configure > context context_name > hnbgw-service service_name > radio-network-plmn mcc mcc_number mnc mnc_number
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hnbgw-radio-plmn)#
```

**Syntax**

```
authorised-macro-lai { macro-info-ie-absent-action { accept | reject } | mcc mcc_id mnc mnc_id lac range range_from to range_to }

default authorised-macro-lai macro-info-ie-absent-action

no authorised-macro-lai mcc mcc_id mnc mnc_id lac range range_from to range_to
```

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configures the default parameters for macro LAI based authorization for the system configuration. Default action is to reject HNB if IE is absent.</td>
</tr>
</tbody>
</table>

<table>

<table>
<thead>
<tr>
<th>range_from</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the LAC range minimum vlaue, which is an integer from 0..65535.</td>
</tr>
</tbody>
</table>
range_to

Specifies the LAC range maximum value, which is also an integer from 0..65535.

Usage

Use this command to configure the macro LAI based authorization parameters for an existing HNB-GW service.

Example

The following command configures the default action for macro LAI based authorization for an existing HNB-GW service.

```
default authorised-macro-lai macro-info-ie-absent-action
```
### end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
end
```

**Usage**

Use this command to return to the Exec mode.
**exit**

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```bash
exit
```

**Usage**

Use this command to return to the parent configuration mode.
rnc-id

Configures the Radio Network Concentrator (RNC) identifier in a Radio Network PLMN associated with HNB-GW service. The RNC identifier is provided to the HNB during HNB-REGISTRATION.

Product  
HNB-GW

Privilege  
Security Administrator, Administrator

Mode  
Exec > Global Configuration > Context Configuration > HNB-GW Service Configuration > HNB-RN PLMN Configuration

```bash
configure > context context_name > hnbw-service service_name > radio-network-plmn mcc mcc_number mnc mnc_number
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hnbw-radio-plmn)#
```

Syntax

```
[ no ] rnc-id rnc_id
```

- `no`
  
  Deletes the RNC id from the system configuration.

- `rnc-id`
  
  Specifies the RNC identifier as an integer from 0 through 4095.

Usage

Use this command to configure RNC id for Radio Network PLMN which will be sent to HNBs from HNB-GW during HNB-REGISTRATION procedure. Depending upon the requirement the RNC Identifier can be provided at the desired granularity.

Example

The following command configures the HNB-GW service to return an RNC identifier as 102 when an HNB-REGISTRATION request is received:

```
global rnc-id 102
```
Chapter 169
HSS Peer Service Configuration Mode Commands

The HSS Peer Service Configuration Mode is used to create and manage the Home Subscriber Server (HSS) Peer Service.

Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration

configure > context context_name > hss-peer-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hss-peer-service)#

⚠️ **Important**: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
auth-request

Configures the number of authentication vectors the MME/SGSN requests in an Authentication-Information-Request (AIR) message to the HSS for each UE requiring authentication.

Product
MME
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration
configure > context context_name > hss-peer-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hss-peer-service)#

Syntax

auth-request num-auth-vectors num

default auth-request num-auth-vectors

num-auth-vectors num

Specifies the number of vectors the MME/SGSN is requesting from the HSS as an integer.
num prior to Release 16, the valid range is 1 through 3. Default = 1.
um beginning with Release 16, the valid range is 1 through 5. Default = 1.

Usage

Use this command to configure the number of authentication vectors the MME/SGSN requests in an Authentication-Information-Request (AIR) message to the HSS for each UE requiring authentication. Receiving multiple vectors from the HSS for a given UE helps reduce the number of messages across the diameter connection plus provides the MME/SGSN with additional vectors for the UE in the event that the connection or the HSS id disabled.

Related Commands:

- To view the current number of requested vectors, execute the show hss-peer-service service name <name> command in the Exec mode.
- To set the minimum number (low watermark) of vectors to be maintained at all times, execute min-unused-auth-vector min_num command from the call control profile configuration mode. (SGSN only)
- For troubleshooting, check the number of free, used, or in-use vectors displayed in the output of the show subscribers [ gprs-only | sgsn-only ] full command. (SGSN only)

Example

The following command sets the number of requested vectors to 2:

auth-request num-auth-vectors 2
diameter hss-dictionary

Specifies the Diameter Credit Control dictionary for the HSS peer service.

Product
MME
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration
configure > context context_name > hss-peer-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hss-peer-service)#

Syntax

diameter hss-dictionary { custom1 | standard | standard-r9 } [ eir-dictionary { custom1 | standard | standard-r9 } ]

default diameter hss-dictionary

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sets the dictionary to default standard-r9 for HSS service.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>custom1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sets the Diameter dictionary to a customer-specific HSS Diameter dictionary. Default: Disabled</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>standard</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sets the Diameter dictionary to the standard (3GPP release 8) HSS peer dictionary. Default: Disabled</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>standard-r9</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sets the Diameter dictionary to the standard HSS peer dictionary for 3GPP release 9. Default: Enabled</td>
</tr>
</tbody>
</table>

| eir-dictionary { custom1 | standard | standard-r9 } |
|-----------------------------------------------------------|
| Specifies that an Equipment Identity Register (EIR) dictionary is to be used in conjunction with the HSS Diameter dictionary. |
| custom1: Sets the EIR Diameter dictionary to a customer-specific EIR Diameter dictionary. |
| standard: Sets the EIR Diameter dictionary to the standard HSS peer dictionary. |
| standard-r9: Sets the EIR Diameter dictionary to the standard HSS peer dictionary for release 9. |

Usage
Use this command to select the Diameter dictionary for the HSS peer service.

Example
The following command sets the Diameter dictionary to IETF RFC 4006 specific:
diameter hss-dictionary standard
diameter hss-endpoint

Associates a preconfigured Diameter origin endpoint with this HSS peer service.

Product
MME
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration

configure > context context_name > hss-peer-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hss-peer-service)#

Syntax

diameter hss-endpoint endpoint_name [ eir-endpoint eir_endpoint_name ] [ auc-endpoint auc_endpoint_name ]

no diameter hss-endpoint

no

Removes previously associated Diameter origin endpoint from this HSS peer service.

endpoint_name

Identifies a preconfigured Diameter endpoint specific to the HSS interface. The endpoint must be present in all Diameter messages and is the endpoint that originates the Diameter message.

endpoint_name is a preconfigured Diameter endpoint name expressed as an alphanumeric string of 1 through 63 characters.

eir-endpoint eir_endpoint_name

Identifies a preconfigured Diameter endpoint specific to the S13 or S13’ Equipment Identity Register (EIR) interface.

eir_endpoint_name must be an existing Diameter endpoint expressed as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to associated a Diameter origin endpoint to create a Diameter-based S6a or S6d (SGSN) interface association in this HSS peer service to provide AAA functionality to the EPS bearer context.

Optionally, use this command to associate a Diameter origin endpoint to create a Diameter-based S13 or S13’ (SGSN) interface association in this HSS peer service to provide IMEI query capability between the MME and an EIR.
The configuration of all endpoints is only valid when all necessary endpoint configuration has been completed. All endpoint listed above must also be defined as valid endpoints using the commands in the Diameter Endpoint configuration mode (refer to the Diameter Endpoint Configuration Mode Commands chapter in the Command Line Interface Reference manual) for more information on Diameter endpoint configuration parameters.

Example

The following command associates the preconfigured Diameter endpoint `hss_1` with this HSS peer service for HSS interface support.

```
diameter hss-endpoint hss_1
```
**diameter suppress**

Configures the MME to restrict the sending of the Notify-Request-Message to the HSS. By default, the Notify-Request-Message is sent to the HSS.

**Product**
MME

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration

```
configure > context context_name > hss-peer-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hss-peer-service)#
```

**Syntax**

```
[ no ] diameter suppress notify-request
```

- **no**
  Sets the command to the default value where the Notify-Request-Message is sent to the HSS.

**Usage**

Use this command to restrict the MME from sending the Notify-Request-Message to the HSS. This can be used to control whether handover to non-3GPP access can occur.
diameter update-dictionary-avps

Specifies which release of 3GPP TS 29.272 is to be used for the HSS peer service.

Product
MME
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration

configure > context context_name > hss-peer-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hss-peer-service)#

Syntax

diameter update-dictionary-avps { 3gpp-r10 | 3gpp-r9 }

no diameter update-dictionary-avps

no
Sets the command to the default value where Release 8 (‘standard’) dictionary is used for backward compatibility of previous releases.

3gpp-r10
Configures the MME/SGSN to signal additional AVPs to HSS in support of Release 10 of 3GPP 29.272.

3gpp-r9
Configures the MME/SGSN to signal Release 9 AVPs to HSS.

Usage
Use this command to configure the 3GPP release that should be supported for this HSS peer service. This command is only applicable for the ‘standard’ diameter dictionary as defined in the diameter hss-dictionary command.
dynamic-destination-realm

Enables the MME to construct the destination realm using the MCC and MNC of foreign subscribers.

**Product**
MME

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration

```
configure > context context_name > hss-peer-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hss-peer-service)#
```

**Syntax**

```
[ default | no ] dynamic-destination-realm
```

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returns the configuration to the default setting, where the MME uses the configured peer realm as the destination realm.</td>
</tr>
</tbody>
</table>

| no |
| Disables the dynamic destination realm configuration. This provides the same behavior as the `default` keyword. |

**Usage**

This command configures the MME to derive the EPC Home Network Realm/Domain based on the user's IMSI (MNC and MCC values) and use it as the Destination Realm in all diameter messages. For a foreign subscriber, the MME does not know the HSS nodes in all the foreign PLMNs. In this case the MME routes S6a/S6d requests directed to foreign PLMNs via a Diameter Routing Agent (DRA) using only the destination realm. The DRA in turn routes the request to the correct HSS based on the destination realm. In order to accomplish this, the MME needs to dynamically construct requests to the DRA/HSS with a Destination Realm representing the foreign PLMN of the UE.

Refer to Configuring Dynamic Destination Realm Construction for Foreign Subscribers in Chapter 2 of the MME Administration Guide for more information about configuring this feature.

**Example**

The following command configures the MME to derive the destination realm for foreign subscribers based on the user’s IMSI (MNC/MCC).

```
dynamic-destination-realm
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
done
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
**failure-handling**

Configures failure handling behavior in the event of a failure with the HSS peer service. It also defines the action on various error codes on the Diameter interface during authentication or session activities.

**Product**
- MME
- SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration

```bash
configure > context context_name > hss-peer-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hss-peer-service)#
```

**Syntax**

```bash
failure-handling { authentication-information-request | check-identity-request | notify-request | purge-ue-request | update-location-request } { diameter-result-code start_error_code [ to end_error_code ] | request-timeout } action { continue | retry-and-terminate | terminate }

no failure-handling { authentication-information-request | check-identity-request | notify-request | purge-ue-request | update-location-request } diameter-result-code start_error_code [ to end_error_code ]

default failure-handling { authentication-information-request | check-identity-request | notify-request | purge-ue-request | update-location-request } request-timeout
```

**no**

Removes the preconfigured failure handling procedures for calls in an HSS peer service.

**default**

Sets the default action for failure handling procedure for calls in an HSS peer service. For default actions on Diameter result/error codes see the *Usage* section below.

**authentication-information-request**

Configures the MME-HSS service to handle the failures in an Auth-Information-Request message.

Configures the SGSN-HSS service to handle the failures in an Auth-Information-Request message.

**check-identity-request**

Configures the MME-HSS service to handle the failures in a Check-Identity-Information-Request message.

Configures the SGSN-HSS service to handle the failures in a Check-Identity-Information-Request message.
notify-request
Configures the MME-HSS service to handle the failures in a Notify-Request message. This option is not supported on SGSN.

purge-ue-request
Configures the MME-HSS service to handle the failures in a Purge-UE-Request message. Configures the SGSN-HSS service to handle the failures in a Purge-UE-Request message.

update-location-request
Configures the HSS peer service to handle the failures in an Update-Location-Request message.

diameter-result-code start_error_code [to end_error_code]
Configures the HSS peer service to handle the failures for various request message having specific single or range of Diameter result codes in a request message. 

start_error_code specifies an individual error code for Diameter protocol as an integer from 3000 through 5999. This will be the starting of code if a range of error codes is specified with the optional keyword to end_error_code.

to end_error_code is used to specify a range of error codes to handle by this command.

end_error_code specifies the end error code for Diameter protocol as an integer from 3000 through 5999.

request-timeout
Configures the HSS peer service to handle the failures for various request messages if response to that message is not received before timeout duration exhausted.

action { continue | retry-and-terminate | terminate }
Specifies the action to be taken on failure of any message as a policy for failure handling.

continue: This option works differently for each system.

For the SGSN: On receipt of any error for MICR session request, the SGSN allows the HSS peer service to continue with the session procedure without any interruption. For all other request/message types, the SGSN behaves as it would if configured for the retry-and-terminate option.

For the MME: The MME does not support this option and if continue is included in the command, the MME behaves as it would if configured for the retry-and-terminate option.

For 12.0 and earlier releases the continue option in failure handling on SGSN for IMEI procedures has the same behavior as that of the retry-and-terminate option.

Important: For releases after 14.0, the continue option for IMEI procedure on SGSN can be configured in case of timeout and error responses requests from HSS so that the requests will be re-tryed on a second peer (if configured) and the call is continued. The configuration of continue option for IMEI procedure is as follows:

configure

class <name>

hss-peer-service <name>
failure-handling check-identity-request request-timeout
action continue

failure-handling check-identity-request diameter-result-code
<range1> to <range2> action continue

failure-handling check-identity-request diameter-result-code
<range1> action continue

exit

exit

exit

• retry-and-terminate: On receipt of any error, once the configured condition (either the request timeout or receipt of the specified result code) occurs, the system retries sending the request (AIR/ULR/NOR/PUR/MICR) to another peer that is configured in the same endpoint. If no response is received for AIR or ULR from the second peer, then the system allows the HSS peer service to terminate the session.

• terminate: On receipt of any error, once the configured condition (either the request timeout or receipt of the specified result code) is met, the system allows the HSS peer service to immediately terminate the session (AIR/ULR/MICR) without any further action.

Usage

Use this command to configure the failure handling behavior in the event of a communication failure with the HSS peer service.

The following are the default actions for Diameter result codes:
• For all protocol error codes 3000 to 3999, the default action is terminate. For all transient error codes 4000, 4001, 4004 to 4180, and 4182 to 4999, the default action is continue.
• For transient error codes 4002, 4003, and 4181, the default action is retry.
• For error code 4001, the default action is terminate.
• For permanent error codes 5000 to 5999, the default action is terminate.

Example

The following command will allow HSS peer service to continue if any failure in Auth-Information-Request message occurred with Diameter error code 3050:

failure-handling authentication-information-request diameter-result-code
3050 action continue
request timeout

Configures the application request timeout between the HSS peer service and HSS node. The MME/SGSN waits for this duration before retransmitting the request to corresponding HSS node.

Product
MME
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration
configure > context context_name > hss-peer-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-hss-peer-service)#

Syntax

request timeout dur

[ no | default ] request timeout

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disables the configured application request timeout value.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sets the application request time out duration to default value of 300 seconds.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>dur</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the application request timeout duration (in seconds) as an integer from 1 through 300. The MME/SGSN will wait for this duration before retrying the request with corresponding HSS. Default: 20</td>
</tr>
</tbody>
</table>

Usage
Use this command to set the waiting period for HSS peer service in seconds after which the request is deemed to have failed or system will resend the request.

Example
The following example configures the application request timeout duration to 20 seconds:

   default request timeout
**zone-code-format**

Configures how the MME must interpret the received zone-code values from the HSS.

**Product**
MME

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > HSS Peer Service Configuration

```
configure > context context_name > hss-peer-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-hss-peer-service)#
```

**Syntax**

```
zone-code-format \{ ascii-string \}

[ default ] zone-code-format
```

- **default**
  Returns the command to the default setting, where the MME interprets the zone-code as an octet string.

- **ascii-string**
  Configures the MME to interpret the zone-code as an ascii string. This option is provided to maintain backward compatibility.
  When configured as ascii-string, the MME interprets the received zone-code as an ASCII string (coded in hexadecimal representation) and converts it byte by byte to an integer value. For example, if the HSS sends the zone-code value as 3032, the MME converts this to 02 (ASCII value of 0 in Hex is 0x30, ASCII value of 2 in Hex is 0x32). With this configuration, the MME accepted zone-codes only within the range of 0 to 99.

**Usage**

This new command specifies the format of the zone-code value received from HSS to MME. The MME uses this configuration to interpret and convert the received zone-code value to an integer value and validate it against the list of allowed zone-code configured for the zone-code restriction feature.

By default, the MME interprets the received zone-code value from HSS as a octet-string (2 bytes) which is coded in full hexadecimal representation. The MME converts the entire 2 byte octet string coded in hexadecimal to integer value and it uses the same for validation for zone-code restriction feature. For example, if the HSS sends the zone-code value as 3032, MME converts this to 12338 (which is the equivalent of 0x3032).

**Example**

The following command configures the HSS Peer Service to interpret the zone-code received from the HSS as an ASCII string.

```
zezone-code-format ascii-string
```
The Internet Group Management Protocol (IGMP) Profile Configuration Mode is used to create and manage the IGMP parameters for an Ethernet interface.

**Mode**

Exec > Global Configuration > Context Configuration > IGMP Profile Configuration

```plaintext
configure > context context_name > ip igmp profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-igmp-profile-<profile_name>)#
```

**Important:** Available commands or keywords/variables vary based on platform type, product version, and installed license(s).
**default ip igmp**

Configures default IGMP parameters.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IGMP Profile Configuration

```
configure > context context_name > ip igmp profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-igmp-profile-<profile_name>)#
```

**Syntax**

```
default ip igmp { query | require | robustness | unsolicited-report-interval | version }
```

**Usage**

Specify the IGMP parameters for the default profile. Refer to the remaining command description in this chapter for additional information.

**Example**

To apply enable echo mode on this interface, use the following command:

```
bfd echo
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

`exit`

**Usage**
Use this command to return to the parent configuration mode.
ip igmp query

Configures the maximum response time for IGMP queries.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IGMP Profile Configuration

```
configure > context context_name > ip igmp profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-igmp-profile-<profile_name>)#
```

**Syntax**

```
ip igmp query max-response-time seconds
```

**max-response-time seconds**
Specify the maximum number of seconds that the system will wait for an IGMP response as an integer from 1 through 25.

**Usage**
Specify the maximum response time for IGMP queries.

**Example**

```
ip igmp query max-response-time 10
```
**ip igmp require router-alert**

Sets the router alert flag to **ON** in IP IGMP packets.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IGMP Profile Configuration

`configure > context context_name > ip igmp profile profile_name`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-igmp-profile-<profile_name>)#`

**Syntax**

```
[ no ] ip igmp require router-alert
```

---

**no**

Sets the router alert flag to **OFF** in IP IGMP packets.

---

**Usage**

Sets the router alert flag to **ON** in IP IGMP packets.

**Example**

```
ip igmp require router-alert
```
ip igmp robustness

Sets the Robustness value in IP IGMP packets. The Robustness variable allows tuning for the expected packet loss on a subnet. If a subnet is expected to be lossy, the Robustness variable may be increased. IGMP is robust to packet losses. The Robustness variable should not be set to 1 (one).

ip igmp robustness value

value
Sets the robustness value as an integer from 1 through 10. Default: 2

Usage
Sets the robustness value in IP IGMP packets.

Example

ip igmp robustness 7
ip igmp unsolicited-report-interval

Sets the Unsolicited Report Interval which is the time between repetitions of a host's initial report of membership in a group.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IGMP Profile Configuration

```
configure > context context_name > ip igmp profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-igmp-profile-<profile_name>)#
```

**Syntax**

```
ip igmp unsolicited-report-interval seconds
```

**seconds**

Specifies the number of seconds between repetitions of a host's initial report of membership in a group as an integer from 1 through 25. Default: 10

**Usage**

Set the Unsolicited Report Interval which is the time between repetitions of a host's initial report of membership in a group.

**Example**

```
ip igmp unsolicited-report-interval 15
```
**ip igmp version**

Sets the IGMP version to be supported by this interface.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IGMP Profile Configuration

configure > context context_name > ip igmp profile profile_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-igmp-profile-<profile_name>)#
```

**Syntax**

```
ip igmp version { v1 | v2 | v3 }
```

<table>
<thead>
<tr>
<th>v1</th>
<th>v2</th>
<th>v3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the IGMP Version number:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• v1: Version 1, RFC 1112</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• v2: Version 2, RFC 2236</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• v3: Version 3, RFC 4604</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Usage**

Set the IGMP version to be supported by this interface.

**Example**

```
ip igmp version v2
```
Chapter 171
IKEv2 Security Association Configuration Mode
Commands

The IKEv2 Security Association Configuration Mode is used to configure a Security Association (SA) at the outset of an IPSec session. A security association is the collection of algorithms and parameters (such as keys) that is being used to encrypt and authenticate a particular flow in one direction. In normal bi-directional traffic, the flows are secured by a pair of security associations.

Mode

Exec > Global Configuration > Context Configuration > IKEv2 Security Association Configuration

configure > context context_name > ikev2-ikesa transform-set set_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(cfg-ctx-ikev2ikesa-tran-set)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**default**

Sets the default properties for the selected parameter.

**Product**
ePDG
PDIF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IKEv2 Security Association Configuration

```bash
configure > context context_name > ikev2-ikesa transform-set set_name
```

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(cfg-ctx-ikev2ikesa-tran-set)#
```

**Syntax**

```bash
default { encryption | group | hmac | lifetime | prf }
```

Set the defaults for the following parameters:

- **encryption**: Default algorithm for the IKEv2 IKE SA is AES-CBC-128.
- **group**: Default Diffie-Hellman group is Group 2.
- **hmac**: Default IKEv2 IKE SA hashing algorithm is SHA1-96.
- **lifetime**: Default lifetime for SAs derived from this transform-set is 86400 seconds.
- **prf**: Default PRF for the IKEv2 IKE SA is SHA1.

**Usage**

Configure default parameters for the IKEv2 IKE SA transform-set.

**Example**

Use the following configuration to set the default encryption algorithm:

```bash
default encryption
```
encryption

Configures the appropriate encryption algorithm and encryption key length for the IKEv2 IKE security association. AES-CBC-128 is the default.

**Product**
ePDG
PDIF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IKEv2 Security Association Configuration

```
configure > context context_name > ikev2-ikesa transform-set set_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(cfg-ctx-ikev2ikesa-tran-set)#
```

**Syntax**

```
encryption { 3des-cbc | aes-cbc-128 | aes-cbc-256 | des-cbc | null }
```

**default encryption**

---

### 3des-cbc

Data Encryption Standard Cipher Block Chaining encryption applied to the message three times using three different cipher keys (triple DES).

### aes-cbc-128

Advanced Encryption Standard Cipher Block Chaining with a key length of 128 bits.

### aes-cbc-256

Advanced Encryption Standard Cipher Block Chaining with a key length of 256 bits.

### des-cbc

### null

Configures no IKEv2 IKE Security Association Encryption Algorithm. All IKEv2 IPsec Child Security Association protected traffic will be sent in the clear.

**Usage**

IKEv2 requires a confidentiality algorithm to be applied in order to work. In cipher block cryptography, the plaintext is broken into blocks usually of 64 or 128 bits in length. In cipher block chaining (CBC) each encrypted block is chained into the next block of plaintext to be encrypted. A randomly-generated vector is applied to the first block of plaintext in lieu of an encrypted block. CBC provides confidentiality, but not message integrity.
Because RFC 4307 calls for interoperability between IPSec and IKEv2, the IKEv2 confidentiality algorithms must be the same as those configured for IPSec in order for there to be an acceptable match during the IKE message exchange. Because of RFC4307, in IKEv2, there is no viable NULL option, it is available for testing only.

**Example**

The following command configures the encryption to be aes-cbc-128:

```
encryption aes-cbc-128
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
group

Configures the appropriate key exchange cryptographic strength by applying a Diffie-Hellman group. Default is Group 2.

Product

ePDG

PDIF

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > IKEv2 Security Association Configuration

configure > context context_name > ikev2-ikesa transform-set set_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(cfg-ctx-ikev2ikesa-tran-set)#

Syntax

```plaintext
group { 1 | 2 | 5 | 14 }
```

**default group**

1

Configures crypto strength at the Group 1 level. Lowest security.

2

Configures crypto strength at the Group 2 (default) level. Medium security. This is the default setting for this command.

5

Configures crypto strength at the Group 5 level. Higher security.

14

Configures crypto strength at the Group 14 level. Highest security

**Usage**

Diffie-Hellman groups are used to determine the length of the base prime numbers used during the key exchange process in IKEv2. The cryptographic strength of any key derived depends, in part, on the strength of the Diffie-Hellman group upon which the prime numbers are based. Group 1 provides 768 bits of keying strength, Group 2 provides 1024 bits, Group 5 provides 1536 bits and Group 14 provides 2048 bits of encryption strength. Configuring a DH group also enables Perfect Forward Secrecy, which is disabled by default.

**Example**

This command configures crypto strength at the Group 14 level. Highest security group 14:
default group
**hmac**

Configures the IKEv2 IKE SA integrity algorithm. Default is SHA1-96.

**Product**
ePDG
PDIF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IKEv2 Security Association Configuration

```
configure > context context_name > ikev2-ikesa transform-set set_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(cfg-ctx-ikev2ikesa-tran-set)#
```

**Syntax**

```
hmac { aes-xcbc-96 | md5-96 | sha1-96 | sha2-256-128 | sha2-384-192 | sha2-512-256 }
```

**default hmac**

```
aes-xcbc-96
HMAC-AES-XCBC uses a 128-bit secret key and produces a 128-bit authenticator value.
```

```
md5-96
HMAC-MD5 uses a 128-bit secret key and produces a 128-bit authenticator value.
```

```
sha1-96
HMAC-SHA-1 uses a 160-bit secret key and produces a 160-bit authenticator value. This is the default setting for this command.
```

```
sha2-256-128
HMAC-SHA-256 uses a 256-bit secret key and produces a 128-bit authenticator value.
```

```
sha2-384-192
HMAC-SHA-384 uses a 384-bit secret key and produces a 192-bit authenticator value.
```

```
sha2-512-256
HMAC-SHA-512 uses a 512-bit secret key and produces a 256-bit authenticator value.
```

**Usage**
IKEv2 requires an integrity algorithm be configured in order to work.
A keyed-Hash Message Authentication Code, or HMAC, is a type of message authentication code (MAC) calculated using a cryptographic hash function in combination with a secret key to verify both data integrity
and message authenticity. A hash takes a message of any size and transforms it into a message of a fixed size: the authenticator value. This is truncated and transmitted. The authenticator value is reconstituted by the receiver and the first truncated bits are compared for a 100 percent match.

**Example**

This command configures HMAC value md5-96:

```
hmac md5-96
```
**lifetime**

Configures the lifetime of a security association (SA) in seconds.

**Product**
ePDG
PDIF

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IKEv2 Security Association Configuration

```
configure > context context_name > ikev2-ikesa transform-set set_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(cfg-ctx-ikev2ikesa-tran-set)#
```

**Syntax**

```
lifetime sec
```

**Usage**

Sets the value of the timeout parameter in seconds as an integer from 60 through 86400. Default: 86400

```
lifetime sec
```

The secret keys that are used for various aspects of a configuration should only be used for a limited amount of time before timing out. This exposes a limited amount of data to the possibility of hacking. If the SA expires, the options are then to either close the SA and open a new one, or renew the existing SA.

**Example**

The following command sets the lifetime timeout to 120 seconds:

```
lifetime 120
```
prf

Selects one of the HMAC integrity algorithms to act as the IKE Pseudo-Random Function. A PRF produces a string of bits that an attacker cannot distinguish from random bit string without knowledge of the secret key. The default is SHA1.

Product
ePDG
PDIF

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IKEv2 Security Association Configuration

configure > context context_name > ikev2-ikesa transform-set set_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(cfg-ctx-ikev2ikesa-tran-set)#

Syntax

prf { aes-xcbc-128 | md5 | sha1 | sha2-256 | sha2-384 | sha2-512 }

default prf

---

aes-xcbc-128

Configure IKEv2 IKE Security Association Pseudo Algorithm to be AES-XCBC-128.

md5

MD5 uses a 128-bit secret key and produces a 128-bit authenticator value.

sha1

SHA-1 uses a 160-bit secret key and produces a 160-bit authenticator value. SHA-1 is considered cryptographically stronger than MD5, but it takes more CPU cycles to compute. This is the default setting for this command.

sha2-256

PRF-HMAC-SHA-256 uses a 256-bit secret key.

sha2-384

PRF-HMAC-SHA-384 uses a 384-bit secret key.

sha2-512

PRF-HMAC-SHA-512 uses a 512-bit secret key.
**Usage**

This command generates keying material for all the cryptographic algorithms used in both the IKE_SA and the CHILD_SAs.

**Example**

This configuration sets the PRF to be value sha2-256:

```
prf sha2-256
```
Chapter 172
IMEI Profile Configuration Mode

The IMEI profile configuration mode defines a set of parameters controlling the SGSN behavior when a Request is received from a device in the specified IMEI (International Mobile Equipment Identity) range. An IMEI profile is a key element in the Operator Policy feature and an IMEI profile is not used or valid unless it is associated with an IMEI range and this association is specified in an operator policy (see the Operator Policy Configuration Mode Commands chapter elsewhere in the Command Line Interface Reference).

Essentially, an IMEI profile is a template which groups a set of device-specific commands that may be applicable to one or more IMEIs. The same IMEI profile can be associated with multiple IMEI ranges and multiple operator policies.

An SGSN supports a total of 1000 IMEI profile configurations.

Mode

Exec > Global Configuration > IMEI Profile Configuration
configure > imei-profile profile_name

Entering the above command sequence results in the following prompt:

[local]host_name(config-imei-profile-profile_name)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**associate**

Associate an APN remap table with this IMEI profile.

Note that an APN remap table can be associated with an IMEI profile before the table has actually been created/configured.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > IMEI Profile Configuration

```
configure > imei-profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-imei-profile-profile_name)#
```

**Syntax**

```
associate apn-remap-table table_name

no associate apn-remap-table
```

*no*

Disables the configured remap table association.

*table_name*

Define the name of an APN remap table that is to be associated with this IMEI profile for call routing based in IMEI.

**Usage**

Use this command to associate an APN remap table with this IMEI profile. With such an association, it is possible to override an APN call-routing based on an IMEI.

For example, with the APN exceptions defined in an APN remap table (refer to the APN Remap Table Configuration Mode chapter), a blank APN or an incorrect APN could be overridden. So during PDP Activation for in incoming call, the call could be rerouted based on an IMEI in the range defined for the IMEI profile.

**Example**

Associate the APN remap table ‘remapHO’ (remaps all calls with blank APNs to the head-office) to this IMEI profile:

```
associate apn-remap-table remapHO
```
**blacklist**

Blacklist all mobile devices that fit the IMEI definitions associated with this IMEI profile.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > IMEI Profile Configuration

```bash
configure > imei-profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(configimei-profile-profile_name)#
```

**Syntax**

- `blacklist`
- `remove blacklist`

**Usage**

- Including this keyword with the command, removes the blacklist command from the IMEI profile configuration.

**Example**

Blacklists subscribers whose devices bear IMEI that match the defined IMEI range for this profile.

Use this command to blacklist all subscribers with IMEI that fall within the range set for this IMEI profile:

```
blacklist
```
**description**

Define a descriptive string relevant to the specific APN profile.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > IMEI Profile Configuration

```plaintext
configure > imei-profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[local] host_name(config-imei-profile-profile_name) #
```

**Syntax**

```
description description
```

```
remove description
```

**remove**

Removes the configured description from this APN profile.

```
description
```

Enter an alphanumeric string of 1 to 100 alphanumeric characters. The string may include spaces, punctuation, and case-sensitive letters if the string is enclosed in double quotes (" ").

**Usage**

Define information that identifies this particularly APN profile.

**Example**

Indicate that this IMEI profile IMEIprof1 is to be used for customers in the United Kingdom and that the profile:

```
description "IMEIprof1 defines routing actions based on IMEI for customers in the UK."
```
**direct-tunnel**

Instruct the SGSN to enable/disable a direct tunnel between the RNC and the GGSN based on the IuPS service configuration.

**Product**  
SGSN

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > Global Configuration > IMEI Profile Configuration

```
configure > imei-profile profile_name
```

Entering the above command sequence results in the following prompt:

```
[local]host_name(config-imei-profile-profile_name)#
```

**Syntax**

```
direct-tunnel check-iups-service

no direct-tunnel
```

This command instructs the SGSN to disable the direct tunnel function between the GGSN and the RNC.

**Usage**

Direct tunnel is enabled by default on the GGSN and often on the RNC. This leaves it to the SGSN’s configuration to actually enable or disable a direct tunnel. With the SGSN, the options for configuring a direct tunnel are complex -- enable/disable on the basis of APNs, or RNCs, or GGSNs, or on the basis of the IMEI range. Refer to the *SGSN Administration Guide* for configuration details.

**Example**

Assuming the IuPS service configuration has enabled DT for associated RNCs, then use this command to enable DT from the RNC to the GGSN associated with this IMEI profile:

```
direct tunnel check-iups-service
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the context configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
exit

**Usage**
Move to the previous configuration mode.
**ggsn-address**

Identify the target GGSN for traffic being managed by this IMEI profile.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > IMEI Profile Configuration

```plaintext
configure > imei-profile profile_name
```

Entering the above command sequence results in the following prompt:

```plaintext
[local]host_name(config-imei-profile-profile_name)#
```

**Syntax**

```plaintext
ggsn-address IPv4/IPv6_address
```

*IPv4/IPv6_address*

Enter the IP address of the target GGSN. Enter the address in either standard IPv4 dotted decimal format or in standard IPv6 colon notation format.

**Usage**

Use this command to define the IP address of the target GGSN to be associated with this IMEI profile.

**Example**

The following command identifies the address of the GGSN associated with this IMEI profile as 123.123.11.1

```plaintext
ggsn-address 123.123.11.1
```
ignore-pdp-data-inactivity

On executing this command the SGSN ignores PDP Data Inactivity configuration under the APN profile for one or more matching IMEIs.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > IMEI Profile Configuration
configure > imei-profile profile_name

Entering the above command sequence results in the following prompt:
[local]host_name(config-imei-profile-profile_name)#

Syntax
ignore-pdp-data-inactivity
remove ignore-pdp-data-inactivity

This command is used to disable or remove the option to ignore PDP data inactivity from the IMEI profile.

Usage
The SGSN supports options to configure PDP Data Inactivity detection duration and actions to be performed on timeout under the APN-Profile. The following configurable actions are supported under APN-Profile in case of PDP Data Inactivity detection in the PDP context:

1. De-activate all PDPs of the subscriber
2. De-activate all PDPs of the bundle (all linked PDPs)
3. Detach the subscriber. This action is triggered when:
   • Data in-activity is detected for all PDPs
   • Data in-activity is detected for any of the PDPs

On the Detection of the PDP Data Inactivity, depending on the configuration option the SGSN either de-activates the PDP or detaches the subscriber.

The ignore-pdp-data-inactivity CLI is added to provide an option under the IMEI-Profile to ignore PDP Data Inactivity configuration for one or more IMEIs. On configuring this CLI, the SGSN ignores the application of in-activity configuration (configured in the APN-Profile) for a specified set of IMEI's.

Example
Use this command to ignore PDP Data Inactivity configuration under the APN profile for one or more matching IMEIs.
ignore-pdp-data-inactivity
pdp-activate

This command enables the operator to configure the SGSN to reject Secondary PDP Activation Requests from the UE based on IMEI range.

Product
SGSN

Privilege
Administrator

Mode
Exec > Global Configuration > IMEI Profile Configuration

configure > imei-profile profile_name

Entering the above command sequence results in the following prompt:

   [local]host_name(config-imei-profile-profile_name)#

Syntax

[ remove ] pdp-activate { drop | restrict } secondary-activation access-type { gprs | umts }

remove
Removes the configured value and returns the pdp-activate configuration to the default ‘not configured’ state.

drop
This keyword causes the GSN to ignore the Request.

restrict
This keyword instructs the SGSN to reject Secondary PDP Activation Requests.

access-type { gprs | umts }
This keyword instructs the SGSN to ignore or reject Secondary PDP Activation Requests on the basis of the UE’s access network type:

- **gprs** : from a 2G network.
- **umts** : from a 3G network.

Usage
The SGSN administrator can use this command to configure the IMEI profile in the operator policy to either ignore or reject Secondary PDP Activation Requests from UEs based on an IMEI range and UE access-type. Restricting secondary PDP activation based on the IMEI (in the IMEI profile) takes precedence over secondary PDP activation that might be configured in the call control profile.

Example
Enable rejection of Secondary PDP Activation Requests for 2G callers:

pdp-activate restrict secondary-activation access-type gprs
Chapter 173
IMS Authorization Service Configuration Mode Commands

The IMS Authorization Service Configuration Mode enables to configure IP Multimedia Subsystem (IMS) authorization services to manage policy control functions and Gx interface support.

Exec > Global Configuration > Context Configuration > IMS Authorization Service Configuration

configure > context context_name > ims-auth-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-imsa-service)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**
Use this command to return to the parent configuration mode.
p-cscf discovery

This command defines the method of Proxy-Call Session Control Function (P-CSCF) discovery to be used.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IMS Authorization Service Configuration
configure > context context_name > ims-auth-service service_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-imsa-service)#
```

**Syntax**

```
p-cscf discovery { table { 1 | 2 } [ algorithm { ip-address-modulus | msisdn-modulus | round-robin } ] | diameter-configured } 
[ default | no ] p-cscf discovery
```

- **default**
  Sets the P-CSCF discovery to default parameter.

- **no**
  Removes/deletes configured parameters for P-CSCF discovery.

- **table { 1 | 2 }**
  Specifies that which P-CSCF table is to be used to obtain the primary and secondary P-CSCF addresses. Total 2 tables can be configured for P-CSCF discovery.

- **algorithm { ip-address-modulus | msisdn-modulus | round-robin }**
  Specifies the algorithm to select the row from the P-CSCF table to be used for P-CSCF discovery.

  - **ip-address-modulus**: This algorithm divides the IP address, in binary, of the subscriber by the number of rows in the table, and the remainder is used as an index into the specified table to select the row.

  - **msisdn-modulus**: This algorithm divides the MSISDN value, in binary without the leading “+”, of the subscriber by the number of rows in the table, and the remainder is used as an index in the specific table to select the row.

  - **round-robin**: This algorithm rotates all rows in the active table for selection of the row in round-robin way. If no algorithm is specified this is the default behavior.

Default: **round-robin**
**diameter-configured**

This option enables the table number and algorithm specified by the `diameter host-select table` configuration in Policy Control Configuration mode.

**Usage**

Use this command to configure the table and row selection methods to select IP address/host address for P-CSCF discovery.

**Example**

The following command specifies table 1 with `round-robin` algorithm to select the rows with IP address for P-CSCF discovery.

```
p-cscf discovery table 1 algorithm round-robin
```
**p-cscf table**

This command adds/appends rows with primary and/or secondary IPv4/IPv6 addresses to a P-CSCF discovery table with precedence for P-CSCF discovery.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IMS Authorization Service Configuration

```
configure > context context_name > ims-auth-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-imsa-service)#
```

**Syntax**

In releases prior to 18:

```
p-cscf table { 1 | 2 } row-precedence precedence_value { address ipv4_address | ipv6-address ipv6_address } [ secondary { address ipv4_address | ipv6-address ipv6_address } ] [ weight value ]
```

```
no p-cscf table { 1 | 2 } row-precedence precedence_value
```

In 18 a

```
p-cscf table { 1 | 2 } row-precedence precedence_value { ipv4-address ipv4_address [ ipv6-address ipv6_address ] | ipv6-address ipv6_address [ ipv4-address ipv4_address ] } [ secondary { ipv4-address ipv4_address [ ipv6-address ipv6_address ] | ipv6-address ipv6_address [ ipv4-address ipv4_address ] } [ weight value ]
```

```
no p-cscf table { 1 | 2 } row-precedence precedence_value
```

**no**

Removes/deletes configured row with precedence in specified table for P-CSCF discovery address.

```
{ 1 | 2 }
```

Specifies which P-CSCF table is to be used to add/append the primary and secondary P-CSCF addresses.

Two tables can be configured for P-CSCF discovery address.

**row-precedence precedence_value**

This keyword adds/appends the row with the specified row-precedence to the P-CSCF address table.

In 8.1 and later releases, `precedence_value` must be an integer from 1 through 128, and a maximum of 128 rows can be added to a table.

In release 8.0, `precedence_value` must be an integer from 1 through 100, and a maximum of 16 rows can be added to a table.
secondary
Specifies the secondary IPv4/IPv6 address to be entered in P-CSCF table rows.

address ip_address
Specifies the primary and/or secondary IPv4 address for P-CSCF discovery table. This keyword, if used with secondary keyword, specifies the secondary IPv4 address. ip_address must be entered in IPv4 dotted-decimal notation.

ipv6-address ipv6_address
Specifies the primary and/or secondary IPv6 address for P-CSCF discovery table. This keyword, if used with secondary keyword, specifies the secondary IPv6 address. ipv6_address must be entered in IPv6 colon-separated-hexadecimal notation.

weight value
This keyword designates weight to a row-precedence relative to other row-precedences configured under this table. Default value is 1. value must be an integer from 1 through 10.
Within the IMS Authorization configuration, the P-CSCF address is selected based on round robin fashion. This feature allows the customer to perform P-CSCF selection based on weight factor. With this CLI option, the user can configure and add weight (in the scale of 1 to 10) to each row, and the rows are selected based on weighted round-robin. That is, the row with higher weight parameter is selected more number of times than the row with less number of weights.

Usage
Use this command to add rows with primary and/or secondary IP addresses for P-CSCF discovery. The row is added with the specified row-precedence.
The operator can add/remove rows to the table that is not currently selected by the diameter host-select table command in Policy Control Configuration Mode.

Example
The following command adds a row in table 2 with primary IP address 10.2.3.4, secondary IP address as 50.6.7.8, and row-precedence value as 20 for P-CSCF discovery.

    p-cscf table 2 row-precedence 20 address 10.2.3.4 secondary 50.6.7.8
policy-control

This command enters the Policy Control Configuration mode for Diameter Policy Control Application (DPCA) to configure Diameter authorization and policy control parameter for IMS authorization.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IMS Authorization Service Configuration

configure > context context_name > ims-auth-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-imsa-service)#

Syntax

[ no ] policy-control

no

Disables the pre-configured policy control parameters for IMS authorization in this IMS authorization service.

Usage

Use this command to enter the Policy Control Configuration Mode to configure the policy control parameters for Diameter authorization and charging policy in IMS Authorization Service. Entering this command results in the following prompt:

[context_name]hostname(config-imsa-dpca)#

Policy Control configuration commands are described in the Policy Control Configuration Mode Commands chapter.
**qos-update-timeout**

This command is obsolete in release 11.0 and later releases. This command sets the Quality of Service update timeout for a subscriber in IMS authorization service.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IMS Authorization Service Configuration

Command

```bash
configure > context context_name > ims-auth-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-imsa-service)#
```

**Syntax**

```
qos-update-timeout timeout_duration

no qos-update-timeout
```

**Usage**

Use this command to set the maximum time to wait for a subscriber to initiate the update QoS procedure in IMS authorization service.

**Example**

The following command sets the QoS update timeout to 90 seconds.

```bash
qos-update-timeout 90
```
signaling-flag

This command specifies whether a request for a PDP context dedicated to signaling (for IMS sessions) should be granted or denied.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IMS Authorization Service Configuration

```bash
configure > context context_name > ims-auth-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-imsa-service)#
```

Syntax

```
signaling-flag { deny | permit }
```

**default signaling-flag**

```bash
default
```

Sets the signaling flag to default mode of deny.

```bash
deny
```

Denies the request for a signaling PDP context for IMS session and keeps signaling co-existed with other traffic on PDP contexts. Default: Enabled

```bash
permit
```

Permits the request for a signaling PDP context for IMS session and a separate signaling context activated. Default: Disabled

**Usage**

Use this command to allow or deny the activation of a dedicated PDP context for signaling. The user equipment (UE) may indicate that the PDP context should be dedicated for IP multimedia (IM) signaling by setting the IP Multimedia Core Network (IM-CN) signaling flag in the Protocol Configuration Options (PCO).

The **deny** option causes the system to inform the UE that the PDP context will not be dedicated for IM signaling and signaling will co-exist with other traffic on PDP context.

The **permit** option is used to activate the signaling context for signal traffic and the other traffic uses other PDP context for traffic with the following destinations:

- Towards the DHCP and DNS servers for the IMS domain
- Towards the P-CSCF(s)

The UE is not trusted to follow these restrictions, and the system monitors and restricts the traffic from the dedicated PDP context. The **signaling-flow class-map** command is used to configure the restrictions.
Example

The following command denies the request for a signaling PDP context for IMS session.

```
default signaling-flag
```
signaling-flow

This command specifies the packet filters and policy servers for bandwidth control and singling context enforcement that define the traffic that is allowed through the dedicated signaling context.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IMS Authorization Service Configuration

configure > context context_name > ims-auth-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-imsa-service)#

Syntax

signaling-flow permit server-address ipv4/ipv6_address [ server-port { port_num | range start_port to end_port } ] [ description STRING ]

no signaling-flow permit server-address ipv4/ipv6_address [ server-port { port_num | range start_port to end_port } ]

no

Disables the signaling flow option configured with this command.

server-address ipv4/ipv6_address

The server address refers to the destination IP address in uplink packets, and the source IP address in downlink packets.

ipv4/ipv6_address is an IP address in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation and can be used with a subnet mask.

A maximum of 16 signaling server addresses can be configured per IMS Authorization service.

server-port { port_num | range start_port to end_port }

Specifies the TCP/UDP port number(s) of the server to be used for communication.

port_num must be an integer from 1 through 65535.

range start_port to end_port provides the option to configure the range of ports on server for communication.

start_port must be an integer from 1 through 65535 but lesser than end_port, and end_port must be an integer from 1 through 65535 but greater than start_port.

description STRING

Specifies the customized description for configured signaling server as an alphanumeric string of 1 through 63 characters.
Usage

Traffic that matches any instance of the signaling-flow command will be forwarded via the signaling PDP context. In addition, the policy server gives policy gates to use for the signaling PDP context.

Example

The following command sets the packet filter server address to 10.2.3.4 with port number 1234 for packet filtering.

```
signaling-flow server-address 10.2.3.4 server-port 1234
```
traffic-policy

This command specifies the action on packets which do not match any policy gates in the general purpose PDP context.

Product

All

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > IMS Authorization Service Configuration

configure > context context_name > ims-auth-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-imsa-service)#

Syntax

traffic-policy general-pdp-context no-matching-gates direction { downlink | uplink } { forward | discard }

default traffic-policy general-pdp-context no-matching-gates direction { downlink | uplink }

default

Sets the default traffic policy for packets without any policy gate match in general purpose PDP context. By default packets which do not have any matching policy gate are forwarded.

no-matching gates

Applies traffic policy for packets which do not match any policy gate.

direction { downlink | uplink }

Specifies the direction of traffic to apply this traffic policy in general PDP context.
downlink: Specifies the traffic from system to MN. Default is set to forward.
uplink: Specifies the traffic from MN to system. Default is set to forward.

forward

Forwards the packets which do not match any policy gates. Default: Enabled

discard

Discards the packets which do not match any policy gates. Default: Disabled

Usage

This command provides configuration on traffic policy applied on packets which are not matching any policy gate in general PDP context. Packets can either be forwarded or discarded on the basis of operator’s configuration.
This command needs to be configured once for downlink and once for uplink separately.
Example

The following command discards uplink packets which do not match any policy gate in general purpose PDP context.

```
traffic-policy general-pdp-context no-matching-gates direction uplink discard
```
Chapter 174
IMS Sh Service Configuration Mode Commands

The IMS Sh Interface Configuration Mode is used to configure various Diameter parameters in order for:
PDIF to communicate with the HSS server. HSS server is used for MAC address validation in the IKEv2 exchanges to set up SAs and for storing part of the user profile.
SCM to communicate with the HSS server. HSS server is used for retrieval and update of call feature parameters and call restriction data.

Mode

Exec > Global Configuration > Context Configuration > IMS Sh Interface Configuration

configure > context context_name > ims-sh-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ims-sh-service)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
diameter

This command configures Diameter parameters.

**Product**
PDIF
SCM

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IMS Sh Interface Configuration

```plaintext
configure > context context_name > ims-sh-service service_name
```

Entering the above command sequence results in the following prompt:

```plaintext
[context_name]host_name(config-ims-sh-service)#
```

**Syntax**

```plaintext
diameter { dictionary { custom1 | standard | endpoint string } }

default diameter { dictionary | endpoint }

no diameter endpoint
```

**no**
Removes previously configured endpoint.

**default**
Configures parameters to the default value.

**dictionary**
Specifies the dictionary to use.
- **custom1**: A custom dictionary
- **standard**: The standard dictionary

**Important:** SCM uses only the standard dictionary.

**endpoint string**
Selects an endpoint to use in the configuration.

*string* must be the endpoint name, and must be an alpha and/or numeric string of 1 through 63 characters in length.

**Usage**
The Diameter endpoint contains information on the peer names and IP addresses and port, and the local IP address to use for Diameter.
You can have more than one Diameter endpoint configured on the chassis and the ims-sh-service needs to know which Diameter endpoint to use. This command is to select the appropriate Diameter endpoint, even if only one has been configured.

Example

The following example selects a diameter endpoint `diam1`:

```
diameter endpoint diam1
```
**end**

Exits the current mode and returns to the Exec Mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to change to the Exec Mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
failure-handling

This command configures the action to take in the event of an HSS server request failure.

Product
PDIF
SCM

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > IMS Sh Interface Configuration
configure > context context_name > ims-sh-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ims-sh-service)#

Syntax

[ default ] failure-handling { profile-update-request | user-data-request } { { diameter-result-code result_code [ to result_code ] } | timeout } action { continue | retry-and-terminate | terminate } }

default
Resets configuration for the specified keyword to the default setting.

profile-update-request
Configures failure-handling as a result of a profile update request error.

user-data-request
Configures failure-handling as a result of a user data request.

diameter-result-code result_code [ to result_code ]
The Result-Code data field contains a space representing errors. Diameter provides the following classes of errors, all identified by the thousands digit in the decimal notation:

- 3xxx (Protocol Errors)
- 4xxx (Transient Failures)
- 5xxx (Permanent Failure)

result_code specifies either a result code value (diameter-result-code 3001) or a range of result code values (diameter-result-code 3000 to 9999) to which the failure-handling applies.

action
Configures the action to take depending on the diameter-result-code:

- Continue the session
- Retry and then terminate
Terminate the session

request-timeout action
Configures the action to take as a result of a request timeout error:
- Continue the session
- Retry and then terminate
- Terminate the session

Usage
Configures all failure-handling parameters.

Example
The following command configures profile-update-request failure-handling using a result-code configuration with the terminate session option:

```
failure-handling profile-update-request diameter-result-code 3005 to 3600 action terminate
```
request

Configures application request timeout.

Product
PDIF
SCM

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration > IMS Sh Interface Configuration

configure > context context_name > ims-sh-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ims-sh-service)#

Syntax

request timeout secs

[ no | default ] request timeout

no
Disables a configured timeout request.

default
Default: 300 seconds
Resets configuration to the default setting.

request timeout secs

Configures the request timeout in seconds.
secs must be an integer from 1 through 300.

Usage
Specifies the session request timeout period in seconds after which the request is deemed to have failed.

Example
The following example configures the default timeout request of 300 seconds:

default request timeout
Chapter 175
IP VRF Context Configuration Mode Commands

The IP VRF Context Configuration Mode is used to create and manage the Virtual Routing and Forwarding (VRF) context instance for BGP/MPLS VPN, GRE, IPSec tunneling or service interfaces for virtual routing, addresses, address resolution options, etc.

**Mode**

Exec > Global Configuration > Context Configuration > IP VRF Context Configuration

```
configure > context context_name > ip vrf vrf_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-context-vrf)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
associate l2-mapping-table

Associates a global QoS-to-Level 2 mapping table with this VRF.

**Product**
ePDG
HSGW
P-GW
SAEGW
S-GW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IP VRF Context Configuration

`configure > context context_name > ip vrf vrf_name`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-context-vrf)#`

**Syntax**

```shell
associate l2-mapping-table { name table_name | system-default }

no associate l2-mapping-table
```

<table>
<thead>
<tr>
<th><strong>no</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Disassociates an existing L2 mapping table from this VRF.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>name table_name</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the name of an existing internal table from which to map QoS to L2 values.</td>
</tr>
<tr>
<td><em>table_name</em> is an alphanumeric string of 0 through 80 characters.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>system-default</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Associates the system-default table with this VRF. This is useful if the base-context has a different explicit mapping.</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to associates a global QoS-to-Level 2 mapping table with this VRF. Internal-QoS will be mapped to an actual L2 value (either or both of 802.1p/MPLS) using a per-VRF based table.

**Important:** If an l2-mapping-table association is made at both the VRF and VPN level, the VRF level takes precedence.
The mapping table is configured via the Global Configuration mode `qos l2-mapping-table` command.

The following command associates this VRF with Qos-to-L2 mapping table `vrf10`.

```
associate l2-mapping-table name vrf10
```
description

Adds a textual description for this VRF.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IP VRF Context Configuration

configure > context context_name > ip vrf vrf_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-context-vrf)#

Syntax

description text

text

Enter a description for this VRF as an alphanumeric string of 1 through 63 characters. This text is case-sensitive. If you add spaces between words in the description, you must enclose the text with double quotation marks (“vfr ent 022”).

Usage
Use this command to add a textual description for this VRF.

Example

The following command adds a textual description to this VRF:

    description vrf-ent-022 arg1
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Use this command to return to the parent configuration mode.
**ip aggregate-address**

Specifies an IPv4 address/mask for aggregating frame routes in the VRF.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IP VRF Context Configuration

```
configure > context context_name > ip vrf vrf_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-context-vrf)#
```

**Syntax**

```
ip aggregate-address ipv4_address/mask [summary-only]

no ip aggregate-address ipv4_address/mask
```

- **no**
  - Deletes the specified IPv4 aggregate address.

- **ipv4_address/mask**
  - Specifies the IP address and mask in IPv4 CIDR dotted-decimal notation.

- **[summary-only]**
  - When this option is configured, the constituent routes are removed from the VRF.

**Usage**

Use this command to configure aggregate framed-routes in a VRF. It enables inserting an aggregate-address in a VRF and its advertisement in the routing domain if at least one constituent framed-route exists in that VRF. By default, the constituent routes will also be present along with the aggregate address. However, if the summary-only option is configured, the constituent routes will be removed from the VRF. Up to 32 aggregate addresses can be configured in a VRF.

**Example**

The following example sets an IPv4 aggregate address for the VRF:

```
ip aggregate-address 196.168.34.55/24
```
ip guarantee

Enables and disables local switching of framed route packets.

Product
GGSN
P-GW
SAEGW

Privilege
Administrator

Mode
Exec > Global Configuration > Context Configuration

configure > context context_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx)#

Syntax

[no] ip guarantee framed-route local-switching

no
Disables local switching of framed route packets.

framed-route local-switching

Enables local switching of framed route packets. By default, this functionality is disabled.

Usage
Use this command to enable and disable local switching of framed route packets. This functionality will be applicable only when there are some NEMO/framed route sessions in a context.

Example
The following command enables local switching of framed route packets:

ip guarantee framed-route local-switching
**ip maximum-routes**

This command configures the maximum number of routes in an IP VRF routing table configured in this context.

---

**Important:** This command should only be used for framed or NEMO (Network Mobility) routes of the VRF.

---

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IP VRF Context Configuration

```configure > context context_name > ip vrf vrf_name```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-context-vrf)#
```

**Syntax**

```ip maximum-routes max_routes```

```no ip maximum-routes```

---

**no**

Disables the configured maximum routes in specific IP VRF context.

---

**max_routes**

Sets the maximum number of routes in a specific IP VRF context.

*max_routes* must be an integer from 1 through 32768 or 65536 (release 17.0+).

---

**Usage**

Use this command to configure the maximum number of routes in a particular VRF routing table. When the number of routes in the VRF is more than the maximum limit configured, a critical log is generated indicating that the number of routes is over the limit. Once the number of routes in the VRF goes under the limit, a *clear log* is generated.

The maximum routes configured using this command will be sent to the threshold configuration logic for appropriate action. For more information on threshold configuration, refer to descriptions of the *threshold route-service bgp-routes* and *threshold poll route-service interval* commands in the *Global Configuration Mode Commands* chapter.

**Example**

The following command sets 1000 routes as a maximum limit for specific VRF context:

```
ip maximum-routes 1000
```
**mpls map-dscp-to-exp**

This command maps the final differentiated services code point (DSCP) bit value in the IP packet header to the final Experimental (EXP) bit value in the MPLS header for incoming traffic.

---

**Important:** This command has been deprecated beginning with Release 15.0.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IP VRF Context Configuration

```bash
configure > context context_name > ip vrf vrf_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-context-vrf)#
```

**Syntax**

```bash
[ no ] mpls map-dscp-to-exp dscp dscp_bit_value exp exp_bit_value
```

- **no**
  Disables the configured DSCP bit value mapping to the EXP bit value from a specific IP VRF context.

- **dscp dscp_bit_value**
  Specifies the final DSCP bit value which is to map with the final EXP bit value in MPLS header for incoming traffic.
  `dscp_bit_value` specifies the value of DSCP bit values separated in eight groups and represented with integers from 0 through 7.

The default representation of DSCP value in eight groups is given in the following table:

<table>
<thead>
<tr>
<th>DSCP Marking Value</th>
<th>DSCP Map Group</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-7</td>
<td>0</td>
</tr>
<tr>
<td>8-15</td>
<td>1</td>
</tr>
<tr>
<td>16-23</td>
<td>2</td>
</tr>
<tr>
<td>24-31</td>
<td>3</td>
</tr>
<tr>
<td>32-39</td>
<td>4</td>
</tr>
<tr>
<td>40-47</td>
<td>5</td>
</tr>
<tr>
<td>48-55</td>
<td>6</td>
</tr>
<tr>
<td>56-63</td>
<td>7</td>
</tr>
</tbody>
</table>
exp exp_bit_value

Specifies the final EXP bit value in MPLS header to which the final DSCP bit value 0 to 7 (represented in eight values) coming from incoming traffic will be mapped.

exp_bit_value is the value of EXP bit in MPLS header and must be an integer between 0 through 7.

Usage

Use this command to map the final DSCP value coming from incoming IP traffic to a final EXP value in MPLS header. This mapping determines the QoS and service parameters to which the packet is assigned.

Example

The following command maps the DSCP value 3 (24 to 31) to EXP bit 3 in MPLS header:

```
mpls map-dscp-to-exp dscp 3 exp 3
```
mpls map-exp-to-dscp

Maps incoming the Experimental (EXP) bit value in MPLS header to the internal differentiated services code point (DSCP) bit value in IP packet headers for outgoing traffic.

**Important:** This command has been deprecated beginning with Release 15.0.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IP VRF Context Configuration

`configure > context context_name > ip vrf vrf_name`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-context-vrf)#`

**Syntax**

```
[ no ] mpls map-exp-to-dscp exp exp_bit_value dscp dscp_bit_value
```

- **no**
  Disables the configured EXP bit value mapping to DSCP bit value from specific IP VRF context.

- **exp exp_bit_value**
  Specifies the incoming EXP bit value in MPLS header to which the internal DSCP bit value 0 to 7 (represented in 8 values) in IP traffic will be mapped.
  
  `exp_bit_value` is the value of the EXP bit in an MPLS header and must be an integer from 0 through 7.

- **dscp dscp_bit_value**
  Maps the DSCP bit value with the incoming EXP bit value in an MPLS header.
  
  `dscp_bit_value` specifies the value of the DSCP bit values separated in eight groups and represented with integers between 0 through 7.

  The default representation of DSCP value in eight groups is given in the following table:

<table>
<thead>
<tr>
<th>DSCP Marking Value</th>
<th>DSCP Map Group</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-7</td>
<td>0</td>
</tr>
<tr>
<td>8-15</td>
<td>1</td>
</tr>
<tr>
<td>16-23</td>
<td>2</td>
</tr>
<tr>
<td>24-31</td>
<td>3</td>
</tr>
<tr>
<td>32-39</td>
<td>4</td>
</tr>
<tr>
<td>40-47</td>
<td>5</td>
</tr>
</tbody>
</table>
Usage

Use this command to map the incoming EXP bit value in MPLS headers to the DSCP bit value in IP traffic. This mapping determines the QoS and service parameters to which the packet is assigned.

Example

The following command maps the EXP bit value 4 to DSCP value 6 (48 to 55) in IP header:

```plaintext
mpls map-exp-to-dscp exp 4 dscp 6
```
Chapter 176
IPMS Client Configuration Mode Commands

The IPMS Client Configuration Mode is used to enable the Intelligent Packet Monitoring System (IPMS) client service on an Access Gateway and to set basic service-wide options in a context.

**Important:** This is a license enabled external application support. For more information on this product, refer to the IPMS Installation and Administration Guide.

```
Mode

Exec > Global Configuration > Context Configuration > IPMS Configuration
configure > context context_name > ipms
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-ipms)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**
Use this command to return to the parent configuration mode.
export keys

Enables the encryption key export in specific key exchange events to IPMS server from IPMS-enabled AGW.

⚠️ **Important:** This is a license enabled customer specific command.

**Product**

IPMS

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IPMS Configuration

`configure > context context_name > ipms`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-ctx-ipms)#`

**Syntax**

```
no
```

Removes the configured source IP address from this context for IPMS client communication with IPMS server.

```
ikeyv2
```

Enables the security association (SA) key export for Internet Key Exchange (IKEv2) protocol to IPMS server.

**Usage**

Monitor subscribers which have complaints of service availability or to monitor a test user for system verification.

**Example**

The following command assigns the IP address `10.2.3.4` to the IPMS client service in context to communicate with IPMS server. This is the IP address allocated for IPMS client service on chassis.

```
source address 10.2.3.4
```
heartbeat

Configures the IPMS heartbeating between the IPMS-enabled AGW and the IPMS server.

**Product**
IPMS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPMS Configuration

```
configure > context context_name > ipms
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-ipms)#
```

**Syntax**

```
heartbeat period dur [ permitted-failure no_of_failures ]
[ no | default ] heartbeat
```

- **default**
  
  Configures the heartbeat period and permitted number of failures to the default values of 10 seconds and 1 failure respectively.

- **no**
  
  Disables/removes the configured heartbeat period and permitted number of failures.

- **period dur**
  
  Specifies the periodicity (in seconds) between heartbeat messages as an integer from 1 through 3600. Default: 10

- **permitted-failure no_of_failures**
  
  Specifies the number of errors/failures allowed before declaring an IPMS server as dead/unreachable as an integer from 1 through 10. Default: 1

**Usage**

Use this command to configure the heartbeat message periodicity and permissible failure of heartbeat message response before declaring an IPMS server as dead or unreachable. When an IPMS server is declared down an SNMP trap is sent.

**Example**

Following command configures the heartbeat message periodicity to 5 second and number of failures allowed as 3 to determine an IPMS server as dead.

```
heartbeat period 5 permitted-failure 3
```
server

Configures the IPMS server address and ports on which the IPMS client on an IPMS-enabled AGW communicates. This is the IP address and port range of the IPMS server.

Product
IPMS

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPMS Configuration

```bash
configure > context context_name > ipms
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-ipms)#
```

Syntax

```
server address ip_address [ secondary ] [ start-port start_port [ end-port end_port ]][
secondary ]
```

no server address ip_address

no

Removes the configured IPMS server IP address and port range from this context.

```
address ip_address
```

Specifies the IP address of the IPMS server to which the IPMS client service communicates in IPv4 dotted-decimal notation.

A maximum of 4 IPMS servers can be configured with this command in one context.

```
[ start-port start_port[ end-port end_port ]]
```

Default: 45001 source port
45005 end port

Specifies the range of UDP ports on which IPMS client communicates with the IPMS server.

- **start-port start_port**: Specifies starting port number as an integer from 1 through 65535 that is less than end_port, if end-port is specified.
- **end-port end_port**: Specifies the end port number as an integer from 1 through 65535 that is more than start_port.

```
secondary
```

The secondary keyword is used to configure the specified server address as secondary IP address on the IPMS client interface.
Usage
Use this command to configure/remove the IPMS servers. Up to 4 different IPMS servers can be configured with this command. UDP port number can also be configured with this command. IPMS client will search for this IP address to push the event and traffic logs.

Example
The following command configures IPMS server having IP address 10.2.3.4 in the IPMS client service export the event and traffic logs for intelligent packet monitoring functionality. It also specifies the UDP port range from 48000 to 48005 for communication.

server address 10.2.3.4 start-port 48000 end-port 48005
source

Configures the source address of the IPMS client in this context to communicate with the IPMS server. This is the IP address for IPMS client on the chassis.

**Product**
IPMS

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPMS Configuration

```text
configure > context context_name > ipms
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-ipms)#
```

**Syntax**

```text
source address ip_address
```

- `address ip_address`
  - Specifies `ip_address` as the IP address of the IPMS client on the AGW in this context. This is the address which is bound to the IPMS client service in this context.
  - `ip_address` is expressed in IPv4 dotted-decimal notation.

**Usage**

Monitor subscribers which have complaints of service availability or to monitor a test user for system verification.

**Example**

The following command assigns the IP address `10.2.3.4` to the IPMS client service in context to communicate with IPMS server. This is the IP address allocated for IPMS client service on chassis.

```text
source address 10.2.3.4
```
The IPSec Transform Set Configuration Mode is used to configure IPSec security parameters. There are two core protocols, the Authentication Header (AH) and Encapsulating Security Payload (ESP). AH may be considered redundant as ESP can provide the same authentication services that AH does.

**Mode**

Exec > Global Configuration > Context Configuration > IPSec Transform Set Configuration

```
configure > context context_name > ipsec transform-set set_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-context-vrf)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
encryption

Configures the appropriate IPSec ESP encryption algorithm and encryption key length. AES-CBC-128 is the default.

**Product**
ePDG
PDIF
SCM

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSec Transform Set Configuration

configure > context context_name > ipsec transform-set set_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-context-vrf)#

**Syntax**

```plaintext
encryption { 3des-cbc | aes-cbc-256 | des-cbc | null }

default encryption
```

---

### 3des-cbc
Data Encryption Standard Cipher Block Chaining encryption applied to the message three times using three different cypher keys (triple DES).

### aes-cbc-128
Advanced Encryption Standard Cipher Block Chaining with a key length of 128 bits. This is the default setting for this command.

### aes-cbc-256
Advanced Encryption Standard Cipher Block Chaining with a key length of 256 bits.

### des-cbc

### null
The NULL encryption algorithm represents the optional use of applying encryption within ESP. ESP can then be used to provide authentication and integrity without confidentiality.

### default
Sets the default IPSec ESP algorithm to AES-CBC-128.
Usage

In cipher block cryptography, the plaintext is broken into blocks usually of 64 or 128 bits in length. In cipher block chaining (CBC) each encrypted block is chained into the next block of plaintext to be encrypted. A randomly generated vector is applied to the first block of plaintext in lieu of an encrypted block. CBC provides confidentiality, but not message integrity. Because RFC 4307 calls for interoperability between IPSec and IKEv2, the IKEv2 confidentiality algorithms must be the same as those configured for IPsec in order for there to be an acceptable match during the IKE message exchange. In IKEv2, there is no NULL option.

Example

The following command configures the encryption to be the default aes-cbc-128:

```
default encryption
```
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
**esn**

Enables support for the use of 64-bit Extended Sequence Numbers (ESNs) for ikev2 Encapsulating Security Payload (ESP) and Authentication Header (AH) packets. The ESN transform is included in an ikev2 proposal used in the negotiation of IKE SAs as part of the IKE_SA_INIT exchange.

**Product**
SecGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSec Transform Set Configuration

```
configure > context context_name > ipsec transform-set set_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-context-vrf)#
```

**Syntax**

```
esn
```

**Usage**

Use this command to enable support for the use of 64-bit ESNs for ikev2. The ESN transform is included in an ikev2 proposal used in the negotiation of IKE SAs as part of the IKE_SA_INIT exchange.

The ESN transform has the following meaning:

- A proposal containing one ESN transform with value 0 means “do not use extended sequence numbers”.
- A proposal containing one ESN transform with value 1 means “use extended sequence numbers”.
- A proposal containing two ESN transforms with values 0 and 1 means “I support both normal and extended sequence numbers, you choose”. This case is only allowed in requests; the response will contain only one ESN transform.

In most cases, the exchange initiator will include either the first or third alternative in its SA payload. The second alternative is rarely useful for the initiator: it means that using normal sequence numbers is not acceptable (so if the responder does not support ESNs, the exchange will fail with NO_PROPOSAL_CHOSEN.

Enabling the *esn* command is the equivalent of sending ESN Transform = 0 and 1; support both 32-bit and 64-bit sequence numbers. If the *esn* command is not enabled, support only 32-bit sequence numbers (default behavior).

Including the ESN transform is mandatory when creating ESP or AH SAs.

For additional information, see the *IPSec Reference*.

---

**Important:** ESN is only supported on ASR 5500 and ASR 9000 Virtualized Services Modules (VSMs). It is not supported on the ASR 5000 or VPC-SI.

**Example**
The following command enables support for 32-bit and 64-bit sequence numbers:

```plaintext
esn arg1
```
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```plaintext
exit
```

**Usage**
Use this command to return to the parent configuration mode.
group

Configures the appropriate key exchange cryptographic strength and activate Perfect Forward Secrecy by applying a Diffie-Hellman group.

Product

ePDG
PDIF
SCM

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > IPSec Transform Set Configuration

configure > context context_name > ipsec transform-set set_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-context-vrf)#

Syntax

group { 1 | 2 | 5 | 14 | none }

default group

  default group

  Configures the default crypto strength to be none and disables Perfect Forward Secrecy.

  1

  Configures crypto strength at the Group 1 level. Lowest security.

  2

  Configures crypto strength at the Group 2 level. Medium security.

  5

  Configures crypto strength at the Group 5 level. Higher security.

  14

  Configures crypto strength at the Group 14 level. Highest security.

  none

  Applies no group and disables Perfect Forward Secrecy. This is the default.

  default

  Sets the default Diffie-Hellman group algorithm to none. This also deactivates PFS.
Usage

Diffie-Hellman groups are used to determine the length of the base prime numbers used during the key exchange process. The cryptographic strength of any key derived depends, in part, on the strength of the Diffie-Hellman group upon which the prime numbers are based. Group 1 provides 768 bits of keying strength, Group 2 provides 1024 bits, Group 5 provides 1536 bits and Group 14 provides 2048 bits. Selecting a group automatically activates Perfect Forward Secrecy. The default value is none, which disables PFS.

Example

This command configures security at Group 2 and activates PFS:

```
  group 2
```
**hmac**

Configures the IPsec ESP integrity algorithm using a Hash-based Message Authentication Code (HMAC).

**Product**
- ePDG
- PDIF
- SCM

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSec Transform Set Configuration

`configure > context context_name > ipsec transform-set set_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-context-vrf)#
```

**Syntax**

```
hmac { aes-xcbc-96 | md5-96 | none | null}
```

default hmac

```
default hmac
Sets the default IPSec hashing algorithm to SHA1-96.
```

```
aes-xcbc-96
AES-XCBC-96 uses a 128-bit secret key and produces a 128-bit authenticator value.
```

```
md5-96
MD5-96 uses a 128-bit secret key and produces a 128-bit authenticator value.
```

```
null
Configures the HMAC value to be null. The NULL encryption algorithm represents the optional use of applying encryption within ESP. ESP can then be used to provide authentication and integrity without confidentiality.
```

```
sha1-96
SHA-1 uses a 160-bit secret key and produces a 160-bit authenticator value. This is the default setting for this command.
```

**Usage**
HMAC is an encryption technique used by IPsec to make sure that a message has not been altered.
A keyed-Hash-based Message Authentication Code (HMAC), is a type of message authentication code that is calculated using a cryptographic hash function in combination with a secret key to verify both data integrity
and message authenticity. A hash takes a message of any size and transforms it into a message of a fixed size: the authenticator value. This is truncated to 96 bits and transmitted. The authenticator value is reconstituted by the receiver and the first 96 bits are compared for a 100 percent match.

Example

The following command configures the default HMAC value (SHA1-96):

```
default hmac
```
**mode**

Configures the security of IP datagrams based on header placement. Tunnel mode applies security to a completely encapsulated IP datagram, while Transport does not. Default is Tunnel mode.

**Product**
ePDG
PDIF
SCM

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSec Transform Set Configuration

```
configure > context context_name > ipsec transform-set set_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-context-vrf)#
```

**Syntax**

```
mode { transport | tunnel }
```

**default mode**

---

**transport**

In Transport mode, the IPSec header is applied only over the IP payload, not over the IP header in front of it. The AH and/or ESP headers appear between the original IP header and the IP payload, as follows:

Original IP header, IPSec headers (AH and/or ESP), IP payload (including transport header).

Transport mode is used for host-to-host communications and is generally unsuited to PDIF traffic.

---

**tunnel**

In Tunnel mode, the original IP header is left intact, so a complete IP datagram is encapsulated, forming a virtual tunnel between IPSec-capable devices. The IP datagram is passed to IPSec, where a new IP header is created ahead of the AH and/or ESP IPSec headers, as follows:

New IP header, IPSec headers (AH and/or ESP), old IP header, IP payload.

Tunnel mode is used for network-to-network communications (secure tunnels between routers) or host-to-host and host-to-host communications over the Internet.

This is the default setting for this command.

---

**default mode**

Sets the default IPSec Mode to Tunnel.

**Usage**

IPSec modes are closely related to the function of the two core protocols, the Authentication Header (AH) and Encapsulating Security Payload (ESP). Both of these protocols provide protection by adding to a datagram a header (and possibly other fields) containing security information. The choice of mode does not
affect the method by which each generates its header, but rather, changes what specific parts of the IP
datagram are protected and how the headers are arranged to accomplish this.

**Example**

The following command configures the default Tunnel mode:

```
default mode
```
Chapter 178
IPSG RADIUS Server Configuration Mode Commands

The IP Services Gateway (IPSG) RADIUS Server Configuration Mode is used to create and configure IPSG RADIUS Server/eWAG services in the current context. This mode enables configuring the system to receive RADIUS accounting requests as if it is a RADIUS accounting server, and reply after accessing those requests for subscriber information.

Mode

Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration
configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-server)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
accounting-context

This command allows you to specify the GTPP accounting context.

**Product**
eWAG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-server)#

**Syntax**

```
accounting-context context_name

no accounting-context
```

- **no**
  - If previously configured, removes the accounting context configuration.

- **context_name**
  - Specifies name of the GTPP accounting context.
  - `context_name` must be an alphanumeric string of 1 through 79 characters in length.

**Usage**

Use this command to specify the GTPP accounting context.

**Example**

The following command specifies to use the GTPP accounting context `context12` for the eWAG service:

```
accounting-context context12
```
**associate sgtp-service**

This command allows you to associate an SGTP service with the current eWAG service.

**Product**  
eWAG

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

```
configure > context context_name > ipsg-service service_name mode radius-server
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipsg-service-radius-server)#
```

**Syntax**

```
associate sgtp-service sgtp_service_name [ context sgtp_context_name ]
```

```
no associate sgtp-service
```

If previously configured, removes the service association from the configuration.

```
sgtp-service sgtp_service_name
```

Specifies name of the SGTP service to associate with this service.  
*sgtp_service_name* must be the name of an SGTP service, and must be an alphanumeric string of 1 through 63 characters in length.

```
context sgtp_context_name
```

Specifies name of the context in which the SGTP service is configured.  
*sgtp_context_name* must be the name of the context, and must be an alphanumeric string of 1 through 63 characters in length.  
If a context is not specified, the current context is used.

**Usage**

Use this command to associate an SGTP service with the IPSG service. This enables the GTP functionality for eWAG supporting GTP-C (GTP Control Plane) messaging and GTP-U (GTP User Data Plane) messaging between eWAG and GGSN over the Gn' interface.

**Important:** Any change to this configuration will result in restart of the eWAG service.

**Example**

The following command associates an SGTP service named *service1*, configured in the context named *context2*, with the IPSG service:
associate sgtp-service service1 context context2
bind

This command allows you to bind the current IPSG/eWAG service to a logical AAA interface, and specify the number of subscriber sessions allowed.

Product
eWAG
IPSG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration
configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-server)#

Syntax

bind accounting-proxy address ipv4/ipv6_address [ max-subscribers max_sessions | port port_number | source-context source_context ]

bind address ipv4/ipv6_address [ disconnect-message [ src-port source_port_number ] | max-subscribers max_sessions | port port_number | source-context source_context ]+

bind authentication-proxy address ipv4/ipv6_address [ acct-port port_number | auth-port port_number | max-subscribers max_sessions | source-context source_context ]

no bind

If previously configured, removes the binding for the service.

bind accounting-proxy address ipv4/ipv6_address [ max-subscribers max_sessions | port port_number | source-context source_context ]

- **accounting-proxy address ipv4/ipv6_address**: Specifies the IP address of the interface where accounting proxy requests are received by this service in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

- **max-subscribers max_sessions**: Specifies the maximum number of subscriber sessions allowed for the service. If this option is not configured, the system defaults to the license limit.
  - In StarOS 9.0 and later releases, `max_sessions` must be an integer from 0 through 4000000.
  - In StarOS 8.3 and earlier releases, `max_sessions` must be an integer from 0 through 3000000.

- **port port_number**: Specifies the port number of the interface where accounting requests are received by this service.
  - `port_number` must be an integer from 1 through 65535.
  - Default: 1813
• **source-context source_context**: Specifies the source context where RADIUS accounting requests are received.
  
  *source_context* must be an alphanumeric string of 1 through 79 characters.

  This keyword should be configured if the source of the RADIUS requests is in a different context than the IPSG service. If this keyword is not configured, the system will default to the context in which the IPSG service is configured.

```plaintext
bind address ipv4/ipv6_address [ disconnect-message [ src-port source_port_number ] | max-subscribers max_sessions | port port_number | source-context source_context ]
```

• **address ipv4/ipv6_address**: Specifies the IP address of the interface where accounting requests are received by this service in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

• **disconnect-message [ src-port source_port_number ]**: Specifies to send RADIUS disconnect message to the configured RADIUS accounting client in call failure scenarios.
  
  *src-port source_port_number*: Specifies the port number to which the disconnect message must be sent.
  
  *source_port_number* must be an integer from 1 through 65535.

• **max-subscribers max_sessions**: Specifies the maximum number of subscriber sessions allowed for the service. If this option is not configured, the system defaults to the license limit.
  
  In StarOS 9.0 and later releases, *max_sessions* must be an integer from 0 through 4000000.
  
  In StarOS 8.3 and earlier releases, *max_sessions* must be an integer from 0 through 3000000.

• **port port_number**: Specifies the port number of the interface where accounting requests are received by this service.
  
  *port_number* must be an integer from 1 through 65535.
  
  Default: 1813

• **source-context source_context**: Specifies the source context where RADIUS accounting requests are received.
  
  *source_context* must be an alphanumeric string of 1 through 79 characters.

  This keyword should be configured if the source of the RADIUS requests is in a different context than the IPSG service. If this keyword is not configured, the system will default to the context in which the IPSG service is configured.

```plaintext
bind authentication-proxy address ipv4/ipv6_address [ acct-port port_number | auth-port port_number | max-subscribers max_sessions | source-context source_context ]
```

• **authentication-proxy address ipv4/ipv6_address**: Specifies the IP address of the interface where authentication proxy requests are received by this service in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

  **Important**: Enabling authentication proxy also enables accounting proxy.

• **acct-port port_number**: Specifies the port number of the interface where accounting proxy requests are received by this service.
  
  *port_number* must be an integer from 0 through 65535.
Default: 1813

• **auth-port** `port_number`: Specifies the port number of the interface where authentication proxy requests are received by this service.

  `port_number` must be an integer from 0 through 65535.

  Default: 1812

• **max-subscribers** `max_sessions`: Specifies the maximum number of subscriber sessions allowed for the service. If this option is not configured, the system defaults to the license limit.

  In StarOS 9.0 and later releases, `max_sessions` must be an integer from 0 through 4000000.

  In StarOS 8.3 and earlier releases, `max_sessions` must be an integer from 0 through 3000000.

• **source-context** `source_context`: Specifies the source context where RADIUS accounting requests are received.

  `source_context` must be an alphanumeric string of 1 through 79 characters.

  This keyword should be configured if the source of the RADIUS requests is in a different context than the IPSG service. If this keyword is not configured, the system will default to the context in which the IPSG service is configured.

Usage

Use this command to bind the IPSG RADIUS Server/eWAG service to a logical AAA interface and specify the number of allowed subscriber sessions. If the AAA interface is not located in this context, configure the `source-context` parameter.

Use the accounting and authentication proxy settings to enable RADIUS proxy server functionality on the IPSG. These commands are used when the NAS providing the RADIUS request messages is incapable of sending them to two separate devices. The IPSG in RADIUS Server mode proxies the RADIUS request and response messages while performing the user identification task in order to provide services to the session.

Example

The following command binds the service to a AAA interface with an IP address of 10.2.3.4 located in the source context named `aaa_ingress`:

```
bind address 10.2.3.4 source-context aaa_ingress
```
connection authorization

This command allows you to configure the RADIUS authorization password that must be matched by the RADIUS accounting requests received by the current IPSG service.

Product

IPSG

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-server)#

Syntax

connection authorization [ encrypted ] password password

no connection authorization

[ encrypted ] password password

- **encrypted**: Specifies that the RADIUS authorization password is encrypted.
- **password password**: Specifies the password that must be matched by incoming RADIUS accounting requests.

In StarOS 12.2 and later releases, password with encryption must be an alphanumeric string of 1 through 132 characters, and without encryption an alphanumeric string of 1 through 63 characters.

In StarOS 12.1 and earlier releases, password must be an alphanumeric string of 1 through 63 characters.

Usage

The IPSG RADIUS server service does not terminate RADIUS user authentication so the user password is unknown.

Use this command to configure the authorization password that the RADIUS accounting requests must match in order for the service to examine and extract user information.

Example

The following command sets the RADIUS authorization password that must be matched by the RADIUS accounting requests sent to this service. The password is encrypted, and the password used in this example is "secret".

connection authorization encrypted password secret
**end**

Exits the current configuration mode and returns to the Exec mode.

Usage
Use this command to return to the parent configuration mode.
gtp max-contexts-per-imsi

This command allows you to configure multiple primary contexts having the same IMSI number.

Product
eWAG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration
configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:
[context_name]host_name(config-ipsg-service-radius-server)#

Syntax

gtp max-contexts-per-imsi max_value min-nsapi min_nsapi_value

default gtp max-contexts-per-imsi

default
Configures this command to disable use of multiple primary contexts. Only one PDP context per user is allowed.

max-contexts-per-imsi: 1
min-nsapi: 15

max-contexts-per-imsi max_value
Specifies the limit for the maximum number of contexts per IMSI.

max_value must be an integer from 1 through 11.

min-nsapi min_nsapi_value
Specifies the range of NSAPI values to be assigned to different PDP context of the same subscriber.

min_nsapi_value must be an integer from 5 through 15.

Usage
Use this command to configure the maximum number of contexts per IMSI, and the range of NSAPI values to be assigned to different PDP context.

Example
The following command configures the maximum contexts per IMSI to 5 and specify the range of values NSAPI value to 7.

    gtp max-context-per-imsi 5 min-nsapi 7
gtp peer-ip-address

This command allows you to configure GGSN IP address under the eWAG service.

Product

eWAG

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

configure > context context_name > ipsg-service service_name mode radius-server

configure > context context_name > ipsg-service service_name mode radius-server
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipsg-service-radius-server)#
```

**Syntax**

```
ip { gnp-qos-dscp | qos-dscp } qci { { 1 | 2 | 3 | 4 | 9 } | { 5 | 6 | 7 | 8 } allocation-retention-priority { 1 | 2 | 3 } } { af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | ef | pt } } +
```

**default** ip { gnp-qos-dscp | qos-dscp }

**no ip { gnp-qos-dscp | qos-dscp } qci { { 1 | 2 | 3 | 4 | 9 } | { 5 | 6 | 7 | 8 } allocation-retention-priority { 1 | 2 | 3 } } +

**default**

Configures this command, for specified option, with default setting for all QoS Class Identifier (QCI) values.

- QCI-based DSCP map:
  - qci 1: ef
  - qci 2: ef
  - qci 3: af11
  - qci 4: af11
  - qci 5: ef
  - qci 6: ef
  - qci 7: af21
  - qci 8: af21
  - qci 9: be

- ARP-based DSCP map for interactive class:
  - qci 5 allocation-retention-priority 1: ef
  - qci 5 allocation-retention-priority 2: ef
  - qci 5 allocation-retention-priority 3: ef
  - qci 6 allocation-retention-priority 1: ef
• qci 6 allocation-retention-priority 2: ef
• qci 6 allocation-retention-priority 3: ef
• qci 7 allocation-retention-priority 1: af21
• qci 7 allocation-retention-priority 2: af21
• qci 7 allocation-retention-priority 3: af21
• qci 8 allocation-retention-priority 1: af21
• qci 8 allocation-retention-priority 2: af21
• qci 8 allocation-retention-priority 3: af21

no

Resets configured value for specified QCI with its default setting.

gnp-qos-dscp

Specifies, for uplink direction, the DiffServ Code Point marking to be used for sending packets of a particular 3GPP QoS class.

qos-dscp

Specifies, for downlink direction, the DiffServ Code Point marking to be used for sending packets of a particular 3GPP QoS class.

qci { 1 | 2 | 3 | 4 | 9 }

Specifies the QCI attribute of QoS.
• 1: QCI 1 attribute of QoS
• 2: QCI 2 attribute of QoS
• 3: QCI 3 attribute of QoS
• 4: QCI 4 attribute of QoS
• 9: QCI 9 attribute of QoS

qci { 5 | 6 | 7 | 8 } allocation-retention-priority { 1 | 2 | 3 }

Specifies the QCI attribute of QoS with ARP.
• 5: QCI 5 attribute of QoS
• 6: QCI 6 attribute of QoS
• 7: QCI 7 attribute of QoS
• 8: QCI 8 attribute of QoS

allocation-retention-priority { 1 | 2 | 3 }: Specifies the ARP.

af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | ef | pt

Specifies the Per-Hop Forwarding Behavior (PHB) to use.
• af11: Assured Forwarding 11 PHB
• af12: Assured Forwarding 12 PHB
• af13: Assured Forwarding 13 PHB
- **af21**: Assured Forwarding 21 PHB
- **af22**: Assured Forwarding 22 PHB
- **af23**: Assured Forwarding 23 PHB
- **af31**: Assured Forwarding 31 PHB
- **af32**: Assured Forwarding 32 PHB
- **af33**: Assured Forwarding 33 PHB
- **af41**: Assured Forwarding 41 PHB
- **af42**: Assured Forwarding 42 PHB
- **af43**: Assured Forwarding 43 PHB
- **be**: Best Effort Forwarding PHB
- **ef**: Expedited Forwarding PHB
- **pt**: Pass Through (do not modify the ToS)

### Usage

Use this command to configure IP parameters for the eWAG service.

### Example

The following command specifies to configure the DiffServ Code Point marking to be used for sending packets specifying QCI as 1 and Assured Forwarding 11 PHB:

```
ip gnp-qos-dscp qci 1 af11
```
map ue-mac-to-imei

This command allows you to map the UE MAC received in the Calling-Station-Id RADIUS attribute to IMEIsV in order to forward it in the GTP CPC message to the GGSN.

Product
eWAG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration
configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-server)#

Syntax

[ default | no ] map ue-mac-to-imei

default
If previously configured, disables mapping of UE MAC address to IMEIsV IE of GTP message in order to forward it to GGSN.
Default: Mapping is disabled.

no
If previously configured, disables mapping of UE MAC address to IMEIsV IE of GTP message in order to forward it to GGSN.

Usage

Use this command to enable or disable mapping of UE MAC address to IMEIsV IE of GTP message in order to forward it to GGSN.
overlapping-ip-address

This command allows you to enable or disable overlapping of IP addresses which enables multiple users to use the same IP address.

**Product**  
IPSG

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

```bash
configure > context context_name > ipsg-service service_name mode radius-server
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipsg-service-radius-server)#
```

**Syntax**

```
[ default | no ] overlapping-ip-address
```

---

**default**

- If previously configured, disables IPSG support of overlapping IP addresses.
- Using overlapping IP addresses is disabled by default.

---

**no**

- If previously configured, disables IPSG support of overlapping IP addresses.

---

**Usage**

Use this command to enable or disable overlapping IP addresses for subscribers on different networks that are independent of each other.

**Example**

The following command enables IPSG overlapping of IP addresses:

```bash
overlapping-ip-address
```
**plmn id**

This command allows you to configure Public Land Mobile Network (PLMN) identifier for the current eWAG service.

**Product**
eWAG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

```
configure > context context_name > ipsg-service service_name mode radius-server
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipseg-service-radius-server)#
```

**Syntax**

```
plmn id mcc mcc_number mnc mnc_number

no plmn id
```

- **no**
  If previously configured, deletes the PLMN ID configuration.

- **mcc mcc_number**
  Specifies the mobile country code (MCC) part of the PLMN identifier for the eWAG service.
  `mcc_number` must be a three-digit number ranging from 200 to 999.

- **mnc mnc_number**
  Specifies the mobile network code (MNC) part of the PLMN identifier for the eWAG service.
  `mnc_number` must be a two- or three-digit number ranging from 00 to 999.

**Usage**

Use this command to configure the location-specific mobile network identifiers included in the Routing Area Identity (RAI) field of the PDP Create Request messages sent to the GGSN.

**Important:** Any change to this configuration will result in restart of the eWAG service.

**Example**

The following command configures the PLMN identifier for the eWAG service as MCC 333 and MNC 99:

```
plmn id mcc 333 mnc 99
```
**profile**

This command allows you to configure the IPSG/eWAG service to use APN or subscriber profile.

**Important:** In release 14.0, eWAG service uses only the APN profile. In release 15.0, ReWAG uses the APN profile and DeWAG uses the subscriber profile. Whereas, the IPSG service uses both APN and subscriber profiles.

**Product**
eWAG
IPSG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration
configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipsg-service-radius-server)#
```

**Syntax**

```
profile { APN [ default-apn apn_name ] | subscriber }
```

**default profile**

```
default
```

Configures this command with its default setting.
Default: APN

```
APN
```

Specifies to use APN profile for the service.

```
default-apn apn_name
```

**Important:** This option is supported only for the eWAG service.

Specifies the default APN to be used for the eWAG service.

*apn_name* must be the name of an APN, it must be an alphanumeric string of 1 through 62 characters in length, and can consist only of the alphabetic characters (A–Z and a–z), digits (0–9), dot (.), and the hyphen (–).

```
subscriber
```

**Important:** This option is supported only for the IPSG RADIUS Server service, and in release 15.0 for DeWAG service. For the DeWAG service, this command must be configured with the *subscriber* option. This is because
DeWAG will operate based on subscriber template profile selection only for connecting users. If the APN profile selection is configured, the DeWAG service will not be started.

Specifies to use subscriber profile for the service.

Usage
Use this command to set the service to support APN profiles (supporting Gx through the enabling of ims-auth-service) or for basic subscriber profile lookup.
For the DeWAG service, this command must be configured with the subscriber option. This is because DeWAG will operate based on subscriber template profile selection only for connecting users. If the APN profile selection is configured, the DeWAG service will not be started.

Example
The following command specifies to use the subscriber profile:

```
profile subscriber
```
radius accounting

This command allows you to specify the IP address and shared secret of the RADIUS accounting client from which RADIUS accounting requests are received. The RADIUS client can be either the access gateway or the RADIUS accounting server depending on which device is sending accounting requests.

Product
eWAG
IPSG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-server)#

Syntax

radius accounting { client { ipv4/ipv6_address | ipv4/ipv6_address/mask } [ encrypted ] key key [ acct-onoff [ aaa-context aaa_context_name ] [ aaa-group aaa_server_group_name ] [ clear-sessions ] + ] [ dictionary dictionary ] [ disconnect-message [ release-on-acct-stop acct_stop_wait_timeout ] [ dest-port destination_port_number ] + ] [ interim create-new-call | validate-client-ip ] }

no radius accounting { client { ipv4/ipv6_address | ipv4/ipv6_address/mask } | interim create-new-call | validate-client-ip }

default radius accounting { interim create-new-call | validate-client-ip }

no
If previously configured, removes the specified configuration.

ipv4/ipv6_address | ipv4/ipv6_address/mask
Specifies the IP address, and optionally subnet mask of the RADIUS client from which RADIUS accounting requests are received.
ipv4/ipv6_address/ipv4/ipv6_address/mask must be in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.
A maximum of 16 IP addresses can be configured.

[ encrypted ] key key

- *encrypted*: Specifies that the shared key between the RADIUS client and this service is encrypted.
- *key key*: Specifies the shared key between the RADIUS client and this service.

In StarOS 12.2 and later releases, *key* with encryption must be an alphanumeric string of 1 through 236 characters, and without encryption an alphanumeric string of 1 through 127 characters. Note that *key* is case sensitive.
In StarOS 12.1 and earlier releases, key must be an alphanumeric string of 1 through 127 characters and is case sensitive.

```
acct-onoff [ aaa-context aaa_context_name ] [ aaa-group aaa_server_group_name ] [ clear-sessions ] +
```

**Important:** In release 12.3 and earlier releases, this option is applicable only to the IPSG Proxy Mode.

**Important:** In release 14.0 and later releases, this option is applicable to the IPSG Proxy and Server Modes.

Specifies to proxy accounting On/Off messages to AAA server.

- **aaa-context aaa_context_name**: Specifies the context to find AAA server groups. If not specified, by default, the AAA context will be the source context.
  
  `aaa_context_name` must be the name of a AAA context, and must be an alphanumeric string of 1 through 79 characters.

- **aaa-group aaa_server_group_name**: Specifies the AAA server group. If not specified, by default, the AAA server group will be `default`.
  
  `aaa_server_group_name` must be the name of AAA server group, and must be an alphanumeric string of 1 through 63 characters.

- **clear-sessions**: Specifies to clear eWAG or IPSG sessions on receiving accounting On/Off messages.

- **+**: Indicates that more than one of the preceding options may be specified in a single command.

**dictionary dictionary**

Specifies the dictionary to use.

**Important:** In this release, eWAG supports only the `starent-vs1` dictionary.

**dictionary** can be one of the following.

<table>
<thead>
<tr>
<th>Dictionary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3gpp2</td>
<td>This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835-A.</td>

This is the default dictionary.</td>
</tr>
</tbody>
</table>

**Important:** In StarOS 12.0 and later releases, no new attributes can be added to the starent-vsal dictionary. If there are new attributes to be added, you can only add them to the starent dictionary. For more information, please contact your Cisco account representative.

**Important:** For information on the specific dictionary to use for your deployment contact your Cisco account representative.

```
disconnect-message [ release-on-acct-stop acct_stop_wait_timeout ] [ dest-port destination_port_number ]
```

Specifies to send RADIUS disconnect message to the configured RADIUS accounting client in call failure scenarios.

- **release-on-acct-stop acct_stop_wait_timeout:** Specifies to wait for the accounting stop request after sending the Packet of Disconnect (PoD) to the client for the specified time. This keyword is disabled by default.
  
  `acct_stop_wait_timeout` must be an integer from 10 through 300 seconds. This indicates the time to wait to clear the call in case IPSG does not receive any accounting stop for the subscriber after sending the PoD.
  
  This keyword is configured on a per RADIUS accounting client basis and not for the entire service.

- **dest-port destination_port_number:** Specifies the port number to which the disconnect message must be sent.
  
  `destination_port_number` must be an integer from 1 through 65535.

```
interim create-new-call
```

**Important:** This option does not apply to the IPSG Proxy Mode.

Specifies to create a new session upon receipt of a RADIUS interim message.

Default: Disabled

```
validate-client-ip
```

Specifies to enable the ipsgmgr to validate RADIUS accounting messages from different configured RADIUS client IP address, and forward requests to the session manager.
Default: The RADIUS client IPs are validated.

**Usage**

Use this command to configure the communication parameters for the RADIUS client from which RADIUS accounting requests are received.

**Example**

The following command configures the service to communicate with a RADIUS client with an IP address of 10.2.3.4 and an encrypted shared secret of key1234:

```
radius accounting client 10.2.3.4 encrypted key key1234
```
radius dictionary

This command allows you to specify the RADIUS dictionary for the current IPSG/eWAG service.

**Product**
eWAG
IPSG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration
configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipsg-service-radius-server)#
```

**Syntax**

```
radius dictionary dictionary_name

default radius dictionary
```

```
default
   Specifies to use the default dictionary.
   Default: starent-vsa1
```

```
dictionary dictionary_name
   Specifies the dictionary to use.
```

---

**Important:** In 15.0 and later releases, for DeWAG use the **starent** dictionary.

**dictionary_name** must be one of the following.

<table>
<thead>
<tr>
<th>Dictionary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3gpp2</td>
<td>This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835-A.</td>

This is the default dictionary.</td>
</tr>
</tbody>
</table>

**Important:** For information on the specific dictionary to use for your deployment contact your Cisco account representative.

**Usage**

Use this command to specify the RADIUS dictionary to use for the IPSG RADIUS Server/eWAG service.

**Example**

The following command specifies to use the `custom10` RADIUS dictionary:

```
radius dictionary custom10
```
sess-replacement

This command allows you to enable/disable the Session Replacement feature for eWAG and IPSG services.

Product
- eWAG
- IPSG

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration
- configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-server)#

Syntax

```
sess-replacement { with-diff-acct-sess-id | with-diff-ip | with-diff-key [ with-diff-acct-sess-id ] }
{ default | no } sess-replacement
```

- **default**
  Configures this command with its default setting.
  Default: Disabled.

- **no**
  If previously configured, deletes the configuration.

- **with-diff-acct-sess-id**
  Specifies to replace current session when a new session request comes with same IP address and same user name/IMSI but different accounting session ID.

- **with-diff-ip**
  Specifies to replace current session when a new session request comes with same user name/IMSI but different IP address.

- **with-diff-key [ with-diff-acct-sess-id ]**
  Specifies to replace current session when a new session request comes with same IP address but different user name/IMSI.
  For IPSG, you can also use a combination of replacement options of different key and different account session ID.
Usage

Use this command to enable/disable the Session Replacement feature. By default, the Session Replacement feature is disabled.

Example

The following command enables session replacement specifying to replace the current session when a new session request comes with same user name/IMSI but different IP address:

```
sess-replacement with-diff-ip
```
setup-timeout

This command allows you to configure a timeout for session setup attempts for the current IPSG/eWAG service.

**Product**
- eWAG
- IPSG

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

    configure > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

    [context_name]host_name(config-ipsg-service-radius-server)#

**Syntax**

    setup-timeout setup_timeout_seconds

**default setup-timeout**

- **default**
  
  Configures this command with its default setting.
  
  Default: 60 seconds

- **setup_timeout_seconds**
  
  Specifies the time period, in seconds, for which a session setup attempt is allowed to continue before being terminated.
  
  `setup_timeout_seconds` must be an integer from 1 through 1000000.

**Usage**

Use this command to configure a timeout for IPSG/eWAG session setup attempts.

**Example**

The following command configures the timeout for session setup attempts to 30 seconds:

    setup-timeout 30
**w-apn**

This command allows you to configure the W-APNs that can be connected through DeWAG, and the default-gateway IP addresses to be used by the UEs for connecting to the W-APN network.

**Product**
eWAG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSG RADIUS Server Configuration

command > context context_name > ipsg-service service_name mode radius-server

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-ipsg-service-radius-server) #
```

**Syntax**

```
w-apn apn_name default-gw ipv4/ipv6_address/maskbits +
```

```
no w-apn apn_name
```

If previously configured, removes the specified configuration.

**apn-name apn_name**

Specifies the APN name.

**default-gw ipv4/ipv6_address/maskbits**

Specifies the IP address of the default gateway to be used by UE for W-APN access. You can configure a maximum of four default gateways per W-APN. Multiple default-gateways are possible as the APN can have different pools of different subnet with different default-gateway IP addresses.

This value should be in the same subnet as that of UE allocated IP address from GGSN for the W-APN. GGSN does not supply subnet-mask along with IP address. Therefore, the identification of whether GGSN-allocated IP address is in same subnet or not is done with the help of configured “/maskbits”. This default-gateway value is sent to the UE as default-gateway IP address using “Router” option in DHCP-OFFER message. The maskbits is sent to the UE as subnet-mask using the “Subnet Mask” option in DHCP-OFFER message.
Usage

Use this command to configure the list of W-APN names that can be connected through DeWAG and the default-gateway IP addresses to be used by UE for connecting to the W-APN network. During DHCP signaling the configured default-gateway value will be notified to UE as the router. This command also configures the subnet-mask to be used for the respective default-gateway IP address in order to find the network prefix of the default-gateway.

Note that DeWAG will be acting as 'default-gateway' for the UE in its connected network.

Important: This command can be configured a maximum of four times to configure four different APNs and the corresponding default-gateways.

Example

The following command configures an APN named `apn123` with the default gateway IP address and mask 192.168.1.1/24:

```bash
w-apn apn123 default-gw 192.168.1.1/24
```
Chapter 179
IPSG RADIUS Snoop Configuration Mode Commands

The IP Services Gateway (IPSG) RADIUS Snoop Configuration Mode is used to create and configure IPSG services within the current context. The IPSG RADIUS Snoop Mode configures the system to inspect RADIUS accounting requests on the way to the RADIUS accounting server and extract user information.

Mode
Exec > Global Configuration > Context Configuration > IPSG RADIUS Snoop Configuration

configure > context context_name > ipsg-service service_name mode radius-snoop

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-snoop)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**bind**

This command allows you to configure the service to accept data on any interface configured in the context. Optionally, you can also configure the system to limit the number of sessions processed by this service.

**Product**
IPSG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSG RADIUS Snoop Configuration
configure > context context_name > ipsg-service service_name mode radius-snoop

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipsg-service-radius-snoop)#
```

**Syntax**

```
bind [ max-subscribers max_sessions ]
no bind
```

- **max-subscribers**
- **max_sessions**

If previously configured, deletes the binding configuration for the service.

**Usage**

Use this command to initiate the service and begin accepting data on any interface configured in the context.

**Example**

The following command prepares the system to receive subscriber sessions on any interface in the context and limits the sessions to 10000:

```
bind max-subscribers 10000
```
connection authorization

This command allows you to configure the RADIUS authorization password that must be matched by the RADIUS accounting requests “snooped” by this service.

Product
IPSG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPSG RADIUS Snoop Configuration

configure > context context_name > ipsg-service service_name mode radius-snoop

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipsg-service-radius-snoop)#

Syntax

connection authorization [ encrypted ] password password

no connection authorization

no

Deletes the RADIUS connection authorization configuration from the current IPSG RADIUS snoop service.

[ encrypted ] password password

• encrypted: Specifies that the received RADIUS authorization password is encrypted.
• password password: Specifies the password that must be matched by incoming RADIUS accounting requests.

In StarOS 12.2 and later releases, password with encryption must be an alphanumeric string of 1 through 132 characters, and without encryption an alphanumeric string of 1 through 63 characters.

In StarOS 12.1 and earlier releases, password must be an alphanumeric string of 1 through 63 characters.

Usage
RADIUS accounting requests being examined by the IPSG RADIUS snoop service are destined for a RADIUS Accounting Server. Since the “snoop” service does not terminate user authentication, the user password is unknown.

Use this command to configure the authorization password that the RADIUS accounting requests must match in order for the service to examine and extract user information.

Example
The following command sets the RADIUS authorization password that must be matched by the RADIUS accounting requests “snooped” by this service. The password is encrypted, and the password used in this example is “secret”.

connection authorization encrypted password secret
end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

exit

Usage
Use this command to return to the parent configuration mode.
profile

This command allows you to configure the service to use APN or subscriber profile.

Product
IPSG

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPSG RADIUS Snoop Configuration

configure > context context_name > ipsg-service service_name mode radius-snoop

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-IPSG-service-radius-snoop)#

Syntax

profile { APN | subscriber }

default profile

default
Configures this command with its default setting.

APN
Specifies the service to support APN configuration required to enable Gx support.

subscriber
Specifies the service to support subscriber profile lookup.

Usage
Use this command to set the service to support APN profiles (supporting Gx through the enabling of ims-auth-service) or for basic subscriber profile lookup.

Example
The following command specifies to use the subscriber profile:

profile subscriber
radius

This command allows you to specify the RADIUS accounting servers where accounting requests are sent after being “inspected” by this service.

**Product**
IPSG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSG RADIUS Snoop Configuration
configure > context context_name > ipsg-service service_name mode radius-snoop

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipsg-service-radius-snoop)#
```

**Syntax**

```
[ no ] radius { accounting server ipv4/ipv6_address [ port port_number | source-context context_name ] | dictionary { 3gpp2 | 3gpp2-835 | customXX | standard | starent | starent-835 | starent-vsa1 | starent-vsa1-835 } }
```

---

**no**
Removes the RADIUS accounting server identifier from this service.

**radius accounting server ipv4/ipv6_address**

Specifies the IP address of a RADIUS accounting server where accounting requests are sent after being “snooped” by this service in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation. Up to 16 addresses can be configured.

**port port_number**

Specifies the port number of the RADIUS Accounting Server where accounting requests are sent after being “snooped” by this service.

`port_number` must be an integer from 1 through 65535.

Default: 1813

**source-context context_name**

Specifies the source context where RADIUS accounting requests are received.

`context_name` must be an alphanumeric string of 1 through 79 characters.

If this keyword is not configured, the system will default to the context in which the IPSG service is configured.

**dictionary { 3gpp2 | 3gpp2-835 | custom XX | standard | starent | starent-835 | starent-vsa1 | starent-vsa1-835 }**

Specifies what dictionary to use. The possible values are described in the following table:

<table>
<thead>
<tr>
<th>Dictionary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Dictionary

<table>
<thead>
<tr>
<th>Dictionary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3gpp</td>
<td>This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in 3GPP 32.015.</td>
</tr>
<tr>
<td>3gpp2</td>
<td>This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835-A.</td>
</tr>
<tr>
<td>3gpp2-835</td>
<td>This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835.</td>
</tr>
<tr>
<td>customXX</td>
<td>These are customized dictionaries. For information on custom dictionaries, please contact your Cisco account representative. XX is the integer value of the custom dictionary.</td>
</tr>
<tr>
<td>standard</td>
<td>This dictionary consists only of the attributes specified in RFC 2865, RFC 2866, and RFC 2869.</td>
</tr>
<tr>
<td>starent</td>
<td>This dictionary consists of all of the attributes in the starent-vsa1 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the dictionaries supported by the system.</td>
</tr>
<tr>
<td>starent-835</td>
<td>This dictionary consists of all of the attributes in the starent-vsa1-835 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the -835 dictionaries supported by the system.</td>
</tr>
<tr>
<td>starent-vsa1</td>
<td>This dictionary consists not only of the 3gpp2 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0–255). This is the default dictionary.</td>
</tr>
<tr>
<td>starent-vsa1-835</td>
<td>This dictionary consists not only of the 3gpp2-835 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0–255). This is the default dictionary.</td>
</tr>
</tbody>
</table>

### Usage

Use this command to specify the RADIUS Accounting Servers where accounting requests are sent after being snooped by this service.

### Example

The following command specifies the IP address (10.2.3.4) of a RADIUS Accounting Server whose accounting requests are to be “snooped”, and the source context (aaa_ingress) where the requests are received on the system:

```
radius accounting server 10.2.3.4 source-context aaa_ingress
```
**sess-replacement**

This command allows you to enable/disable session replacement.

> **Important:** This command is not supported in this release. The Session Replacement feature is under development for future use.

**Product**
IPSG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSG RADIUS Snoop Configuration

```bash
configure > context context_name > ipsg-service service_name mode radius-snoop
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipsg-service-radius-snoop)#
```

**Syntax**

```bash
sess-replacement { with-diff-acct-sess-id | with-diff-ip | with-diff-key }
{ default | no } sess-replacement
```

- **default**
  
  Configures this command with its default setting.
  
  Default: Disabled.

- **no**
  
  If previously configured, deletes the configuration.

- **with-diff-acct-sess-id**
  
  Specifies to replace current session when a new session request comes with same IP address and same user name/IMSI but different accounting session ID.

- **with-diff-ip**
  
  Specifies to replace current session when a new session request comes with same user name/IMSI but different IP address.

- **with-diff-key**
  
  Specifies to replace current session when a new session request comes with same IP address but different user name/IMSI.
**Usage**

Use this command to enable/disable session replacement. By default, session replacement is disabled.

**Example**

The following command enables session replacement specifying to replace the current session when a new session request comes with same user name/IMSI but different IP address:

```
  sess-replacement with-diff-ip
```
**setup-timeout**

This command allows you to configure the timeout value for IPSG session setup attempts.

**Product**
IPSG

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPSG RADIUS Snoop Configuration
`configure > context context_name > ipsg-service service_name mode radius-snoop`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-ipsg-service-radius-snoop)#`

**Syntax**

```
setup-timeout setup_timeout

default setup-timeout
```

---

**Usage**

Specifies the period of time (in seconds) the IPSG session setup is allowed to continue before the setup attempt is terminated.

*setup_timeout* must be an integer from 1 through 1000000.

Default: 60

---

**Example**

Use this command to prevent IPSG session setup attempts from continuing without termination.

The following command configures the session setup timeout setting to 20 seconds:

```
setup-timeout 20
```
Chapter 180
IPSP Configuration Mode Commands

The IPSP Configuration Mode is used to configure properties for the IP Pool Sharing Protocol (IPSP). System-based HA services use IPSP during an offline-software upgrade to avoid the assignment of duplicate IP addresses to sessions while allowing them to maintain the same address, and to preserve network capacity.

**Important:** For information on configuring and using IPSP refer to the *System Administration Guide*.

Mode

Exec > Global Configuration > Context Configuration > Ethernet Interface Configuration > IP Pool Sharing Protocol Configuration

```
configure > context context_name > interface interface_name broadcast > pool-share-protocol { primary ip_address | secondary ip_address }
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
dead-interval

Configures the retry time to connect to the remote system for the IP Pool Sharing Protocol.

Product
- PDSN
- HA

Privilege
- Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Ethernet Interface Configuration > IP Pool Sharing Protocol Configuration

Syntax
```
dead-interval seconds
[ no | default ] dead-interval
```

**no**

Disables the dead interval. On loss of connectivity to the remote system, no retries are attempted and the remote system is marked dead immediately on failure.

**default**

Resets the dead interval to the default of 3600 seconds.

**seconds**

Default: 3600 seconds

The amount of time in seconds to wait before retrying the remote system. `seconds` must be an integer from 25 through 259200.

Usage

Use this command to set the amount of time to wait before retrying to connect with the remote system for the IP pool sharing protocol.

Example

Use the following command to set the interval to 180 seconds (3 minutes):
```
dead-interval 180
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
reserved-free-percentage

This command is used to set the amount of free addresses reserved for use on the primary HA.

**Product**
PDSN
HA

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Ethernet Interface Configuration > IP Pool Sharing Protocol Configuration

```
configure > context context_name > interface interface_name broadcast > pool-share-protocol { primary ip_address | secondary ip_address }
```

**Syntax**

```
reserved-free-percentage value

default reserved-free-percentage
```

```
value

Default: 100

value specifies the percentage of free addresses reserved for the use on the primary HA for IP pool sharing during upgrade. It must be an integer from 0 through 100.
```

**Usage**

This command is used with `pool-sharing-protocol active mode` on the primary HA. Before using this command, `pool-sharing-protocol` in the Ethernet Interface Configuration Mode must be configured.

For more information, refer to the `Ethernet Interface Configuration Mode Commands` chapter in this guide.

**Example**

To reserve 40 percent of free addresses in primary HA for IP pool sharing, enter the following command:

```
reserved-free-percentage 40
```
Chapter 181
IPv6 ACL Configuration Mode Commands

The IPv6 Access Control List Configuration Mode is used to create and manage IPv6 access privileges.

**Mode**

Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
deny/permit (by source IP address masking)

Used to filter subscriber sessions based on the IPv6 address mask sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

{ deny | permit } [ log ] source_address source_wildcard

after { deny | permit } [ log ] source_address source_wildcard

before { deny | permit } [ log ] source_address source_wildcard

no { deny | permit } [ log ] source_address source_wildcard

after
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change

no
Removes the rule which exactly matches the options specified.

deny | permit
Specifies the rule is either block (deny) or an allow (permit) filter.
deny/permit (by source IP address masking)

- **deny**: Indicates the rule, when matched, drops the corresponding packets.
- **permit**: Indicates the rule, when matched, allows the corresponding packets.

**log**
Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

**source_address**
The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important**: The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**Usage**
Define a rule when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rules as it does not require a rule for each source and destination pair.

**Important**: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Example**
The following command defines two rules with the second logging filtered packets:

```
permit 2001:4A2B::1f3F
deny log 2001:4A2B::1f3F
```

The following sets the insertion point to before the first rule defined above:

```
before permit 2001:4A2B::1f3F
```

The following command sets the insertion point after the second rule defined above:

```
after deny log 2001:4A2B::1f3F
```
The following deletes the first rule defined above:

    no permit 2001:4A2B::1f3F
deny/permit (any)

Used to filter subscriber sessions based on any packet received. This command is also used to set the access control list insertion point.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:
```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**
```
{ deny | permit } [ log ] any
after { deny | permit } [ log ] any
before { deny | permit } [ log ] any
no { deny | permit } [ log ] any
```

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.
deny | permit

Specifies the rule is either block (deny) or an allow (permit) filter.

- **deny**: Indicates the rule, when matched, drops the corresponding packets.
- **permit**: Indicates the rule, when matched, allows the corresponding packets.

log

Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

any

Indicates all packets will match the filter regardless of source and/or destination.

Usage

Define a catch all rule to place at the end of the list of rules.

Important: It is suggested that any rule which is added to be a catch all should also have the log option specified. The logged packets may be used to determine if the current list of rules is adequate or needs modification to ensure proper security. The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*.

Example

The following command defines two rules with the second logging filtered packets:

```plaintext
permit any
deny log any
```

The following sets the insertion point to before the first rule defined above:

```plaintext
before permit any
```

The following command sets the insertion point after the second rule defined above:

```plaintext
after deny log any
```

The following deletes the first rule defined above:

```plaintext
no permit any
```
deny/permit (by host IP address)

Used to filter subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

{ deny | permit } [ log ] host source_host_address
after { deny | permit } [ log ] host source_host_address
before { deny | permit } [ log ] host source_host_address
no { deny | permit } [ log ] host source_host_address

**after**

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**

Removes the rule which exactly matches the options specified.
deny | permit
Specifies the rule is either block (deny) or an allow (permit) filter.

- **deny**: Indicates the rule, when matched, drops the corresponding packets.
- **permit**: Indicates the rule, when matched, allows the corresponding packets.

log
Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

**Usage**
Define a rule when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rules to be very clear and concise.

**Important**: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*.

**Example**
The following command defines two rules with the second logging filtered packets:

```plaintext
permit host 2001:4A2B::1f3F
deny log host 2001:4A2B::1f3F
```
The following sets the insertion point to before the first rule defined above:

```plaintext
before permit host 2001:4A2B::1f3F
```
The following command sets the insertion point after the second rule defined above:

```plaintext
after deny log host 2001:4A2B::1f3F
```
The following deletes the first rule defined above:

```plaintext
no permit host 2001:4A2B::1f3F
```
deny/permit (by source ICMP packets)

Used to filter subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
{ deny | permit } [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

after { deny | permit } [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

before { deny | permit } [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

no { deny | permit } [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]
```

**Important:**
If the options specified do not exactly match an existing rule, the insertion point does not change.

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
deny/permit (by source ICMP packets)

**Important**: If the options specified do not exactly match an existing rule, the insertion point does not change.

IPv6 ACL Configuration Mode Commands

deny/permit (by source ICMP packets)

**dest_address**
The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

**dest_wildcard**
This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**icmp_type**
Specifies that all ICMP packets of a particular type are to be filtered. The type is an integer from 0 through 255.

**icmp_code**
Specifies that all ICMP packets of a particular code are to be filtered. The type is an integer from 0 through 255.

**Usage**
Define a rule to block ICMP packets which can be used for address resolution and possible be a security risk. The IP filtering allows flexible controls for pairs of individual hosts or groups by IP masking which allows the filtering of entire subnets if necessary.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*.

**Example**
The following command defines two rules with the second logging filtered packets:

```
permit icmp host 2001:4A2B::1f3F4 any 168
deny log icmp 2001:4A2B::1f3F 2001:4a2b::1f00 host fe80::a02:410 168 11
```

The following sets the insertion point to before the first rule defined above:

```
before permit icmp host 2001:4A2B::1f3F any 168
```

The following command sets the insertion point after the second rule defined above:
deny/permit (by source ICMP packets)

after deny log icmp 2001:4A2B::1f3F 2001:4a2b::1f00 host fe80::a02:410 168 11

The following deletes the first rule defined above:

no permit icmp host 2001:4A2B::1f3F any 168
deny/permit (by IP packets)

Used to filter subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

Syntax

{ deny | permit } [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocolnum ]

after { deny | permit } [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocolnum ]

before { deny | permit } [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocolnum ]

no { deny | permit } [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocolnum ]

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
**deny/permit (by IP packets)**

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

- **no**
  Removes the rule which exactly matches the options specified.

- **deny | permit**
  Specifies the rule is either block (deny) or an allow (permit) filter.
  - **deny**: indicates the rule, when matched, drops the corresponding packets.
  - **permit**: indicates the rule, when matched, allows the corresponding packets.

- **log**
  Default: packets are not logged.
  Indicates all packets which match the filter are to be logged.

- **source_address**
  The IP address(es) form which the packet originated.
  This option is used to filter all packets from a specific IP address or a group of IP addresses.
  When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the **source_wildcard** parameter.

- **source_wildcard**
  This option is used in conjunction with the **source_address** option to specify a group of addresses for which packets are to be filtered.
  The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the **source_address** parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the **source_address** parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

- **any**
  Specifies that the rule applies to all packets.

- **host**
  Specifies that the rule applies to a specific host as determined by its IP address.

- **source_host_address**
  The IP address of the source host to filter against expressed in IPv6 colon notation.

- **dest_host_address**
  The IP address of the destination host to filter against expressed in IPv6 colon notation.
**dest_address**

The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the `dest_wildcard` parameter.

**dest_wildcard**

This option is used in conjunction with the `dest_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**fragment**

Indicates packet filtering is to be applied to IP packet fragments only.

**protocol num**

Indicates that the packet filtering is to be applied to a specific protocol number. `num` can be any integer ranging from 0 to 255.

---

**Usage**

Block IP packets when the source and destination are of interest.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*.

**Example**

The following command defines two rules with the second logging filtered packets:

```
permit ip host 2001:4A2B::1f3F any fragment
deny log ip 2001:4A2B::1f3F 2001:4a2b::1f00 host fe80::a02:410
```

The following sets the insertion point to before the first rule defined above:

```
before permit ip host 2001:4A2B::1f3F any fragment
```

The following command sets the insertion point after the second rule defined above:

```
after deny log ip 2001:4A2B::1f3F 2001:4a2b::1f00 host fe80::a02:410
```

The following deletes the first rule defined above:

```
no permit ip host 2001:4A2B::1f3F any fragment
```
deny/permit (by TCP/UDP packets)

Used to filter subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
{ deny | permit } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port ] }

after { deny | permit } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port ] }

before { deny | permit } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port ] }

no { deny | permit } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port ] }
```

**after**

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

---

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.
IPv6 ACL Configuration Mode Commands

deny/permit (by TCP/UDP packets)

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.

**deny | permit**
Specifies the rule is either block (deny) or an allow (permit) filter.

- **deny**: Indicates the rule, when matched, drops the corresponding packets.
- **permit**: Indicates the rule, when matched, allows the corresponding packets.

**log**
Default: packets are not logged. Indicates all packets which match the filter are to be logged.

**tcp | udp**
Specifies the filter is to be applied to IP-based transmission control protocol or the user datagram protocol.

- **tcp**: Filter applies to TCP packets.
- **udp**: Filter applies to UDP packets.

**source_address**
The IP address(es) form which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source wildcard* parameter.

**source wildcard**
This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**any**
Specifies that the rule applies to all packets.
### IPv6 ACL Configuration Mode Commands

- **deny/permit (by TCP/UDP packets)**

<table>
<thead>
<tr>
<th>Command Line Reference, StarOS Release 16</th>
</tr>
</thead>
</table>

### host
Specifies that the rule applies to a specific host as determined by its IP address.

#### source_host_address
The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

#### dest_host_address
The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

### eq source_port
Specifies a single, specific source TCP port number to be filtered.

- **source_port** must be configured to an integer from 0 through 65535.

### gt source_port
Specifies that all source TCP port numbers greater than the one specified are to be filtered.

- **source_port** must be configured to an integer from 0 through 65535.

### lt source_port
Specifies that all source TCP port numbers less than the one specified are to be filtered.

- **source_port** must be configured to an integer from 0 through 65535.

### neq source_port
Specifies that all source TCP port numbers not equal to the one specified are to be filtered.

- **source_port** must be configured to an integer from 0 through 65535.

### dest_address
The IP address(es) to which the packet is to be sent.

- This option is used to filter all packets to a specific IP address or a group of IP addresses.
- When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.

### dest_wildcard
This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered.

- The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.

### Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

### eq dest_port
Specifies a single, specific destination TCP port number to be filtered.

---

---
IPv6 ACL Configuration Mode Commands

deny/permit (by TCP/UDP packets)

**Command Line Interface Reference, StarOS Release 16**

---

**Usage**
Block IP packets when the source and destination are of interest but for only a limited set of ports.

---

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*.

---

**Example**

The following command defines four rules with the second and fourth rules logging filtered packets:

```text
permit tcp host 2001:4A2B::1f3F any
deny log udp 2001:4A2B::1f3F 2001:4a2b::1f00 host fe80::a02:410
permit tcp host 2001:4A2B::1f3F gt 1023 any
```

The following sets the insertion point to before the first rule defined above:

```text
before permit tcp host 2001:4A2B::1f3F any
```

The following command sets the insertion point after the second rule defined above:

```text
after deny log udp 2001:4A2B::1f3F 2001:4a2b::1f00 host fe80::a02:410
```

The following deletes the third rule defined above:

```text
no permit tcp host 2001:4A2B::1f3F gt 1023 any
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
end

**Usage**
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the parent configuration mode.
readdress server

Alter the destination address and port number in TCP or UDP packet headers to redirect packets to a different server.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

```
after
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.
```

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

```
before
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
```

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

```
no
Removes the rule which exactly matches the options specified.
```

```
redirect_address
The IP address to which the IP packets are redirected. TCP or UDP packet headers are rewritten to contain the new destination address. This must expressed in IPv6 colon-separated-hexadecimal notation.
```

```
port port_number
The number of the port at the redirect address where the packets are sent. TCP or UDP packet headers are rewritten to contain the new destination port number.
```
IPv6 ACL Configuration Mode Commands

**tcp | udp**

Specifies the redirect is to be applied to the IP-based transmission control protocol or the user datagram protocol.

- **tcp**: Redirect applies to TCP packets.
- **udp**: Redirect applies to UDP packets.

**source_address**

The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the **source_wildcard** parameter.

**any**

Specifies that the rule applies to all packets.

**host**

Specifies that the rule applies to a specific host as determined by its IP address.

**source_host_address**

The IP address of the source host to filter against expressed in IPv6 colon notation.

**dest_host_address**

The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**eq source_port**

Specifies a single, specific source TCP port number to be filtered. **source_port** must be configured to an integer from 0 through 65535.

**gt source_port**

Specifies that all source TCP port numbers greater than the one specified are to be filtered. **source_port** must be configured to an integer from 0 through 65535.

**lt source_port**

Specifies that all source TCP port numbers less than the one specified are to be filtered. **source_port** must be configured to an integer from 0 through 65535.

**neq source_port**

Specifies that all source TCP port numbers not equal to the one specified are to be filtered. **source_port** must be configured to an integer from 0 through 65535.

**dest_address**

The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.
**eq dest_port**

Specifies a single, specific destination TCP port number to be filtered.  

*dest_port* must be configured to an integer from 0 through 65535.

**gt dest_port**

Specifies that all destination TCP port numbers greater than the one specified are to be filtered.  

*dest_port* must be configured to an integer from 0 through 65535.

**lt dest_port**

Specifies that all destination TCP port numbers less than the one specified are to be filtered.  

*dest_port* must be configured to an integer from 0 through 65535.

**neq dest_port**

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered.  

*dest_port* must be configured to an integer from 0 through 65535.

**Usage**

Use this command to define a rule that redirects packets to a different destination address. The TCP and UDP packet headers are modified with the new destination address and destination port.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule that redirects packets to the server at `fe80::c0a8:a04`, UDP packets coming from any host with a destination of any host are matched:

```
readdress server fe80::c0a8:a04 udp any any
```

The following sets the insertion point to before the rule defined above:

```
before readdress server fe80::c0a8:a04 udp any any
```

The following deletes the rule defined above:

```
no readdress server fe80::c0a8:a04 udp any any
```
redirect context (by IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)##

Syntax

redirect context context_id [ log ] source_address source_wildcard
after redirect context context_id [ log ] source_address source_wildcard
before redirect context context_id [ log ] source_address source_wildcard
no redirect context context_id [ log ] source_address source_wildcard

after
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no
Removes the rule which exactly matches the options specified.
**IPv6 ACL Configuration Mode Commands**

**redirect context (by IP address masking)**

- **context context_id**
  Specifies the context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

- **log**
  Default: packets are not logged.
  Indicates all packets which match the redirect are to be logged.

- **source_address**
  Filters by the IP address(es) from which the packet originated. This option filters all packets from a specific IP address or a group of IP addresses.
  When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

- **source_wildcard**
  Filters packets for a group of addresses specified in conjunction with the `source_address` option.
  The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**Usage**

Define a rule when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of redirect rules as it does not require a rule for each source and destination pair.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule that redirects packets to the context with the context ID of 23 and the source IP and wildcard of 2002::c6a2:1600 and 2002::c6a2:1600:

```
redirect context 23 2002::c6a2:1600 2002::c6a2:1600
```

The following sets the insertion point to before the first rule defined above:

```
before redirect context 23 2002::c6a2:1600 2002::c6a2:1600
```

The following command sets the insertion point after the second rule defined above:

```
after redirect context 23 2002::c6a2:1600 2002::c6a2:1600
```
The following deletes the first rule defined above:

```
no redirect context 23 2002::c6a2:1600 2002::c6a2:1600
```
redirect context (any)

Used to redirect subscriber sessions based on any packet received. This command is also used to set the access control list insertion point.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

`configure > context context_name > ipv6 access-list ipv6_acl_name`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-ipv6-acl)#`

**Syntax**

- `redirect context context_id [ log ] any`
- `after redirect context context_id [ log ] any`
- `before redirect context context_id [ log ] any`
- `no redirect context context_id [ log ] any`

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.
redirect context (any)

context context_id
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the show context all command to display context names and context IDs.

log
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

any
Indicates all packets will match the redirect regardless of source and/or destination.

Usage
Define a catch all rule to place at the end of the list of rules to provide explicit handling of rules which do not fit any other criteria.

Important: It is suggested that any rule which is added to be a catch all should also have the log option specified. The logged packets may be used to determine if the current list of rules is adequate or needs modification to ensure proper security. The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example
The following command defines a rule that redirects packets to the context with the context ID of 23 and any source IP:

```
redirect context 23 any
```

The following sets the insertion point to before the first rule defined above:

```
before redirect context 23 any
```

The following command sets the insertion point after the second rule defined above:

```
after redirect context 23 any
```

The following deletes the first rule defined above:

```
no redirect context 23 any
```
redirect context (by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```plaintext
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```plaintext
redirect context context_id [ log ] host source_ip_address

after redirect context context_id [ log ] host source_ip_address

before redirect context context_id [ log ] host source_ip_address

no redirect context context_id [ log ] host source_ip_address
```

**after**

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**

Removes the rule which exactly matches the options specified.
redirect context (by host IP address)

```
context context_id
The context identification number of the context to which packets are redirected. At the executive mode
prompt, use the show context all command to display context names and context IDs.
```

```
log
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.
```

```
host
Specifies that the rule applies to a specific host as determined by its IP address.
```

```
source_host_address
The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.
```

Usage
Define a rule when a very specific remote host is to be blocked. In simplified networks where the access
controls need only block a few hosts, this command allows the rules to be very clear and concise.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is
to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also
note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific
context.

Example
The following command defines a rule that redirects packets to the context with the context ID of 23 and a
host IP address of fe80::c0a8:c80b:

```
redirect context 23 host fe80::c0a8:c80b
```

The following sets the insertion point to before the first rule defined above:

```
before redirect context 23 host fe80::c0a8:c80b
```

The following command sets the insertion point after the second rule defined above:

```
after redirect context 23 host fe80::c0a8:c80b
```

The following deletes the first rule defined above:

```
no redirect context 23 host fe80::c0a8:c80b
```
redirect context (by source ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect context context_id [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]
```

```
before redirect context context_id [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]
```

```
no redirect context context_id [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]
```

**after**

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.

**context context_id**
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

**log**
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**source_address**
The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**any**
Specifies that the rule applies to all packets.

**host**
Specifies that the rule applies to a specific host as determined by its IP address.

**source_host_address**
The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**dest_host_address**
The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.
**dest_address**

The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.

**dest_wildcard**

This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**icmp_type**

Specifies that all ICMP packets of a particular type are to be filtered. Type is an integer from 0 through 255.

**icmp_code**

Specifies that all ICMP packets of a particular code are to be filtered. Type is an integer from 0 through 255.

**Usage**

Define a rule to block ICMP packets which can be used for address resolution and possibly be a security risk.
The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule that redirects packets to the context with the context ID of 23, and ICMP packets coming from the host with the IP address 2002::c6a2:6419:

```
redirect context 23 icmp host 2002::c6a2:6419
```

The following sets the insertion point to before the first rule defined above:

```
before redirect context 23 icmp host 2002::c6a2:6419
```

The following command sets the insertion point after the second rule defined above:

```
after redirect context 23 icmp host 2002::c6a2:6419
```
The following deletes the first rule defined above:

```plaintext
no redirect context 23 icmp host 2002::c6a2:6419
```
redirect context (by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

```
redirect context context_id [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]

after redirect context context_id [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]

before redirect context context_id [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]

no redirect context context_id [ log ] ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.

**context context_id**
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

**log**
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**source_address**
The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**any**
Specifies that the rule applies to all packets.

**host**
Specifies that the rule applies to a specific host as determined by its IP address.

**source_host_address**
The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**dest_host_address**
The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.
IPv6 ACL Configuration Mode Commands

redirect context (by IP packets)

Command
Line Interface Reference, StarOS Release 16

---

**dest_address**
The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

---

**dest_wildcard**
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

---

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

---

**fragment**
Indicates packet redirection is to be applied to IP packet fragments only.

---

**protocol num**
Indicates that the packet filtering is to be applied to a specific protocol number. num is an integer from 0 through 255.

---

**Usage**
Block IP packets when the source and destination are of interest.

---

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

---

**Example**
The following command defines a rule that redirects packets to the context with the context ID of 23, and IP packets coming from the host with the IP address 2002::c6a2:6419, and fragmented packets for any destination are matched:

```
redirect context 23 ip host 2002::c6a2:6419 any fragment
```

The following sets the insertion point to before the first rule defined above:

```
before redirect context 23 ip host 198.162.100.25 any fragment
```

The following command sets the insertion point after the second rule defined above:

```
after redirect context 23 ip host 2002::c6a2:6419 any fragment
```
The following deletes the first rule defined above:

```
no redirect context 23 ip host 2002::c6a2:6419 any fragment
```
**redirect context (by TCP/UDP packets)**

Used to redirect subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```bash
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```bash
redirect context context_id [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port ] }

after redirect context context_id [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port ] }

before redirect context context_id [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port ] }

no redirect context context_id [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port ] }
```

**after**

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.
**before**

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**

Removes the rule which exactly matches the options specified.

**context context_id**

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

**log**

Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

**tcp | udp**

Specifies the redirect is to be applied to IP-based transmission control protocol or the user datagram protocol.

* `tcp`: Redirect applies to TCP packets.
* `udp`: Redirect applies to UDP packets.

**source_address**

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

* Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
* One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**any**

Specifies that the rule applies to all packets.
**host**
Specifies that the rule applies to a specific host as determined by its IP address.

**source_host_address**
The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**dest_host_address**
The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**eq source_port**
Specifies a single, specific source TCP port number to be filtered.
*source_port* must be configured to an integer from 0 through 65535.

**gt source_port**
Specifies that all source TCP port numbers greater than the one specified are to be filtered.
*source_port* must be configured to an integer from 0 through 65535.

**lt source_port**
Specifies that all source TCP port numbers less than the one specified are to be filtered.
*source_port* must be configured to an integer from 0 through 65535.

**neq source_port**
Specifies that all source TCP port numbers not equal to the one specified are to be filtered.
*source_port* must be configured to an integer from 0 through 65535.

**dest_address**
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

**dest_wildcard**
This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**eq dest_port**
Specifies a single, specific destination TCP port number to be filtered.
dest_port must be configured to an integer from 0 through 65535.

- **gt dest_port**
  Specifies that all destination TCP port numbers greater than the one specified are to be filtered.
  dest_port must be configured to an integer from 0 through 65535.

- **lt dest_port**
  Specifies that all destination TCP port numbers less than the one specified are to be filtered.
  dest_port must be configured to an integer from 0 through 65535.

- **neq dest_port**
  Specifies that all destination TCP port numbers not equal to the one specified are to be filtered.
  dest_port must be configured to an integer from 0 through 65535.

**Usage**
Block IP packets when the source and destination are of interest but for only a limited set of ports.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the *Engineering Rules* appendix in the *System Administration Guide*. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule that redirects packets to the context with the context ID of 23, and UDP packets coming from any host are matched:

```
redirect context 23 udp any
```

The following sets the insertion point to before the rule defined above:

```
before redirect context 23 udp any
```

The following command sets the insertion point after the rule defined above:

```
after redirect context 23 udp any
```

The following deletes the rule defined above:

```
no redirect context 23 udp any
```
redirect css delivery-sequence

This is a restricted command. In StarOS 9.0 and later, this command is obsoleted.
**redirect css service (any)**

Used to redirect subscriber sessions based on any packet received with Content Service Steering (CSS) enabled. This command is also used to set the access control list insertion point.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

`configure > context context_name > ipv6 access-list ipv6_acl_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect css service svc_name [ log ] any
after redirect css service svc_name [ log ] any
before redirect css service svc_name [ log ] any
no redirect css service svc_name [ log ] any
```

**after**

Indicates all rule definitions defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definitions which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**

Removes the rule definition which exactly matches the options specified.
**redirect css service (any)**

```
css service svc_name
```

The name of the CSS service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services. `svc_name` must be a string of 1 through 15 characters.

```
log
```

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

```
any
```

Indicates all packets will match the redirect regardless of source and/or destination.

**Usage**

Define a catch all rule definitions to place at the end of the list of rule definitions to provide explicit handling of rule definitions which do not fit any other criteria.

**Important:** It is suggested that any rule definition which is added to be a catch all should also have the `log` option specified. The logged packets may be used to determine if the current list of rule definitions is adequate or needs modification to ensure proper security.

**Important:** A maximum of 16 rule definitions can be configured per ACL.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the CSS service with the name `css-svcl` and any source IP:

```
redirect css service css-svcl any
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service css-svcl any
```

The following command sets the insertion point after the second rule definitions above:

```
after redirect css service css-svcl any
```

The following deletes the first rule definition above:

```
no redirect css service css-svcl any
```
redirect css service (by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

redirect css service svc_name [ log ] host source_host_address
after redirect css service svc_name [ log ] host source_host_address
before redirect css service svc_name [ log ] host source_host_address
no redirect css service svc_name [ log ] host source_host_address

**after**
 Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
 Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**
 Removes the rule definition which exactly matches the options specified.
**css service svc_name**

The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services. `svc_name` must be an alphanumeric string of 1 through 15 characters.

**log**

Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

**host**

Specifies that the rule definition applies to a specific host as determined by its IP address.

**source_host_address**

The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**Usage**

Define a rule definition when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rule definitions to be very clear and concise.

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the CSS service with the name `css-svc1` and a host IP address of `fe80::c0a8:c80b`:

```
redirect css service css-svc1 host fe80::c0a8:c80b
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service css-svc1 host fe80::c0a8:c80b
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service css-svc1 host fe80::c0a8:c80b
```

The following deletes the first rule definition above:

```
no redirect css service css-svc1 host fe80::c0a8:c80b
```
redirect css service (by ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl) #

Syntax

redirect css service svc_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [icmp_type [ icmp_code ] ]

after redirect css service svc_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [icmp_type [ icmp_code ] ]

before redirect css service svc_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [icmp_type [ icmp_code ] ]

no redirect css service svc_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [icmp_type [ icmp_code ] ]

after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.
**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

css service svc_name

The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured charging services. `svc_name` must be an alphanumeric string of 1 through 15 characters.

log

Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) form which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

source_wildcard

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

any

Specifies that the rule definition applies to all packets.

host

Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.
IPv6 ACL Configuration Mode Commands

redirect css service (by ICMP packets)

---

**dest_host_address**

The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

---

**dest_address**

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.

---

**dest_wildcard**

This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.

---

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

---

**icmp_type**

Specifies that all ICMP packets of a particular type are to be filtered. The type can be an integer value from 0 through 255.

---

**icmp_code**

Specifies that all ICMP packets of a particular code are to be filtered. The type is an integer from 0 through 255.

---

**Usage**

Define a rule definition to block ICMP packets which can be used for address resolution and possibly be a security risk.

The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

---

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

---

**Example**

The following command defines a rule definition that redirects packets to the CSS service named `css-svcl`, and ICMP packets coming from the host with the IP address `2002::c6a2:6419`:

```
redirect css service css-svcl icmp host 2002::c6a2:6419
```

The following sets the insertion point to before the first rule definition above:
before redirect css service css-svcl icmp host 2002::c6a2:6419

The following command sets the insertion point after the second rule definition above:

after redirect css service css-svcl icmp host 2002::c6a2:64195

The following deletes the first rule definition above:

no redirect css service css-svcl icmp host 2002::c6a2:6419
**redirect css service (by IP packets)**

Used to redirect subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```bash
configure > context context_name > ipv6 access-list ipv6_acl_name`
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```bash
redirect css service svc_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]
```

```bash
after redirect css service svc_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]
```

```bash
before redirect css service svc_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]
```

```bash
no redirect css service svc_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]
```

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```bash
after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.
```

```bash
before
Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.
```
**Important**: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```no```
Removes the rule definition which exactly matches the options specified.

```css service svc_name```
The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services.

`svc_name` must be an alphanumeric string of 1 through 15 characters.

```log```
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

```source_address```
The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

```source_wildcard```
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important**: The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

```any```
Specifies that the rule definition applies to all packets.

```host```
Specifies that the rule definition applies to a specific host as determined by its IP address.

```source_host_address```
The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.
**dest_host_address**

The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**dest_address**

The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the `dest_wildcard` parameter.

**dest_wildcard**

This option is used in conjunction with the `dest_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**fragment**

Indicates packet redirection is to be applied to IP packet fragments only.

**Usage**

Block IP packets when the source and destination are of interest.

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the CSS service named `css-svcl`, and IP packets coming from the host with the IP address `2002::c6a2:6419`, and fragmented packets for any destination are matched:

```
redirect css service css-svcl ip host 2002::c6a2:6419 any fragment
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service css-svcl ip host 2002::c6a2:6419 any fragment
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service css-svcl ip host 2002::c6a2:6419 any fragment
```
The following deletes the first rule definition above:

```
no redirect css service css-svcl ip host 2002::c6a2:6419 any fragment
```
redirect css service (by source IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
config > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect css service svc_name [ log ] source_address source_wildcard
after redirect css service svc_name [ log ] source_address source_wildcard
before redirect css service svc_name [ log ] source_address source_wildcard
no redirect css service svc_name [ log ] source_address source_wildcard
```

**after**
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**
Removes the rule definition which exactly matches the options specified.
**css service svc_name**

The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services. 

`svc_name` must be an alphanumeric string of 1 through 15 characters.

**log**

Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

**source_address**

The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**Usage**

Define a rule definition when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rule definitions as it does not require a rule definition for each source and destination pair.

**Important:** A maximum of 16 rule definitions can be configured per ACL.

**Example**

The following command defines a rule definition to redirect packets to a CSS service named `css-svc1`:

```
redirect css service css=svc1 2002::c6a2:6419
```
redirect css service (by TCP/UDP packets)

Used to redirect subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

Product

Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

redirect css service svc_name [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

after redirect css service svc_name [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

after redirect css service svc_name [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

no redirect css service svc_name [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.
**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**
Removes the rule definition which exactly matches the options specified.

**css service svc_name**
The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured charging services. `svc_name` must be an alphanumeric string of 1 through 15 characters.

**log**
Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

**tcp | udp**
Specifies the redirect is to be applied to IP-based transmission control protocol or the user datagram protocol.
- **tcp**: Redirect applies to TPC packets.
- **udp**: Redirect applies to UDP packets.

**source_address**
The IP address(es) form which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.
**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

- **any**
  Specifications that the rule definition applies to all packets.

- **host**
  Specifications that the rule definition applies to a specific host as determined by its IP address.

- **source_host_address**
  The IP address of the source host to filter against expressed in IPv6 colon notation.

- **dest_host_address**
  The IP address of the destination host to filter against expressed in IPv6 colon notation.

- **eq source_port**
  Specifies a single, specific source TCP port number to be filtered. 
  `source_port` must be configured to an integer from 0 to 65535.

- **gt source_port**
  Specifies that all source TCP port numbers greater than the one specified are to be filtered. 
  `source_port` must be configured to an integer from 0 to 65535.

- **lt source_port**
  Specifies that all source TCP port numbers less than the one specified are to be filtered. 
  `source_port` must be configured to an integer from 0 to 65535.

- **neq source_port**
  Specifies that all source TCP port numbers not equal to the one specified are to be filtered. 
  `source_port` must be configured to an integer from 0 to 65535.

- **range start_source_port end_source_port**
  Specifies that all source TCP ports within a specific range are to be filtered. 
  `start_source_port` is the initial port in the range and `end_source_port` is the final port in the range. 
  Both `start_source_port` and `end_source_port` can be configured to an integer from 0 to 65535.

- **dest_address**
  The IP address(es) to which the packet is to be sent. 
  This option is used to filter all packets to a specific IP address or a group of IP addresses. 
  When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the `dest_wildcard` parameter.

- **dest_wildcard**
  This option is used in conjunction with the `dest_address` option to specify a group of addresses for which packets are to be filtered. 
  The mask must be entered as a complement.
IPv6 ACL Configuration Mode Commands

- Zero-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

```
eq dest_port
```
Specifies a single, specific destination TCP port number to be filtered. `dest_port` must be configured to an integer from 0 to 65535.

```
lt dest_port
```
Specifies that all destination TCP port numbers less than the one specified are to be filtered. `dest_port` must be configured to an integer from 0 to 65535.

```
neq dest_port
```
Specifies that all destination TCP port numbers not equal to the one specified are to be filtered. `dest_port` must be configured to an integer from 0 to 65535.

```
range start_dest_port end_dest_port
```
Specifies that all destination TCP ports within a specific range are to be filtered. `start_dest_port` is the initial port in the range and `end_dest_port` is the final port in the range. Both `start_dest_port` and `end_dest_port` can be configured to an integer from 0 to 65535.

**Usage**
Block IP packets when the source and destination are of interest but for only a limited set of ports.

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**
The following command defines a rule definition that redirects packets to the CSS service named `css-svc1`, and UDP packets coming from any host are matched:

```
redirect css service css-svc1 udp any
```
The following sets the insertion point to before the rule definition above:

```
before redirect css service css-svc1 udp any
```
The following command sets the insertion point after the rule definition above:

```
```
after redirect css service css-svcl udp any

The following deletes the rule definition above:

no redirect css service css-svcl udp any
redirect css service (for downlink, any)

Used to redirect subscriber sessions based on any packet received in the downlink (from the Mobile Node) direction. This command is also used to set the access control list insertion point.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

redirect css service svc_name [ log ] downlink any
after redirect css service svc_name [ log ] downlink any
before redirect css service svc_name [ log ] downlink any
no redirect css service svc_name [ log ] downlink any

**after**
Indicates all rule definitions defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no
Removes the rule definition which exactly matches the options specified.
**css service svc_name**

The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services. `svc_name` must be an alphanumeric string of 1 through 15 characters.

**downlink**

Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

**log**

Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

**any**

Indicates all packets will match the redirect regardless of source and/or destination.

### Usage

Define a catch all rule definition to place at the end of the list of rule definitions to provide explicit handling of rule definitions which do not fit any other criteria.

#### Important:

It is suggested that any rule definition which is added to be a catch all should also have the `log` option specified. The logged packets may be used to determine if the current list of rule definitions is adequate or needs modification to ensure proper security.

#### Important:

A maximum of 16 rule definitions can be configured per ACL.

#### Important:

Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

### Example

The following command defines a rule definition that redirects packets to the CSS service with the name `css-svc1` and any source IP:

```plaintext
redirect css service css-svc1 downlink any
```

The following sets the insertion point to before the first rule definition above:

```plaintext
before redirect service css-svc1 downlink any
```

The following command sets the insertion point after the second rule definition above:

```plaintext
after redirect service css-svc1 downlink any chgsvc1 downlink any
```

The following deletes the first rule definition above:

```plaintext
no redirect service css-svc1 downlink any
```
redirect css service (for downlink, by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address in the downlink (from the Mobile Node) direction.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

redirect css service svc_name [ log ] downlink host source_host_address

after redirect css service svc_name [ log ] downlink host source_host_address

before redirect css service svc_name [ log ] downlink host source_host_address

no redirect css service svc_name [ log ] downlink host source_host_address

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.
**css service** `svc_name`

The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services. `svc_name` must be an alphanumeric string of 1 through 15 characters.

**downlink**

Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

**log**

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**host**

Specifies that the rule definition applies to a specific host as determined by its IP address.

**source_host_address**

The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

---

**Usage**

Define a rule definition when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rule definitions to be very clear and concise.

---

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

---

**Example**

The following command defines a rule definition that redirects packets to the charging service with the name `css-svc1` and a host IP address of `fe80::c0a8:c80b`:

```
redirect service css-svc1 downlink host fe80::c0a8:c80b
```

The following sets the insertion point to before the first rule definition above:

```
before redirect service css-svc1 downlink host fe80::c0a8:c80b
```

The following command sets the insertion point after the second rule definition above:

```
after redirect service css-svc1 downlink host fe80::c0a8:c80b
```

The following deletes the first rule definition above:

```
no redirect service css-svc1 downlink host fe80::c0a8:c80b
```
redirect css service (for downlink, by ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets in the downlink (from the Mobile Node) direction.

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect css service svc_name [ log ] downlink icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type | icmp_code ]
```

```
after redirect css service svc_name [ log ] downlink icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type | icmp_code ]
```

```
before redirect css service svc_name [ log ] downlink icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type | icmp_code ]
```

```
o redirect css service svc_name [ log ] downlink icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ icmp_type | icmp_code ]
```

---

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

---

```
before
```

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.
**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

---

**no**

Removes the rule definition which exactly matches the options specified.

---

**css service svc_name**

The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services. `svc_name` must be an alphanumeric string of 1 through 15 characters.

---

**downlink**

Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

---

**log**

Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

---

**source_address**

The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

---

**source_wildcard**

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

---

**any**

Specifies that the rule definition applies to all packets.

---

**host**

Specifies that the rule definition applies to a specific host as determined by its IP address.

---

**source_host_address**

The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.
redirect css service (for downlink, by ICMP packets)

dest_host_address
The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

dest_address
The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

dest_wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
• Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
• One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

icmp_type
Specifies that all ICMP packets of a particular type are to be filtered. The type can be an integer value from 0 through 255.

icmp_code
Specifies that all ICMP packets of a particular code are to be filtered. The type can be an integer value from 0 through 255.

Usage
Define a rule definition to block ICMP packets which can be used for address resolution and possibly be a security risk.
The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

Important: A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example
The following command defines a rule definition that redirects packets to the charging service named css-svcl, and ICMP packets coming in the downlink (from the Mobile Node) direction from the host with the IP address 2002::c6a2:6419:

    redirect css service css-svcl downlink icmp host 2002::c6a2:6419

The following sets the insertion point to before the first rule definition above:
before redirect css service css-svcl downlink icmp host 2002::c6a2:6419

The following command sets the insertion point after the second rule definition above:

after redirect css service css-svcl downlink icmp host 2002::c6a2:6419

The following deletes the first rule definition above:

no redirect css service css-svcl downlink icmp host 2002::c6a2:6419
redirect css service (for downlink, by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets in the downlink (from the Mobile Node) direction.

Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect css service svc_name [ log ] downlink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]
```

```
after redirect css service svc_name [ log ] downlink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]
```

```
before redirect css service svc_name [ log ] downlink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]
```

```
no redirect css service svc_name [ log ] downlink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]
```

---

**after**
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

---

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

---

**before**
Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

---

6566

Command Line Interface Reference, StarOS Release 16
**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```markdown
no

Removes the rule definition which exactly matches the options specified.

css service *svc_name*

The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the **show css service all** command to display the names of all configured CSS services.

*svc_name* must be a string of 1 through 15 characters.

downlink

Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

log

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the **source_wildcard** parameter.

source_wildcard

This option is used in conjunction with the **source_address** option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the **source_address** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **source_address** parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule definition applies to all packets.

host

Specifies that the rule definition applies to a specific host as determined by its IP address.
source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

dest_wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

fragment
Indicates packet redirection is to be applied to IP packet fragments only.

**Usage**
Block IP packets when the source and destination are of interest.

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**
The following command defines a rule definition that redirects packets to the charging service named css-svc1, and downlink IP packets coming from the host with the IP address 2002::c6a2:6419, and fragmented packets for any destination are matched:

```
redirect css service(css-svc1) downlink ip host 2002::c6a2:6419 any fragment
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service(css-svc1) downlink ip host 2002::c6a2:6419 any fragment
```

The following command sets the insertion point after the second rule definition above:

```
```
after redirect css service css-svc1 downlink ip host 2002::c6a2:6419 any fragment

The following deletes the first rule definition above:

no redirect css service css-svc1 downlink ip host 2002::c6a2:6419 any fragment
redirect css service (for downlink, by source IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source in the downlink (from the Mobile Node) direction.

Product
All

Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

redirect css service svc_name [ log ] downlink source_address source_wildcard

after redirect css service svc_name [ log ] downlink source_address source_wildcard

before redirect css service svc_name [ log ] downlink source_address source_wildcard

no redirect css service svc_name [ log ] downlink source_address source_wildcard

after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before
Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.
**redirect css service (for downlink, by source IP address masking)**

- **no**
  Removes the rule definition which exactly matches the options specified.

- **css service svc_name**
  The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services.
  *svc_name* must be an alphanumeric string of 1 through 15 characters.

- **downlink**
  Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

- **log**
  Default: packets are not logged.
  Indicates all packets which match the filter are to be logged.

- **source_address**
  The IP address(es) form which the packet originated.
  This option is used to filter all packets from a specific IP address or a group of IP addresses.
  When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

- **source_wildcard**
  This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
  The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**Usage**
Define a rule definition when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rule definitions as it does not require a rule definition for each source and destination pair.

**Important:** A maximum of 16 rule definitions can be configured per ACL.

**Example**
The following command defines a rule definition to redirect packets to a charging service named `css-svc1`:

```
redirect css service css-svc1 downlink fe80::c0a8:a04
```
redirect css service (for downlink, by TCP/UDP packets)

Used to redirect subscriber sessions to a charging service based on the transmission control protocol/user datagram protocol packets in the downlink (from the Mobile Node) direction.

no redirect css service svc_name [ log ] downlink { tcp | udp } { { source_address source wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.
redirect css service (for downlink, by TCP/UDP packets)

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```plaintext
before
```
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```plaintext
no
```
Removes the rule definition which exactly matches the options specified.

```plaintext
css service svc_name
```
The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services.
`svc_name` must be an alphanumeric string of 1 through 15 characters.

```plaintext
downlink
```
Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

```plaintext
log
```
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

```plaintext
tcp | udp
```
Specifies the redirect is to be applied to IP-based transmission control protocol or the user datagram protocol.
- **tcp**: Redirect applies to TCP packets.
- **udp**: Redirect applies to UDP packets.

```plaintext
source_address
```
The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

```plaintext
source_wildcard
```
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- **Zero-bits** in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
IPv6 ACL Configuration Mode Commands

- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

## Important

The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

### any

Specifies that the rule definition applies to all packets.

### host

Specifies that the rule definition applies to a specific host as determined by its IP address.

- **source_host_address**
  
  The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

- **dest_host_address**
  
  The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

### eq source_port

Specifies a single, specific source TCP port number to be filtered.

- **source_port** must be configured to an integer value from 0 to 65535.

### gt source_port

Specifies that all source TCP port numbers greater than the one specified are to be filtered.

- **source_port** must be configured to an integer value from 0 to 65535.

### lt source_port

Specifies that all source TCP port numbers less than the one specified are to be filtered.

- **source_port** must be configured to an integer value from 0 to 65535.

### neq source_port

Specifies that all source TCP port numbers not equal to the one specified are to be filtered.

- **source_port** must be configured to an integer value from 0 to 65535.

### range start_source_port end_source_port

Specifies that all source TCP ports within a specific range are to be filtered.

- **start_source_port** is the initial port in the range and **end_source_port** is the final port in the range.

- Both **start_source_port** and **end_source_port** can be configured to an integer value from 0 to 65535.

### dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.
IPv6 ACL Configuration Mode Commands

redirect css service (for downlink, by TCP/UDP packets)

dest_wildcard

This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

eq dest_port

Specifies a single, specific destination TCP port number to be filtered. dest_port must be configured to an integer value from 0 to 65535.

gt dest_port

Specifies that all destination TCP port numbers greater than the one specified are to be filtered. dest_port must be configured to an integer value from 0 to 65535.

lt dest_port

Specifies that all destination TCP port numbers less than the one specified are to be filtered. dest_port must be configured to an integer value from 0 to 65535.

neq dest_port

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered. dest_port must be configured to an integer value from 0 to 65535.

range start_dest_port end_dest_port

Specifies that all destination TCP ports within a specific range are to be filtered. start_dest_port is the initial port in the range and end_dest_port is the final port in the range. Both start_dest_port and end_dest_port can be configured to an integer value from 0 to 65535.

Usage

Block IP packets when the source and destination are of interest but for only a limited set of ports.

Important: A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule definition that redirects packets to the charging service named css-svcl, and UDP packets coming from any host are matched:

    redirect css service css-svcl downlink udp any

The following sets the insertion point to before the rule definition above:
redirect css service (for downlink, by TCP/UDP packets)

before redirect css service css-svcl downlink udp any

The following command sets the insertion point after the rule definition above:

after redirect css service css-svcl downlink udp any

The following deletes the rule definition above:

no redirect css service css-svcl downlink udp any
redirect css service (for uplink, any)

Used to redirect subscriber sessions based on any packet received in the uplink (to the Mobile Node) direction. This command is also used to set the access control list insertion point.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration
configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

Syntax

redirect css service svc_name [ log ] uplink any
after redirect css service svc_name [ log ] uplink any
before redirect css service svc_name [ log ] uplink any
no redirect css service svc_name [ log ] uplink any

after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no
Removes the rule definition which exactly matches the options specified.
**css service svc_name**

The name of the Content Service steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services.

`svc_name` must be an alphanumeric string of 1 through 15 characters.

**uplink**

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

**log**

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**any**

Indicates all packets will match the redirect regardless of source and/or destination.

**Usage**

Define a catch all rule definition to place at the end of the list of rule definitions to provide explicit handling of rule definitions which do not fit any other criteria.

**Important:** It is suggested that any rule definition which is added to be a catch all should also have the `log` option specified. The logged packets may be used to determine if the current list of rule definitions is adequate or needs modification to ensure proper security.

**Important:** A maximum of 16 rule definitions can be configured per ACL.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the charging service with the name `css-svcl` and any source IP:

```
redirect css service css-svcl uplink any
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service css-svcl uplink any
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service css-svcl uplink any
```

The following deletes the first rule definition above:

```
no redirect css service css-svcl uplink any
```
redirect css service (for uplink, by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address in the uplink (to the Mobile Node) direction.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

`configure > context context_name > ipv6 access-list ipv6_acl_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect css service svc_name [ log ] uplink host source_host_address
after redirect css service svc_name [ log ] uplink host source_host_address
before redirect css service svc_name [ log ] uplink host source_host_address
no redirect css service svc_name [ log ] uplink host source_host_address
```

---

**uplink**

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

---

**after**

Indicates all rule definitions defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

---

**before**

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.
Redirect CSS service (for uplink, by host IP address)

The command allows an IPv6 ACL to redirect packets to a CSS service based on the IP address of the host.

Syntax:
```
redirect service css svc_name uplink host source_host_address
```

Options:
- `no`: Removes the rule definition which exactly matches the options specified.
- `css service svc_name`: The name of the CSS service to which packets are to be redirected. Use `show css service all` to display the names of all configured CSS services. The `svc_name` must be an alphanumeric string of 1 through 15 characters.
- `uplink`: Applies this rule definition only to packets in the uplink (to the Mobile Node) direction.
- `log`: Indicates all packets which match the redirect are to be logged.
- `host`: Specifies that the rule definition applies to a specific host as determined by its IP address.
- `source_host_address`: The IP address of the source host to filter against expressed in IPv6 colon notation.

Usage:
Define a rule definition when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rule definitions to be very clear and concise.

Important: A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example:
The following command defines a rule definition that redirects packets to the charging service with the name `css-svc1` and a host IP address of `fe80::c0a8:c80b`:
```
redirect service css-svc1 uplink host fe80::c0a8:c80b
```
The following sets the insertion point to before the first rule definition above:
```
before redirect service css-svc1 uplink host fe80::c0a8:c80b
```
The following command sets the insertion point after the second rule definition above:
```
after redirect service css-svc1 uplink host fe80::c0a8:c80b
```
The following deletes the first rule definition above:
```
no redirect service css-svc1 uplink host fe80::c0a8:c80b
```
redirect css service (for uplink, by ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets in the uplink (to the Mobile Node) direction.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl) #

Syntax

redirect css service svc_name [ log ] uplink icmp { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.
**Redirect CSS Service (for Uplink, by ICMP Packets)**

**css service svc_name**

The name of the Content Service Steering (CSS) service to which packets are to be redirected. At the executive mode prompt, use the `show css service all` command to display the names of all configured CSS services.

*s svc_name must be an alphanumeric string of 1 through 15 characters.

**uplink**

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

**log**

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**source_address**

The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**any**

Specifies that the rule definition applies to all packets.

**host**

Specifies that the rule definition applies to a specific host as determined by its IP address.

**source_host_address**

The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**dest_host_address**

The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

**dest_address**

The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the `dest_wildcard` parameter.

### dest_wildcard

This option is used in conjunction with the `dest_address` option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be ignored.

---

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

### icmp_type

Specifies that all ICMP packets of a particular type are to be filtered. The type can be an integer value from 0 through 255.

### icmp_code

Specifies that all ICMP packets of a particular code are to be filtered. The type can be an integer value from 0 through 255.

---

**Usage**

Define a rule definition to block ICMP packets which can be used for address resolution and possibly be a security risk.

The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

---

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

---

**Example**

The following command defines a rule definition that redirects packets to the charging service named `chgsvc1`, and ICMP packets in the uplink (to the Mobile Node) direction from the host with the IP address 198.162.100.25:

```
redirect css service chgsvc1 uplink icmp host 198.162.100.25
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service chgsvc1 uplink icmp host 198.162.100.25
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service chgsvc1 uplink icmp host 198.162.100.25
```

The following deletes the first rule definition above:
redirect css service (for uplink, by ICMP packets)

no redirect css service chgsvc1 uplink icmp host 198.162.100.25
redirect css service (for uplink, by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets in the uplink (to the Mobile Node) direction.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

`configure > context context_name > ipv6 access-list ipv6_acl_name`

Entering the above command sequence results in the following prompt:

`[context_name]host_name(config-ipv6-acl)#`

**Syntax**

```plaintext
redirect css service svc_name [ log ] uplink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

after redirect css service svc_name [ log ] uplink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

before redirect css service svc_name [ log ] uplink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

no redirect css service svc_name [ log ] uplink ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]
```

**after**
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.
**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**
Removes the rule definition which exactly matches the options specified.

**css service svc_name**
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services.

*svc_name* must be a string of 1 through 15 characters.

**uplink**
Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

**log**
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**source_address**
The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**any**
Specifies that the rule definition applies to all packets.

**host**
Specifies that the rule definition applies to a specific host as determined by its IP address.
source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address
The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

dest_wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

fragment
Indicates packet redirection is to be applied to IP packet fragments only.

Usage
Block IP packets when the source and destination are of interest.

Example
The following command defines a rule definition that redirects packets to the charging service named chgsvcl, and uplink IP packets going to the host with the IP address 198.162.100.25, and fragmented packets for any destination are matched:

    redirect css service chgsvcl uplink ip host 198.162.100.25 any fragment

The following sets the insertion point to before the first rule definition above:

    redirect css service chgsvcl uplink ip host 198.162.100.25 any fragment

The following command sets the insertion point after the second rule definition above:

    after redirect css service chgsvcl uplink ip host 198.162.100.25 any fragment

The following deletes the first rule definition above:

    no redirect css service chgsvcl uplink ip host 198.162.100.25 any fragment
redirect css service (for uplink, by source IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source in the uplink (to the Mobile Node) direction.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect css service svc_name [ log ] uplink source_address source_wildcard
```

**after**

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**before**

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**no**

Removes the rule definition which exactly matches the options specified.

**css service svc_name**

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services.

**svc_name** must be a string of 1 through 15 characters.

**uplink**

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

**log**

Default: packets are not logged.

Indicates all packets which match the filter are to be logged.
source_address
The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the source_wildcard parameter.

source_wildcard
This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

Usage
Define a rule definition when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rule definitions as it does not require a rule definition for each source and destination pair.

Example
The following command defines a rule definition to redirect packets to a charging service named chgsvc1:

```bash
redirect css service chgsvc1 uplink 1:1:1:1:1:1:1:1
```
redirect css service (for uplink, by TCP/UDP packets)

Used to redirect subscriber sessions to a charging service based on the transmission control protocol/user datagram protocol packets in the uplink (to the Mobile Node) direction.

Product
All

| lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

no redirect css service svc_name [ log ] uplink { tcp | udp } { { source_address
source_wildcard | any | source_host_address } [ eq source_port | gt source_port | lt
source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port
| lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.
**IPv6 ACL Configuration Mode Commands**

**redirect css service (for uplink, by TCP/UDP packets)**

---

**before**

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

---

**no**

Removes the rule definition which exactly matches the options specified.

---

**css service svc_name**

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services. `svc_name` must be a string of 1 through 15 characters.

---

**uplink**

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

---

**log**

Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

---

**tcp | udp**

Specifies the redirect is to be applied to IP-based transmission control protocol or the user datagram protocol.

- **tcp**: Redirect applies to TCP packets.
- **udp**: Redirect applies to UDP packets.

---

**source_address**

The IP address(es) form which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source wildcard` parameter.

---

**source wildcard**

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

---

**any**

Specifies that the rule definition applies to all packets.
**host**
Specifies that the rule definition applies to a specific host as determined by its IP address.

**source_host_address**
The IP address of the source host to filter against expressed in IPv6 colon notation.

**dest_host_address**
The IP address of the destination host to filter against expressed in IPv6 colon notation.

**eq source_port**
Specifies a single, specific source TCP port number to be filtered. 
source_port must be configured to an integer value from 0 to 65535.

**gt source_port**
Specifies that all source TCP port numbers greater than the one specified are to be filtered.
source_port must be configured to an integer value from 0 to 65535.

**lt source_port**
Specifies that all source TCP port numbers less than the one specified are to be filtered.
source_port must be configured to an integer value from 0 to 65535.

**neq source_port**
Specifies that all source TCP port numbers not equal to the one specified are to be filtered.
source_port must be configured to an integer value from 0 to 65535.

**range start_source_port end_source_port**
Specifies that all source TCP ports within a specific range are to be filtered.
start_source_port is the initial port in the range and end_source_port is the final port in the range.
Both start_source_port and end_source_port can be configured to an integer value from 0 to 65535.

**dest_address**
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the destWildcard parameter.

**destWildcard**
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.
### eq dest_port

Specifies a single, specific destination TCP port number to be filtered.
- `dest_port` must be configured to an integer value from 0 to 65535.

### gt dest_port

Specifies that all destination TCP port numbers greater than the one specified are to be filtered.
- `dest_port` must be configured to an integer value from 0 to 65535.

### lt dest_port

Specifies that all destination TCP port numbers less than the one specified are to be filtered.
- `dest_port` must be configured to an integer value from 0 to 65535.

### neq dest_port

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered.
- `dest_port` must be configured to an integer value from 0 to 65535.

### range start_dest_port end_dest_port

Specifies that all destination TCP ports within a specific range are to be filtered.
- `start_dest_port` is the initial port in the range and `end_dest_port` is the final port in the range.
- Both `start_dest_port` and `end_dest_port` can be configured to an integer value from 0 to 65535.

---

### Usage

Block IP packets when the source and destination are of interest but for only a limited set of ports.

### Example

The following command defines a rule definition that redirects packets to the charging service named `chgsvcl`, and UDP packets coming from any host are matched:

```markdown
redirect css service chgsvcl uplink udp any
```

The following sets the insertion point to before the rule definition above:

```markdown
before redirect css service chgsvcl uplink udp any
```

The following command sets the insertion point after the rule definition above:

```markdown
after redirect css service chgsvcl uplink udp any
```

The following deletes the rule definition above:

```markdown
no redirect css service chgsvcl uplink udp any
```
redirect nexthop (by IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
source_address source_wildcard
```

```
after redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
source_address source_wildcard
```

```
before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
source_address source_wildcard
```

```
no redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
source_address source_wildcard
```

*after*

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

*before*

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.
IPv6 ACL Configuration Mode Commands

redirect nexthop (by IP address masking)

no
Removes the rule which exactly matches the options specified.

nexthop nexthop_addr
The IP address to which the IP packets are redirected.

context context_id
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the show context all command to display context names and context IDs.

interface interface_name
The name of the logical interface to which the packets should be redirected. interface_name must be an alpha and/or numeric string from 1 to 79 characters.

log
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

source_address
The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the source wildcard parameter.

source_wildcard
This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

Usage
Define a rule when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of redirect rules as it does not require a rule for each source and destination pair.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also
note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the next hop host at 192.168.10.4, the context with the context ID of 23 and the source IP and wildcard of 198.162.22.0 and 0.0.0.31:

   redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31

The following sets the insertion point to before the first rule defined above:

   before redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31

The following command sets the insertion point after the second rule defined above:

   after redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31

The following deletes the first rule defined above:

   no redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31
redirect nexthop (any)

Used to redirect subscriber sessions based on any packet received. This command is also used to set the access control list insertion point.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] any

after redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] any

before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] any

no redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] any
```

- **after**
  Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
  This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

- **Important**: If the options specified do not exactly match an existing rule, the insertion point does not change.

- **before**
  Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
  This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

- **Important**: If the options specified do not exactly match an existing rule, the insertion point does not change.
**redirect nexthop (any)**

---

**no**
Removes the rule which exactly matches the options specified.

**nexthop** *nexthop_addr*
The IP address to which the IP packets are redirected.

**context** *context_id*
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

**interface** *interface_name*
The name of the logical interface to which the packets should be redirected. *interface_name* must be an alpha and/or numeric string from 1 to 79 characters.

**log**
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**any**
Indicates all packets will match the redirect regardless of source and/or destination.

---

**Usage**
Define a catch all rule to place at the end of the list of rules to provide explicit handling of rules which do not fit any other criteria.

---

**Important**: It is suggested that any rule which is added to be a catch all should also have the `log` option specified. The logged packets may be used to determine if the current list of rules is adequate or needs modification to ensure proper security. The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

---

**Example**
The following command defines a rule that redirects packets to the next hop host at 192.168.10.4, the context with the context ID of 23 and any source IP:

```
redirect nexthop 192.168.10.4 context 23 any
```

The following sets the insertion point to before the first rule defined above:

```
before redirect nexthop 192.168.10.4 context 23 any
```

The following command sets the insertion point after the second rule defined above:

```
after redirect nexthop 192.168.10.4 context 23 any
```

The following deletes the first rule defined above:
no redirect next-hop 192.168.10.4 context 23 any
**redirect nexthop (by host IP address)**

Used to redirect subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ipv6-acl)#

**Syntax**

```plaintext
redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
host source_ip_address

after redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] host source_ip_address

before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] host source_ip_address

no redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] host source_ip_address
```

**Important:**
If the options specified do not exactly match an existing rule, the insertion point does not change.

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:**
If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:**
If the options specified do not exactly match an existing rule, the insertion point does not change.
no
Removes the rule which exactly matches the options specified.

nexthop nexthop_addr
The IP address to which the IP packets are redirected.

context context_id
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the show context all command to display context names and context IDs.

interface interface_name
The name of the logical interface to which the packets should be redirected. interface_name must be an alpha and/or numeric string from 1 to 79 characters.

log
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

host
Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

Usage
Define a rule when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rules to be very clear and concise.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example
The following command defines a rule that redirects packets to the next hop host at 192.168.10.4, the context with the context ID of 23 and a host IP address of 192.168.200.11:

    redirect nexthop 192.168.10.4 context 23 host 192.168.200.11

The following sets the insertion point to before the first rule defined above:

    before redirect nexthop 192.168.10.4 context 23 host 192.168.200.11

The following command sets the insertion point after the second rule defined above:

    after redirect nexthop 192.168.10.4 context 23 host 192.168.200.11
The following deletes the first rule defined above:

```
no redirect nexthop 192.168.10.4 context 23 host 192.168.200.11
```
**redirect nexthop (by source ICMP packets)**

Used to redirect subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Mode**

Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

configure > context context_name > ipv6 access-list ipv6_acl_name

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
icmp { source_address source_wildcard | any | host source_host_address }{ dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

after redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
icmp { source_address source_wildcard | any | host source_host_address }{ dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
icmp { source_address source_wildcard | any | host source_host_address }{ dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

no redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
icmp { source_address source_wildcard | any | host source_host_address }{ dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]
```

**after**

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Removes the rule which exactly matches the options specified.</td>
</tr>
<tr>
<td><code>nexthop</code></td>
<td>The IP address to which the IP packets are redirected.</td>
</tr>
<tr>
<td><code>context</code></td>
<td>The context identification number of the context to which packets are redirected. At the executive mode prompt, use the <code>show context all</code> command to display context names and context IDs.</td>
</tr>
<tr>
<td><code>interface</code></td>
<td>The name of the logical interface to which the packets should be redirected. <em>interface_name</em> must be an alpha and/or numeric string from 1 to 79 characters.</td>
</tr>
<tr>
<td>log</td>
<td>Default: packets are not logged. Indicates all packets which match the redirect are to be logged.</td>
</tr>
<tr>
<td><code>source_address</code></td>
<td>The IP address(es) form which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the <code>source_wildcard</code> parameter.</td>
</tr>
</tbody>
</table>
| `source_wildcard` | This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:  
  - Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.  
  - One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.  
  
**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous. |
| `any`       | Specifies that the rule applies to all packets.                              |
| `host`      | Specifies that the rule applies to a specific host as determined by its IP address. |
IPv6 ACL Configuration Mode Commands

**redirect nexthop (by source ICMP packets)**

- **source_host_address**
  The IP address of the source host to filter against expressed in IPv6 colon notation.

- **dest_host_address**
  The IP address of the destination host to filter against expressed in IPv6 colon notation.

- **dest_address**
  The IP address(es) to which the packet is to be sent. 
  This option is used to filter all packets to a specific IP address or a group of IP addresses. 
  When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the `dest_wildcard` parameter.

- **dest_wildcard**
  This option is used in conjunction with the `dest_address` option to specify a group of addresses for which packets are to be filtered. 
  The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be ignored.

  **Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

- **icmp_type**
  Specifies that all ICMP packets of a particular type are to be filtered. The type can be an integer value from 0 through 255.

- **icmp_code**
  Specifies that all ICMP packets of a particular code are to be filtered. The type can be an integer value from 0 through 255.

**Usage**

Define a rule to block ICMP packets which can be used for address resolution and possible be a security risk. 
The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule that redirects packets to the next hop host at `fe80::c0a8:a04`, the context with the context ID of 23, and ICMP packets coming from the host with the IP address `2002::c6a2:64195`.
redirect nexthop fe80::c0a8:a04 context 23 icmp host 2002::c6a2:6419

The following sets the insertion point to before the first rule defined above:

before redirect nexthop fe80::c0a8:a04 context 23 icmp host 2002::c6a2:6419

The following command sets the insertion point after the second rule defined above:

after redirect nexthop fe80::c0a8:a04 context 23 icmp host 2002::c6a2:6419

The following deletes the first rule defined above:

no redirect nexthop fe80::c0a8:a04 context 23 icmp host 2002::c6a2:6419
**redirect nexthop (by IP packets)**

Used to redirect subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)#
```

**Syntax**

```
redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ]
ip { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [ protocol num ]
```

- **after**
  Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
  This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

  **Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

- **before**
  Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
  This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

  **Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

- **no**
  Removes the rule which exactly matches the options specified.

```
nexthop nexthop_addr
```

The IP address to which the IP packets are redirected.
redirect nexthop (by IP packets)

context context_id

The context identification number of the context to which packets are redirected. At the executive mode
prompt, use the show context all command to display context names and context IDs.

interface interface_name

The name of the logical interface to which the packets should be redirected. interface_name must be an
alphanumeric string from 1 through 79 characters.

log

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then
be configured using the source wildcard parameter.

source wildcard

This option is used in conjunction with the source_address option to specify a group of addresses for
which packets are to be filtered.
The mask must be entered as a complement:
• Zero-bits in this parameter mean that the corresponding bits configured for the source_address
  parameter must be identical.
• One-bits in this parameter mean that the corresponding bits configured for the source_address
  parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

any

Specifies that the rule applies to all packets.

host

Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal
notation.

dest_address

The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the `dest_wildcard` parameter.

**dest_wildcard**

This option is used in conjunction with the `dest_address` option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

**fragment**

Indicates packet redirection is to be applied to IP packet fragments only.

**protocol num**

Indicates that the packet filtering is to be applied to a specific protocol number.

`num` can be an integer from 0 through 255.

**Usage**

Block IP packets when the source and destination are of interest.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.
**redirect nexthop (by TCP/UDP packets)**

Used to redirect subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IPv6 ACL Configuration

```
configure > context context_name > ipv6 access-list ipv6_acl_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ipv6-acl)>
```

**Syntax**

```
redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }
```

```
after redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }
```

```
before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }
```

```
no redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }
```

**after**

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.
**before**

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

---

**no**

Removes the rule which exactly matches the options specified.

---

**nexthop** `nexthop_addr`

The IP address to which the IP packets are redirected.

---

**context** `context_id`

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

---

**interface** `interface_name`

The name of the logical interface to which the packets should be redirected. `interface_name` must be an alphanumeric string from 1 through 79 characters.

---

**log**

Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

---

**tcp | udp**

Specifies the redirect is to be applied to IP-based transmission control protocol or the user datagram protocol.

- **tcp**: Redirect applies to TCP packets.
- **udp**: Redirect applies to UDP packets.

---

**source_address**

The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

---

**source_wildcard**

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.
**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB).

- **any**
  Specifies that the rule applies to all packets.

- **host**
  Specifies that the rule applies to a specific host as determined by its IP address.

- **source_host_address**
  The IP address of the source host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

- **dest_host_address**
  The IP address of the destination host to filter against expressed in IPv6 colon-separated-hexadecimal notation.

- **eq source_port**
  Specifies a single, specific source TCP port number to be filtered.
  `source_port` must be configured to an integer value from 0 to 65535.

- **gt source_port**
  Specifies that all source TCP port numbers greater than the one specified are to be filtered.
  `source_port` must be configured to an integer value from 0 to 65535.

- **lt source_port**
  Specifies that all source TCP port numbers less than the one specified are to be filtered.
  `source_port` must be configured to an integer value from 0 to 65535.

- **neq source_port**
  Specifies that all source TCP port numbers not equal to the one specified are to be filtered.
  `source_port` must be configured to an integer value from 0 to 65535.

- **dest_address**
  The IP address(es) to which the packet is to be sent.
  This option is used to filter all packets to a specific IP address or a group of IP addresses.
  When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the `dest_wildcard` parameter.

- **dest_wildcard**
  This option is used in conjunction with the `dest_address` option to specify a group of addresses for which packets are to be filtered.
  The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be ignored.
Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**eq** *dest_port*

Specifies a single, specific destination TCP port number to be filtered.
*dest_port* must be configured to an integer value from 0 to 65535.

**gt** *dest_port*

Specifies that all destination TCP port numbers greater than the one specified are to be filtered.
*dest_port* must be configured to an integer value from 0 to 65535.

**lt** *dest_port*

Specifies that all destination TCP port numbers less than the one specified are to be filtered.
*dest_port* must be configured to an integer value from 0 to 65535.

**neq** *dest_port*

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered.
*dest_port* must be configured to an integer value from 0 to 65535.

**Usage**

Block IP packets when the source and destination are of interest but for only a limited set of ports.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule that redirects packets to the next hop host at `fe80::c0a8:a04`, the context with the context ID of 23, and UDP packets coming from any host are matched:

```
redirect nexthop fe80::c0a8:a04 context 23 udp any
```

The following sets the insertion point to before the rule defined above:

```
before redirect nexthop fe80::c0a8:a04 context 23 udp any
```

The following command sets the insertion point after the rule defined above:

```
after redirect nexthop fe80::c0a8:a04 context 23 udp any
```

The following command deletes the first rule defined above:

```
no redirect nexthop fe80::c0a8:a04 context 23 udp any
```
Chapter 182
IPv6 to IPv4 Tunnel Interface Configuration Mode
Commands

The IPv6 to IPv4 Tunnel Interface Configuration Mode is used to create and manage the IP interface for addresses, address resolution options, etc.

Mode

Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > IPv6 to IPv4 Tunnel Interface Configuration

configure > context context_name > interface interface_name tunnel > tunnel-mode ipv6ip

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-if-tunnel-ipv6ip)#

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
destination address

Configures the destination of the tunneled packets for a manual tunnel.

**Product**
All

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > IPv6 to IPv4 Tunnel Interface Configuration

```bash
configure > context context_name > interface interface_name tunnel > tunnel-mode ipv6ip
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-if-tunnel-ipv6ip)#
```

**Syntax**

```
destination address address
no destination address
```

- **no**
  Removes configuration for the specified keyword.

- **address**
  Specifies the IP address of the destination device. `address` must be specified in IPv4 dotted decimal or IPv6 colon-separated-hexadecimal notation.

**Usage**

Use this command to configure the IP address of the destination end of the tunnel.

**Example**

The following command sets the destination address for packets on this tunneled interface to `10.2.3.4`:

```
destination address 10.2.3.4
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

end

Usage

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

exit

**Usage**

Use this command to return to the parent configuration mode.
mode

Configures the mode of IPv6 to IPv4 tunneling. The default is set to manual mode.

Product
All

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > IPv6 to IPv4 Tunnel Interface Configuration
configure > context context_name > interface interface_name tunnel > tunnel-mode ipv6ip

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-if-tunnel-ipv6ip)#

Syntax

mode { 6to4 | manual }
default mode

6to4
Configures automatic IPv6-to-IPv4 (6to4) tunnels as specified in RFC 3056.

manual
Configures point-to-point manual IPv6-to-IPv4 tunnels by specifying the IPv4 address of the tunnel remote end.

default
Resets the mode of IPv6-to-IPv4 tunneling to manual mode.

Usage
There can be only one IPv6-to-IPv4 tunnel possible in a context. Once an IPv6-to-IPv4 tunnel is configured, all subsequent tunnels will be configured as manual tunnels.

Example
The following command configures the mode to IPv6-to-IPv4 (6to4).

    mode 6to4

The following command configures the mode to 6to4.

    mode manual
source

Configures the source of tunneled packets.

Product
PDSN
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > IPv6 to IPv4 Tunnel Interface Configuration

```
configure > context context_name > interface interface_name tunnel > tunnel-mode ipv6ip
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-if-tunnel-ipv6ip)#
```

Syntax

```
source { address ip_address | interface interface_name }
no source { address | interface }
```

address ip_address
Specifies the IPv4 address to use as the source address of the tunnel.

*ip_address* must be expressed in IPv4 dotted-decimal notation.

```
interface interface_name
```

Specifies the name of a non-tunnel IPv4 interface, whose address is used as the source address of the tunnel.

*interface* must be an alphanumeric string of 1 through 79 characters.

```
no source { address | interface }
```

Removes configuration for the specified keyword.

Usage

Configures the source IPv4 address of the tunnel by either specifying the IP address (host address) or by specifying another configured non-tunnel IPv4 interface. The source address must be an existing interface address before it is used. State of source address will affect the operational state of the tunnel.

Example

The following command configures the source address of the tunnel.

```
source address 10.2.3.4
```

The following command specifies the source interface as *testsourcel*.

```
source interface testsourcel
```
tos

Configures the type of service (TOS) settings of the outer IPv4 header of the tunneled packets.

Product

PDSN
HA

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > IPv6 to IPv4 Tunnel Interface Configuration

configure > context context_name > interface interface_name tunnel > tunnel-mode ipv6ip

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-if-tunnel-ipv6ip)#

Syntax

tos { copy | value tos_value }

default tos

copy

Copies the DC octet of the IPv6 packet to the TOS octet of IPv4 packet.

default

Configures default setting for the specified keyword.

value tos_value

Configures the raw TOS value ranging from 0 to 255. The default is 0.

Usage

Sets the TOS parameter to be used in the tunnel transport protocol or copies the TOS value from the original IPv6 DC byte to the TOS value of the encapsulating IPv4 header.

Example

The following command sets the tos value to 1:

    tos value 1
ttl

Configures the TTL (Time to live) value of the outer IPv4 header of the tunneled packets.

Product
PDSN
HA

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > Tunnel Interface Configuration > IPv6 to IPv4 Tunnel Interface Configuration

configure > context context_name > interface interface_name tunnel > tunnel-mode ipv6ip

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-if-tunnel-ipv6ip)#

Syntax

ttl value ttl_value

default

Configures default setting for the specified keyword.

value ttl_value

ttl_value is an integer from 1 through 255. The default is 16.

Usage

Configures the TTL parameter to be used in the tunnel transport protocol.

Example

The following command sets the TTL value to 25.

```
ttl value 25
```
Chapter 183
ISAKMP Configuration Mode Commands

The ISAKMP Configuration Mode is used to configure Internet Security Association Key Management Protocol (ISAKMP) policies that are used to define Internet Key Exchange (IKE) security associations (SAs).

Modification(s) to an existing ISAKMP policy configuration will not take effect until the related security association has been cleared. Refer to the `clear crypto security-association` command described in the Exec Mode (A–C) Commands chapter for more information.

Mode

Exec > Global Configuration > Context Configuration > ISAKMP Configuration

`configure > context context_name > isakmp policy policy_number`

> **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
authentication

Configures the ISAKMP policy authentication mode.

**Product**
- PDSN
- HA
- GGSN

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > ISAKMP Configuration

**Syntax**
```
authentication preshared-key

[ default | no ] authentication
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>default authentication</strong></td>
<td>Restores the default setting of this parameter. This command is enabled by default.</td>
</tr>
<tr>
<td><strong>no authentication</strong></td>
<td>Disables the preshared key authentication mode.</td>
</tr>
<tr>
<td><strong>preshared-key</strong></td>
<td>Specifies that the policy will be authenticated through the use of the pre-shared key.</td>
</tr>
</tbody>
</table>

**Usage**
When the system is configured to use ISAKMP-type crypto maps for establishing IPSec tunnels, this command is used to indicate that the policy will be authenticated through the use of the pre-shared key configured in the ISAKMP crypto map.

**Example**
The following command sets policy authentication mode to use a pre-shared key:
```
authentication preshared-key
```
encryption

Configures the encryption protocol to use to protect subsequent IKE SA negotiations.

**Product**
- PDSN
- HA
- GGSN

**Privilege**
- Security Administrator, Administrator

**Mode**
`Exec > Global Configuration > Context Configuration > ISAKMP Configuration`  
`configure > context context_name > isakmp policy policy_number`

**Syntax**
```
encryption { 3des-cbc | aes-cbc-128 | aes-cbc-256 | des-cbc }
[ default | no ] encryption
```

---

**default encryption**
Restores the default setting of this parameter.

**no encryption**
Removes a previously configured encryption type.

**3des-cbc**
Specifies that the encryption protocol is Triple Data Encryption Standard (3DES) in chain block (CBC) mode.

**aes-cbc-128**
Specifies that the encryption protocol is Advanced Encryption Standard (AES) in CBC mode with a 128-bit key.

**aes-cbc-256**
Specifies that the encryption protocol is Advanced Encryption Standard (AES) in CBC mode with a 256-bit key.

**des-cbc**
Specifies that the encryption protocol is DES in CBC mode. This is the default setting.

**Usage**
Once the D-H exchange between the system and the security gateway has been successfully completed, subsequent IKE SA negotiations will be protected using the protocol specified by this command.

**Example**
The following command sets the IKE encryption method to 3des-cbc:

```
encryption 3des-cbc
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```bash
exit
```

**Usage**

Use this command to return to the parent configuration mode.
group

Configures the Oakely group (also known as the Diffie-Hellman [D-H] group) in which the D-H exchange occurs.

Product

PDSN
HA
GGSN

Privilege

Security Administrator, Administrator

Mode

Exec > Global Configuration > Context Configuration > ISAKMP Configuration
configure > context context_name > isakmp policy policy_number

Syntax

```plaintext
    group { 1 | 2 | 5 }
    [ default | no ] group
```

**default group**

Restores the default setting of this parameter.

**no group**

Removes a previously configured group.

```plaintext
    { 1 | 2 | 5 }
```

Default: 1

Specifies the number of the Oakley group. The following groups are allowed:

- **1**: Enables Oakley Group 1 using a 768-bit modp as defined in RFC 2409.
- **2**: Enables Oakley Group 2, using a 1024-bit modp as defined in RFC 2409.
- **5**: Enables Oakley Group 5, using a 1536-bit modp as defined in RFC 3526.

**Usage**

Specifies the Oakley group that determine the length of the base prime numbers that are used during the key exchange process.

**Example**

The following command sets the group to 5 which specifies 1536-bit base prime numbers:

```plaintext
    group 5
```
hash

Configures the IKE hash protocol to use during IKE SA negotiations.

**Product**
- PDSN
- HA
- GGSN

**Privilege**
- Security Administrator, Administrator

**Mode**
```
Exec > Global Configuration > Context Configuration > ISAKMP Configuration

configure > context context_name > isakmp policy policy_number
```

**Syntax**
```
hash { md5 | sha1 }
[ default | no ] hash
```

- **default**
  Restores the default setting of this parameter.

- **no**
  Removes a previously configured hash algorithm.

- **md5**
  Specifies that the hash protocol is Message Digest 5 truncated to 96 bits.

- **sha1**
  Specifies that the hash protocol is Secure Hash Algorithm-1 truncated to 96 bits. This is the default setting for this command.

**Usage**
Use this command to configure the hash algorithm used during key negotiation.

**Example**
Set the hash algorithm to Message-Digest 5 by entering the following command:
```
hash md5
```
**lifetime**

Configures the lifetime of the IKE Security Association (SA).

**Product**
- PDSN
- HA
- GGSN

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > ISAKMP Configuration
  - `configure > context context_name > isakmp policy policy_number`

**Syntax**

```
lifetime seconds
```

```
default lifetime
```

```
default lifetime
  Restores the default setting of this parameter.
```

```
seconds
```

Default: 86400
- The number of seconds for the SA to live. `seconds` must be an integer from 60 to 86400.

**Usage**

Use this command to set the time that an ISAKMP SA will be valid. The lifetime is negotiated with the peer and the lowest configured lifetime duration is used.

**Example**

The following command sets the SA lifetime to 100 seconds:

```
lifetime 100
```
Chapter 184
IuPS Service Configuration Mode Commands

The IuPS Service configuration mode is used to define properties for the IuPS service which controls the Iu-PS interface connections to Radio Network Controllers (RNCs) of the UMTS Terrestrial Radio Access Network (UTRAN).

Mode

Exec > Global Configuration > Context Configuration > IuPS Service Configuration

configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
access-protocol

This command configures the access protocol parameters for the IuPS service.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax

access-protocol sccp-network sccp_net_id

no access-protocol sccp-network

no

Removes a previously configured access protocol value.

sccp-network sccp_net_id

Specifies the Signaling Connection Control Part (SCCP) for this IuPS service to use. sccp_net_id must be an integer from 1 to 16.

Usage

Use this command to configure access protocol parameters for the current IuPS service.

Example

The following command specifies that the current Iu-PS service should use SCCP 1:

access-protocol sccp-network 1
**associate**

This command associates a configured DSCP marking template with this IuPS service and associated Iu interface.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
associate dscp-template downlink dscp_template_name

no associate dscp-template downlink
```

- **no**
  - Removes a previously configured association.

- **dscp_template_name**
  - Specifies a DSCP marking template that was previously configured with the commands in the DSCP Template configuration mode.
  - Enter an alphanumeric string of 1 to 64 characters, including dots (.), dashes (-), and forward slashes (/), to identify a unique instance of a DSCP marking template.

**Usage**

Use this command to associate a specific DSCP marking template with this IuPS service and associated Iu interface. The DSCP template provides a mechanism for differentiated services code point (DSCP) marking of control packets and signaling messages at the SGSN’s M3UA level on the Iu interface. This DSCP marking enables the SGSN to perform classifying and managing of network traffic and to determine quality of service (QoS) for the interface to the IP network.

**Example**

The following command associates a DSCP marking template named `dscptempl1` with the Iu interface:

```
associate dscp-template downlink dscptempl1
```

The following command disassociates a previously associated DSCP marking template named `template4` with this IuPS service configuration:

```
no associate dscp-template downlink
```
blacklist-timeout-gtpu-bind-addresses

This command specifies the time period that a GTP-U bind address (loopback address) will not be used (is blacklisted) in RAB-Assignment requests after a RAB assignment request, with that GTP-U bind address, has been rejected by an RNC with the cause - Unspecified Error. This is a failure at the RNC’s GTP-U IP interface.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax
blacklist-timeout-gtpu-bind-addresses seconds

default blacklist-timeout-gtpu-bind-addresses

default
Resets the blacklist time to 60 seconds.

seconds
Number of seconds that the GTP-U bind (loopback) address will not be used in a RAB-Assignment request.
seconds: Must be an integer from 1 to 1800.

Usage
Use this command to configure the blacklist period.

Example
The following command specifies a 15 minutes (460 seconds) blacklist period.

blacklist-timeout-gtpu-bind-addresses 460
empty-cr

This command allows the operator to determine how empty Connection Request messages will be handled.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
empty-cr procedure reject
```

[ default | no ] empty-cr procedure reject

```
default | no
```

Using either `default` or `no` with the command disables the rejection function and returns the system to the default behavior, which is to ignore receipt of the empty CRs.

**Usage**
Use this command to enable/disable the procedure for handling empty (not containing dataparameters) Connection Request (CR) messages.

This feature can be used in the following scenario: During 4G to 3G handovers, some Connection Requests from mobile subscribers might be ignored by the SGSN, even though their UE would display that the WCDMA was available. The RNC would send an SCCP Connection Request (CR) over the Iu interface to the SGSN. Normally, this message contains a RANAP message and GMM, but according to 3GPP and ITU Q.713 standards, it is permissible to send an SCCP CR without any data parameters. In such a situation, normally the SGSN would ignore these SCCP CR messages, because without these data parameters the SGSN would be unable to derive the DeMux key which is the basis for determining the Session Manager instance to be used for a subscriber. Using this feature allows the SGSN to send a Reject to the mobile subscriber when an “empty” SCCP CR is sent from their UE.

Fields have been added to the output of the following CLI show commands to track the receipt and rejection of Connect Request (CR) messages:

- `show gmm-sm statistics`
- `show gmm-sm statistics verbose`

**Example**
The following command enables the empty CR handling procedure:

```
empty-cr procedure reject
```

The following command disables the empty CR handling procedure:
default empty-cr procedure reject
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Return to the Exec mode.
**exit**

Exits the current configuration mode and returns to the previous configuration mode, the context configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Return to the context configuration mode.
force-authenticate consecutive-security-failure

Disable/enable authentication when the MS/UE security fails and configures the procedures and frequency for authentication.

Product: SGSN

Privilege: Security Administrator, Administrator, Operator

Mode:

Exec > Global Configuration > Context Configuration > IuPS Service Configuration
configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax:

force-authenticate consecutive-security-failure { inter-sgsn-rau | local-messages count frequency | non-local-messages count frequency }

[ default | no ] force-authenticate consecutive-security-failure { inter-sgsn-rau | local-messages | non-local-messages }

---

default

Resets the values to defaults. Forced authentication is enabled for all the types of event procedures with the default values for determining frequency for authentication.

---

no

Disables the specified authentication configuration.

---

inter-sgsn-rau

Default: enabled

Enables/disables authentication for inter-SGSN RAU.
The SGSN does not remember previous inter-SGSN-RAU failures for a P-TMSI/RAI because the SGSN clears all contexts on the occurrence of an inter-SGSN-RAU security failure. So the next inter-SGSN-RAU can only be authenticated forcefully if it comes before the previous context is cleared. This type of forced authentication is enabled by default because this type of failure is fairly common.

---

local-messages count frequency

Default: 5

Enables/disables authentication for local messages (such as local RAUs, Service Requests, Detach Requests, etc.). Consecutive security failures is fairly rare for local messages so the default count frequency is fairly high, 5. Setting the count frequency enables the feature and sets the number of consecutive local message security failures that must occur prior to authentication being forced.

frequency: Enter an integer from 1 to 10.
**non-local-messages count count**

Default: 1

Enables/disables authentication for non-local messages (such as inter-RAT RAUs and all types of attaches). Consecutive security failures for non-local messages is fairly common so the default count frequency is 1. Setting the count frequency enables the feature and sets the number of consecutive non-local message security failures that must occur prior to authentication being forced.

*frequency*: Enter an integer from 1 to 10.

**Usage**

GMM authentication is optional for UMTS. When GMM authentication is skipped, the SGSN and the MS continue to re-use the latest keys exchanged during the most recent GMM authentication procedure. This can result in the SGSN and the MS going out of sync with the CK and IK currently in use. If a mismatch occurs when the MS continues to use the correct parameters (e.g., cksn or P-TMSI signature) in the next Iu and if the SGSN skips authentication on the Iu, then, usually, the security mode will timeout or be rejected because the MS will not be able to decipher or perform an integrity check on the network messages. This scenario results in a lot of useless signaling in the network. This command allows the operator to enable a forced GMM authentication that will either resolve this type of problem or avoid it. As well, the operator can configure a frequency of authentication that best meets their needs.

**Example**

The following command enables forced authentication after every 3rd local message security failure:

```
force-authenticate consecutive-security-failure local-messages count 3
```
gtpu

This command configures parameters for the GTP user (GTP-U) dataplane.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
gtpu { bind ip_addr | echo-interval seconds | max-retransmissions number | retransmission-timeout seconds | sync-echo-with-peer }

no gtpu { bind address ip_addr | echo-interval | max-retransmissions | retransmission-timeout | sync-echo-with-peer }

default gtpu { echo-interval | max-retransmissions | retransmission-timeout | sync-echo-with-peer }
```

---

**no**

Removes the configured parameter value.

---

**default**

Sets the specified parameter to its default setting.

---

**bind address ip_addr**

This command binds the specified IP address to the Iu-PS GTP-U endpoint.

*ip_addr*: Must be an IP v4 IP address in dotted decimal notation.

---

**echo-interval seconds**

Default: 60

Configures the rate, in seconds, at which GTP-U echo packets are sent to the UTRAN over the Iu-PS interface.

*seconds*: Must be an integer from 60 through 3600.

---

**max-retransmissions number**

Default: 5

Configures the maximum number of transmission retries for GTP-U packets.

*number*: Must be an integer from 0 through 15.
retransmission-timeout seconds

Default: 5
Configures the retransmission timeout for GTPU packets in seconds.
seconds: Must be an integer from 1 through 20.

sync-echo-with-peer

This keyword is applicable to the SGSN only.
This keyword enables the SGSN to synchronize path management procedures with the peer after a GTP service restart recovery.
After GTP service recovery, the SGSN restarts the timers for GTP echo transmission, hence a drift in echo request transmission time (from the pre-recovery time) can occur causing the SGSN to be out of sync with the peer. By using this keyword, when the SGSN receives the first Echo Request (GTPC or GTPU) from the peer after the GTP service restart, in addition to replying with an ECHO Response, the SGSN transmits an ECHO Request to the peer and the SGSN restarts the timers associated with the path management procedures. This causes the path management procedure at SGSN to synchronize with the peer node.
Default: Enabled

Usage

Use this command to configure GTP-U parameters for the Iu-PS interface.

Example

The following command binds the IP address 192.168.0.10 to the Iu-PS interface for communication with the UTRAN:

```
gtpu bind address 192.168.0.10
```
**inter-rnc-procedures**

This command enables the processing of SRNS relocation when the source RNC is behaving as the target RNC

**Product**
SGSN

Insert product and tag this paragraph appropriately.

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
[no] inter-rnc-procedures source-rnc-as-target-rnc
```

**Usage**

```
inter-rnc-procedures source-rnc-as-target-rnc
```

Configures the SGSN to complete SRNS relocation when the source RNC is behaving as the target RNC. For example, in the case of a Femtocell-to-Femtocell handoff - the femtocell gateway may act both as the source and target RNC to the femtocells, although from the SGSN’s perspective it is the same RNC.

```
no
```

Disables SRNS relocation when the source RNC is behaving as the target RNC. This is the default setting.

**Example**

Use this command to enable/disable SRNS relocation when the source RNC is behaving as the target RNC.

Enter this command to enable SRNS relocation for those scenarios where the source RNC is behaving as the target RNC.```
inter-rnc-procedures source-rnc-as-target-rnc
```

```
```
**iu-hold-connection**

Defines the type and duration of the Iu hold connection.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
iu-hold-connection [ always | requested-by-ms ] [ hold-time seconds ]

default iu-hold-connection

no iu-hold-connection
```

---

**default**

Resets the Iu hold connection parameters to requested-by-ms and 100 second duration.

---

**no**

Removes the configuration information for the specified Iu hold connection parameter.

---

**always**

Specifies that there is always to be an Iu hold connection procedure.

---

**requested-by-ms**

Specifies that there is only an Iu hold connection procedure if requested by the MS/UE.

This is the default setting for Iu-hold-connection.

---

**hold-time time**

This variable configures the interval (in seconds) that the SGSN holds the Iu connection.

- time: must be an integer from 1 to 3600.
- time: must be an integer from 10 to 3600.

---

**Important:** It is recommended to use a minimum value of “10” seconds. If a value less than “10” seconds is used, more collisions may be observed. If the minimum value of “1” is set, after a re-load, INTRA-RAU (with unknown ptmsi, old-rai known) will be released in “1” second if the Identity Rsp does not come within “1” second.

Default is 100.
Usage
Define the amount of time the Iu connection will be held open.

Example
Instruct the SGSN to hold the Iu connection open for 120 seconds

    iu-hold-connection always hold-time 120
### iu-recovery

**Important:** This command has been deprecated and is no longer available.

**Product**
SGSN

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```bash
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```
**iu-release-complete-timeout**

Configures the SGSN’s timer for waiting for an Iu Release Complete message from the RNC.

**Product**  
SGSN

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > Global Configuration > Context Configuration > IuPS Service Configuration  
```bash  
configure > context context_name > iups-service service_name  
```

Entering the above command sequence results in the following prompt:
```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```bash  
iu-release-complete-timeout time
```

**default iu-release-complete-timeout**

```bash  
default
```

Resets the timer to its default setting.

```bash  
time
```

This variable defines the amount of time (in seconds) that the SGSN waits to receive an ‘Iu Release Complete’ message from the RNC.  
Default: 10.  

**time**: Must be an integer from 1 to 60.

**Usage**

Configure the number of seconds that the SGSN waits to receive the Iu Release Complete message.

**Example**

Set the SGSN to wait 20 seconds for Iu-Release-Complete:
```
iu-release-complete-timeout 20
```
loss-of-radio-coverage ranap-cause

This command sets the detection cause included in the Iu Release message. This command is unique to releases 9.0 and higher.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax

loss-or-radio-coverage ranap-cause cause_number

default loss-of-radio-coverage ranap-cause

---

default

This keyword resets the configuration to the default cause ID number.

---

ranap-cause cause_number

This number identifies the reason the SGSN has detected, from Iu Release messages, for the loss of radio coverage (LORC). This value is included in the IE messages the SGSN sends to either the GGSN or the GGSN and the peer SGSN to indicate LORC state. The range of reasons is a part of the set defined by 3GPP 25413.

cause_number: Must be an integer from 1 to 512.
Default: 46 (MS/UE radio connection lost)

---

Usage

By defining a cause code, the SGSN knows to detect the LORC state of the mobile from Iu Release messages it receives for the subscriber. This configuration also instructs the SGSN to include the defined cause code for the LORC state in the IE portion of various messages sent to the GGSN and optionally the peer SGSN. This command is one of the two commands required to enable the SGSN to work with the GGSN and, optionally the peer SGSN, to implement the Overcharging Protection feature (see the SGSN Overview in the SGSN Administration Guide for feature details. The other command needed to implement the Overcharging Protection feature is the gtp private extension command explained in the SGSN APN Policy Configuration Mode chapter of the Command Line Interface Reference.

Example

Use the following command to set the cause code to indicate that there are no radio resources available in the target cell, cause 53.

loss-or-radio-coverage ranap-cause 53
mbms

This command is in development for future use so the command and keywords that you might see are not currently supported.
network-sharing cs-ps-coordination

Enables/disables the SGSN service to perform a CS-PS coordination check.

**Important:** With the release of 15.0, both 2G and 3G MOCN functionality is license controlled and the license is required to use all previously available network sharing SGSN configuration commands. For additional information, contact your Cisco Account Representative.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

`configure > context context_name > iups-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
network-sharing cs-ps-coordination [ homer | roamer ]

default network-sharing cs-ps-coordination

no network-sharing cs-ps-coordination
```

**Usage**

Use this command to facilitate the network sharing functionality. With this command, the SGSN can be instructed to perform a check to determine if CS-PS coordination is needed.

3GPP TS 25.231 section 4.2.5 describes the functionality of the SGSN to handle CS-PS (circuit-switching/packet-switching) coordination for attached networks not having a Gs-interface. In compliance with the standard, the SGSN rejects an Attach in a MOCN configuration with cause 'CS-PS coordination not supported'.

Including this keyword resets the SGSN service to allow the check to be performed.

Disables this CS-PS coordination checking for this IuPS service.

Enables checking for CS-PS co-ordination for homers (UEs registered in the home network) only.

Enables checking for CS-PS co-ordination for roamers (UEs from outside the home network) only.
required', after learning the IMSI, to facilitate the RNC choosing the same operator for both CS and PS domains.

Example

Use the following syntax to disable the CS-PS coordination check:

```
no network-sharing cs-ps-coordination
```

Use the following command to enable the CS-PS coordination check only for UEs from outside the home network:

```
no network-sharing cs-ps-coordination roamer
```
network-sharing failure-code

Configure the reject cause code to included in network-sharing Reject messages.

**Important:** With the release of 15.0, both 2G and 3G MOCN functionality is now license controlled and the license is required to use all previously available network sharing SGSN configuration commands. For additional information, contact your Cisco Account Representative.

**Product**  
SGSN

**Privilege**  
Security Administrator, Administrator

**Mode**  
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```bash
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```bash
network-sharing failure failure_code
```

```bash
default network-sharing failure
```

**default**

Resets the SGSN service to use the default cause code, 14 (GPRS services not allowed in this PLMN).

**failure_code**

Enter one of the GMM failure cause codes listed below (from section 10.5.5.14 of the 3GPP TS 124.008 v7.2.0 R7):

- 2 - IMSI unknown in HLR
- 3 - Illegal MS
- 6 - Illegal ME
- 7 - GPRS services not allowed
- 8 - GPRS services and non-GPRS services not allowed
- 9 - MSID cannot be derived by the network
- 10 - Implicitly detached
- 11 - PLMN not allowed
- 12 - Location Area not allowed
- 13 - Roaming not allowed in this location area
- 14 - GPRS services not allowed in this PLMN
- 15 - No Suitable Cells In Location Area
• 16 - MSC temporarily not reachable
• 17 - Network failure
• 20 - MAC failure
• 21 - Synch failure
• 22 - Congestion
• 23 - GSM authentication unacceptable
• 40 - No PDP context activated
• 48 to 63 - retry upon entry into a new cell
• 95 - Semantically incorrect message
• 96 - Invalid mandatory information
• 97 - Message type non-existent or not implemented
• 98 - Message type not compatible with state
• 99 - Information element non-existent or not implemented
• 100 - Conditional IE error
• 101 - Message not compatible with the protocol state
• 111 - Protocol error, unspecified

Usage

Use this command to determine which failure code will be included in Reject messages sent by the SGSN when there is a network-sharing failure.

Example

Use the following syntax to indicate that roaming is not allowed (#13) as the cause for the network-sharing failure:

```
network-sharing failure 13
```
network-sharing non-shared

This command allows non-shared area access when network-sharing is enabled.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax

network-sharing non-shared

[ default | no ] network-sharing non-shared

default

Resets the default to disable non-shared access.

Usage
When non-shared area access is enabled, the SGSN sends the selected-plmn value in Attach/RAU accept if LAI is having one of the selected-plmn and "selected-plmn" or "Redirect-attempt flag" IEs are not included in the request message.

Example
Disable non-shared area access if it has already been configured:

no network-sharing non-shared
network-sharing stop-redirect-reject-cause

Enables the operator to disable the default behavior which sends Redirection Indication IE in RANAP Reject messages when reject is due to GMM cause #17 (network failure) related to System Failure or Unexpected Data value MAP errors from the HLR. This change of the default behavior would only be applicable to 3G Roamers.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration
configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax

network-sharing stop-redirect-reject-cause network-failure

{ default | no } network-sharing stop-redirect-reject-cause

---

default

Instructs the SGSN to use the default behavior and send redirect indication in Attach Reject or RAU Reject if reject is due to GMM cause "network failure" which resulted from one of the MAP errors unexpected data value or system failure.

---

no

Disables this function and returns to the default behavior.

Usage

With this command, the operator would change the SGSN’s default behavior (complies with 3GPP Release 11) for roaming subscribers and send Redirection Complete IE in Attach and RAU Reject messages when the reject is due to GMM cause #17 (network failure) in response to receiving System Failure or Unexpected Data value MAP errors from the HLR

Example

Configure the SGSN to send Redirect Indication IE in RANAP reject messages:

    default network-sharing stop-redirect-reject-cause
plmn

Configures the PLMN (public land mobile network) related parameters for the IuPS service. This command is applicable to releases 8.1 and higher.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
```

```
no plmn id
```

**no**

Removes the PLMN ID from the configuration.

**id**

Creates a PLMN configuration instance based on the PLMN ID (comprised of the MCC and MNC). In accordance with TS 25.413, the SGSN supports up to 32 PLMN configurations for shared networks.

```
mcc mcc_num
```

Specifies the mobile country code (MCC) portion of the PLMN’s identifier.

**mcc_num**: The PLMN MCC identifier and can be configured to any integer value between 100 and 999.

```
mnc mnc_num
```

Specifies the mobile network code (MNC) portion of the PLMN’s identifier.

**mnc_num**: The PLMN MNC identifier and can be configured to any 2-digit or 3-digit value between 00 and 999.

```
network-sharing common-plmn mcc mcc_num mnc mnc_num
```

When network sharing is employed, this set of keywords is required to define the PLMN Id of the common PLMN. The common PLMN is usually not the same as the local PLMN.

**Important**: With the release of 15.0, both 2G and 3G MOCN functionality is now license controlled and the license is required to use all previously available network sharing SGSN configuration commands. For additional information, contact your Cisco Account Representative.
IuPS Service Configuration Mode Commands

plmn-list mcc mcc_num mnc mnc_num

When network sharing is employed and more than two PLMNs are available, then use the `plmn-list` keyword to begin a list of all additional PLMNs.

Usage

Use this command to configure the PLMN associated with the SGSN. There can only be one PLMN associated with an SGSN unless one of the following features is enabled and configured: network sharing or multiple PLMN.
For network sharing, use of the `network-sharing` keywords make it possible to identify more than one PLMN. Including the PLMN identified initially. None have precedence. They are all treated equally but they must each be unique. In a MOCN configuration, the PLMN list will not be used as there would only be one local PLMN.
For multiple PLMN support, the SGSN can support up to 8 Iu-PS configurations for PLMNs. These Iu-PS service configurations must be associated with the SGSN via the `ran-protocol` command in the SGSN Service configuration mode.

Example

Use the following command to identify a PLMN by the MCC 313 and MNC 23 and instruct the SGSN to perform network sharing with a single common PLMN identified by MCC 404 and MNC 123:

```
plmn id mcc 313 mnc 23 network-sharing common-plmn mcc 404 mnc 123
```
rab-assignment-response-timeout

Configures the RAB assignment timer.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration
configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax

rab-assignment-response-timeout time

default rab-assignment-response-timeout

default
Resets the timer to its default setting.

time
This variable configures the amount of time (in seconds) that the SGSN waits to receive a RAB assignment from the RNC.
time: must be an integer from 1 to 60.
Default: 8.

Usage
This command defines time the SGSN waits for the completion of the RAB assignment procedure.

Example
Change the timer setting to 11 seconds.

rab-assignment-response-timeout 11
radio-network-controller

This command creates an instance of an RNC configuration to associate with the IuPS service for the SGSN. This command is only available in release 8.0; use the rnc command for releases 8.1 and higher.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration
configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctx-iups-service)#

Syntax

radio-network-controller id rnc_id mcc mcc_num mnc mnc_num
no radio-network-controller id rnc_id mcc mcc_num mnc mnc_num

no
Removes the configuration information for the specified RNC.

id rnc_id
Define the instance number of the RNC configuration.
rnc_id: Must be an integer from 0 to 4095.

mcc mcc_num
Specifies the mobile country code (MCC).
mcc_num: Must be an integer between 100 and 999.

mnc mnc_num
Specifies the mobile network code (MNC).
mnc_num: Must be an integer between 00 and 999.

Usage
Use this command to configure information for the IuPS service to use to contact specific RNCs. This command also provides access to the RNC configuration mode.

Example
The following command creates or accesses RNC configuration instance #1 with MCC of 131 and MNC of 22:

radio-network-controller id 1 mcc 131 mnc 22
relocation.alloc.timeout

This command defines the amount of time the SGSN waits for a Relocation Request message.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
relocation.alloc.timeout timeout_value

default relocation.alloc.timeout
```

---

**default**

Resets the configuration to a 5 second wait time.

**timeout_value**

Time in seconds that the SGSN waits to receive a Relocation Request message.

- timeout_value: Must be an integer from 1 to 60.
- Default: 5 seconds.

**Usage**

Use this command to configure the number of seconds the SGSN will wait for a Relocation Request message to be received. This timeout needs to be set with sufficient time so that SRNS procedure aborts can be avoided if the peer fails to respond in a timely fashion in the case of a hard handoff.

**Example**

The following command sets the wait time to 10 seconds.

```
relocation.alloc.timeout 10
```
relocation-complete-timeout

This command specifies the maximum time for the SGSN to wait for a Relocation Completion from the core network.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```bash
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```bash
relocation-complete-timeout timeout_value

default relocation-complete-timeout
```

- **default**
  
  Resets the configuration to a 5 second wait time.

- **timeout_value**
  
  Time in seconds that the SGSN waits for relocation to be completed.

  - **timeout_value**: Must be an integer from 1 to 60.
  - **Default**: 5 seconds.

**Usage**

Use this command to configure the number of seconds the SGSN will wait for a relocation to be completed. This timeout needs to be set with sufficient time so that SRNS procedure aborts can be avoided if the peer fails to respond in a timely fashion in the case of a hard handoff.

**Example**

The following command sets the wait time for 10 seconds.

```bash
relocation-complete-timeout 10
```
**reset**

Defines the configuration specific to the RESET procedure.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

`configure > context context_name > iups-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
reset { ack-timeout time | guard-timeout time | max-retransmissions retries | sgsn-initiated }
```

```
default reset { ack-timeout | guard-timeout | max-retransmissions | sgsn-initiated }
```

```
no reset sgsn-initiated
```

**default**

Returns to the default settings for the Reset procedure.

**no**

Removes the SGSN-initiated reset procedure from the configuration.

**ack-timeout time**

Configures the interval (in seconds) for which the SGSN waits for RESET-ACK from the RNC. `time` must be an integer from 5 to 60. Default: 20.

**guard-timeout**

Configures the interval (in seconds) after which the SGSN sends RESET-ACK to the RNC. `time` must be an integer from 5 to 60. Default: 10.

**max-retransmissions**

Configures maximum retries for RESET message. `retries` must be an integer from 0 to 2. Default: 1.

**sgsn-initiated**

Enables SGSN initiated RESET procedure.
Default: disabled.

**Usage**

Configures the parameters that determine a RESET.

**Example**

Use the following to have the SGSN initiate the RESET procedure:

```
reset sgsn-initiated
```
rnc

This command creates or accesses an instance of an RNC (radio network controller) configuration.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name] host_name(config-ctx-iups-service)#

Syntax

rnc id rnc_id

no rnc id rnc_id

no
Removes the configuration information for the specified RNC.

id rnc_id
Set the identification number of the RNC configuration instance.

rnc_id: Must be an integer from 0 to 4095 for 8.1 releases. Must be an integer from 0 to 65535 for releases 9.0 and higher.

Usage

Use this command to configure information for the IuPS service to use to contact specific RNCs. This command also provides access to the RNC configuration mode.

Example

The following command creates an RNC configuration instance #3442:

    rnc id 3442
security-mode-complete-timeout

This command configures the security mode timer.

Product
SGSN

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-ctxt-iups-service)#

Syntax

security-mode-complete-timeout time

default security-mode-complete-timeout

default
 Resets the timer configuration to the default settings.

time
 Configures the interval (in seconds) the SGSN waits for the security mode from the MS to complete.
 time must be an integer from 1 to 60.
 Default is 5

Usage

Use this command to configure the timer that determines how long the SGSN waits for a Security Mode Complete message from the MS (mobile station).

Example

Instruct the SGSN to wait 7 seconds:

    security-mode-complete-timeout 7
**service-request-follow-on**

Instructs the SGSN not to release an Iu immediately.

**Product**
SGSN

**Privilege**
Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

```
configure > context context_name > iups-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
[ default | no ] service-request-follow-on
```

- **default**
  
  Resets the configuration to the default, this function is enabled.

- **no**
  
  Disables this function so that Iu is released without waiting for the Iu-Hold-Timer to expire.

**Usage**

For an Iu established as the result of a Service Request (signaling), the SGSN, by default, waits for the Iu-Hold-Timer to expire.

Use this command with the ‘no’ prefix to disable this function.

Use this command with the ‘default’ prefix or without any prefix if the configuration was modified previously with by no service-request-follow-on.

**Example**

Disable this function to wait for the Iu-Hold-Timer to expire:

```
no service-request-follow-on
```

Enable this function if it was previously disabled:

```
service-request-follow-on
```
srns-context-response-timeout

This command configures the SGSN context response timer.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration
configure > context context_name > iups-service service_name

Entering the above command sequence results in the following prompt:

\[
[context_name]host_name(config-ctx-iups-service)#
\]

**Syntax**

- `srns-context-response-timeout time`
- `default srns-context-response-timeout`

**Example**

Configure the SGSN to wait 7 seconds for an SRNS Context-Request response:

```
    srns-context-response-timeout 7
```
**tigoc-timeout**

This command configures the TigOc interval.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

`configure > context context_name > iups-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name] host_name(config-ctx-iups-service)#
```

**Syntax**

```
tigoc-timeout time

default tigoc-timeout
```

**default tigoc-timeout**

```
default

Resets the timer configuration to the default setting.
```

```
time

This command sets the time in seconds.

time: Must be an integer from 1 to 60.
Default: 5.
```

**Usage**

Define the amount of time that the SGSN ignores any overload messages for TigOc interval after receiving one overload message from the RNC.

**Example**

Use the following command to change the default TigOc interval to 4 seconds:

```
tigoc-timeout 4
```
**tintc-timeout**

This command configures the TinTc interval.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > IuPS Service Configuration

`configure > context context_name > iups-service service_name`

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-ctx-iups-service)#
```

**Syntax**

```
tintc-timeout time

default tintc-timeout
```

**default tintc-timeout**

```
default

Resets the timer configuration to the default setting.
```

```
time

Set the number of seconds to wait.

time: Must be an integer from 1 to 60.
Default: 30.
```

**Usage**

Define 4 as the number of seconds that the SGSN waits before decrementing (by one) the traffic level of the RNC.

**Example**

```
tintc-timeout 4
```
Chapter 185
LAC Service Configuration Mode Commands

The LAC Service Configuration Mode is used to create and manage L2TP services within contexts on the system. L2TP
Access Concentrator (LAC) services facilitate tunneling to peer L2TP Network Servers (LNSs).

**Mode**

Exec > Global Configuration > Context Configuration > LAC Service Configuration

```plaintext
configure > context context_name > lac-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lac-service)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product
version, and installed license(s).
allow

This command configure the system to allow different attributes in the LAC Hostname Attribute Value Pair (AVP) and Called-Number AVP for L2TP messages exchanged between LAC and LNS.

Product
GGSN
PDSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LAC Service Configuration
configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lac-service)#

Syntax

allow { aaa-assigned-hostname | called-number value apn | calling-number value imsi }

default allow { aaa-assigned-hostname | called-number value apn }

no allow { aaa-assigned-hostname | called-number value apn | calling-number }

no

Disable the configured attribute and returns to the behavior that uses the LAC-Service name as the HostName AVP.

aaa-assigned-hostname

When enabled if AAA assigns a valid Tunnel-Client-Auth-ID attribute for the tunnel, it is used as the HostName AVP in the L2TP tunnel setup message.
This keyword works in conjunction with the local-hostname hostname keyword applied via the tunnel 12tp command in APN Configuration mode.
When Tunnel parameters are not received from the RADIUS Server, Tunnel parameters configured in an APN are considered for the LNS peer selection. When APN configuration is selected, the local-hostname configured with the tunnel 12tp command in the APN for the LNS peer will be used as an LAC Hostname.

called-number value apn

Configures the system to send the APN name in the Called-Number AVP as a part of ICRQ message sent to the LNS. If this keyword is not configured, Called-Number AVP will not be included in ICRQ message sent to the LNS.
allow calling-number value imsi

Configures the system to allow the IMSI to be used as Calling-Number as a part of ICRQ message sent to the LNS. If this keyword is not configured, then MSISDN will be used as Calling-Number.

**Important:** This is a customer-specific keyword available for PDSN. Please contact your local Cisco sales representative for more information.

**Usage**

Use this command to configure the attribute for the HostName AVP for L2TP messages exchanged between LAC and LNS. LAC Hostname will be different for the subscribers corresponding to the different corporate APNs. In the absence of a AAA assigned HostName, the LAC-Service name is used as HostName. By default the LAC-Service name is used as the HostName AVP.

**Example**

The following command enables the use of the value of Tunnel-Client-Auth-ID attribute for the HostName AVP:

```
allow aaa-assigned-hostname
```

Use the following command to reset the behavior so that the LAC-Service uses the LAC-Service name as the HostName AVP:

```
no allow aaa-assigned-hostname
```
bind

This command assigns a local end point address to the LAC service in the current context.

Product
- GGSN
- PDSN
- P-GW
- SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LAC Service Configuration

configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lac-service)#

Syntax

bind ip_address [ max-subscribers ]

no bind ip_address

no

Unassign, or unbind, the local end point to the LAC service.

ip_address

This must be a valid IP address entered using IPv4 dotted-decimal notation.

max-subscribers

The maximum number of subscribers that can use the endpoint for this LAC service. Must be an integer from 1 to 2500000.

Usage

Use this command to bind a local end point IP address to the LAC service.

Example

The following command binds the local end point IP address 10.10.10.100 to the LAC service in the current context:

bind 10.10.10.100

The following command removes the binding of the local end point to the LAC service:

no bind
**data sequence-number**

Enables data sequence numbering for sessions that use the current LAC service. Data sequence numbering is enabled by default.

**Product**
- GGSN
- PDSN
- P-GW
- SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LAC Service Configuration

```
configure > context context_name > lac-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lac-service)#
```

**Syntax**

```
[ no ] data sequence-number
```

- **no**
  Disables data sequence numbering for sessions.

**Usage**
An L2TP data packet header has an optional data sequence numbers field. The data sequence number may be used to ensure ordered delivery of data packets. This command is used to re-enable or disable the use of the data sequence numbers for data packets.

**Example**

Use the following command to disable the use of data sequence numbering:

```
no data sequence-number
```

Use the following command to re-enable data sequence numbering:

```
data sequence-number
```
**default**

This command sets the specified LAC service parameter to its default value or setting.

**Product**
- GGSN
- PDSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LAC Service Configuration

```
configure > context context_name > lac-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lac-service)#
```

**Syntax**

```
default { data sequence-number | hide-attributes | keepalive-interval | load-balancing | local-receive-window | max-retransmission | max-session-per-tunnel | max-tunnel-challenge-length | max-tunnels | proxy-lcp-authentication | retransmission-timeout-first | retransmission-timeout-max | trap all | tunnel-authentication }
```

---

**data sequence-number**

Enables data sequence numbering for sessions.

**hide-attributes**

Disables hiding attributes in control messages sent from the LAC to the LNS.

**keepalive-interval**

Sets the interval for send L2TP Hello keepalive if there is no control or data transactions to the default value of 60 seconds.

**load-balancing**

Sets the load balancing algorithm to be used when many LNS peers have been configured to the default of round robin.

**local-receive-window**

Sets the window size to be used for the local side for the reliable control transport to the default of 16.

**max-retransmission**

Sets the maximum number of retransmissions to the default of 5.
max-session-per-tunnel
Sets the maximum number of sessions per tunnel at any point in time to the default of 512.

max-tunnel-challenge-length
Sets the maximum length of the tunnel challenge to the default of 16 bytes.

max-tunnels
Sets the maximum number of tunnels for this service to the default of 32000.

proxy-lcp-authentication
Sets sending of proxy LCP authentication parameters to the LNS to the default state of enabled.

retransmission-timeout-first
Sets the first retransmit interval to the default of 1 second.

retransmission-timeout-max
Sets the maximum retransmit interval to the default of 8 seconds.

trap all
Generates all supported SNMP traps.

tunnel-authentication
Sets tunnel authentication to the default state of enabled.

Usage
Use the default command to set LAC service parameters to their default states.

Example
Use the following command to set the keep alive interval to the default value of 60 seconds:

```
default
keepalive-interval
```

Use the following command to set the maximum number of sessions per tunnel to the default value of 512:

```
default max-session-per-tunnel
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Use this command to return to the Exec mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

exit

Usage
Use this command to return to the parent configuration mode.
hide-attributes

Enables hiding certain attributes (such as proxy-auth-name and proxy-auth-rsp) in control messages sent from the LAC to the LNS. The LAC hides such attributes only if tunnel authentication is enabled between the LAC and the LNS.

Product
- GGSN
- PDSN
- P-GW
- SAEGW

Privilege
- Security Administrator, Administrator

Mode
- Exec > Global Configuration > Context Configuration > LAC Service Configuration
- configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lac-service)#

Syntax

[ no ] hide-attributes

no
Disable hiding attributes.

Usage
Use this command to hide certain attributes from control messages when tunnel authentication is enabled between the LAC and the LNS.

Example
The following command enables hiding attributes:

hide-attributes
keepalive-interval

This command specifies the amount of time to wait before sending a Hello keep alive message.

**Product**
- GGSN
- PDSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > LAC Service Configuration

**Syntax**

```plaintext
keepalive-interval seconds
no keepalive-interval
```

**Usage**

Use this command to set the amount of time to wait before sending a Hello keep alive message or disable the generation of Hello keep alive messages completely. A keepalive mechanism is employed by L2TP in order to differentiate tunnel outages from extended periods of no control or data activity on a tunnel. This is accomplished by injecting Hello control messages after a specified period of time has elapsed since the last data or control message was received on a tunnel. As for any other control message, if the Hello message is not reliably delivered then the tunnel is declared down and is reset. The transport reset mechanism along with the injection of Hello messages ensures that a connectivity failure between the LNS and the LAC is detected at both ends of a tunnel.

**Example**

Use the following command to set the Hello keepalive message interval to 120 seconds:

```plaintext
keepalive-interval 120
```

Use the following command to disable the generation of Hello keepalive messages:
no keepalive-interval
load-balancing

Configures how LNSs are selected for this LAC service.

**Product**
- GGSN
- PDSN
- P-GW
- SAEGW

**Privilege**
- Security Administrator, Administrator

**Mode**
- Exec > Global Configuration > Context Configuration > LAC Service Configuration

```
configure > context context_name > lac-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lac-service)#
```

**Syntax**

```
load-balancing { balanced | prioritized | random }
```

<table>
<thead>
<tr>
<th>balanced</th>
</tr>
</thead>
<tbody>
<tr>
<td>LNS selection is made without regard to prioritization, but in a sequential order that balances the load across the total number of LNS nodes available.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>prioritized</th>
</tr>
</thead>
<tbody>
<tr>
<td>LNS selection is made based on the priority assigned in the Tunnel-Preference attribute. An example of this method is three LNS nodes, with preferences of 1, 2, and 3 respectively. In this example, the RADIUS server always tries the tunnel with a preference of 1 before using any of the other LNS nodes.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>random</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: Enabled</td>
</tr>
<tr>
<td>LNS selection is random in order, wherein the RADIUS server does not use the Tunnel-Preference attribute in determining which LNS to select.</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to configure the load-balancing algorithm that defines how the LNS node is selected by the LAC when there are multiple peer LNSs configured in the LAC service.

**Example**

The following command sets the LAC service to connect to LNSs in a sequential order;

```
load-balancing balanced
```

The following command sets the LAC service to connect to LNSs according to the priority assigned through the Tunnel-Preference attribute:
load-balancing prioritized
local-receive-window

Specifies the number of control messages the remote peer LNS can send before waiting for an acknowledgement.

Product

Exec > Global Configuration > Context Configuration > LAC Service Configuration

configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lac-service)#

Syntax

local-receive-window integer

integer
Default: 4
Specifies the number of control messages to send before waiting for an acknowledgement. The number can be configured to an integer from 1 to 256.

Usage
Use this command to set the size of the control message receive window being offered to the remote peer LNS. The remote peer LNS may send the specified number of control messages before it must wait for an acknowledgment.

Example
The following command sets the local receive window to 10 control messages:

local-receive-window 10
max-retransmission

Sets the maximum number of retransmissions of a control message to a peer before the tunnel and all sessions within it are cleared.

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LAC Service Configuration
configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lac-service)#

Syntax

max-retransmission integer

integer
Default: 5
Specifies the maximum number of retransmissions of a control message to a peer. This value must be an integer from 1 through 10.

Usage
Each tunnel maintains a queue of control messages to be transmitted to its peer. After a period of time passes without acknowledgement, a message is retransmitted. Each subsequent retransmission of a message employs an exponential backoff interval. For example; if the first retransmission occurs after 1 second, the next retransmission occurs after 2 seconds has elapsed, then the next after 4 seconds. If no peer response is detected after the number of retransmissions set by this command, the tunnel and all sessions within are cleared.
Use this command to set the maximum number of retransmissions that the LAC service sends before closing the tunnel and all sessions within it.

Example
The following command sets the maximum number of retransmissions of a control message to a peer to 7:

max-retransmissions 7
**max-session-per-tunnel**

Sets the maximum number of sessions that can be facilitated by a single a tunnel at any time.

**Product**
- GGSN
- PDSN
- P-GW
- SAEGW

**Privilege**
Security Administrator, Administrator

**Mode**
Exec > Global Configuration > Context Configuration > LAC Service Configuration

```
configure > context context_name > lac-service service_name
```

Entering the above command sequence results in the following prompt:

```
[context_name]host_name(config-lac-service)#
```

**Syntax**
```
max-sessions-per-tunnel integer
```

- `integer`
- Default: 512
- The maximum number of sessions expressed as an integer from 1 through 65535.

**Usage**
Use this command to set the maximum number of sessions you want to allow in a tunnel.

**Example**
The following command sets the maximum number of sessions in a tunnel to 5000:

```
max-sessions-per-tunnel 5000
```
max-tunnel-challenge-length

Sets the maximum length of the tunnel challenge in bytes. The challenge is used for tunnel authentication purposes during tunnel creation.

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LAC Service Configuration
configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lac-service)#

Syntax
max-tunnel-challenge-length bytes

bytes
Default: 16
Specifies the maximum length (in bytes) of the tunnel challenge. This must be an integer from 4 through 32.

Usage
Use this command to set the maximum length (in bytes) for the tunnel challenge that is used during tunnel creation.

Example
The following command sets the maximum length of the tunnel challenge to 32 bytes:

max-tunnel-challenge-length 32
max-tunnels

The maximum number of tunnels that the current LAC service can support.

Product

PDSN
P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LAC Service Configuration

configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lac-service)#

Syntax

max-tunnels integer

integer

Default: 32000
The maximum number of tunnels expressed as an integer from 1 through 32000.

Usage
Use this command to set the maximum number tunnels that this LAC service can support at any on time.

Example
Use the following command to set the maximum number of tunnels for the current LAC service to 20000:

max-tunnels 20000
peer-lns

Adds a peer LNS address for the current LAC service. Up to eight peer LNSs can be configured for each LAC service.

P-GW
SAEGW

Privilege
Security Administrator, Administrator

Mode
Exec > Global Configuration > Context Configuration > LAC Service Configuration
configure > context context_name > lac-service service_name

Entering the above command sequence results in the following prompt:

[context_name]host_name(config-lac-service)#

Syntax

peer-lns ip_address [ encrypted ] secret secret [ crypto-map map_name { [ encrypted ]
isakmp-secret secret } ] [ description text ] [ preference integer ]

no peer-lns ip_address

Deletes the peer LNS at the IP address specified by ip_address. ip_address must be entered in IPv4 dotted-decimal notation.

ip_address

The IP address of the peer LNS for the current LAC service. ip_address must be entered in IPv4 dotted-decimal notation.

[ encrypted ] secret secret

Designates the secret which is shared between the current LAC service and the peer LNS. secret must be an alphanumeric string of 1 through 256 characters that is case sensitive.

encrypted secret secret: Specifies that encryption should be used when communicating the secret with the peer LNS.

crypto-map map_name { [ encrypted ] isakmp-secret secret }

map_name is the name of a crypto map that has been configured in the current context. map_name must be an alphanumeric string of 1 through 127 characters that is case sensitive.
