- **nw-specific**: Network-specific encoding scheme
- **unknown**: Unknown encoding scheme

**Usage**
Select BCD even encoding for GTT

**Example**

```
encoding scheme bcd-even
```
end

Exits the configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

end

Usage
Change the mode back to the Exec mode.
exit

Exits the configuration mode and returns to the Global configuration mode.

**Product**
- SGSN

**Privilege**
- Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the Global configuration mode.
**nature-of-address**

Configures the indicator to identify the nature of the address.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
nature-of-address ( international | national | subscriber )
```

- **international**
  Identifies the numbers as international.

- **national**
  Identifies the numbers as matching the national configuration.

- **subscriber**
  Identifies the numbers as subscriber numbers.

**Usage**
Configure the identify of the GT format as national.

**Example**

```plaintext
nature-of-address national
```
numbering-plan

Configures the GTT process to apply one of the numbering-plans during the GT translation process.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
numbering-plan plan_type
```

```
plan_type
Select one of the following numbering plans be employed during GTT:
  • data: Data numbering plan
  • generic: Generic number plan
  • isdn: ISDN tel numbering plan
  • isdn-mobile: ISDN mobile numbering plan
  • land-mobile: Land mobile numbering plan
  • maritime-mobile: Maritime mobile numbering plan
  • mw-specific: Private network/ network-specific numbering plan
  • telex: Telex numbering plan
  • unknown: Unknown numbering plan
```

Usage
Select ISN telephone number plan for GTT process.

Example

```
numbering-plan isdn
```
translation-type

Configures the GTT process to apply a specific number for translation during the GTT process.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
translation-type number
```

number
Must be an integer between 0 and 255.
Default is 0.

Usage
Use this command to configure the translation-type to be implemented during the global title translation process.

Example

```
translation-type 231
```
Chapter 111
GTPP Server Group Configuration Mode Commands

The GTPP Server Group Configuration Mode is used to create and manage the GTPP server groups within the context or system.

GTPP server group commands facilitate the setup of the SMC hard disk for CDR storage. As well, for accounting and charging functionality within a context, these commands can be used to configure the management of a group (list) of charging gateway function (CGF) servers on a per subscriber or per GGSN APN level.

In this mode, your prompt will be similar to `[context_name] hostname(config-gtpp-group)#`
gtp attribute

Enables the specification of some of the optional fields in the CDRs that the GSN (GGSN or SGSN) generates and/or how the information is to be presented.

**Product**
GGSN, SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
gtp attribute { camel-info | cell-plmn-id | diagnostics | duration-ms | imei | local-record-sequence-number | msisdn | node-id-suffix STRING | plmn-id | rat | record-extensions rat | sms { destination-number | recording-entity | service-centre } } +

default gtp attribute { cell-plmn-id | diagnostics | duration-ms | imei | local-record-sequence-number | msisdn | plmn-id | rat | record-extensions rat | sms { destination-number | recording-entity | service-centre } }

no gtp attribute { cell-plmn-id | diagnostics | duration-ms | imei | local-record-sequence-number | msisdn | node-id-suffix | plmn-id | rat | record-extensions rat | sms { destination-number | recording-entity | service-centre } }
```

**default**

Resets the default attribute values for this GTPP group configuration.

**no**

Disables the specified optional field so that the information will not be present in generated CDRs.

**camel-info**

SGSN only
Default: Disabled
Enter this keyword to include CAMEL-specific fields in SGSN CDRs.

**cell-plmn-id**

SGSN only
Default: Disabled
Enter this keyword to enable the system to include the Cell PLMN ID field in the M-CDR.

**diagnostics**

Default: Disabled
Enter this keyword to enable the system to include the Diagnostic field in the CDR that is created when PDP contexts are released. The field will include one of the following values:

- **26** - For GGSN: if the GGSN sends “delete PDP context request” for any other reason (e.g., the operator types “clear subscribers” on the GGSN). For SGSN: The SGSN includes this cause code in
the S-CDR to indicate that a secondary PDP context activation request or a PDP context modification request has been rejected due to insufficient resources.

- **36** - For GGSN: this cause code is sent in the G-CDR to indicate the PDP context has been deactivated in the GGSN due to the SGSN having sent a “delete PDP context request” to the GGSN. For SGSN, this cause code is used to indicate a regular MS or network-initiated PDP context deactivation.

- **37** - when the network initiates a QoS modification, the SGSN sends in the S-CDR to indicate that the MS initiation deactivate request message has been rejected with QoS not accepted as the cause.

- **38** - if the GGSN sends “delete PDP context request” due to GTP-C/GTP-U echo timeout with SGSN. If the SGSN sends this cause code, it indicates PDP context has been deactivated due to path failure, specifically GTP-C/GTP-U echo timeout.

- **39** - SGSN only - this code indicates the network (GGSN) has requested a PDP context reactivation after a GGSN restart.

- **40** - if the GGSN sends “delete PDP context request” due to receiving a RADIUS Disconnect-Request message.

---

**duration-ms**

Default: Disabled

Specifies that the information contained in the mandatory Duration field be reported in milliseconds instead of seconds (as the standards require).

**imei**

Default: Disabled

For SGSN: includes the IMEI value in the S-CDR.
For GGSN: includes the IMEISV value in the G-CDR.

**local-record-sequence-number**

Default: Disabled

This keyword provides both the local record sequence number and the Node ID. In the x-CDRs, this field indicates the number of CDRs generated by the node and is unique within the session manager.

The Node ID field is included in the x-CDR for any of several reasons, such as when PDP contexts are released or if partial-CDR is generated based on configuration. The field will consist of a AAA Manager identifier automatically appended to the name of the SGSN or GGSN service.

The name of the SGSN or GGSN service may be truncated, because the maximum length of the Node ID field is 20 bytes. Since each AAA Manager generates CDRs independently, this allows the Local Record Sequence Number and Node ID fields to uniquely identify a CDR.

---

**Important:** If this keyword is enabled and the **gtpp centralized-lrsn-creation** option is enabled with the **gtpp single-source centralized-lrsn** command, then the Node ID format changes as follows:

- **1-byte-AAAProxy-restart-counter**
- **3-byte AAAProxy instance number**
- **<node-id-suffix>**
  - If “centralized-lrsn-creation” is not enabled, then node-id format for CDRs generated by Sessmgr is as follows:
    - **1-byte Sessmgr restart-value**
    - **3-byte Sessmgr instance number**
    - **<node-id-suffix>**
  - If “centralized-lrsn-creation” is not enabled, then node-id format for CDRs generated by ACSMgr is as follows:
    - **1-byte ACSmgr restart-value**
    - **3-byte ACSmgr instance number**
    - **<Active charging service-name>**

**msisdn**

Default: Enabled

For SGSN: includes the MSISDN value in the S-CDR.
For GGSN: includes the MSISDN value in the G-CDR.

**node-id-suffix STRING**

Default: Disabled
Specifies the string suffix to use in the NodeID field of GTPP CDRs. Each Session Manager task generates a unique NodeID string per GTPP context.

*STRING*: This is the configured Node-ID-Suffix having any string between 1 to 16 characters.

---

**Important**: The NodeID field is a printable string of the \( ndddSTRING \) format: \( n \): The first digit is the Sessmgr restart counter having a value between 0 and 7. \( ddd \): The number of sessmgr instances. Uses the specified NodeID-suffix in all CDRs. The “Node-ID” field consists of sessMgr Recovery counter (1 digit) \( n \) + AAA Manager identifier (3 digits) \( ddd \) + the configured Node-Id-suffix (1 to 16 characters) *STRING*. If the centralized LRSN feature is enabled, the “Node-ID” field will consist of only the specified NodeID-suffix (NodeID-prefix is not included). If this option is not configured, then GTPP group name will be used instead (For default GTPP groups, context-name will be used).

**Important**: If this *node-id-suffix* is not configured, the GGSN uses the GTPP context name as the Node-id-suffix (truncated to 16 characters) and the SGSN uses the GTPP group named as the node-id-suffix.

**plmn-id [ unknown-use ]**

Default: Enabled
For SGSN, reports the SGSN PLMN Identifier value (the RAI) in the S-CDR provided if the dictionary supports it.
For GGSN, reports the SGSN PLMN Identifier value (the RAI) in the G-CDR if it was originally provided by the SGSN in the GTP create PDP context request. It is omitted if the SGSN does not supply one. Normally when SGSN PLMN-id information is not available, the attribute sgsnPLMNIdentifier is not included in the CDR. This keyword enables the inclusion of the sgsnPLMNIdentifier with a specific value when the SGSN PLMN-id is not available.

*unknown-use* *hex_num* must be a hexadecimal number from 0x0 through 0xFFFFFF to identify a foreign SGSN that has not provided a PLMN-id. For GGSN only.

**rat**

Default: Enabled
For SGSN: includes the RAT (identifies the radio access technology type) value in the S-CDR.
For GGSN: includes the RAT (identifies the radio access technology type) value in the G-CDR.

**record-extensions rat**

Default: Disabled
Enables network operators and/or manufacturers to add their own recommended extensions to the CDRs according to the standard record definitions from 3GPP TS 32.298 Release 7 or higher.

**sms { destination-number | recording-entity | service-centre }**

This keyword is specific to the SGSN.
Entering this keyword causes the inclusion of an SMS-related field in the SMS-MO-CDR or SMS-MT-CDR.

*destination-number* - Entering this option includes the "destinationNumber" field in the SMS-MO-CDR or SMS-MT-CDR.

*recording-entity* - Entering this option includes the "recordingEntity" field in the SMS-MO-CDR or SMS-MT-CDR.
**service-centre** - Entering this option includes the "serviceCentre" field in the SMS-MO-CDR or SMS-MT-CDR.

+ Indicates that this command can be entered multiple times to configure multiple attributes.

**Usage**

This command dictates some of the optional information fields that should be reported in CDRs generated by the GGSN. In addition, it controls how the information for some of the mandatory fields are reported. Fields described as optional by the standards but not listed above will always be present in the CDRs, except for Record Extensions (which will never be present).

**Example**

The following command dictates that the time provided in the Duration field of the CDR is reported in milliseconds:

```
gtpp attribute duration-ms
```
gtpp charging-agent

Configures the IP address and port of the system interface within the current context used to communicate with the CGF or the GSS.

Product
GGSN, SGSN

Privilege
Security Administrator, Administrator

Syntax

gtpp charging-agent address ip_address [ port port ]

no gtpp charging-agent

no
Removes a previously configured charging agent address.

address ip_address
Specifies the IP address of the interface configured within the current context that is used to transmit G-CDR records to the CGF or the GSS. ip_address must be configured using dotted decimal notation.

port port
It is an optional parameter. It specifies the Charging Agent UDP port. If port is not defined, the IP will take the default port number 49999.
Default: 49999
port must be followed by an integer, ranging from 1 to 65535.

Important: Configuring GTPP charging-agent on port 3386 may interfere with ggsn-service configured with the same ip address.

Usage
This command can be used to establish a UDP interface to connect to the GSS or this command can establish a Ga interface to connect to the CFG. These interfaces must exist in the same context in which GTPP functionality is configured (refer to the gtpp commands in this chapter).
This command instructs the system as to what interface to use. The IP address supplied is also the address by which the GGSN/SGSN is known to the CGF or the GSS. Therefore, the IP address used for the Ga or UDP interface could be identical to one bound to a GGSN/SGSN service (a Gn interface).
If no GGSN/SGSN services are configured in the same context as the Ga/UDP interface, the address configured by this command is used to receive unsolicited GTPP packets.

Example
The following command configures the system to use the interface with an IP address of 192.168.13.10 as the accounting interface with port 20000 to the CGF:

```
gtpp charging-agent address 192.168.13.10

gtpp charging-agent address 192.168.13.10 port 20000
```
**gtpp data-request sequence-numbers**

Configures the range of sequence numbers to be used in the GTPP data record transfer record (DRT). Use this command to set the start value for the sequence number.

**Product**

GGSN, SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
gtpp data-request sequence-numbers start { 0 | 1 }
default gtpp data-request sequence-numbers start
```

**Usage**

When the GGSN/SGSN is configured to send GTPP echo request packets, the SGSN always uses 0 as the sequence number in those packets. Re-using 0 as a sequence number in the DRT packets is allowed by the 3GPP standards; however, this CLI command ensures the possibility of inter-operating with CGFs that can not properly handle the re-use of sequence number 0 in the echo request packets.

**Example**

The following command sets the sequence to start at 1.

```plaintext
gtpp data-request sequence-numbers start 1
```
gtpp deadtime

Configures the amount of time the GGSN/SGSN waits before attempting to communicate with a CGF that was previously marked as unreachable (non-responsive).

Product
GGSN, SGSN

Privilege
Security Administrator, Administrator

Syntax

```
gtpp deadtime time

default deadtime
```

default
Resets the deadtime to the default of 120 seconds.

```
time
```

Default: 120
Specifies the amount of time that must elapse before the system attempts to communicate with a CGF that was previously unreachable.

`time` is measured in seconds and can be configured to any integer value from 1 to 65535.

Usage
If the system is unable to communicate with a configured CGF, after a pre-configured number of failures the system marks the CGF as being down.
This command specifies the amount of time that the system waits prior to attempting to communicate with the downed CGF.
Refer to the `gtpp detect-dead-server` and `gtpp max-retries` commands for additional information on the process the system uses to mark a CGF as down.

Example
The following command configures the system to wait 60 seconds before attempting to re-communicate with a CGF that was marked as down:

```
gtpp deadtime 60
```
**gtpp dead-server suppress-cdrs**

This command configures the action the GGSN or the SGSN will take on CDRs generated during a communication failure between the GGSN or the SGSN and the GTPP servers.

**Product**  
GGSN, SGSN

**Privilege**  
Security Administrator, Administrator

**Syntax**

```
[ no | default ] gtpp dead-server suppress-cdrs
```

- **no**
  
  Removes the suppression instruction from the configuration and sets the CDR suppression mode as disabled.

- **default**
  
  Resets the GGSN or the SGSN to the default mode: disable suppression of CDRs when GTPP server detected as “dead” or unreachable.

**Usage**

**For the GGSN:** This command works in conjunction with the `gtpp detect-dead-server` to set an action when a communication failure is detected between the GGSN and a configured GTPP server. It disables the archiving of CDRs on the system when the GTPP server is unreachable or dead.

**For the GGSN and the SGSN:** Typically, during a communication or server failure, the GGSN or SGSN retains the GTPP requests until the system buffer runs out of resources. This command enables suppression of the CDRs, so with this command the GGSN or the SGSN will start purging all CDRs associated with this GTPP group as soon as the GGSN/SGSN detects that the GTPP server is down or that a communication failure has occurred. The CDRs generated, for the period while the server is down/unreachable, will also be purged.

**Example**

The following command configures the system to start purging CDRs when a communication failure with a server is detected:

```
gtpp dead-server suppress-cdrs
```
**gtpp detect-dead-server**

Configures the number of consecutive communication failures that could occur before the system marks a CGF as ‘dead’ (unreachable).

**Product**
GGSN, SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
gtpp detect-dead-server consecutive-failures max_number
```

```
default gtpp detect-dead-server consecutive-failures
```

- **default**
  Resets the system to the default number of consecutive failures.

- **consecutive-failures max_number**
  Default: 5
  Specifies the number of failures that could occur before marking a CGF as down. If 0 (zero) is the value entered, then the system will mark the CGF as dead after a single instance of max-retries has been attempted with no success, regardless of configured deadline. `max_number` could be configured to any integer value from 0 to 1000.

**Usage**

This command works in conjunction with the `gtpp max-retries` parameter to set a limit to the number of communication failures that can occur with a configured CGF. The `gtpp max-retries` parameter limits the number of attempts to communicate with a CGF. Once that limit is reached, the system treats it as a single failure. The `gtpp detect-dead-server` parameter limits the number of consecutive failures that can occur before the system marks the CGF as down and communicate with the CGF of next highest priority.

If all of the configured CGFs are down, the system ignores the detect-dead-server configuration and attempt to communicate with highest priority CGF again.

If the system receives a GTPP Node Alive Request, Echo Request, or Echo Response message from a CGF that was previously marked as down, the system immediately treats it as being active.

Refer to the `gtpp max-retries` command for additional information.

**Example**

The following command configures the system to allow 8 consecutive communication failures with a CGF before it marks it as down:

```
  gtpp detect-dead-server consecutive-failures 8
```
**gtpp dictionary**

This command designates specific dictionary used by GTPP for specific context.

**Product**
GGSN, SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
gtpp dictionary {custom1 | custom10 | custom11 | custom12 | custom13 | custom14 | custom15 | custom16 | custom17 | custom18 | custom19 | custom20 | custom21 | custom22 | custom23 | custom24 | custom25 | custom26 | custom27 | custom28 | custom29 | custom3 | custom30 | custom4 | custom5 | custom6 | custom7 | custom8 | custom9 | standard}
```

```
default gtpp dictionary
```

</tr>
</tbody>
</table>
### Custom26
Custom-defined dictionary for customization of G-CDR records for GGSN only. This is compliant to 3GPP TS 32298 (R6 v 6.5.0) for proprietary fields and encoding.

### Custom27
Custom-defined dictionary for customization of S-CDR records for SGSN only. This is compliant to 3GPP TS 32298 (R6 v 6.6.0) for proprietary fields and encoding.

### Custom28 ... Custom30
Custom-defined dictionaries for GGSN only.

### Standard
Default: Enabled
A dictionary conforming to TS 32.215 v 4.6.0 for R4 (and also R5 - extended QoS format).

#### Usage
Use this command to designate specific dictionary used by GTPP for specific context.

#### Example
The following command configures the system to use custom3 dictionary to encode IP address in Binary format in G-CDRs:

```plaintext
gtp dictionary custom3
```
**gtpp duplicate-hold-time**

This command configures the number of minutes to hold onto CDRs that are possibly duplicates while waiting for the primary CGF to come back up.

**Product**
GGSN, SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
gtpp duplicate-hold-time minutes minutes
```

**Usage**

Resets the configuration to the default value of 60 minutes for the duplicate hold time.

```
default gtpp duplicate-hold-time
```

**Example**

Use the following command to set the amount of time to hold onto CDRs to 2 hours (120 minutes):

```
gtpp duplicate-hold-time minutes 120
```
gtpp echo-interval

Configures the frequency at which the system sends GTPP echo packets to configured CGFs.

Product
GGSN, SGSN

Privilege
Security Administrator, Administrator

Syntax

```
gtpp echo-interval time
{ default | no } gtpp echo-interval
```

- **default**
  Resets the configuration to the default echo-interval of 60 seconds.

- **no**
  Disables the use of the echo protocol except for the scenarios described in the Usage section for this command.

- **time**
  Specifies the number of seconds for sending GTPP echo packets.
  *time* must be an integer from 60 to 3600. Default: 60

Usage
The GTPP echo protocol is used by the system to ensure that it can communicate with configured CGFs. The system initiates this protocol for each of the following scenarios:
- Upon system boot
- Upon the configuration of a new CGF server on the system using the *gtpp server* command as described in this chapter
- Upon the execution of the *gtpp test accounting* command as described in the Exec Mode Commands chapter of this reference
- Upon the execution of the *gtpp sequence-numbers private-extensions* command as described in this chapter

The echo-interval command is used in conjunction with the *gtpp max-retries* and *gtpp timeout* commands as described in this chapter.

In addition to receiving an echo response for this echo protocol, if we receive a GTPP Node Alive Request message or a GTPP Echo Request message from a presumed dead CGF server, we will immediately assume the server is active again.

The alive/dead status of the CGFs is used by the AAA Managers to affect the sending of CDRs to the CGFs. If all CGFs are dead, the AAA Managers will still send CDRs, (refer to the *gtpp deadtime* command), albeit at a slower rate than if a CGF were alive. Also, AAA Managers independently determine if CGFs are alive/dead.
Example
The following command configures an echo interval of 120 seconds:

```
gtpp echo-interval 120
```
gtpp egcdr

Configures the eG-CDR parameters and triggers.

Product
GGSN

Privilege
Security Administrator, Administrator

Syntax

```plaintext

default gtpp egcdr {final-record include-content-ids only-with-traffic closing-cause same-in-allpartials | losdv-max-containers | lotdv-max-containers | service-idle-timeout 0}

no gtpp egcdr service-data-flow threshold {interval | volume { downlink [ uplink ] | total | uplink [ downlink ] } }
```

| final-record [ closing-cause [ same-in-allpartials | unique ] | include-content-ids [ all | only-with-traffic ] ] |
| Enables configuration of the final eG-CDR. |
| • closing-cause - Configures closing cause for the final eG-CDR. |
| • same-in-allpartials - Specifies that the same closing cause is to be included for multiple final eG-CDRs |
| • unique - Specifies that the closing cause for final eG-CDRs is to be unique. |
| • include-content-ids - Controls which content-ids are being included in the final eG-CDR. |
| • all - Specifies that all content-ids be included in the final eG-CDR. |
| • only-with-traffic - Specifies that only content-ids with traffic be included in the final eG-CDRs. |

| losdv-max-containers number |
| The maximum number of List of Service Data Volume (LoSDV) containers in one eG-CDR. number can be configured to any integer value from 1 to 255. |
| Default: 10 |

| lotdv-max-containers number |
| The maximum number of List of Traffic Data Volume (LoTDV) containers in one eG-CDR. number can be configured to any integer value from 1 to 8. |
| Default: 8 |
**GTPP Server Group Configuration Mode Commands**

**gtpp egcdr**

### Configuration of the Thresholds for Closing a Service Data Flow Container within an eG-CDR

**service-data-flow threshold [ interval seconds | volume { downlink | total | uplink } bytes ]**

Configures the thresholds for closing a service data flow container within an eG-CDR.

- *interval* - configures the time interval in seconds
- *volume* - can specify uplink or downlink or combined total (uplink + downlink) byte thresholds.

A service data flow container has statistics for an individual content-id. When the threshold is reached, the service data flow container is closed.

Default: disabled

### Configuration of the Idle Timeout for Service Data Flows

**service-idle-timeout seconds**

Specifies a time period where if no data is reported for a service flow, then the service container is closed and added to eG-CDR (as part of LOSDV container list) with service condition change as ServiceIdleOut.

*seconds* can be configured to any integer value from 10 to 86,400.

Default: 0. This means there is no service-idle-timeout trigger.

### Usage

Use this command to configure individual triggers for eG-CDR generation.

### Example

Use the following command to set the maximum number of LoSDV containers to 7.

```
gtpp egcdr losdv-max-containers 7
```
gtpp error-response

This command configures the response when the system receives an error response after transmitting a DRT (data record transfer) request.

Product
GGSN, SGSN

Privilege
Security Administrator, Administrator

Syntax

```
gtpp error-response { discard-cdr | retry-request }

default gtpp error-response
```

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>discard-cdr</td>
<td>Instructs the system to purge the request upon receipt of an error response and not to retry.</td>
</tr>
<tr>
<td>retry-request</td>
<td>Instructs the system to retry sending a DRT after receiving an error response. This is the default behavior.</td>
</tr>
</tbody>
</table>

Usage
This command configures the system’s response to receiving an error message after sending a DRT request.

Example
```
gtpp error-response discard-cdr
```
gtpp max-cdrs

Configures the maximum number of charging data records (CDRs) to be included in a packet.

Product
GGSN, SGSN

Privilege
Security Administrator, Administrator

Syntax

```
gtpp max-cdrs number_cdrs [ wait-time seconds ]
default gtpp max-cdrs
```

default
Sets the default configuration.

```
number_cdrs
Default: 1
Specifies the maximum number of CDRs to insert in a single packet must be an integer from 1 to 255.
```

```
wait-time seconds
Default: Disabled
Configures the number of seconds the GSN waits to send the packet while accumulating CDRs as defined by max-cdr. If the wait-time interval expires before max-cdrs is reached, then this keyword over-rides and the packet is sent.
seconds any integer from 1 to 300.
```

```
Important: wait-time interval can only be enabled if the value for max-cdrs number_cdrs is greater than 1.
```

Usage
The system places CDRs into a packet until either max-cdrs is met, wait-time times out, or the maximum PDU size, configured by the gtpp max-pdu-size command, is met.
The gtpp max-pdu-size and the wait-time parameters take priority over max-cdrs.

```
Important: This command’s configuration is ignored if CDRs are stored on an SMC hard disk.
```

Example
The following command configures the system to place a maximum of 10 CDRs in a single GTPP packet with a wait-time of 30 seconds:

```
gtpp max-cdrs 10 wait-time 30
```
GTPP Server Group Configuration Mode Commands

gtp max-cdrs
gtpp max-pdu-size

Configures the maximum payload size of a single GTPP packet that could be sent by the system.

**Product**
GGSN, SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
gtpp max-pdu-size pdu_size
```

```
default gtpp max-pdu-size
```

**default**
Resets the default `max-pdu-size` of 4096.

**pdu_size**
Default: 4096
Specifies the maximum payload size of the GTPP packet. The payload includes the CDR and the GTPP header. 
`pdu_size` is measured in octets and can be configured to any integer value from 1024 to 65400.

**Usage**
The GTPP packet contains headers (layer 2, IP, UDP, and GTPP) followed by the CDR. Each CDR contains one or more volume containers. If a packet containing one CDR exceeds the configured maximum payload size, the system creates and send the packet containing the one CDR regardless. The larger the packet data unit (PDU) size allowed, the more volume containers that can be fit into the CDR. The system performs standard IP fragmentation for packets that exceed the system’s maximum transmission unit (MTU).

**Important:** The maximum size of an IPv4 PDU (including the IPv4 and subsequent headers) is 65,535. However, a slightly smaller limit is imposed by this command because the system’s `max-pdu-size` doesn't include the IPv4 and UDP headers, and because the system may need to encapsulate GTPP packets in a different/larger IP packet (for sending to a backup device).

**Example**
The following command configures a maximum PDU size of 2048 octets:

```
gtpp max-pdu-size 2048
```
gtpp max-retries

Configures the maximum number of times the system attempts to communicate with an unresponsive CGF.

Product
GGSN, SGSN

Privilege
Security Administrator, Administrator

Syntax

```
gtpp max-retries max_attempts

default gtpp max-retries
```

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resets the systems max-retries to the default of 4.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>max_attempts</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 4</td>
</tr>
<tr>
<td>Specifies the number of times the system attempts to communicate with a CGF that is not responding.</td>
</tr>
<tr>
<td>max_attempts can be configured to any integer value from 1 to 15.</td>
</tr>
</tbody>
</table>

Usage

This command works in conjunction with the gtpp detect-dead-server and gtpp timeout parameters to set a limit to the number of communication failures that can occur with a configured CGF. When the value specified by this parameter is met, a failure is logged. The gtpp detect-dead-server parameter specifies the number of consecutive failures that could occur before the server is marked as down. In addition, the gtpp timeout command controls the amount of time between re-tries. If the value for the max-retries is met, the system begins storing CDRs in Random Access Memory (RAM). The system allocates memory as a buffer, enough to store one million CDRs for a fully loaded chassis (a maximum of one outstanding CDR per PDP context). Archived CDRs are re-transmitted to the CGF until they are acknowledged or the system’s memory buffer is exceeded. Refer to the gtpp detect-dead-server and gtpp timeout commands for additional information.

Example
The following command configures the maximum number of re-tries to be 8.

```
gtpp max-retries 8
```
gtpp mbms bucket

This command configures the traffic data volume (bucket) limit of charging buckets due to QoS changes of tariff time that can occur before a G-GBMS-CDR should be closed.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
gtpp mbms buckets number
[ no ] gtpp mbms buckets
```

- **no**
  Disables the configured traffic data volume bucket limits trigger for G-GBMS-CDR generation for MBM user service data.

- **buckets number**
  Default: 4
  Specifies the number of statistics container changes due to QoS changes or tariff time that can occur before a G-GBMS-CDR should be closed.
  number can be configured to any integer value from 1 through 4.

**Usage**

Use this command to configure the traffic data volume (bucket) based G-GBMS-CDR generation triggers for MBMS user data service.

**Example**

The following command configures the bucket-based trigger to generate G-GBMS-CDRs after changes in 2 container:

```
gtpp mbms buckets 2
```
**gtpp mbms interval**

This command configures the interval duration for interval-based triggers for GTPP MBMS Charging Data Record (G- MBMS-CDR) generation.

**Product**

GGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
gtpp mbms interval duration_sec
```

```
no gtpp mbms interval
```

**no**

Disables the interval-based trigger for G- MBMS-CDR generation for MBMs user service data.

```
interval duration_sec
```

Default: Disabled

Specifies the normal time duration that must elapse before closing an accounting record provided that any or all of the following conditions occur:

- Downlink traffic volume is reached within the time interval
- Tariff time based trigger occurred within the time interval
- Data volume (up and downlink) bucket trigger occurred within the time interval

`duration_sec` is measured in seconds and can be configured to any integer value from 60 through 40,000,000.

**Usage**

Use this command to configure the G- MBMS-CDR generation triggers for MBMS user data service.

**Example**

The following command configures the interval-based trigger to generate G- MBMS-CDRs in every 60 seconds:

```
gtpp mbms interval 60
```
**gtpp mbms tariff**

This command configures the tariff slots for tariff-based triggers for GTPP MBMS Charging Data Record (G-MBMS-CDR) generation.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
gtpp mbms tariff time1 mins hours [ time2 mins hours [ time3mins hours [ time4mins hours ] ] ]
[ no ] gtpp mbms tariff
```

- **no**
  - Disables the tariff-based triggers for GTPP MBMS Charging Data Record (G-MBMS-CDR) generation.

```
tariff time1 mins hours [ time2 mins hours [ time3mins hours [ time4mins hours ] ] ]
```

- **Default:** Disabled
- **Specifies time-of-day time values to close the current statistics container (but not necessarily the accounting record).**

**Important:** The system assumes that the billing system uses the day/date to determine if the statistics container represents an actual tariff period.

For each of the different tariff times, the following parameters must be configured:

- **mins:** The minutes of the hour, an integer value from 0 through 59.
- **hours:** The hour of the day, an integer value from 0 through 23.

**Usage**

Use this command to configure the tariff-time-based triggers for G-MBMS-CDR generation in MBMS user data service.

**Example**

The following command configures the tariff-time-based trigger to generate G-MBMS-CDRs every day at 11 hours and 30 min:

```
gtpp mbms tariff time1 30 11
```
gtp mbms volume

This command configures the download traffic data volume based trigger for GTPP MBMS Charging Data Record (GMBMS-CDR) generation.

Product
GGSN

Privilege
Security Administrator, Administrator

Syntax

gtp mbms volume download_bytes
[ no ] gtp mbms volume

- **no**
  - Disables the configured download traffic data volume based trigger for G- MBMS-CDR generation for MBMs user service data.

- **volume download_bytes**
  - Default: Disabled
  - Specifies the threshold of downlink data volumes that must be met before a G- MBMS-CDR should be closed.
  - `download_bytes` is the total download traffic volume measured in octets and can be configured to any integer value from 100,000 through 4,000,000,000.

Usage
Use this command to configure the traffic data volume (download) based G-MBMS-CDR generation triggers for MBMS user data service.

Example
The following command configures the traffic data volume (download) limit to trigger to generate G-MBMS-CDRs after reaching 150,000 octets:

```
gtp mbms volume download_bytes
```
gtpp redirection-allowed

Configures the system to allow/disallow the redirection of CDRs when the primary CGF is unavailable.

Product
GGSN, SGSN

Privilege
Security Administrator, Administrator

Syntax

[ default | no ] gtpp redirection-allowed

default
Resets the system to allow redirection of CDRs.

no
Removes the redirection definition from the configuration.

Usage
This command allows operators to better handle erratic network links, without having to remove the configuration of the backup server(s) via the no gtpp server command. This functionality is enabled by default.
If the no gtpp redirection-allowed command is executed, the system only sends CDRs to the primary CGF. If that CGF goes down, the system will buffer the CDRs in memory until the CGF comes back or until the system runs out of buffer memory. In addition, if the primary CGF announces its intent to go down (with a GTPP Redirection Request message), the system responds to that request with an error response.

Example
The following command configures the system to allow the redirection of CDRs when the primary CGF is unavailable:

default gtpp redirection-allowed
gtp redirection-disallowed

This command has been obsoleted and is replaced by the gtp redirection-allowed command.
**gtpp server**

Configures the charging gateway function (CGF) accounting server(s) with in GTPP server group that the system is to communicate with.

**Product**

GGSN, SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```bash
gtpp server ip_address [ max msgs ] [ priority priority ] [ udp-port port ] [ node-alive { enable | disable } ] [ -noconfirm ]
```

```bash
no gtpp server ip_address [ udp-port port ]
```

- **ip_address**
  Specifies the IP address of the CGF in dotted decimal notation for IPv4 or colon notation for IPv6.

- **max msgs**
  Default: 256
  Specifies the maximum number of outstanding or unacknowledged GTPP packets (from any one AAA Manager task) allowed for this CGF before the system begins buffering the packets.
  `msgs` can be configured to any integer value from 1 to 256.

- **priority priority**
  Default: 1000
  Specifies the relative priority of this CGF. When multiple CGFs are configured, the priority is used to determine which CGF server to send accounting data to.
  `priority` can be configured to any integer value from 1 to 1000. When configuring two or more servers with the same priority you will be asked to confirm that you want to do this. If you use the `-noconfirm` option, you are not asked for confirmation and multiple servers could be assigned the same priority.

- **udp-port port**
  Default: 3386
  Specifies the UDP port over which the GGSN communicates with the CGF.`port` can be configured to any integer value between 1 and 65535.

- **node-alive { enable | disable }**
  Default: Disable.
  This optional keyword allows operator to enable/disable GGSN to send Node Alive Request to GTPP Server (i.e. CGF). This configuration can be done per GTPP Server basis.
-noconfirm

Indicates that the command is to execute without any additional prompt and confirmation from the user.

Usage

Use this command to configure the CGF(s) that the system sends CDR accounting data to. Multiple CGFs can be configured using multiple instances of this command subject to the following limits:

- Up to 4 CGFs can be configured in one GTPP server group
- Total 32 CGFs can be configured per context.

Each configured CGF can be assigned a priority. The priority is used to determine which server to use for any given subscriber based on the routing algorithm that has been implemented. A CGF with a priority of “1” has the highest priority.

Important: The configuration of multiple CGFs with the same IP address but different port numbers is not supported.

Each CGF can also be configured with the maximum allowable number of unacknowledged GTPP packets. Since multiple AAA Manager tasks could be communicating with the same CGF, the maximum is based on any one AAA Manager instance. If the maximum is reached, the system buffers the packets Random Access Memory (RAM). The system allocates memory as a buffer, enough to store one million CDRs for a fully loaded chassis (a maximum of one outstanding CDR per PDP context).

Example

The following command configures a CGF with an IP address of 192.168.2.2 and a priority of 5.

```
gtp server 192.168.2.2 priority 5
```

The following command deletes a previously configured CGF with an IP address of 100.10.35.7:

```
no gtpp server 100.10.35.7
```
gtpp source-port-validation

This command configures whether the system validates the UDP source port in received GTPP messages.

**Product**
GGSN, SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[no | default] gtpp source-port-validation
```

- **no**
  Validates the IP source address but not the UDP source port.

- **default**
  Restores this parameter to its default setting of enabled.

**Usage**
This command configures whether the system validates the UDP source port in received GTPP messages.

**Example**
The following command disables UDP port validation:

```
no gtpp source-port-validation
```
**gtpp storage-server**

Configures information for the GTPP back-up storage server.

**Product**

GGSN, SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
gtpp storage-server ip_address port port_num
no gtpp storage-server ip_address port port_num
```

- **no**
  Removes a previously configured back-up storage server.

- **ip_address**
  The IP address of the back-up storage server expressed in dotted decimal notation.

- **port port_num**
  Default: 3386
  Specifies the UDP port number over which the GGSN communicates with the back-up storage server.

**Usage**

This command identifies the connection to the GSS. One backup storage server can be configured per GTPP group.

**Example**

The following command configures a GSS with an IP address of 192.168.1.2:

```plaintext
gtpp storage-server 192.168.1.2
```
gtpp storage-server local file

Configures the parameters for GTPP files stored locally on the GTPP storage server.

Product
GGSN, SGSN

Privilege
Security Administrator, Administrator

Syntax

```
gtpp storage-server local file { compression { gzip | none } | format { custom1 | custom2 | custom3 | custom4 | custom5 | custom6 | custom7 | custom8 | } name prefix prefix | purge-processed-files [ purge-interval purge_dur ] | rotation { cdr-count count | time-interval time | volume size } }
```

default gtpp storage-server local file { compression | format | name prefix | purge-processed-files | rotation { cdr-count | time-interval | volume } }

```
no gtpp storage-server local file rotation { purge-processed-files | rotation { cdr-count | time-interval } }
```

no

Removes a previously configured parameters for local storage of CDR files on HDD on SMC card.

```
compression { gzip | none }
```

Configures the type of compression to be used on the files stored locally.

gzip – Enables Gzip file compression.
none – Disables Gzip file compression -this is the default value.

```
format custom1 .. 8
```

Configures the file format to be used to format files to be stored locally.
custom1 – File format custom1 - this is the default file format.
custom2 to custom5 Customer specific CDR file formats.
custom6 – File format custom6 with a block size of 8K for CDR files.
custom7 – File format custom7 is a customer specific CDR file formate.
custom8 – File format custom8 is a customer specific CDR file format. It uses node-id-
suffix_date_time_fixed-length-seq-numu format for file naming where:

- `date` is date in MMDYYYY (01312010) for mat
- `time` is time in HHMMSS (023508) format
- `fixed-length-seq-numu` is the fixed length of sequence number for specific file having 6 digit
  counter starting from 000001 and end to 999999. Once file sequence reached to 999999 the
  sequence will be reset to 000001.

```
name prefix prefix
```

Defines the prefix to be used for the file name. By default the file name prefix would be ‘GTPP-group-name + VPN-ID’.
prefix—Enter a string of 1 to 64 alphanumeric characters.

GTPP Server Group Configuration Mode Commands

gtp storage-server local file

prefix

purge-processed-files [ purge-interval  purge_dur ]
Default: Disabled
Enables the GSN to periodically delete locally processed (*.p) CDR files from the HDD on the SMC card.

Important: This option is available only when GTPP server storage mode is configured for local storage of CDRs with the `gtp storage-server mode local` command.

purge-interval purge_dur provides an option for user to control the purge interval duration in minutes by setting purge_dur.

purge_dur must be an integer from 1 through 259200.
Default: 60 minutes

rotation {cdr-count  count  |  time-interval  time  |  volume  size  }

Specifies rotation related configuration for GTPP files stored locally.

cdr-count count - Configure the CDR count for the file rotation. Enter a value from 1000 to 65000. Default value 10000.

time-interval time - Configure the time interval for file rotation. Enter a value in seconds ranging from 30 to 86400. Default value is 3600 seconds (1 hour).

volume size—Configure the file volume, in MB, for file rotation. Enter a value ranging from 2 to 40. This trigger can not be disabled. Default value is 10MB.

Usage
This command configures the parameters for storage of GTPP packets as files on the local server - meaning the hard disk.

Example
The following command configures rotation for every 1.5 hours for locally stored files.

```
gtp storage-server local file rotation time-interval 5400
```
gtpp storage-server max-retries

Configures the maximum number of times the system attempts to communicate with an unresponsive GTPP back-up storage server.

Product
GGSN, SGSN

Privilege
Security Administrator, Administrator

Syntax

```
gtpp storage-server max-retries max_attempts
```

```
default gtpp storage-server max-retries
```

```
default
Restores the system to the default value of 2 retry attempts.
```

```
max_attempts
Default: 2
Specifies the number of times the system attempts to communicate with a GTPP back-up storage server that is not responding.
```

```
max_attempts can be configured to any integer value from 1 to 15.
```

Usage
This command works in conjunction with the `gtpp storage-server timeout` parameters to set a limit to the number of communication failures that can occur with a configured GTPP back-up storage server. The `gtpp storage-server` timeout command controls the amount of time between re-attempts. Refer to the `gtpp storage-server` timeout command for additional information.

Example
The following command configures the maximum number of re-attempts to be 8.

```
gtpp storage-server max-retries 8
```
gtpp storage-server mode

This command configures storage mode, local or remote, for CDRs. Local storage mode is available with ASR 5000 platforms only.

Product
GGSN, SGSN

Privilege
Security Administrator, Administrator

Syntax

gtpp storage-server mode { local | remote | streaming }

default gtpp storage-server mode

---
default
Returns the GTPP group configuration to the default ‘remote’ value for the GTPP storage server mode.

---
local
Default: Disabled
Specifies the use of the hard disk on the SMC for storing CDRs.

**Important:** This option is available with ASR 5000 platforms only.

---
remote
Specifies the use of an external server for storing CDRs. This is the default value.

**Important:** When the external server is down, the Session Managers will start buffering up to a maximum of 26400 CDRs or a total of 120 MB worth of CDRs, whichever limit reaches first.

---
streaming
Default: Disabled
This keyword allows the operator to configure “streaming” mode of operation for GTPP group. When this keyword is supplied the CDRs will be stored in following fashion:

- When GTPP link is active with CGF, CDRs are sent to a CGF via GTPP and local hard disk is NOT used as long as every record is acknowledged in time.

- If the GTPP connection is considered to be down, all streaming CDRs will be saved temporarily on the local hard disk and once the connection is restored, unacknowledged records will be retrieved from the hard disk and sent to the CGF.

**Important:** This option is available with ASR 5000 platforms only.
gtpp storage-server mode

Usage
This command configures whether the CDRs should be stored on the hard disk of the SMC or remotely, on an external server.

Example
The following command configures use of a hard disk for storing CDRs.

```
gtpp storage-server mode local
```
gtpp storage-server timeout

Configures the amount of time that must pass with no response before the system re-attempts to communicate with the GTPP back-up storage server.

Product
GGSN, SGSN

Privilege
Security Administrator, Administrator

Syntax

**gtpp storage-server timeout** *duration*

**default gtpp storage-server timeout**

- **default**
  Restores the timeout duration to the 30-second default.

- **duration**
  Default: 30
  Specifies the maximum amount of time the system waits for a response from the GTPP back-up storage server before assuming the packet is lost.
  *duration* is measured in seconds and can be configured to any integer value from 30 to 120.

Usage
This command works in conjunction with the **gtpp storage-server max-retries** command to establish a limit on the number of times that communication with a GTPP back-up storage server is attempted before a failure is logged.
This parameter specifies the time between retries.

Example
The following command configures a retry timeout of 60 seconds:

```
gtpp storage-server timeout 60
```
gtpp suppress-cdrs zero-volume-and-duration

This command suppresses the CDRs created by session having zero duration and/or zero volume. By default this mode is 'disabled'.

**Product**

GGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

- `gtpp suppress-cdrs zero-volume-and-duration { gcdrs [ egcdrs ] | egcdrs [ gcdrs ] }`

**Usage**

Use this command to suppress the CDRs (G-CDRs and eG-CDRs) which were created due with zero-duration session and zero-volume session due to any reason. By default this command is disabled and system will not suppress any CDR.

**Example**

The following command configures the system to suppression the eG-CDRs created for a zero duration session or zero volume session:

- `gtpp suppress-cdrs zero-volume-and-duration egcdrs gcdrs`
gtpp timeout

Configures the amount of time that must pass with no response before the system re-attempts to communicate with the CGF.

**Product**
GGSN, SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
gtpp timeout time
```

default gtpp timeout

default
Resets the systems GTPP timeout value to 20 seconds.

time
Default: 20
Specifies the maximum amount of time the system waits for a response from the CGF before assuming the packet is lost.
time is measured in seconds and can be configured to any integer value from 1 to 60.

**Usage**
This command works in conjunction with the `gtpp max-retries` command to establish a limit on the number of times that communication with a CGF is attempted before a failure is logged. This parameter specifies the time between retries.

**Example**
The following command configures a retry timeout of 30 seconds:

```
gtpp timeout 30
```
gtpp trigger

This command disables GTPP trigger conditions that cause either partial CDR record closure or opening of a new CDR record container. GTPP Triggers are specified in 3GPP TS 32.251 v6.6.0. All GTPP trigger changes take affect immediately, except `volume-limit`.

Product
ECS, GGSN, SGSN

Privilege
Security Administrator, Administrator

Syntax

```
```

default gtpp trigger

```
default
Sets the specified trigger condition back to the default setting. All trigger conditions are enabled by default.

no
Re-enables the specified trigger condition.
```

cell-update
Enables the cell update trigger for S-CDRs, if the dictionary specified in the `gtpp dictionary` configuration includes support for cell update. This trigger is available only for 2G. Currently, custom18 dictionary supports the cell update trigger.

direct-tunnel
Enables the direct tunnel trigger for CDRs.

egcdr max-losdv
Default: Disabled
Enables the trigger for an eG-CDR if the List of Service Data Volume (LoSDV) containers crosses the configured limit for LOSDV containers.

inter-plmn-sgsn-change
This keyword is for GGSN only.
Default: Enabled
Disabling this trigger ignores an Inter-PLMN SGSN change and doesn't release a G-CDR.

ms-timezone-change
This keyword is specific to GGSN.
Default: Enabled
No partial record closure for a time zone change occurs when this trigger is disabled. MS Time zone change should be applicable only for 3GPP R6 based GTPP dictionaries.

**plmn-id-change**

This trigger keyword is specific to the 2G SGSN and is proprietary (non-standard).

Default: Disabled

Enables the PLMNID change trigger for S-CDRs if the dictionary specified in the GTPP dictionary configuration supports the PLMNID change. If enabled, the SGSN generates a partial S-CDR when the MS changes the PLMN while under the same SGSN (intra-system intra-SGSN PLMN-ID handover). Currently, custom18 dictionary supports this trigger.

**qos-change**

Default: Enabled

Enables the QoS-change trigger for CDRs. Disabling this trigger ignores a QoS-change and does not open a new CDR for it.

**rat-change**

Default: Enabled

This keyword enable/disable the partial record closure for a RAT change. If disabled no partial record closure for a RAT change occurs. RAT change should be applicable only for 3GPP R6 based GTPP dictionaries. In SGSN, RAT change trigger (2G<>3G) means inter-service handoff (SGSN service <-> GPRS service). If this trigger is enabled, after the RAT change interim CDR is generated. After this RAT change CDR, CDR thresholds such as volume/time etc. and GTPP Group are applicable from new service. If RAT change trigger is disabled, the CDR thresholds and GTPP group etc. will not change and will continue to use from old service.

After the RAT change the **System Type** field in CDR changes to indicate the new system type. If this trigger is disabled then the next CDR generated will indicate **System Type** but the data count in the CDR does not necessarily belong to the system type indicated in CDR instead it may belong to both 2G and 3G as CDR is not closing when handover takes place.

**Important:** However **System Type** field in CDR related change is not applicable to customized CDR formats which does not use **System Type** field

**routing-area-update**

Enables the routing-area-update trigger for CDRs.

**sgsn-change-limit [ also-intra-sgsn-multiple-address-group-change ]**

This keyword is for GGSN only.

Default: Enabled

Disabling this trigger ignores an SGSN change and does not add the SGSN IP address into the SGSN address list of the CDR. This helps to reduce the release of CDRs due to SGSN changes crossing the configured limit.

also-intra-sgsn-multiple-address-group-change : This keyword includes Intra-SGSN group changes as an SGSN change.

**tariff-time-change**

Default: Enabled

When this trigger is disabled container closure does not happen for a tariff-time change. This trigger is applicable for G-MB-CDRs for MBMS session too.
**time-limit**
Default: Enabled
When this trigger is disabled no partial record closure occurs when the configured time limit is reached.
This trigger is applicable for G-MB-CDRs for MBMS session too.

**volume-limit**
Default: Enabled
When this trigger is disabled no partial record closure occurs when volume limit is reached.
This trigger is applicable for G-MB-CDRs for MBMS session too.

**Usage**
Use this command to disable or re-enable GTTP triggers that can cause partial CDR record closure or cause a new CDR to be created.

**Example**
The following command disables partial record closure when a configured time limit is reached:

```
gtp trigger time-limit
```

The following command re-enables partial record closure when a configured time limit is reached:

```
no gtp trigger time-limit
```
**gtpp transport-layer**

This command selects the transport layer protocol for Ga interface for communication between AGW (GSNs) and GTPP servers.

**Product**
GGSN, SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
gtpp transport-layer { tcp | udp }
default gtpp transport-layer
```

**default**
Resets the transport layer protocol to GTPP servers to the default UDP.

**tcp**
Default: Disabled
Enables the system to implement TCP as transport layer protocol for communication with GTPP server.

**udp**
Default: Enabled
Enables the system to implement UDP as transport layer protocol for communication with GTPP server.

**Usage**
Use this command to select the TCP or UDP as the transport layer protocol for Ga interface communication between GTPP servers and AGWs (GSNs).

**Example**
The following command enables TCP as the transport layer protocol for the GSN’s Ga interface.

```
gtpp transport-layer tcp
```
The GTP-U Service Configuration Mode is used to manage parameters applied to incoming GTP-U packets.
bind

Configures the IP address to use for GTP-U data packets.

Product
GGSN, P-GW, S-GW

Privilege
Administrator

Syntax

[ no ] bind { ipv4-address ipv4_address [ ipv6-address ipv6_address ] | ipv6-address ipv6_address [ ipv4-address ipv4_address ] }

[ no ] bind { ipv4-address ipv4_address [ ipv6-address ipv6_address ] | ipv6-address ipv6_address [ ipv4-address ipv4_address ] }

no

removes a configured IP address from this service.

bind { ipv4-address ipv4_address [ ipv6-address ipv6_address ] | ipv6-address ipv6_address [ ipv4-address ipv4_address ] }

Binds the service to an interface with an IPv4 address, IPv6 address or both.

ipv4-address ipv4_address [ ipv6-address ipv6_address ]: Binds this service to the IPv4 address of a configured interface. Optionally, bind the service to a configured interface with an IPv6 address. ipv4_address must be entered as a standard IPv4 address in dotted decimal notation.

ipv6-address ipv6_address: Binds this service to the IPv6 address of a configured interface. Optionally, bind the service to a configured interface with an IPv4 address. ipv6_address must be entered as a standard IPv6 address in colon-separated notation.

ipv4-address ipv4_address [ ipv4-address ipv4_address ]: Binds this service to the IPv4 address of a configured interface. Optionally, bind the service to a configured interface with an IPv4 address. ipv4_address must be entered as a standard IPv4 address in dotted decimal notation.

ipv4-address ipv4_address [ ipv4-address ipv4_address ]: Binds this service to the IPv4 address of a configured interface. Optionally, bind the service to a configured interface with an IPv4 address. ipv4_address must be entered as a standard IPv4 address in dotted decimal notation.

Usage

Use this command to bind the service to an interface for sending/receiving GTP-U packets.

Example

The following command configures the IPv4 address for this GTP-U service as 1.2.3.4:

bind ipv4-address 1.2.3.4
**echo-interval**

Configures the rate at which GPRS Tunneling Protocol (GTP) v1-U echo packets are sent.

**Product**
GGSN, P-GW, S-GW

**Privilege**
Administrator

**Syntax**

```
echo-interval seconds
[ default | no ] echo-interval
```

- **default**
  Returns the command to its default setting of disabled.

- **no**
  Removes the configured echo-interval setting.

- **seconds**
  Specifies the number of seconds between the sending of a GTP-Uv1 echo packet. *seconds* must be an integer value from 60 to 3600.

**Usage**
Use this command to configure the rate at which GTP-Uv1 echo packets are sent.

**Example**
The following command sets the rate between the sending of echo packets at 120 seconds:

```
echo-interval 120
```
end

Exits the current mode and returns to the Exec Mode.

**Product**
All

**Privilege**
Administrator

**Syntax**

```
end
```

**Usage**

Change the mode back to the Exec mode.
exit

Exits the current mode and returns to the previous mode.

Product
All

Privilege
Administrator

Syntax

```
exit
```

Usage

Return to the previous mode.
extension-header

Configures the addition of an extension header in the GTP-U packet header, allowing for error indication messages.

Product
GGSN, P-GW, S-GW

Privilege
Administrator

Syntax

[ default | no ] extention-header source-udp-port

default
Returns the command to its default setting of disabled.

no
Disables the feature.

source-udp-port
Configures extension header type UDP Port support in GTP-U header for GTP-U Error Indication messages.

Usage

Example
The following command enables the inclusion of an extension header to allow for error indication messages:

extension-header source-udp-port
max-retransmissions

Configures the maximum retry limit for GTP-U echo retransmissions.

Product
GGSN, P-GW, S-GW

Privilege
Administrator

Syntax

```
max-retransmissions num

no max-retransmissions
```

```
no
Disables the feature.
```

```
num
Default: 4
Specifies the number of GTP-U echo message retransmissions allowed before triggering a path failure error condition. num must be an integer value from 0 to 15.
```

Usage
Use this command to set the maximum number of GTP-U echo message retransmissions in order to define a limit that triggers a path failure error.

Example
The following command sets the maximum GTP-U echo message retransmissions for this service to 10:

```
max-retransmissions 10
```
### path-failure detection-policy

Configures a path failure detection policy on GTP-U echo messages that have been retransmitted the maximum number of retry times.

**Product**

GGSN, P-GW, S-GW

**Privilege**

Administrator

**Syntax**

```plaintext
path-failure detection-policy gtp echo
[ default | no ] path-failure detection-policy
```

- **default**
  
  Resets the command to its default setting of enabled.

- **no**
  
  Disables the feature.

- **gtp echo**
  
  Sets the detection policy to detect a failure upon reaching the maximum number of GTP-U echo message retransmissions.

**Usage**

Use this command to set the detection policy for path failures.

**Example**

The following command sets the path failure detection policy to detect failures upon reaching the maximum number of GTP-U echo message retries:

```plaintext
path-failure detection-policy gtp echo
```
retransmission-timeout

Configures retransmission timeout for GTPU echo message retransmissions for this service.

**Product**
GGSN, P-GW, S-GW

**Privilege**
Administrator

**Syntax**

```
retransmission-timeout seconds
```

default retransmission-timeout

**Usage**
Use this command to set the number of seconds between the retransmission of GTP-U echo messages.

**Example**
The following command sets the number of seconds between the sending of GTP-U echo messages to 7:

```
retransmission-timeout 7
```
Chapter 113
HA Proxy DNS Configuration Mode Commands

The HA Proxy DNS Configuration Mode is used to create rules for HA proxy DNS intercept lists that redirect packets with unknown foreign DNS addresses to a home network DNS server.

**Important:** HA Proxy DNS Intercept is a license-enabled feature.

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the HA Proxy DNS Configuration Mode and returns to the Exec Mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.
exit

Exits the HA Proxy DNS Configuration Mode and returns to the Context Configuration Mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the Context Configuration Mode.
pass-thru

Sets IP addresses that should be allowed through the proxy DNS intercept feature.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] pass-thru ip_address [ /ip_mask ]
```

- **no**
  Removes the DNS IP address from the pass-thru rule.

- **pass-thru ip_address [ /ip_mask ]**
  Specifies an DNS IP address that is allowed through the intercept feature.
  *ip_address[/ip_mask]*: Specifies the IP address and network mask bits. *ip_address[/ip_mask]* is specified using the standard IPv4 or IPv6 dotted decimal notation and the mask bits are a numeric value which is the number of bits in the subnet mask (x.x.x.x/x).

**Usage**

Use this command to identify DNS IP addresses that should be allowed through the intercept feature. For a more detailed explanation of the proxy DNS intercept feature, see the `proxy-dns intercept-list` command in the Context Configuration Mode Commands chapter. A maximum of 16 intercept rules (either `redirect` or `pass-thru`) are allow for each intercept list.

**Important**: To allow packets through that do not match either the `pass-thru` or `redirect` rules, set a `pass-thru` rule address as: 0.0.0.0/0. If a packet does not match either the `pass-thru` or `redirect` rule, the packet is dropped.

**Example**
The following command allows a foreign network’s DNS with an IP address of 12.3.456.789 to avoid being redirected:

```
pass-thru 12.3.456.789
```
redirect

DNS IP addresses from foreign networks matching an IP address in this command are redirected to a home network DNS.

Product
HA

Privilege
Security Administrator, Administrator

Syntax

[ no ] redirect any [ primary-dns ip_address [ secondary-dns ip_address ] ]

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
</table>
| Removes the DNS IP address from the redirect rule.

<table>
<thead>
<tr>
<th>primary-dns ip_address</th>
</tr>
</thead>
</table>
| Specifies the IP address of the primary home network DNS. ip_address is specified using the standard IPv4 or IPv6 dotted decimal notation.

<table>
<thead>
<tr>
<th>secondary-dns ip_address</th>
</tr>
</thead>
</table>
| Specifies the IP address of the secondary home network DNS. ip_address is specified using the standard IPv4 or IPv6 dotted decimal notation.

Usage

Use this command to identify DNS IP addresses from foreign networks that are to be redirected to the home DNS. For a more detailed explanation of the Proxy DNS feature, see the proxy-dns intercept-list command in the Context Configuration Mode Commands chapter. A maximum of 16 intercept rules (either redirect or pass-thru) are allow for each intercept list.

Since this command is configured in the source context, the destination context containing the path to the home network DNS is identified using the Context Configuration Mode command ip dns-proxy source-address.

**Important:** If a packet does not match the pass-thru or redirect rule, the packet is dropped. If primary-dns or secondary-dns is not configured, DNS messages are redirected to the primary-dns-server (or the secondary-dns-server) configured for the subscriber OR inside the context.

The following command identifies a foreign network DNS with an IP address of 1.23.456.789 and redirects it to a primary home network DNS with an IP address of 1.98.765.432:

redirect 1.23.456.789 primary-dns 1.98.765.432.
Chapter 114
HA Service Configuration Mode Commands

The Home Agent Service Configuration Mode is used to create and manage the Home Agent (HA) services associated with the current context.
aaa

Configures the sending of subscriber session AAA accounting by the HA service.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
aaa { accounting | group string }

   { accounting | group }
```

**no**
Disables AAA accounting for the HA service.

**accounting**

**accounting** Enables the sending of AAA accounting information for subscriber sessions by the Home Agent (HA), by default is enabled.

**group**

**group** configures aaa group for ha-service. **group** has lower priority than subscriber/apn config.

**Usage**

Enabling the HA service will send all accounting data (start, stop, and interim) to the configured AAA servers.
The chassis is shipped from the factory with the AAA accounting enabled.

**Important:** In order for this command to function properly, AAA accounting must be enabled for the context in which the HA service is configured using the `aaa accounting subscriber radius` command.

**Example**
The following command disables aaa accounting for the HA service:

```
no aaa accounting
```
authentication

Configures authentication parameters for a specific HA service of a specific context.

Product
HA, ASN-GW

Privilege
Security Administrator, Administrator

Syntax

```
authentication { aaa-distributed-mip-keys [ disabled | optional | required ] | dmu-refresh-key | imsi-auth | mn-aaa { allow-noauth | always | dereg-noauth | noauth | renew-reg-noauth | renew-and-dereg-noauth } | mn-ha { allow-noauth | always } | pmip-auth | stale-key-disconnect }
```

```
no authentication { imsi-auth | pmip-auth }
```

```
default authentication { aaa-distributed-mip-keys | dmu-refresh-key | imsi-auth | mn-aaa | mn-ha | pmip-auth | stale-key-disconnect }
```

```
no
```

Disable the parameter.

```
default
```

Reset the specified option to its default setting.

```
aaa-distributed-mip-keys [ disabled | optional | required ]
```

Configures use of AAA distributed MIP keys for authenticating RRQ for WiMAX HA calls. Default is disabled.

**disabled**: Disables using AAA distributed WiMAX MIP keys for authenticating MIP RRQ.

**optional**: Use AAA distributed WiMAX MIP keys for authenticating RRQ with fallback option to use static/3GPP2 based MIP keys.

**required**: AAA distributed WiMAX MIP keys for authenticating MIP RRQ are mandatory

```
dmu-refresh-key
```

Typically, when a DMU resets then the next MIP re-registration causes MN-HA authorization failure and the HA rejects the MIP RRQ. This parameter enables the HA to retrieve the MN-HA key again from the AAA during the call and to use the freshly retrieved key value to recheck authentication. Default is disabled.

```
imsi-auth
```

Enable uses the IMSI to determine if MN-AAA or MN-FAC extensions are not present in the RRQ. Default is disabled.
**mn-aaa { allow-noauth | always | dereg-noauth | noauth | renew-reg-noauth | renew-and-dereg-noauth }**

Specifies how mobile node-to-AAA authentication extension in registration requests from the mobile node should be handled by the HA service.

Default is always.

- **allow-noauth**: Specifies that the HA service does not require authentication for every mobile node registration request. However, if the mn-aaa extension is received, the HA service will authenticate it.
- **always**: Specifies that the HA service will perform authentication each time a mobile node registers.
- **dereg-noauth**: Enables authentication request upon de-registration.
- **noauth**: Specifies that the HA service will not look for mn-aaa extension and will not authenticate it.
- **renew-reg-noauth**: Specifies that the HA service will not perform authentication for mobile node re-registrations. Initial registration and de-registration will be handled normally.
- **renew-and-dereg-noauth**: Enables authentication request upon re-registration and de-registration.

---

**mn-ha { allow-noauth | always }**

Specifies whether the HA service looks for an MN-HA authentication extension in the RRQ.

Default is always.

- **allow-noauth**: Allows a request that does not contain the auth extension.
- **always**: A request should always contain the auth extension to be accepted.

---

**pmip-auth**

Specifies whether the HA service looks for an MN-HA authentication extension in the RRQ.

Default is always.

- **allow-noauth**: Allows a request that does not contain the auth extension.
- **always**: A request should always contain the auth extension to be accepted.

---

**stale-key-disconnect**

If MN-HA auth fails for MIP renew and dereg, disconnects the call immediately.

Disabled by default.

---

**Usage**

The authentication command, combined with a keyword, can be used to specify how the system will perform authentication of registration request messages.

---

**Example**

The following command configures the HA service to always perform mobile node authentication for every registration request.

```
authentication mn-aaa always
```

The following command configures the HA service to always look for an MN-HA authentication extension in the RRQ.

```
authentication mn-ha always
```
bind

Binds the HA service to a logical IP interface serving as the Pi interface and specifies the maximum number of subscribers that can access this service over the interface.

Product
HA

Privilege
Security Administrator, Administrator

Syntax

```
bind address address [max-subscribers count]

no bind address
```

---

`address`

Specifies the IP address (address) of the interface configured as the Pi interface. address is specified in dotted decimal notation.

`max-subscribers count`

Default: 500000

Specifies the maximum number of subscribers that can access this service on this interface.

`count` can be configured to any integer value between 0 and 4,000,000.

---

**Important:** The maximum number of subscribers supported is dependant on the license key installed and the number of active PACs/PSCs installed in the system. A fully loaded system with 13 active PACs/PSCs can support 1,000,000 total subscribers. Refer to the license key command for additional information.

---

**Usage**

Associate the HA service to a specific logical IP address. The logical IP address or interface takes on the characteristics of an Pi interface. Only one interface can be bound to a service. The interface should be configured prior to issuing this command.

This command also sets a limit as to the number of simultaneous subscribers sessions that can be facilitated by the service/interface at any given time.

When configuring the `max-subscribers` option, be sure to consider the following:

- The total number of interfaces that you will configuring for use as Pi interfaces
- The maximum number of subscriber sessions that all of these interfaces may handle during peak busy hours
- The average bandwidth for each of the sessions
- The type of physical port (10/100Base-T or 1000Base-Tx) that these interfaces will be bound to

Taking these factors into account and distributing your subscriber session across all available interfaces will allow you to configure your interfaces to optimally handle sessions without degraded performance.

Use the `no bind address` command to delete a previously configured binding.
Example
The following command would bind the logical IP interface with the address of 192.168.3.1 to the HA service and specifies that a maximum of 600 simultaneous subscriber sessions can be facilitated by the interface/service at any given time.

```
bind address 192.168.3.1 max-subscribers 600
```

The following command disables a binding that was previously configured:

```
no bind address
```
default subscriber

Specifies the name of a subscriber profile configured within the same context as the HA service from which to base the handling of all other subscriber sessions handled by the HA service.

Product
HA
Privilege
Security Administrator, Administrator
Syntax

```plaintext
default subscriber profile_name
no default subscriber profile_name
```

`profile_name`
Specifies the name of the configured subscriber profile. `profile_name` can be between 1 and 127 alpha and/or number characters and is case sensitive.

Usage
Each subscriber profile specifies “rules” such as permissions, PPP settings, and timeout values. By default, the HA service will use the information configured for the subscriber named default within the same context. This command allows for multiple HA services within the same context to apply different “rules” to sessions they process. Each set of rules can be configured under a different subscriber name which is pointed to by this command.

Use the `no default subscriber profile_name` command to delete the configured default subscriber.

Example
To configure the HA service to apply the rules configured for a subscriber named `user1` to every other subscriber session it processes, enter the following command:

```plaintext
default subscriber user1
```
encapsulation allow gre

Enables or disables the use of Generic Routing Encapsulation (GRE) when establishing a MIP (Mobile IP) session with an FA. When enabled, if requested by the FA, GRE encapsulation is used when establishing a Mobile IP (MIP) session. If disabled, when an FA requests GRE encapsulation, the HA denies the request.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
encapsulation allow { gre | keyless-gre }
no encapsulation allow { gre | keyless-gre }
```

**gre**
Default: Enabled.
Configures the use of GRE in Mobile IP session with an FA.

**keyless-gre**
Default: Disabled.
Configures the GRE without key encapsulation in Mobile IP session with an FA.

**Usage**
Use to disable or re-enable the use of GRE encapsulation or Key-less encapsulation for MIP sessions.
In case of chassis HA operating with other vendor equipment, which does not support the 3GPP2 to exchange key, this command with `keyless-gre` keyword will make the chassis HA to accept MIP data with legacy GRE.

**Example**
To disable GRE encapsulation for MIP sessions, enter the following command:
```
no encapsulation allow gre
```
To re-enable GRE encapsulation for MIP sessions, enter the following command:
```
encapsulation allow gre
```
To enable Key-less GRE encapsulation for MIP sessions, enter the following command:
```
encapsulation allow keyless-gre
```
end

Exits the HA service configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Change the mode back to the Exec mode.
**exit**

Exits the HA service configuration mode and returns to the context configuration mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the context configuration mode.
fa-ha-spi

Configures the security parameter index (SPI) between the HA service and the FA.

Product
HA

Privilege
Security Administrator, Administrator

Syntax

```
fa-ha-spi remote-address fa_ip_address spi-number number { encrypted secret
enc_secret | secret secret } [ description string ] [ hash-algorithm { hmac-md5 |
md5 | rfc2002-md5 } ] [ replay-protection { timestamp | timestamp-tolerance
tolerance || nonce } ] +
no fa-ha-spi remote-address ha_ip_address spi-number number
```

remote-address fa_ip_address

Specifies the IP address of the FA. fa_ip_address is an IP address or an IP address and mask expressed in dotted decimal notation.

**Important:** The system supports unlimited peer FA addresses per HA but only maintains statistics for a maximum of 8192 peer FAs. If more than 8192 FAs are attached, older statistics are identified and overwritten.

**spi-number number**

Specifies the SPI (number) which indicates a security context between the FA and the HA in accordance with RFC 2002.

number can be configured to any integer value between 256 and 4294967295.

**encrypted secret enc_secret | secret secret**

Configures the shared-secret between the HA service and the FA. The secret can be either encrypted or non-encrypted.

**encrypted secret enc_secret:** Specifies the encrypted shared key (enc_secret) between the HA service and the FA. enc_secret must be between 1 and 254 alpha and/or numeric characters and is case sensitive.

**secret secret:** Specifies the shared key (secret) between the HA service and the FA. secret must be between 1 and 127 alpha and/or numeric characters and is case sensitive.

The `encrypted` keyword is intended only for use by the chassis while saving configuration scripts. The system displays the `encrypted` keyword in the configuration file as a flag that the variable following the `secret` keyword is the encrypted version of the plain text secret key. Only the encrypted secret key is saved as part of the configuration file.

**description string**

This is a description for the SPI. string must be an alpha and or numeric string of from 1 through 31 characters.

**hash-algorithm { hmac-md5 | md5 | rfc2002-md5 }**

Default: hmac-md5
Specifies the hash-algorithm used between the HA service and the FA.

**hmac-md5**: Configures the hash-algorithm to implement HMAC-MD5 per RFC 2002bis.

**md5**: Configures the hash-algorithm to implement MD5 per RFC 1321.

**rfc2002-md5**: Configures the hash-algorithm to implement keyed-MD5 per RFC 2002.

```
replay-protection { timestamp [timestamp-tolerance tolerance] | nonce }
```

Specifies the replay-protection scheme that should be implemented by the FA service for this SPI.

- **nonce**: Configures replay protection to be implemented using NONCE per RFC 2002.
- **timestamp**: Configures replay protection to be implemented using timestamps per RFC 2002.
- **timestamp-tolerance**: Specifies the allowable difference (tolerance) in timestamps that is acceptable. If the difference is exceeded, then the session will be rejected. **tolerance** is measured in seconds and can be configured to any integer value between 1 and 65535. The default is 60.

```
traffic-group grp_num
```

The traffic-group attribute is meant to tag the remote FA so that traffic policy can be enforced according to the traffic-group value. This attribute can be used by ECS to handle subscriber traffic coming from FAs with a specified traffic group differently.

**Note**: the functionality controlled by this keyword is only available if a License for Content Access Control has been purchased and enabled.

**grp_num** must be an integer from 1 through 255.

More than one of the above keywords can be entered within a single command.

### Usage

An SPI is a security mechanism configured and shared by the HA service and the FA. Please refer to RFC 2002 for additional information.

Though it is possible for FAs and HAs to communicate without SPIs being configured, the use of them is recommended for security purposes. It is also recommended that a "default" SPI with a remote address of 0.0.0.0/0 be configured on both the HA and FA to prevent hackers from spoofing addresses.

**Important**: The SPI configuration on the HA must match the SPI configuration for the FA service on the system in order for the two devices to communicate properly.

A maximum of 2048 SPIs can be configured per HA service.

Use the **no** version of this command to delete a previously configured SPI.

**Example**

The following command configures the FA service to use an SPI of 512 when communicating with an HA with the IP address 192.168.0.2. The key that would be shared between the HA and the FA service is q397F65. When communicating with this HA, the FA service will also be configured to use the rfc2002-md5 hash-algorithm.

```
fa-ha-spi remote-address 192.168.0.2 spi-number 512 secret q397F65 hash-algorithm rfc2002-md5
```

The following command deletes the configured SPI of 400 for an HA with an IP address of 172.100.3.200:

```
no fa-ha-spi remote-address 172.100.3.200 spi-number 400
```
# gre

Configures Generic Routing Encapsulation (GRE) parameters.

## Syntax

```
gre { checksum | checksum-verify | reorder-timeout timeout | sequence-mode { none | reorder | sequence-numbers } }
```

```
no gre { checksum | checksum-verify | sequence-numbers }
```

Disables the specified functionality.

## Options

### checksum

Default: disabled

Enables the introduction of the checksum field in outgoing GRE packets.

### checksum-verify

Default: disabled

Enables verification of the GRE checksum (if present) in incoming GRE packets.

### reorder-timeout timeout

Default: 100

Configures maximum number of milliseconds to wait before processing reordered out-of-sequence GRE packets. `timeout` must be an integer from 0 through 5000.

### sequence-mode { none | reorder }

Default: none

Configures how incoming out-of-sequence GRE packets should be handled.

- **none**: Disables reordering of incoming out-of-sequence GRE packets.
- **reorder**: Enables reordering of incoming out-of-sequence GRE packets.

### sequence-numbers

Default: Disabled

Enables the insertion of sequence numbers into the GRE packets.

## Usage

Use this command to configure how the HA service handles GRE packets.

## Example

To set maximum number of milliseconds to wait before processing reordered out-of-sequence GRE packets to 500 milliseconds, enter the following command:
gre reorder-timeout 500
To enable the reordering of incoming out of sequence GRE packets, enter the following command:
gre sequence-mode reorder
To enable the insertion or removal of GRE sequence numbers in GRE packets, enter the following command:
gre sequence-numbers
idle-timeout-mode

Configures the method the HA service uses to determine when to reset a session idle timer.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**
```
idle-timeout-mode {aggressive|handoff|normal} [upstream-only]
default idle-timeout-mode
```

**Default**
Reset the idle timeout mode to the default settings.
Defaults: aggressive, upstream-only is disabled.

**aggressive**
The session idle timer is reset only when MIP user data is detected. This is the default behavior.

**handoff**
The session idle timer is reset when MIP user data is detected and when an inter-Access Gateway/FA handoff occurs.

**normal**
The session idle timer is reset when MIP user data is detected and when any MIP control signaling occurs.

**upstream-only**
Only upstream user data (data from the mobile node) resets the idle timer for the session. This is disabled by default.

**Usage**
Use this command to set how the current HA service resets the idle timer for a session.

**Example**
To reset the idle timer whenever user data is detected or whenever an inter-Access Gateway/FA occurs, use the following command:
```
idle-timeout-mode handoff
```
**ip context-name**

Specifies name of the destination context to be applied to the subscribers; this would take precedence over the same in subscriber configuration and RADIUS return attributes.

This new configuration overrides the local subscriber configuration as well as the return attributes sent by RADIUS. All calls coming to this HA service are assigned this particular destination context and IP address is allocated from the specified IP pool or group that is configured in the context specified in the service.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
   ip context-name name
```

- **name**
  Specifies the name of the context to assign the subscriber to once authenticated. name must be from 1 to 79 alpha and/or numeric characters.

- **no**
  Removes the current assigned context from the subscriber’s data. Set the name of the destination context to be applied to the subscribers.

**Example**

```
ip context-name sampleName
no ip context-name sampleName
```
ip local-port

Configures the local User Datagram Protocol (UDP) port for the Pi interfaces’ IP socket on which to listen for MOibile IP Registration messages.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
ip local-port number
```

*number*

Specifies the UDP port number.
*number* can be any integer value between 1 and 65535.

**Usage**
Specify the UDP port that should be used for communications between the FA service and the HA. The chassis is shipped from the factory with the local port set to 434.

**Example**
The following command specifies a UDP port of 3950 for the HA service to use to communicate with the HA on the Pi interface:
```
ip local-port 3950
```
**ip pool**

Specifies name of the IP address pool or group to use for subscriber IP address allocation; this takes precedence over the same in subscriber configuration and RADIUS return attributes.

This new configuration overrides the local subscriber configuration as well as the return attributes sent by RADIUS. All calls coming to this HA service are assigned this particular destination context and IP address is allocated from the specified IP pool or group that is configured in the context specified in the service.

**Syntax**

```
ip pool name
```

**name**

Specifies the logical name of the IP address pool. *name* must be from 1 to 31 alpha and/or numeric characters.

**no**

Indicates the IP address pool specified is to be removed from the current context’s configuration or disable the specified option for an IP pool.

**Usage**

Define a pool of IP addresses for the context to use in assigning IPs for this service.

**Example**

```
ip pool pool1
no ip pool pool1
```
isakmp

Configures the crypto map for a peer HA and configures the default crypto map for the FA service.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```bash
isakmp { peer-fa fa_address | skew-lifetime time | aaa-context context_name }
```

**no**

Deletes the reference to the crypto map for the specified HA, deletes the reference for the default crypto map, resets the skew-lifetime to the default, or resets the aaa-context to the default.

**peer-fa fa_address {crypto map map_name [[ encrypted ] secret secret ]}**

Configures a crypto map for a peer FA.

- `fa_address`: IP address of the peer FA to which this IPSEC SA will be established.
- `crypto map map_name`: The name of a crypto map configured in the same context that defines the IPSec tunnel properties. `map_name` is the name of the crypto map and can be from 1 to 63 alpha and/or numeric characters.
- `encrypted`: This keyword is intended only for use by the chassis while saving configuration scripts. The system displays the `encrypted` keyword in the configuration file as a flag that the variable following the `secret` keyword is the encrypted version of the plain text secret key. Only the encrypted secret key is saved as part of the configuration file.
- `secret secret`: The pre-shared secret that will be used during the IKE negotiation. `secret` is the secret string and can be from 1 to 127 alpha and/or numeric characters.

**skew-lifetime time**

Default: 10 seconds

Configures the IKE pre-shared key’s time skew.

`time` is the amount of time the IKE S key fetched from AAA is considered valid after the key has expired. It is measured in seconds and can be configured to any integer value from 1 to 65534.

**aaa-context context_name**

Default: The context in which the service is configured

Configures the name of the context on the system in which AAA functionality is performed. `context_name` is the name of the context through which the HA service accesses the HAAA server to fetch the IKE S Key and S Lifetime parameters. The name must be from 1 to 63 alpha and/or numeric characters and is case sensitive.

**Usage**

Use this command to configure the FA-service’s per-HA IPSec parameters. These dictate how the HA service is to establish an IPSec SA with the specified FA.
**Important:** For maximum security, it is recommended that the above command be executed for every possible FA that the HA service communicates with.

Note that once an IPSec tunnel is established between the FA and HA for a particular subscriber, all new Mobile IP sessions using the same FA and HA are passed over the tunnel regardless of whether or not IPSec is supported for the new subscriber sessions. Data for existing Mobile IP sessions is unaffected.

**Example**
The following command creates a reference for an HA with the IP address 1.2.3.4 to a crypto map named map1:

```
isakmp peer-fa 1.2.3.4 crypto-map map1
```

The following command deletes the crypto map reference for the HA with the IP address 1.2.3.4.

```
o isakmp peer-fa 1.2.3.4
```

The following command sets the time an S key can used after the S lifetime expires to 120 seconds.

```
isakmp skew-lifetime 120
```

The following command creates the default reference for an HA to a crypto map named `map1`, where peer address is unknown:

```
isakmp default crypto-map map1
```
mn-ha-spi

Configures the security parameter index (SPI) between the HA service and the mobile node.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
mn-ha-spi  spi-number number[description string][encrypted secret
enc_secret|secret secret][hash-algorithm { hmac-md5|md5|rfc2002-md5}][
permit-any-hash-algorithm][replay-protection {nonce|timestamp}][
timestamp-tolerance tolerance]
```

```
no mn-ha-spi  spi-number number
```

**spi-number number**

Specifies the SPI (number) which indicates a security context between the mobile node and the HA service in accordance with RFC 2002. number can be configured to any integer value between 256 and 4294967295.

**description string**

This is a description for the SPI. string must be an alpha and or numeric string of from 1 through 31 characters.

**encrypted secret enc_secret | secret secret**

Configures the shared-secret between the HA service and the mobile node. The secret can be either encrypted or non-encrypted.

**encrypted secret enc_secret:** Specifies the encrypted shared key (enc_secret) between the HA service and the mobile node. enc_secret must be be between 1 and 254 alpha and/or numeric characters and is case sensitive.

**secret secret:** Specifies the shared key (secret) between the HA service and the mobile node. secret must be between 1 and 127 alpha and/or numeric characters and is case sensitive.

The encrypted keyword is intended only for use by the chassis while saving configuration scripts. The system displays the encrypted keyword in the configuration file as a flag that the variable following the encrypted keyword is the encrypted version of the plain text secret key. Only the encrypted secret key is saved as part of the configuration file.

**hash-algorithm { hmac-md5 | md5 | rfc2002-md5 }**

Default: hmac-md5

Specifies the hash-algorithm used between the HA service and the mobile node.

**hmac-md5:** Configures the hash-algorithm to implement HMAC-MD5 per RFC 2002bis.

**md5:** Configures the hash-algorithm to implement MD5 per RFC 1321.

**rfc2002-md5:** Configures the hash-algorithm to implement keyed-MD5 per RFC 2002.

**permit-any-hash-algorithm**

Default: disabled
Allows verification of the MN-HA authenticator using all other hash-algorithms after failure with configured hash-algorithm. Successful algorithm is logged to aid in troubleshooting and is used to create the MN-HA authenticator in the Registration Reply message.

```
replay-protection { nonce | timestamp }
```

- **Default**: timestamp
- Specifies the replay-protection scheme that should be implemented by the HA service for this SPI.
- `nonce`: configures replay protection to be implemented using NONCE per RFC 2002.
- `timestamp`: configures replay protection to be implemented using timestamps per RFC 2002.

```
timestamp-tolerance tolerance
```

- **Default**: 60
- Specifies the allowable difference (tolerance) in timestamps that is acceptable. If the difference is exceeded, then the session will be rejected. If this is set to 0, then time stamp tolerance checking is disabled at the receiving end.
- Tolerance is measured in seconds and can be configured to any integer value between 0 and 65535.

**Usage**

An SPI is a security mechanism configured and shared by the HA service and the mobile node. Please refer to RFC 2002 for additional information.

Use the no version of this command to delete a previously configured SPI.

**Example**

The following command configures the HA service to use an SPI of 640 when communicating with a mobile node. The key that would be shared between the mobile node and the HA service is q397F65.

```
mn-ha-spi spi-number 640 secret q397F65
```

The following command deletes the configured SPI of 400:

```
no mn-ha-spi spi-number 400
```
nat-traversal

This command enables NAT traversal and also configures the forcing of UDP tunnels for NAT traversal.

Product
HA

Privilege
Security Administrator, Administrator

Syntax

```
nat-traversal [force-accept]
no nat-traversal [force-accept]
default nat-traversal [force-accept]
```

```
no
Disables NAT traversal or disables forcing the acceptance of UDP tunnels for NAT traversal.
```

```
default
Reset the defaults for this command.
Default: NAT traversal disabled, force-accept disabled.
```

```
force-accept
This keyword configures the HA to accept requests when NAT is not detected but the Force (F) bit is set in the RRQ with the UDP Tunnel Request. By default this type of request is rejected if NAT is not detected.
```

Usage

Use this command to enable NAT traversal and enable the forcing of UDP tunnels for NAT traversal.

Example

The following command enables NAT traversal for the current HA service and forces the HA to accept UDP tunnels for NAT traversal:

```
nat-traversal force-accept
```
optimize tunnel-reassembly

Configures HA to FA optimization for tunnel reassembly.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
optimize tunnel-reassembly
no optimize tunnel-reassembly
```

**Usage**
Enabling this functionality fragments large packets prior to encapsulation for easier processing. Tunnel reassembly optimization is disabled by default.

**Important:** Cisco Systems strongly recommends that you do not use this command without first consulting Cisco Systems Technical Support. This command applies to very specific scenarios where packet reassembly is not supported at the far end of the tunnel. There are cases where the destination network may either discard the data, or be unable to reassemble the packets.

**Important:** This functionality works best when the HA service is communicating with an FA service running in a system. However, an HA service running in the system communicating with an FA from a different manufacturer will operate correctly even if this parameter is enabled.

Use the **no** version of this command to disable tunnel optimization if enabled.

**Example**
The following command enables tunnel reassembly optimization:

```
optimize tunnel-reassembly
```
policy bc-query-result

Configures the response code to send in a binding cache (BC) query result in response to a network failure or error.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
policy bc-query-result network-failure code
```

[ default ] policy bc-query-result network-failure

```
  network-failure code
  Default: 0xFFFF
  Specify the response code for BC responses sent on network failures.
  code must be either 0xFFFF or 0xFFFE.
```

**Usage**
Use this command to specify the type of response code to send in a P-MIP BC query result.

**Example**
The following command sets the P-MIP BC query result response code to 0xFFFE:
```
policy bc-query-result network-failure 0xFFFE
```
policy nw-reachability-fail

Specifies the action to take upon detection of an up-stream network-reachability failure.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

policy nw-reachability-fail { reject [ use-reject-code { admin-prohibited | insufficient-resources } ] | redirect ip_addr1 [ weight value ] [ ip_addr2 [ weight value ] ... ip_addr16 [ weight value ] ] }  
no policy nw-reachability-fail [ redirect ip_addr1 ... ip_addr16 ]

no policy nw-reachability-fail [ redirect ip_addr1 ... ip_addr16 ]

Deletes the network reachability policy completely or deletes the specified redirect addresses from the policy.

reject [ use-reject-code { admin-prohibited | insufficient-resources } ]

Upon network reachability failure reject all new calls for this context.

use-reject-code { admin-prohibited | insufficient-resources }: When rejecting calls send the specified reject code. If this keyword is not specified the admin-prohibited reject code is sent by default.

reject [ use-reject-code { admin-prohibited | insufficient-resources } ]

Upon network reachability failure reject all new calls for this context. If no reject code is specified, the HA sends a registration reply code of 81H (admin-prohibited).

use-reject-code { admin-prohibited | insufficient-resources }: Use the specified reject code when rejecting traffic.

admin-prohibited: When this keyword is specified and traffic is rejected, the error code 81H (admin-prohibited) is returned.

insufficient-resources: When this keyword is specified and traffic is rejected, the error code 82H (insufficient resources) is returned.

redirect ip_addr1 [ weight value ] [ ip_addr2 [ weight value ] ... ip_addr16 [ weight value ] ]

Upon network reachability failure redirect all calls to the specified IP address.

ip_addr1: This must be an IPv4 address specified in dotted decimal notation. Up to 16 IP addresses and optional weight values can be entered on one command line.

weight value: When multiple addresses are specified, they are selected in a weighted round-robin scheme. If a weight is not specified the entry is automatically assigned a weight of 1. value must be an integer from 1 through 10.

Usage

Use this command to set the action for the HA service to take upon a network reachability failure.
**Important:** Refer to the context configuration mode command `nw-reachability server` to configure network reachability servers.

**Important:** Refer to the subscriber configuration mode command `nw-reachability-server` to bind the network reachability to a specific subscriber.

**Important:** Refer to the `nw-reachability server server_name` keyword of the context configuration mode `ip pool` command bind the network reachability server to an IP pool.

**Example**
To set the HA service to reject all new calls on a network reachability failure, enter the following command:

```
policy nw-reachability-fail reject
```

Use the following command to set the HA service to redirect all calls to the HA at IP address 192.168.100.10 and 192.168.200.10 on a network reachability failure:

```
policy nw-reachability-fail redirect 192.168.100.10 192.168.200.10
```
policy overload

Configures the overload policy within the HA service.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

policy overload { redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ] | reject [ use-reject-code { admin-prohibited | insufficient-resources } ] }

no policy overload [ redirect address [ address2...address16 ] ]

Deletes a previously set policy or removes a redirect IP address.

overload: This keyword without any options deletes the complete overload policy from the PDSN service.

overloadredirect address [ address2 ... address16 ]; deletes up to 16 IP addresses from the overload redirect policy. The IP addresses must be expressed in IP v4 dotted decimal notation.

redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ]

This option enables a redirect policy for overloading conditions. When a redirect policy is invoked, the HA service rejects new sessions with a Registration Reply Code of 136H (unknown home agent address) and provides the IP address of an alternate HA. This command can be issued multiple times.

address: The IP address of an alternate HA expressed in IP v4 dotted decimal notation. Up to 16 IP addresses can be specified either in one command or by issuing the redirect command multiple times. If you try to add more than 16 IP addresses to the redirect policy the CLI issues an error message. If you specify an IP address and weight that already exists in the redirect policy the new values override the existing values.

weight weight_num: When multiple addresses are specified, they are selected in a weighted round-robin scheme. Entries with higher weights are more likely to be chosen. If a weight is not specified the entry is automatically assigned a weight of 1. weight_num must be an integer from 1 through 10.

reject [ use-reject-code { admin-prohibited | insufficient-resources } ]

This option causes any overload traffic to be rejected. If no reject code is specified, the HA sends a registration reply code of 81H (admin-prohibited).

use-reject-code { admin-prohibited | insufficient-resources }; Use the specified reject code when rejecting traffic.

admin-prohibited: When this keyword is specified and traffic is rejected, the error code 81H (admin-prohibited) is returned.

insufficient-resources: When this keyword is specified and traffic is rejected, the error code 82H (insufficient resources) is returned.
The system invokes the overload policy if the number of calls currently being processed exceeds the licensed limit for the maximum number of sessions supported by the system. The system automatically invokes the overload policy when an on-line software upgrade is started. Use the `no` version of this command to restore the default policy. The setting for overload policy is `reject`.

**Example**
The following command enables an overload redirect policy for the HA service that will send overload calls to either of two destinations with weights of 1 and 10 respectively:

```
policy overloadredirect 192.168.100.10 weight 1 192.168.100.20 weight 10
```
policy null-username

Configures the current HA service to accept or reject an RRQ without an NAI extension.

**Important:** This command is customer specific and is license enabled.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
policy null-username { accept-static | reject }
no policy null-username

no
Set the HA back to the default behavior of rejecting an RRQ without an NAI extension.

accept-static
This enable the HA to accept an RRQ with a static (i.e, non-zero) home address request but without NAI extension, when MN-AAA authentication is disabled at the HA. MN-NAI is required for MN-AAA authentication.

reject
Default. This is the default behavior of rejecting an RRQ without an NAI extension.
```

**Usage**
Use this command to enable or disable the HA from accepting an RRQ without an NAI.

**Example**
The following command enables the current HA service to accept RRQs that do not have an NAI extension:

```
policy null-username accept-static
```
private-address allow-no-reverse-tunnel

This command allows the HA service to accept private addresses without using reverse tunneling.

**Important:** This command is customer specific and is license enabled.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
private-address allow-no-reverse-tunnel
no private-address allow-no-reverse-tunnel
```

**Usage**
Use this command to enable or disable the HA from accepting calls that use private addresses without reverse tunneling.

**Example**
The following command enables the current HA service to accept MIP calls that use private addresses but do not use reverse tunneling:

```
private-address allow-no-reverse-tunnel
```
**reg-lifetime**

Specifies the longest registration lifetime that the HA service will allow in any Registration Request message from the mobile node.

**Product**

HA

**Privilege**

Security Administrator, Administrator

**Syntax**

```
reg-lifetime time
no reg-lifetime
```

- **no**
  
  Sets the registration lifetime to infinite.

- **time**
  
  Specifies the registration lifetime.
  time is measured in seconds and can be configured to any integer value between 1 and 65534.

**Usage**

Use to limit a mobile nodes lifetime. If the mobile node requests a shorter lifetime than what is specified, it is granted. However, Per RFC 2002, should a mobile node request a lifetime that is longer than the maximum allowed by this parameter, the HA service will respond with the value configured by this command as part of the Registration Reply.

The chassis is shipped from the factory with the registration lifetime set to 600 seconds.

**Example**

The following command configures the registration lifetime for the HA service to be 2400 seconds:

```plaintext
reg-lifetime 2400
```

The following command configures an infinite registration lifetime for MIP calls:

```plaintext
no reg-lifetime
```
reverse-tunnel

Enables the use of reverse tunneling for a Mobile IP sessions when requested by the mobile node.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
reverse-tunnel

no reverse-tunnel
```

**no**
Indicates the reverse tunnel option is to be disabled. When omitted, the reverse tunnel option is enabled.

**Usage**
Reverse tunneling involves tunneling datagrams originated by the mobile node to the HA service via the FA. When an MN arrives at a foreign network, it listens for agent advertisements and selects an FA that supports reverse tunnels. The MN requests this service when it registers through the selected FA. At this time, the MN may also specify a delivery technique such as Direct or the Encapsulating Delivery Style. Among the advantages of using reverse-tunneling are that:

- All datagrams from the mobile node seem to originate from its home network
- The FA can keep track of the HA that the mobile node is registered to and tunnel all datagrams from the mobile node to its HA

Use the **no** version of this command to disable reverse tunneling. If reverse tunneling is disabled, and the mobile node does not request it, triangular routing will be performed. Routing will be used.

The chassis is shipped from the factory with the reverse tunnel enabled.

**Important:** If reverse tunneling is disabled on the system and a mobile node requests it, the call will be rejected with a reply code of 74H (reverse-tunneling unavailable).

**Example**
The following command disables reverse-tunneling support for the HA service:

```
no reverse-tunnel
```
revocation

Enables the MIP revocation feature and configures revocation parameters.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
revocation { enable | max-retransmission number | negotiate-i-bit | retransmission-timeout secs | send-nai-ext | trigger { handoff | idle-timeout } }
no revocation { enable | negotiate-i-bit | send-nai-ext | trigger { handoff | idle-timeout } }
```

**no**
Completely disables registration revocation on the HA, disables trigger handoff, or disables revocation on idle timer expiration.

**enable**
Enables the MIP registration revocation feature on the HA. When enabled, if revocation is negotiated with an FA and a MIP binding is terminated, the HA can send a Revocation message to the FA. This feature is disabled by default.

**max-retransmission number**
Default: 3
The maximum number of retransmissions of a Revocation message before the revocation fails. `number` must be an integer from 0 through 10.

**negotiate-i-bit**
Default: disabled
Enables the HA to negotiate the i-bit via PRQ/RRP messages and processes the i-bit revocation messages.

**retransmission-timeout secs**
Default: 3
The number of seconds to wait for a Revocation Acknowledgement from the FA before retransmitting the Revocation message. `secs` must be an integer from 1 through 10.

**send-nai-ext**
Default: off
Enables sending the NAI extension in the revocation message.

**trigger { handoff | idle-timeout }**

`handoff`: Default: Enabled
Triggers the HA to send a Revocation message to the FA when an inter-Access Gateway/FA handoff of the MIP session occurs. If this is disabled, the HA is never triggered to send a Revocation message.

**idle-timeout:** Default: Enabled
Triggers the HA to send a Revocation message to the FA when a session idle timer expires.

### Usage
Use this command to enable or disable the MIP revocation feature on the HA or to change settings for this feature. Both the HA and the FA must have Registration Revocation enabled and FA/HA authorization must be in use for Registration Revocation to be negotiated successfully.

### Example
The following command enables Registration Revocation on the HA:

```
revocation enable
```

The following command sets the maximum number of retries for a Revocation message to 10:

```
revocation max-retransmission 10
```

The following command sets the timeout between retransmissions to 3:

```
revocation retransmission-timeout 3
```

The behavior of send MIP revocation to FA is as follows:
1st retry: Retransmit in 3 seconds after previous MIP revocation send.
2nd retry: Retransmit in 6 seconds after previous MIP revocation send (9 seconds after sending initial MIP revocation).
3rd retry: Retransmit in 12 seconds after previous MIP revocation send (21 seconds after sending initial MIP revocation).
4th retry: Retransmit in 24 seconds after previous MIP revocation send (45 seconds after sending initial MIP revocation).
5th retry: Retransmit in 48 seconds after previous MIP revocation send (93 seconds after sending initial MIP revocation).

**Important:** The value of retransmission-timeout doubles. HA disconnects the session forcibly in 120 seconds after sending initial MIP revocation.
setup-timeout

The maximum amount of time allowed for session setup.

Product
HA

Privilege
Security Administrator, Administrator

Syntax

```
setup-timeout seconds
```

seconds
Default: 60 seconds
The maximum amount of time, in seconds, to allow for setup of a session. must be an integer from 1 through 1000000

Usage
Use this command to set the maximum amount of time allowed for setting up a session.

Example
To set the maximum time allowed for setting up a session to 5 minutes (300 seconds), enter the following command:
```
setup-timeout 300
```
simul-bindings

Specifies the maximum number of “care-of” addresses that can simultaneously be bound for the same user as identified by NAI and Home address.

Product
HA

Privilege
Security Administrator, Administrator

Syntax

```
simul-bindings number
```

number

Configures the maximum number of simultaneous “care-of” bindings that the HA service will maintain for any given subscriber.

number can be configured to any integer value between 1 and 3.

Usage

Per RFC 2002, the HA service creates a mobile binding record (MBR) for each subscriber session it is facilitating. Each MBR is associated with a care-of address. As the mobile node roams, it is possible that the session will be associated with a new care of address. Typically, the HA service will delete an old binding and create a new one when the information in the Registration Request changes. However, the mobile could request that the HA maintains previously stored MBRs. This command allows you to configure the maximum number of MBRs that can be stored per subscriber if the requested.

The chassis is shipped from the factory with the simultaneous sessions set to 3.

Example

The following command configures the HA service to support up to 4 MBRs per subscriber:

```
simul-bindings 4
```
threshold init-rrq-rcvd-rate

Set an alarm or alert based on the average number of calls setup per second for the context.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
threshold init-rrq-rcvd-rate high_thresh [ clear low_thresh ]
no threshold init-rrq-rcvd-rate
```

no

Deletes the alert or alarm.

```
high_thresh
Default: 0
The high threshold average number of calls setup per second must be met or exceeded within the polling
interval to generate an alert or alarm. It can be configured to any integer value between 0 and 100000.
```

```
clear low_thresh
Default: 0
The low threshold average number of calls setup per second that must be met or exceeded within the polling
interval to clear an alert or alarm. It can be configured to any integer value between 0 and 100000.
```

**Important**: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm
model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the average number of calls setup per second is equal to or
greater than a specified number of calls per second.
Alerts or alarms are triggered for the number of calls setup per second based on the following rules:

- **Enter condition**: Actual number of calls setup per second $>$ High Threshold
- **Clear condition**: Actual number of calls setup per second $\leq$ Low Threshold

Example

The following command configures a number of calls setup per second threshold of 1000 and a low threshold of 500 for
a system using the Alarm thresholding model:

```
threshold init-rrq-rcvd-rate 1000 clear 500
```
threshold ipsec-call-req-rej

 Configures a threshold for the total IPSec calls request rejected.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
threshold ipsec-call-req-rej high_thresh [ clear low_thresh ]
no threshold ipsec-call-req-rej
```

**no**

Deletes the alert or alarm.

**high_thresh**

Default: 0
The high threshold number of IPSec call requests rejected per second must be met or exceeded within the polling interval to generate an alert or alarm.
`high_thresh` can be configured to any integer value between 0 and 1000000.

**clear low_thresh**

Default: 0
The low threshold number of IPSec call requests rejected per second that must be met or exceeded within the polling interval to clear an alert or alarm.
`low_thresh` can be configured to any integer value between 0 and 1000000.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to set an alert or an alarm when the number of IPSec call requests rejected is equal to or greater than a specified number per second.
Alerts or alarms are triggered for the number of IPSec IKE requests on the following rules:

- **Enter condition:** Actual number of IPSec IKE requests > High Threshold
- **Clear condition:** Actual number of IPSec IKE requests £ Low Threshold

**Example**

The following command configures a number of IPSec call requests rejected threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-call-req-rej 1000 clear 800
```
threshold ipsec-ike-failrate

Configures a threshold for the percentage of IPSec IKE failures.

Product
HA

Privilege
Security Administrator, Administrator

Syntax

threshold ipsec-ike-failrate high_thresh [ clear low_thresh ]

no threshold ipsec-ike-failrate

no

Deletes the alert or alarm.

high_thresh

Default: 0
The high threshold percentage of IPSec IKE failures per second must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh can be configured to any integer value between 0 and 100.

clear low_thresh

Default: 0
The low threshold percentage of IPSec IKE failures per second that must be met or exceeded within the polling interval to clear an alert or alarm.
low_thresh can be configured to any integer value between 0 and 100.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the percentage of IPSec IKE failures is equal to or greater than a specified number per second.
Alerts or alarms are triggered for the percentage of IPSec IKE failures on the following rules:
• Enter condition: Percentage of IPSec IKE failures > High Threshold
• Clear condition: Percentage of IPSec IKE failures ≤ Low Threshold

Example

The following command configures a percentage of IPSec IKE failures threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:
threshold ipsec-ike-failrate 90 clear 80
threshold ipsec-ike-requests

Configures a threshold for the total IPSec IKE failures.

Product
- HA

Privilege
- Security Administrator
- Administrator

Syntax

```
threshold ipsec-ike-failures [high_THRESH [clear low_THRESH]]

no threshold ipsec-ike-failures
```

**high_THRESH**
Default: 0
The high threshold number of IPSec IKE failures per second must be met or exceeded within the polling interval to generate an alert or alarm.

**clear low_THRESH**
Default: 0
The low threshold number of call IPSec IKE failures per second that must be met or exceeded within the polling interval to clear an alert or alarm.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
Use this command to set an alert or an alarm when the number of IPSec IKE failures is equal to or greater than a specified number per second.

Alerts or alarms are triggered for the number of IPSec IKE failures on the following rules:

- **Enter condition:** Actual number of IPSec IKE failures > High Threshold
- **Clear condition:** Actual number of IPSec IKE failures £ Low Threshold

Example
The following command configures a number of IPSec IKE failures threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-ike-failures 1000 clear 800
```
threshold ipsec-ike-failures

Configures a threshold for the total IPSec IKE failures.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
threshold ipsec-ike-failures high_thresh [ clear low_thresh ]
```

```
no threshold ipsec-ike-failures
```

Deletes the alert or alarm.

```
no
```  

**high_thresh**
Default: 0
The high threshold number of IPSec IKE failures per second must be met or exceeded within the polling interval to generate an alert or alarm.
`high_thresh` can be configured to any integer value between 0 and 1000000.

```
clear low_thresh
```  

Default: 0
The low threshold number of call IPSec IKE failures per second that must be met or exceeded within the polling interval to clear an alert or alarm.
`low_thresh` can be configured to any integer value between 0 and 1000000.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Use**

Use this command to set an alert or an alarm when the number of IPSec IKE failures is equal to or greater than a specified number per second.
Alerts or alarms are triggered for the number of IPSec IKE failures on the following rules:

- **Enter condition:** Actual number of IPSec IKE failures > High Threshold
- **Clear condition:** Actual number of IPSec IKE failures ≤ Low Threshold

**Example**
The following command configures a number of IPSec IKE failures threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-ike-failures 1000 clear 800
```
threshold ipsec-tunnels-established

Configures a threshold for the total IPSec tunnels established.

Product
HA

Privilege
Security Administrator, Administrator

Syntax

```
threshold ipsec-tunnels-established high_thresh [ clear low_thresh ]

no threshold ipsec-tunnels-established
```

no

Delete the alert or alarm.

```
high_thresh
Default: 0
The high threshold number of IPSec tunnels established per second must be met or exceeded within the polling interval to generate an alert or alarm.
high_thresh can be configured to any integer value between 0 and 1000000.
```

```
clear low_thresh
Default: 0
The low threshold number of call IPSec tunnels established per second that must be met or exceeded within the polling interval to clear an alert or alarm.
low_thresh can be configured to any integer value between 0 and 1000000.
```

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of IPSec tunnels established is equal to or greater than a specified number per second.
Alerts or alarms are triggered for the number of IPSec tunnels established on the following rules:

- **Enter condition:** Actual number of IPSec tunnels established > High Threshold
- **Clear condition:** Actual number of IPSec tunnels established £ Low Threshold

Example

The following command configures a number of IPSec tunnels established threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-tunnels-established 1000 clear 800
```
threshold ipsec-tunnels-setup

Configures a threshold for the total IPSec tunnels setup.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
threshold ipsec-tunnels-setup high_thresh [ clear low_thresh ]
```  
```
no threshold ipsec-tunnels-setup
```  
```
no
```

Deletes the alert or alarm.

```
high_thresh
```

Default: 0
The high threshold number of IPSec tunnels setup per second must be met or exceeded within the polling interval to generate an alert or alarm.

`high_thresh` can be configured to any integer value between 0 and 1000000.

```
clear low_thresh
```

Default: 0
The low threshold number of call IPSec tunnels setup per second that must be met or exceeded within the polling interval to clear an alert or alarm.

`low_thresh` can be configured to any integer value between 0 and 1000000.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**
Use this command to set an alert or an alarm when the number of IPSec tunnels setup is equal to or greater than a specified number per second.
Alerts or alarms are triggered for the number of IPSec tunnels setup on the following rules:

- **Enter condition:** Actual number of IPSec tunnels setup > High Threshold
- **Clear condition:** Actual number of IPSec tunnels setup ≤ Low Threshold

**Example**
The following command configures a number of IPSec tunnels setup threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-tunnels-setup 1000 clear 800
```
threshold reg-reply-error

Set an alarm or alert based on the number of registration reply errors per HA service.

Product
HA

Privilege
Security Administrator, Administrator

Syntax

```
threshold reg-reply-error high_thresh [ clear low_thresh ]
no threshold reg-reply-error
```

**no**

Deletes the alert or alarm.

**high_thresh**

Default: 0
The high threshold number of registration reply errors that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to any integer value between 0 and 100000.

**clear low_thresh**

Default: 0
The low threshold number of registration reply errors that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to any integer value between 0 and 100000.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to set an alert or an alarm when the number of registration reply errors is equal to or greater than a specified number of calls per second.

Alerts or alarms are triggered for the number of registration reply errors on the following rules:

- **Enter condition:** Actual number of registration reply errors > High Threshold
- **Clear condition:** Actual number of registration reply errors £ Low Threshold

**Example**

The following command configures a registration reply error threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```
threshold reg-reply-error 1000 clear 500
```
threshold rereg-reply-error

Set an alarm or alert based on the number of re-registration reply errors per HA service.

Product
HA

Privilege
Security Administrator, Administrator

Syntax

threshold rereg-reply-error high_thresh [ clear low_thresh ]
no threshold rereg-reply-error

no
Deletes the alert or alarm.

high_thresh
Default: 0
The high threshold number of re-registration reply errors that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to any integer value between 0 and 100000.

clear low_thresh
Default: 0
The low threshold number of re-registration reply errors that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to any integer value between 0 and 100000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
Use this command to set an alert or an alarm when the number of re-registration reply errors is equal to or greater than a specified number of calls per second.
Alerts or alarms are triggered for the number of re-registration reply errors on the following rules:

• Enter condition: Actual number of re-registration reply errors > High Threshold
• Clear condition: Actual number of re-registration reply errors £ Low Threshold

Example
The following command configures a reregistration reply error threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:
threshold rereg-reply-error 1000 clear 500
threshold dereg-reply-error

Set an alarm or alert based on the number of de-registration reply errors per HA service.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
threshold dereg-reply-error high_thresh [ clear low_thresh]
no threshold dereg-reply-error
```

- `no`
  Deletes the alert or alarm.

- `high_thresh`
  Default: 0
  The high threshold number of de-registration reply errors that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to any integer value between 0 and 100000.

- `clear low_thresh`
  Default: 0
  The low threshold number of de-registration reply errors that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to any integer value between 0 and 100000.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to set an alert or an alarm when the number of de-registration reply errors is equal to or greater than a specified number of calls per second.

Alerts or alarms are triggered for the number of de-registration reply errors on the following rules:

- **Enter condition:** Actual number of de-registration reply errors > High Threshold
- **Clear condition:** Actual number of de-registration reply errors £ Low Threshold

**Example**
The following command configures a de-registration reply error threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```
threshold reg-reply-error 1000 clear 500
```
wimax-3gpp2 interworking

Configures the interworking between WiMAX and 3GPP2 network at HA. This support provides handoff capabilities from 4G to 3G (PDSN) network access and vice-versa.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[no | default] wimax-3gpp2 interworking
```

- **no**
  Disables the pre-configured interworking between WiMAX and 3GPP2 networks at HA level.

- **default**
  Configures the WiMAX-3GPP2 interworking to default setting; i.e. disabled.

**Usage**
Use this command to enable/disable the interworking between WiMAX and 3GPP2 network for seamless session continuity.
This functionality provides HA support for both 4G and 3G technology HA (WiMAX HA and PDSN/HA) for handoff from 4G and 3G network access (ASN GW/FA and PDSN/FA) and vice-versa.

**Important:** Use this command in conjunction with authentication aaa-distributed-mip-keys required command.

**Example**
The following command enables the interworking for a subscriber between WiMAX and 3GPP2 network.
```
wimax-3gpp2 interworking
```
Chapter 115
HD RAID Configuration Mode Commands

This mode develops default policies designed to minimize administrative intervention when setting up a RAID on ASR 5000 SMC hard disks.
default

Sets or restores the default condition for the selected parameter

Product
All

Privilege
Security Administrator, Administrator

Syntax

default ( overwrite { invalid | unknown | valid } disk | select )

overwrite { invalid | unknown | valid } disk
Configures the system to overwrite any of the disk types

select
Selects the newer of the valid RAID disks when two valid RAID disks are available.

Usage
Selects default parameters

Example
Use the following example to select the newest disk in an SMC pair:

default select
end

Exits the HD RAID configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

end

Usage
Change the mode back to the Exec mode.
exit

Exits the HD RAID configuration mode and returns to the previous mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**
Return to the previous mode.
**overwrite**

Sets the RAID overwrite properties.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no | default ] overwrite { invalid | unknown | valid } disk [ -noconfirm ]
```

- **no**
  Prevents a disk from being overwritten.

- **default**
  Configures the default overwrite action:

- **invalid**
  This option allows the system to automatically overwrite invalid disks including empty disks, wrongly partitioned disks, and partially constructed disks.
  This is the default overwrite action.

- **unknown**
  This option allows the system to automatically overwrite unknown disks that has a valid RAID superblock but is not configured in the standard way; most likely because it has data from a different version.

- **valid**
  This option allows the system to automatically overwrite a disk that is a clean RAID component but not part of the current or selected RAID.

- **-noconfirm**
  Indicates that the command is to execute without any additional prompt and confirmation from the user.

**Usage**
Sets a policy for automatically overwriting different disk types. If there is a disk that satisfies the changed overwrite policy then the disk would overwrite immediately.

**Example**
The following command configures a policy for overwriting invalid RAID disks:

```
overwrite invalid disk -noconfirm
```
select

Configures the disk preference when both hard disks on the ASR 5000 have valid RAID information.

Product
All

Privilege
Security Administrator, Administrator

Syntax

[ default ] select { newer | none } disk [ -noconfirm ]

- **default**
  Configures the command to its default condition.

- **newer**
  Selects the newer disk by timestamp and event counter in superblocks. If all are the same, then the same array will start with both SMC disks, but a different array will need admin intervention).

- **none**
  Does not select any disk but defers to administrator intervention.

- **-noconfirm**
  Indicates that the command is to execute without any additional prompt and confirmation from the user.

Usage
Determine the selected disc when two valid disks from either the same or different RAIDs are running on the ASR 5000.

Example
This command forces the RAID to be configured on the newer SMC hard disk:

```
select newer disk -noconfirm
```
Chapter 116
HD Storage Policy Configuration Mode Commands

The HD Storage Policy Configuration Mode is used to configure directory name and file parameters for Diameter record files being stored on the HD storage device.

Diagram:
- Exec Mode
  - configure
    - Global Configuration Mode
      - hd storage-policy
        - name
          - HD Storage Policy Configuration Mode
**directory**

Configures the name of the directory on the HD storage drive where Diameter records are stored.

**Product**
HSGW, P-GW, S-GW

**Privilege**
Administrator

**Syntax**

```
directory name dir_name
```

```
default directory name
```

---

**default**

Returns the command to its default setting of using the policy name as the directory name.

```
name dir_name
```

Specifies the name to be applied to the directory. `dir_name` must be an alpha and or numeric string from 1 to 63 characters.

When configured, the actual directory path is:

```
/hd-raid/records/<record-type>/<dir_name>/
```

So if the directory name variable is entered as "sgwpgw", the path is:

```
/hd-raid/records/acr/sgwpgw
```

---

**Usage**

Use this command to name a directory on the HD storage drive where Diameter records are to be stored.

---

**Example**

The following command configures a directory named `cdr1`:

```
directory name cdr1
```
end

Exits the current mode and returns to the Exec Mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Change the mode back to the Exec mode.
exit

Exits the current mode and returns to the previous mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
exit

**Usage**
Return to the previous mode.
file

Configures file parameters for Diameter records being stored on the HD storage device.

Product
HSGW, P-GW, S-GW

Privilege
Administrator

Syntax

file { format acr { custom1...custom10 } | name { extension string | prefix string } | rotation { record-count num | time-interval sec | volume mb mbytes } }

default file { format acr | name prefix | rotation { record-count | time-interval | volume } }

no file { extension | rotation { record-count | time-interval } }

default

Returns the command to the default settings for the specified keywords.

no

Removes the configuration for the specified parameters.

format acr { custom1...custom10 }

Default: custom1

Specifies the file format used when storing records on the HD storage device. custom1 is a vendor-specific file format.

name { extension string | prefix string }

Specifies a string to be prepended or appended to the filenames. By default, the policy name is used for the prefix.

extension string: Specifies a file extension to append to the filename. string must be an alpha and/or numeric string from 1 to 10 characters.

prefix string: Specifies a file prefix to append to the filename. string must be an alpha and/or numeric string from 1 to 63 characters. This parameter replaces the policy name used by default.

rotation { record-count num | time-interval sec | volume mb mbytes }

Specifies the triggers that prompt file rotation on the HD storage drive. All options can be configured and upon reaching any of the thresholds, file rotation is initiated.

record-count num: Specifies that file rotation is to occur when the number of records reaches the number configured in this keyword. num must be an integer value from 1000 to 65000. Default = 10000

time-interval sec: Specifies that file rotation is to occur a time intervals configure in this keyword. sec must be an integer value from 30 to 86400. Default = 3600 (1 hour)

volume mb mbytes: Specifies that file rotation is to occur when the record volume exceeds the value configured in the keyword. mbytes must be an integer value from 2 to 40. Default = 4 (mb)
Usage
Use this command to configure file parameters for Diameter records being stored on the HD storage device.

Example
The following command set the file rotation thresholds for files being stored on the HD storage device:

```
file rotation volume mb 4
file rotation record-count 15000
file rotation time-interval 7200
```

The following command replaces the policy name as the prefix of all files being stored through this policy with the prefix `sgw`:

```
file name prefix sgw
```
Chapter 117
HLR Configuration Mode Commands

The HLR Configuration Mode provides the commands and parameters to configure the home location register (HLR) node that is the database containing the subscriber profile and connection information for a specific GPRS/UMTS core network.

In this mode, your prompt will look similar to:

```
[<context_name>]hostname(config-map-service-<svr_name>-hlr)#
```

The HLR Configuration Mode is a sub-mode derived from the MAP Configuration Mode which controls the MAP service configuration. It is the MAP service that provides the application-layer protocol support used to connect the HLR to other nodes in the network such as the SGSN.
**Important**: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**acn-version-retention**

This command configures the ACN version retention method.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
acn-version-retention { per-imsi-prefix | per-subscriber }

default acn-version-retention
```

- **default**
  Returns the configuration to the default value: retains the version information per IMSI prefix.

- **per-imsi-prefix**
  Retain ACN version information, for communication with the HLR, on a per IMSI prefix basis.

- **per-subscriber**
  Retain ACN version information, for communication with the HLR, on a per subscriber basis.

**Usage**
By default, the SGSN sends ACN version 3 SAI (service area identity) to the HLR. If the SGSN receives an error message indicating that the HLR does not support that version, then the SGSN tries again with an ACN version 2 SAI. Next time the SGSN communicates with that HLR, it retains that version information and version persists based on the IMSI prefix.

Use this command to enable the SGSN to retain version according to subscriber.

**Example**
Configure the SGSN to retain version information according to the IMSI prefix:

```plaintext
default acn-version-retention
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Return to the Exec mode.
exit

Exits the current configuration mode and returns to the global configuration mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Return to the context configuration mode.
imsi

This command sets up IMSI (International Mobile Subscriber Identity)-based configuration. (IMSI) prefix which includes the Mobile Country Code (MCC), the Mobile Network Code (MNC).

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

[ no ] imsi { any | starts-with prefix_number } { imsi [ sgsn-source-address-format point-code-ssn [ source-ssn ssn ] | isdn isdn_number | mobile-global-title mgt_number | point-code pt-code } }

- **no**
  Removes the imsi-prefix definition from the configuration.

- **any**
  Configures acceptance of any IMSI prefix.

- **starts-with prefix_number**
  Selects IMSI prefix-based routing.
  *prefix_number* is a string of up to 15 integers.

- **imsi**
  Enables configurable default behavior for routing.
  Entering *imsi* with the *any* keyword preserves the default behavior and the E.212 address is used as a destination address and the MAP request will be sent towards the HLR.
  If this keyword is not used with the *any* keyword, then the MAP request will be rejected.

- **isdn isdn_number**
  Defines the E.164 number of the HLR.
  *isdn_number* is a string of integers, up to 15.

- **mobile-global-title mgt_number**
  *mgt_number* is a string of integers, up to 15.

- **point-code pt-code source-ssn ssn**
  Defines the point code for the HLR.
  *pt-code* is a string of digits, up to 11; SS7 format preferred.

- **sgsn-source-address-format point-code-ssn**
  Selects HLR call process according to SCCP calling party address of the SGSN. This will be filled at MAP level, including the ITU point code address.
source-ssn \textit{ssn}

Defines the SSN of the source that will be used for the call filtering.

\textit{ssn}: Must be an integer from 1 to 255.

\textbf{Usage}

Routing will be done according to IMSI parameters configured with this command.

\textbf{Example}

\begin{verbatim}
imsi starts-with 3 isdn 123456789 sgsn-source-address-form at point-code-ssn
\end{verbatim}
policy routing

This command configures the policy for the routing of MAP messages. If this command is not configured or disabled (with the default keyword), then routing is done according to the configuration of the IMSI parameters.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

[ default | no ] policy routing { hlr-isdn | ms-isdn }

default
Resets the policy routing to the system default, disabled.

no
Removes the policy routing configuration from the system.

hlr-isdn
Selects HLR-ISDN based routing.

ms-isdn
Selects mobile station (MS)-ISDN based routing.

Usage
Use this command to set the policy for routing MAP messages.

Example

policy routing hlr-isdn
Chapter 118
HSGW Service Configuration Mode Commands

The HSGW Service Configuration Mode is used to create and manage a configuration allowing the HSGW to communicate, send and receive call data, and session flows to/from a eAN/PCF in an eHRPD network.

**Important**: This appendix will be added to the CLI Reference when the product releases. Use this appendix in conjunction with the latest release of the Command Line Interface Reference.
associate

Associates accounting policies and QCI-QoS mapping parameters with this HSGW service.

Product
HSGW

Privilege
Administrator

Syntax

```
associate { accounting-policy name | qci-qos-mapping name }
no associate { accounting-policy [ name ] | qci-qos-mapping }
```

no
Removes the specified associated policy or mapping from the service.

```
accounting-policy name
```
Specifies the accounting policy to associate with the HSGW service. `name` must be an existing accounting policy and be from 1 to 63 alpha and/or numeric characters.

```
qci-qos-mapping name
```
Associates the HSGW service with QCI to QoS mapping parameters. `name` must be an existing QCI-QoS mapping configuration and be from 1 to 63 alpha and/or numeric characters.

QCI-QoS mapping is configured through the qci-qos-mapping command in the Global Configuration Mode.

Usage
Use this command to associate an accounting policy with the HSGW service.

Example
The following command associates an accounting policy named `acct2` to the HSGW service:

```
associate accounting-policy acct2
```
bind address

Binds the service to a logical IP interface serving as the A10 interface and specifies the maximum number of subscribers that can access this service over the configured interface.

Product
HSGW

Privilege
Administrator

Syntax

bind address ip_address [ max-subscribers num ]

no bind address

no
Removes the interface binding from this service.

ip_address
Specifies the IPv4 address of the interface configured as the A10/A11 interface. ip_address is specified in dotted decimal notation.

max-subscribers num
Default: 2500000
Specifies the maximum number of subscribers that can access this service on this interface. num must be configured to an integer between 0 and 2,500,000.

**Important**: The maximum number of subscribers supported is dependant on the license key installed and the number of active PSCs in the system. A fully loaded system with 13 active PSCs can support 3,000,000 total subscribers. Refer to the license key command and the Usage section (below) for additional information.

Usage

Associate the HSGW service to a specific logical IP address. The logical IP address or interface takes on the characteristics of an A10/A11 interface that provides the session connectivity to/from an eAN/PCF. Only one interface can be bound to a service. The interface should be configured prior to issuing this command. This command also sets a limit as to the number of simultaneous subscriber sessions that can be facilitated by the service/interface at any given time.

When configuring the max-subscribers option, be sure to consider the following:
- The total number of A10/A11 interfaces you will configure
- The total number of subscriber sessions that all of the configured interfaces may handle during peak busy hours
- An average bandwidth per session multiplied by the total number of sessions
- The type of physical port (10/100Base-T or 1000Base-Tx) that these interfaces will be bound to
Taking these factors into account and distributing your subscriber session across all available interfaces will allow you to configure your interfaces to optimally handle sessions without degraded performance.

**Example**
The following command would bind the logical IP interface with the address of 112.334.556.778 to the HSGW service and specifies that a maximum of 200,000 simultaneous subscriber sessions can be facilitated by the interface/service at any given time:

```
bind address 112.334.556.778 max-subscribers 200000
```
context-retention-timer

Configures the maximum number of consecutive seconds that a UE session context (which includes the LCP, authentication and A10 session context for a given UE) is maintained by the HSGW before it is torn down.

Product
HSGW

Privilege
Administrator

Syntax

context-retention-timer timeout [ sec ]

[ default | no ] context-retention-timer timeout

default
Disables the timer.

no
Disables the timer.

timeout [ sec ]

Default: 60
Specifies the amount of time, in seconds, that the session context is maintained before it is disassembled. sec must be an integer value from 1 to 3600.

Usage
Use this command to configure a timer to retain session contexts for a specified amount of time before disassembling it.

Example
The following command allows the HSGW to maintain session contexts for 120 seconds before tearing them down:

context-retention-timer timeout 120
data-available-indicator

Enable sending Data Available Indicator extension in A10/A11 Registration Reply messages.

Product
HSGW

Privilege
Administrator

Syntax

data-available-indicator

Usage
Use this command to enable the sending of the Data Available Indicator extension in A10/A11 Registration Reply messages
**data-over-signaling**

Enable the data-over-signaling marking feature for A10 packets.

**Product**
HSGW

**Privilege**
Administrator

**Syntax**

```
[ default | no ] data-over-signaling
```

- **default**
  Enables the data-over signaling feature for A10 packets.

- **no**
  Disable the data-over signaling feature for A10 packets.

**Usage**

Use this command to enable or disable the data-over signaling feature for A10 packets.
**dns-pgw**

Identifies to the HSGW service the location of the DNS client. The DNS client is used to identify a FQDN for the peer P-GW. This command defaults to the same context as the HSGW service.

**Product**
HSGW

**Privilege**
Administrator

**Syntax**

```bash
dns-pgw context name

[ default | no ] dns-pgw context
```

---

**default**

Returns the command to its default setting of the current context.

---

**no**

Removes the configured DNS client context name from this service.

---

**context name**

Specifies the context in which the DNS client is configured. `name` must be an existing context and be from 1 to 63 alpha and/or numeric characters.

---

**Usage**

Use this command to identify to the HSGW service the context where the DNS client is configured.

---

**Example**

The following command identifies the context where the DNS client is configured as `isp3`:

```bash
dns-pgw context isp3
```
end

Exits the current mode and returns to the Exec Mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Change the mode back to the Exec mode.
exit

Exits the current mode and returns to the previous mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**
Return to the previous mode.
fqdn

Configures the Fully Qualified Domain Name (FQDN) for this HSGW service.

**Product**
HSGW

**Privilege**
Administrator

**Syntax**

```
fqdn domain_name
[ default | no ] fqdn
```

- **default**
  Returns the command to the default setting of “null”.

- **no**
  Removes the configured FQDN name from this service.

- **domain_name**
  Specifies an FQDN for the HSGW service. *domain_name* must be from 1 to 256 alpha and/or numeric characters.

**Important:** In order to properly interact with other nodes in the network, the FQDN should be 96 alpha and/or numeric characters or less.

**Usage**

Use this command to configure an FQDN for this HSGW service. The FQDN is used when matching a P-GW with an HSGW.

**Topology Matching**

You may specify which P-GW you wish an HSGW interface to connect with by enabling topology matching within the FQDNs for both the HSGW service and P-GW service. Topology matching selects geographically closer nodes and reduces backhaul traffic for a specified interface.

The following optional keywords enable or disable topology matching when added to the beginning of an FQDN:

- **topon<interface_name>**.
  Beginning an FQDN with **topon** initiates topology matching with available P-GWs in the network. Once this feature is enabled, the rest of the FQDN is processed from right to left until a matching regional designator is found on a corresponding P-GW FQDN.

- **topoff<interface_name>**.
  By default, topology matching is disabled. If you enable topology matching for any interfaces within a node, however, all interfaces not using this feature should be designated with **topoff**.
Example

The following command configures this HSGW service with an FQDN of `abc123.com`:

```
fqdn abc123.com
```

The following command configures this HSGW service with an FQDN that enables topology matching:

```
fqdn topon.<interface_name>.hsgw01.bos.ma.node.epc.mnc<value>.mcc<value>.3gppnetwork.org
```

**Important:** The associated P-GW service must have a corresponding FQDN similar to the following:

```
topon.<interface_name>.pgw01.bos.ma.node.epc.mnc<value>.mcc<value>.3gppnetwork.org
```
fragment

Enables/Disables PPP payload fragmentation.

Product
HSGW

Privilege
Administrator

Syntax

[ default | no ] fragment ppp-data

---

default
Returns the command to its default setting of enabled.

---

no
Disables PPP payload fragmentation.

Usage

Use this command to enable or disable PPP payload fragmentation.
gre

Configures Generic Routing Encapsulation (GRE) parameters for the A10 protocol within the HSGW service.

**Product**
HSGW

**Privilege**
Administrator

**Syntax**

```plaintext
gre { checksum | checksum-verify | flow control [ action { disconnect-session | resume-session } ] [ timeout msecs ] + | ip-header-dscp value { all-control-packets | setup-packets-only } | reorder-timeout msecs | segmentation | sequence-mode { none | reorder } | sequence-numbers | threegpp2-ext-headers qos-marking }

default gre { checksum | checksum-verify | flow-control | ip-header-dscp | reorder-timeout | sequence-mode | sequence-numbers | threegpp2-ext-headers qos-marking }

no gre { checksum | checksum-verify | flow-control | ip-header-dscp | segmentation | sequence-numbers | threegpp2-ext-headers qos-marking }
```

**default**
Restores the specified parameter to its default setting.

**no**
Disables the specified functionality.

**checksum**
Default: disabled
Enables the introduction of the checksum field in outgoing GRE packets.

**checksum-verify**
Default: disabled
Enables verification of the GRE checksum (if present) in incoming GRE packets.

**flow-control [ action { disconnect-session | resume-session } ] [ timeout msecs ] +**
Default: no GRE flow-control
Enables 3GPP2 GRE flow control which causes the HSGW to send flow control enabled Normal Vendor Specific Extensions (NVSE) in A11 RRPs.

**action { disconnect-session | resume-session }**:
Default: disconnect-session
Specifies the action to be taken when timeout is reached:

- **disconnect-session**: Ends the session and releases the call.
- **resume-session**: Switches flow control to XON and resumes delivery of packets to the RAN.
timeout \textit{msecs}
Default: 1000 milliseconds (10 seconds)
Sets the amount of time wait for an XON indicator from the RAN (after receiving an XOFF). Also sets the action to be taken if the timeout limit is reached.
\textit{msecs}: Specifies the amount of time in milliseconds before the timeout is reached. \textit{msecs} must be an integer from 1 through 1000000.

\textbf{ip-header-dscp} \textit{value} \{ \textit{all-control-packets} \mid \textit{setup-packets-only} \}
Default: Disabled
Used to configure the QoS Differentiated Services Code Point (DSCP) marking for GRE packets.
• \textit{value}: Represents the DSCP setting. It represents the first six most-significant bits of the ToS field. It can be configured to any hex value from 0x0 through 0x3F.
• \textit{all-control-packets}: Dictates that the DSCP marking is to be provided in all GRE control packets.
• \textit{setup-packets-only}: Dictates that the DSCP marking is to be provided only in GRE setup packets.

reorder-timeout \textit{msecs}
Default: 100
Configures max number of milliseconds to wait before processing reordered out-of-sequence GRE packets.
\textit{msecs} must be an integer from 0 through 5000.

segmentation
Default: disabled
Enables GRE Segmentation for the HSGW service.

sequence-mode \{ \textit{none} \mid \textit{reorder} \}
Default: none
Configures handling of incoming out-of-sequence GRE packets.
\textit{none}: Specifies that sequence numbers in packets are ignored and all arriving packets are processed in the order they arrive.
\textit{reorder}: Specifies that out of sequence packets are stored in a sequencing queue until one of the conditions is met:
• The reorder timeout occurs: All queued packets are sent for processing and the accepted sequence number is updated to the highest number in the queue.
• The queue is full (five packets): All packets in the queue are sent for processing, the reorder timer is stopped and the accepted sequence number is updated to the highest number in the queue.
• An arriving packet has a sequence number such that the difference between this and the packet at the head of the queue is greater than five. All the packets in the queue are sent for processing, the reorder timer is stopped and the accepted sequence number is updated to the highest number that arrived.
• A packet arrives that fills a gap in the sequenced numbers stored in the queue and creates a subset of packets whose sequence numbers are continuous with the current accepted sequence number. This subset of packets in the queue is sent for processing. The reorder timer continues to run and the accepted sequence number is updated to the highest number in the subset delivered.
sequence-numbers

Enables insertion of GRE sequence numbers in data that is about to be transmitted over the A10 interface. Data coming into the system containing sequence numbers but that is out of sequence is not re-sequenced.

threegpp2-ext-headers qos-marking

When threegpp2-ext-headers qos-marking is enabled and the PCF negotiates capability in the A11 RRQ, the HSGW will include the QoS optional data attribute in the GRE 3gpp2 extension header. The no keyword, enables qos-marking in the GRE header based on the tos value in the header.

Usage

Use the no gre sequence-numbers command to disable the inclusion of GRE sequence numbers in the A10 data path. More Usage....

Example

The following command configures the HSGW service to support the inclusion of GRE sequence numbers in outgoing traffic:

```plaintext
gre sequence-numbers
```
ip

Sets the use of Robust Header Compression (RoHC) and enters the HSGW Service ROHC Configuration Mode where RoHC parameters are configured for the service.

Configures the local User Datagram Protocol (UDP) port for the A10/A11 interface IP socket.

Sets the parameters for IP source validation. Source validation is useful if packet spoofing is suspected or for verifying packet routing and labeling within the network.

Source validation requires the source address of received packets to match the IP address assigned to the subscriber (either statically or dynamically) during the session.

Product
HSGW

Privilege
Administrator

Syntax

ip { header-compression rohc | local-port number | source-violation { clear-on-valid-packet | drop-limit num | period secs | reneg-limit num } }

default ip { local-port | source-violation drop-limit | period | reneg-limit }

no { header-compression rohc | ip source-violation clear-on-valid-packet }

---

default

Resets the keyword to its default value.

---

no

header-compression rohc: Removes the RoHC configuration from this service.

ip source-violation clear-on-valid-packet: Disables the ability of the service to reset the reneg-limit and drop-limit counters after receipt of a properly addressed packet.

---

header-compression rohc

Specifies that Robust Header Compression will be applied to sessions using this service and enters the HSGW Service RoHC Configuration Mode where RoHC parameters are configured.

local-port number

Default: 699
Specifies the UDP port number.
number can be any integer value between 1 and 65535.

source-violation { clear-on-valid-packet | drop-limit num | period secs | reneg-limit num }

clear-on-valid-packet

Default: disabled
Configures the service to reset the reneg-limit and drop-limit counters after receipt of a properly addressed packet.
drop-limit num
Default: 10
Sets the number of allowed source violations within a detection period before forcing a call disconnect. If num is not specified, the value is set to the default.
num can be any integer value from 1 to 1000000.
period secs
Default: 120
The length of time, in seconds, for a source violation detection period to last. drop-limit and reneg-limit counters are decremented each time this value is reached.
The counters are decremented in this manner: reneg-limit counter is reduced by one (1) each time the period value is reached until the counter is zero (0); drop-limit counter is halved each time the period value is reached until the counter is zero (0). If secs is not specified, the value is set to the default.
secs must be an integer value from 1 to 1000000.
reneg-limit num
Default: 5
Sets the number of allowed source violations within a detection period before forcing a PPP renegotiation. If num is not specified, the value is set to the default.
num can be any integer value from 1 to 1000000.

Usage

Header Compression RoHC: Use this command to specify that sessions using this service will have Robust Header Compression applied and configure parameters supporting RoHC.
Entering this command results in the following prompt:

[context_name]hostname(config-ip-header-compression-rohc)#

HSGW Service RoHC Configuration Mode commands are defined in the HSGW Service RoHC Configuration Mode Commands chapter.
Local Port: Specify the UDP port that should be used for communications between the Packet Control Function (PCF) and the HSGW.

Important: The UDP port setting on the PCF must match the local-port setting for the HSGW service on the system in order for the two devices to communicate.

Source Violation: This function is intended to allow the operator to configure a network to prevent problems such as when a user gets handed back and forth between two HSGWs a number of times during a handoff scenario.
This function operates in the following manner:
When a subscriber packet is received with a source address violation, the system increments both the IP source-violation reneg-limit and drop-limit counters and starts the timer for the IP-source violation period.
Every subsequent packet received with a bad source address during the IP-source violation period causes the reneg-limit and drop-limit counters to increment.
For example, if reneg-limit is set to 5, then the system allows 5 packets with a bad source address (source violations), but on the 5th packet, it re-negotiates PPP.
If the drop-limit is set to 10, the above process of receiving 5 source violations and renegotiating PPP occurs only once. After the second 5 source violations, the call is dropped. The period timer continues to count throughout this process.
If the configured source-violation period is exceeded at any time before the call is dropped, the reneg-limit counter is checked. If the reneg-limit counter is greater than zero (0), the reneg-limit is decremented by 1. If the reneg-limit counter equals zero, the drop-limit is decremented by half.
**Example**

The following command specifies a UDP port of 3950 for the HSGW service to use to communicate with the PCF on the A10/A11 interface:

```
ip local-port 3950
```

The following command sets the drop limit to 15 and leaves the other values at their defaults:

```
ip source-violation drop-limit 15
```
**lifetime**

Specifies the time that an A10 connection can exist before its registration is considered expired.

**Syntax**

```plaintext
lifetime time
[ default | no ] lifetime
```

- **default**
  Resets the lifetime value to the default setting of 1800 seconds.

- **no**
  Specifies that an A10 connection can exist for an infinite amount of time.

- **time**
  Default: 1800
  Specifies the time that an A10 connection can exist before its registration is considered expired. 
  `time` is measured in seconds and can be configured to any integer value between 1 and 65534.

**Usage**

Use this command to set a limit to the amount of time that a subscriber session can remain up whether or not the session is active or dormant. If the lifetime timer expires before the subscriber terminates the session, the connection is terminated automatically.

**Example**
The following command specifies a time of 3600 seconds (1 hour) for subscriber sessions on this HSGW service:

```plaintext
lifetime 3600
```
max-retransmissions

Configures the maximum number of times the HSGW service will attempt to communicate with an eAN/PCF before it marks it as unreachable.

**Product**: HSGW

**Privilege**: Administrator

**Syntax**

```
max-retransmissions count
```  

```
default max-retransmissions
```  

**Usage**

Use this command to limit the number of retransmissions to an eAN/PCF before marking it as unreachable. If the value configured is reached, the call is dropped.

**Example**

The following command configures the maximum number of retransmissions for the HSGW service to 3:

```
max-retransmissions 3
```
mobile-access-gateway

Identifies the mobile access gateway (MAG) context through which MIPv6 calls are to be routed.

Product
HSGW

Privilege
Administrator

Syntax

```
mobile-access-gateway context context_name [ mag-service service_name ]
```

```
no mobile-access-gateway context
```

```
no

Removes the configured MAG context route from this service.
```

```
context context_name [ mag-service service_name ]
```

Specifies the name of the context and, optionally, the service through which MIPv6 sessions are to be routed. `context_name` must be an existing context and be from 1 to 79 alpha and/or numeric characters. `service_name` must be an existing Mag service and be from 1 to 63 alpha and/or numeric characters.

Usage
Use this command to specify where MIPv6 sessions are routed through this service.

Example
The following command identifies the MAG context `MAG1` as the context through which MIPv6 sessions are to be routed and further narrows the route by specifying the service name (`mag_serv3`):

```
mobile-access-gateway context MAG1 mag-service mag_serv3
```
plmn id

Configures Public Land Mobile Network identifiers used to determine if a mobile station is visiting, roaming, or belongs to this network.

Product
HSGW

Privilege
Administrator

Syntax

plmn id mcc number mnc number

Usage
The PLMN identifier is used to aid the HSGW service in the determination of whether or not a mobile station is visiting, roaming, or home. Multiple P-GW services can be configured with the same PLMN identifier. Up to five PLMN IDs can be configured for each P-GW Service. The configured IDs are used in Diameter-EAP-Request messages (as a Visited-Network-Identifier AVP).

Example
The following command configures the PLMN identifier with an MCC of 462 and MNC of 02:

plmn id mcc 462 mnc 02
**policy overload**

Specifies how an HSGW service should handle overload conditions.

**Product**
HSGW

**Privilege**
Administrator

**Syntax**

```
policy overload [ redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ] | reject [ use reject-code { admin-prohibite | insufficient-resources } ] ]
```

```
default policy overload
```

```
no policy overload [ redirect address [ address2 ] ... [ address16 ]
```

```
default
```

Returns the command to its default setting of “reject” with the “admin-prohibited” code.

```
no
```

Removes a specified “redirect address” from this service.

```
redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ]
```

This option enables a redirect policy for overloading conditions. When a redirect policy is invoked, the HSGW service rejects new sessions with an A11 Registration Reply Code of 88H (unknown HSGW address) and provides the IP address of an alternate HSGW. This command can be issued multiple times.

`address`: The IP address of an alternate HSGW expressed in IPv4 dotted decimal notation. Up to 16 IP addresses can be specified either in one command or by issuing the redirect command multiple times. If you try to add more than 16 IP addresses to the redirect policy, the CLI issues an error message. If you specify an IP address and weight that already exists in the redirect policy, the new values override the existing values.

`weight`: When multiple addresses are specified, they are selected in a weighted round-robin scheme. Entries with higher weights are more likely to be chosen. If a weight is not specified, the entry is automatically assigned a weight of 1 (default). `weight_num` must be an integer value from 1 through 10.

```
reject [ use reject-code { admin-prohibite | insufficient-resources } ]
```

This option will cause any overload traffic to be rejected. The HSGW sends an A11 Registration Reply Code of 82H (insufficient resources).

**use-reject-code admin-prohibited**: When this keyword is specified and traffic is rejected, the error code admin prohibited is returned instead of the error code “insufficient resources”. This is the default behavior.

**use-reject-code insufficient-resources**: When this keyword is specified and traffic is rejected, the error code “insufficient resources” is returned instead of the error code admin prohibited.
Usage

Policies can be implemented to dictate HSGW service behavior for overload conditions. The system invokes the overload policy if the number of calls currently being processed exceeds the licensed limit for the maximum number of sessions supported by the system. The system automatically invokes the overload policy when an on-line software upgrade is started. Use the `no policy overload` command to delete a previously configured policy. If after deleting the policy setting you desire to return the policy parameter to its default setting, use the `default policy` command. The chassis is shipped from the factory with the policy options overload disabled.

Example
The following command configures the HSGW service to redirect overload traffic to two IPv4 address, one priority weighted 1 and the other priority weighted 5:

```
policy overload redirect 1.2.3.4 weight 1 1.2.3.5 weight 5
```
profile-id-qci-mapping

Associates a configured mapping table for RP QoS Profile ID to LTE QoS Class Index (QCI) mapping with this service.

**Product**
HSGW

**Privilege**
Administrator

**Syntax**

```bash
profile-id-qci-mapping name

no profile-id-qci-mapping [ name ]
```

- **no**
  Removes all profile maps or a specific profile map from this service.

- **name**
  Specifies the name of the table to be associated with this service. *name* must be an existing Profile ID - QCI Mapping table and be from 1 to 63 alpha and/or numeric characters in length.

**Usage**
Use this command to associate the HSGW service with a configured Profile ID - QCI Mapping table. The table is configured in the Global Configuration Mode using the `profile-id-qci-mapping-table` command.

**Example**
The following command associates a Profile ID - QCI Mapping table named *table3* with this service:

```bash
profile-id-qci-mapping table3
```
registration-deny

Configures parameters related to registration rejection.

**Product**

HSGW

**Privilege**

Administrator

**Syntax**

```plaintext
registration-deny { handoff connection-setup-record-absent | newcall connection-setup-record-absent } [ use-denies-code { poorly-formed-request | reason-unspecified } ]
```

**handoff connection-setup-record-absent**

When enabled, the HSGW denies or discards handoff sessions that do not have an Airlink Connection Setup record in the A11 Registration Request. Default is disabled. Default HSGW behavior is to accept such requests.

**newcall connection-setup-record-absent**

When enabled, the HSGW denies or discards new sessions that do not have the airlink connection setup record in the RRQ.

[ use-denies-code { poorly-formed-request | reason-unspecified } ]

Sets the specified Registration Deny Code when denying a new call or handoff because of a missing connection setup record.

**Usage**

Use this command to configure parameters relating to the rejection of registration requests.

**Example**

The following command denies registration for registration requests missing the connection setup record and replies with a use deny code of “poorly formed request”:

```plaintext
registration-deny handoff connection-setup-record-absent use-denies-code poorly-formed-request
```
retransmission-timeout

Configures the maximum allowable time for the HSGW service to wait for a response from the eAN/PCF before it attempts to communicate with the eAN/PCF again (if the system is configured to retry the PCF) or marks the eAN/PCF as unreachable.

Product
HSGW

Privilege
Administrator

Syntax

retransmission-timeout time

{ default | no } retransmission-timeout

default
Resets the timeout setting to the default value of 3.

no
Deletes a previously configured timeout value.

time
Default: 3
Specifies the maximum allowable time, in seconds, for the HSGW service to wait for a response from the eAN/PCF before it: a) attempts to communicate with the eAN/PCF again (if the system is configured to retry the PCF) or b) marks the eAN/PCF as unreachable.
time must be an integer value between 1 and 1000000.

Usage
Use the retransmission timeout command in conjunction with the max-retransmissions command in order to configure the HSGW services behavior when it does not receive a response from a particular PCF.

Example
The following command configures a retransmission timeout value of 5 seconds:

retransmission-timeout 5
**setup-timeout**

The maximum amount of time allowed for session setup.

**Product**
HSGW

**Privilege**
Administrator

**Syntax**

```
setup-timeout seconds
[ default| no ] setup-timeout
```

- **default**
  Rests the command to the default value of enabled with a timeout of 60 seconds.

- **no**
  Disables the feature.

- **seconds**
  Default: 60
  The maximum amount of time, in seconds, to allow for setup of a session in this service. **seconds** must be an integer value from 1 through 1000000.

**Usage**

Use this command to set the maximum amount of time allowed for setting up a session.

**Example**

The following command sets the maximum time allowed for setting up a session to 5 minutes (300 seconds):

```
setup-timeout 300
```
**spi remote-address**

Configures the security parameter index (SPI) between the HSGW service and the eAN/ePCF. This command also configures the redirection of call based on the PCF zone.

**Product**
HSGW

**Privilege**
Administrator

**Syntax**

```
spi remote-address { pcf_ip_address | ip_addr_mask_combo } spi-number number { encrypted secret enc_secret | secret secret } [ description string ] [ hash-algorithm { md5 | rfc2002-md5 } ] [ replay-protection { nonce | timestamp } ] [ timestamp-tolerance tolerance ] [ zone zone_id ]
```

```
no spi remote-address pcf_ip_address spi-number number
```

- **pcf_ip_address**: Specifies the IP address of the ePCF. *pcf_ip_address* is an IP address expressed in IPv4 dotted decimal notation or IPv6 colon separated notation.
- **ip_addr_mask_combo**: Specifies the IP address of the PCF and specifies the IP address network mask bits. *ip_addr_mask_combo* must be specified using the form ‘IP Address/Mask Bits’ where the IP address must either be an IPv4 address expressed in dotted decimal notation or an IPv6 address expressed in colon separated notation and the mask bits are a numeric value which is the number of bits in the subnet mask.

- **spi-number number**: Specifies the SPI (*number*) which indicates a security context between the PCF and the HSGW. *number* can be configured to any integer value between 256 and 4294967295.

- **encrypted secret enc_secret | secret secret**: Configures the shared-secret between the HSGW service and the PCF. The secret can be either encrypted or non-encrypted.
  - **encrypted secret enc_secret**: Specifies the encrypted shared key (*enc_secret*) between the PCF and the HSGW service. *enc_secret* must be between 1 and 254 alpha and/or numeric characters and is case sensitive.
  - **secret secret**: Specifies the shared key (*secret*) between the PCF and the HSGW services. *secret* must be between 1 and 127 alpha and/or numeric characters and is case sensitive.

The **encrypted** keyword is intended only for use by the chassis while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **encrypted** keyword is the encrypted version of the plain text secret key. Only the encrypted secret key is saved as part of the configuration file.

- **description string**: This is a description for the SPI. *string* must be an alpha and/or numeric string from 1 through 31 characters.
hash-algorithm \{ md5 | rfc2002-md5 \}
Default: md5
Specifies the hash-algorithm used between the HSGW service and the PCF.
- **md5**: Configures the hash-algorithm to implement MD5.
- **rfc2002-md5**: Configures the hash-algorithm to implement keyed-MD5.

replay-protection \{ nonce | timestamp \}
Default: timestamp
Specifies the replay-protection scheme that should be implemented by the HSGW service.
- **nonce**: Configures replay protection to be implemented using NONCE.
- **timestamp**: Configures replay protection to be implemented using timestamps.

timestamp-tolerance tolerance
Default: 60
Specifies the allowable difference (tolerance) in timestamps that is acceptable. If the difference is exceeded, then the session will be rejected. If this is set to 0, then time stamp tolerance checking is disabled at the receiving end.
- **tolerance** is measured in seconds and can be configured to any integer value between 0 and 65535.

zone zone_id
Specifies the different PCF zones to configure in HSGW service. Mapping of a zone-number to a set of HSGWs can be done per HSGW service basis.
- **zone_id** must be an integer value between 1 and 32. A maximum of 32 PCF zones can be configured for a HSGW service.

Usage
An SPI is a security mechanism configured and shared by the PCF and the HSGW service. Please refer to IOS 4.1 and RFC 2002 for additional information.
Multiple SPIS can be configured if the HSGW service is communicating with multiple eAN/PCFs.

**Important**: The SPI configuration on the PCF must match the SPI configuration for the HSGW service on the system in order for the two devices to communicate properly.

This command used with the **zone** keyword redirects all calls on the basis of PCF zone to the specific HSGW on the basis of parameters configured using the **policy pcf-zone-match** command.

Example
The following command configures the HSGW service to use an SPI of 256 when communicating with a PCF with the IP address 192.168.0.2. The key that would be shared between the PCF and the HSGW service is q397F65.

```
spi remote-address 192.168.0.2 spi-number 256 secret q397F65
```

The following command creates the configured SPI of 400 for a PCF with an IP address of 172.100.3.200 and zone id as 11:

```
spi remote-address 172.100.3.200 spi-number 400 zone 11
```
spi remote-address
authorized-flows

Configures the service to wait a specified number of seconds before triggering a QoS update to downgrade an unauthorized flow.

Product  
HSGW

Privilege  
Administrator

Syntax

`authorized-flows qos-update wait-timeout seconds`

[ default | no ] `authorized-flows qos-update wait-timeout`

- default  
Returns the command to its default setting of

- no  
Removes the configure wait-timeout setting for this service.

- `qos-update wait-timeout seconds`

Specifies the number of seconds to wait before triggering the QoS update to downgrade the unauthorized flow. `seconds` must be an integer value from 1 to 65534.

Usage

Use this command to specific a wait timeout trigger for flows that are unauthorized by policy rules received via the Gxa interface from the PCRF. When the wit timer expires, the HSGW triggers a QoS update to downgrade the unauthorized flow.

Example

The following command configures the HSGW service to apply the wait time of 30 seconds after receiving an flow unauthorized by the PCRF:

`authorized-flow qos-update wait-timeout 30`
Chapter 119
HSGW Service RoHC Configuration Mode Commands

The HSGW Service RoHC Configuration Mode is used to configure RoHC parameters for the service.

```
Exec Mode
configure
Global Configuration Mode
context name
Context Configuration Mode
hsgw-service name
HSGW Service Configuration Mode
ip header-compression rohc
HSGW Service RoHC Config Mode
```
cid-mode

This mode allows you to configure options that apply during RoHC compression for the service.

Product
HSGW

Privilege
Administrator

Syntax

cid-mode { large | small } max-cid integer

default cid-mode

default
Reset all options in the RoHC Profile Compression Configuration mode to their default values.

large
Use large packets with optional information for RoHC

small
This is the default packet size.
Use small RoHC packets.

max-cid integer
Default: 15
The highest context ID number to be used by the compressor. integer must be an integer from 0 through 15 when small packet size is selected and must be an integer from 0 through 31 when large packet size is selected.

Usage
Use this command to set the RoHC packet size and define the maximum

Example
The following command sets large RoHC packet size and sets the maximum CID to 100:

cid-mode large max-cid 100

The following command sets the cid-mode to the default settings of small packets and max-cid 0:

default cid-mode
end

Exits the current mode and returns to the Exec Mode.

Product
All

Privilege
Administrator

Syntax
end

Usage
Change the mode back to the Exec mode.
exit

Exits the current mode and returns to the previous mode.

**Product**
All

**Privilege**
Administrator

**Syntax**
exit

**Usage**
Return to the previous mode.
mrru

This command sets the size of the largest reconstructed reception unit, in octets, that the decompressor is expected to reassemble from segments. The size includes the CRC. If MRRU is negotiated to be 0, no segment headers are allowed on the channel.

**Product**

HSGW

**Privilege**

Administrator

**Syntax**

```
mrru num_octets
```

```
default mrru
```

```
default
reset the value of this command to its default setting
```

```
num_octets
Default: 0
This is the number of octets for the maximum size of the largest reconstructed reception unit allowed.
num_octets must be an integer from 0 through 65535.
```

**Usage**

Use this command to set the size, in octets, of the largest reconstructed reception unit that the decompressor is expected to reassemble from segments.

**Example**

The following command sets the largest reconstructed reception unit to 1024 octets:

```
mrru 1024
```

The following command resets the MRRU size to its default of 0 octets:

```
default mrru
```
profile

This command specifies the header compression profiles to use. A header compression profile is a specification of how to compress the headers of a specific kind of packet stream over a specific kind of link. At least one profile must be specified.

Product
HSGW

Privilege
Administrator

Syntax

```
profile { [ esp-ip ] [ rtp-udp ] [ udp-ip ] [ uncompressed-ip ] }
```

default profile

```
default
Default: esp-ip rtp-udp udp-ip uncompressed-ip
Returns the RoHC profile configuration to its default setting.
```

```
esp-ip
This enables RoHC Profile 0x0003 which is for ESP/IP compression, compression of the header chain up to and including the first ESP header, but not subsequent subheaders.
```

```
rtp-udp
This enables RoHC Profile 0x0001 which is for RTP/UDP/IP compression
```

```
udp-ip
This enables RoHC Profile 0x0002 which is for UDP/IP compression, compression of the first 12 octets of the UDP payload is not attempted.
```

```
uncompressed-ip
This enables RoHC Profile 0x0000 which is for sending uncompressed IP packets.
```

Usage

Usage this command to specify the RoHC header compression profiles to use.

Example

The following command sets the profiles to use as esp-ip and rtp-udp:

```
profile esp-ip rtp-udp
```
Chapter 120
IKEv2 Security Association Configuration Mode
Commands

The IKEv2 Security Association Configuration Mode is used to configure a Security Association at the outset of an IPsec session. A security association is the collection of algorithms and parameters (such as keys) that is being used to encrypt and authenticate a particular flow in one direction. In normal bi-directional traffic, the flows are secured by a pair of security associations.

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
default

Sets the default properties for the selected parameter.

Product
PDIF

Privilege
Security Administrator, Administrator

Syntax

default { encryption | group | hmac | lifetime | prf }

default { encryption | group | hmac | lifetime | prf }

Set the defaults for the following parameters:

- **encryption**: Default algorithm for the IKEv2 IKE SA is AES-CBC-128.
- **group**: Default Diffie-Hellman group is Group 2.
- **hmac**: Default IKEv2 IKE SA hashing algorithm is SHA1-96.
- **lifetime**: Default lifetime for SAs derived from this transform-set is 86400 seconds.
- **prf**: Default PRF for the IKEv2 IKE SA is SHA1.

Usage

Configure default parameters for the IKEv2 IKE SA transform-set.

Example

Use the following configuration to set the default encryption algorithm:

default encryption
encryption

Configure the appropriate encryption algorithm and encryption key length for the IKEv2 IKE security association. AES-CBC-128 is the default.

Product
PDIF

Privilege
Security Administrator, Administrator

Syntax

```
encryption { 3des-cbc | aes-cbc-128 | aes-cbc-256 | des-cbc }

default encryption
```

<table>
<thead>
<tr>
<th>3des-cbc</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Encryption Standard Cipher Block Chaining encryption applied to the message three times using three different cypher keys (triple DES).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>aes-cbc-128</th>
</tr>
</thead>
<tbody>
<tr>
<td>Advanced Encryption Standard Cipher Block Chaining with a key length of 128 bits.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>aes-cbc-256</th>
</tr>
</thead>
<tbody>
<tr>
<td>Advanced Encryption Standard Cipher Block Chaining with a key length of 256 bits.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>des-cbc</th>
</tr>
</thead>
</table>

Usage
IKEv2 requires a confidentiality algorithm to be applied in order to work. In cipher block cryptography, the plaintext is broken into blocks usually of 64 or 128 bits in length. In cipher block chaining (CBC) each encrypted block is chained into the next block of plaintext to be encrypted. A randomly-generated vector is applied to the first block of plaintext in lieu of an encrypted block. CBC provides confidentiality, but not message integrity.
Because RFC 4307 calls for interoperability between IPsec and IKEv2, the IKEv2 confidentiality algorithms must be the same as those configured for IPsec in order for there to be an acceptable match during the IKE message exchange. Because of RFC4307, in IKEv2, there is no viable NULL option, it is available for testing only.

Example
The following command configures the encryption to be the default aes-cbc-128:

```
default encryption
```
end

Exits the current mode and returns to the Exec Mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Change the mode back to the Exec Mode.
exit

Exits the current mode and returns to the previous mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

exit

Usage
Returns to the previous mode.
```plaintext
**group**

Configure the appropriate key exchange cryptographic strength by applying a Diffie-Hellman group. Default is Group 2.

**Product**
PDIF

**Privilege**
Security Administrator, Administrator

**Syntax**

```
group { 1 | 2 | 5 | 14 }
```

**default group**

1
Configs crypto strength at the Group 1 level. Lowest security.

2
Configs crypto strength at the Group 2 (default) level. Medium security. This is the default setting for this command.

5
Configs crypto strength at the Group 5 level. Higher security.

14
Configs crypto strength at the Group 14 level. Highest security.

**Usage**
Diffie-Hellman groups are used to determine the length of the base prime numbers used during the key exchange process in IKEv2. The cryptographic strength of any key derived depends, in part, on the strength of the Diffie-Hellman group upon which the prime numbers are based.
Group 1 provides 768 bits of keying strength, Group 2 provides 1024 bits, Group 5 provides 1536 bits and Group 14 provides 2048 bits of encryption strength.
Configuring a DH group also enables Perfect Forward Secrecy, which is disabled by default.

**Example**
This command configures security at the default level (Group 2):

```
default group
```
hmac

Configures the IKEv2 IKE SA integrity algorithm. Default is SHA1-96.

Product
PDIF

Privilege
Security Administrator, Administrator

Syntax

hmac { md5-96 | sha1-96 }
default hmac

md5-96
HMAC-MD5 uses a 128-bit secret key and produces a 128-bit authenticator value.

sha1-96
HMAC-SHA-1 uses a 160-bit secret key and produces a 160-bit authenticator value. This is the default setting for this command.

Usage
IKEv2 requires an integrity algorithm be configured in order to work. A keyed-Hash Message Authentication Code, or HMAC, is a type of message authentication code (MAC) calculated using a cryptographic hash function in combination with a secret key to verify both data integrity and message authenticity. A hash takes a message of any size and transforms it into a message of a fixed size: the authenticator value. This is truncated to 96 bits and transmitted. The authenticator value is reconstituted by the receiver and the first 96 bits are compared for a 100 percent match. Because RFC 4306 calls for interoperability between IPsec and IKEv2, the IKEv2 integrity algorithms must be the same as those configured for IPsec in order for there to be an acceptable match during the IKE message exchange.

Example
The following command configures the default HMAC value (SHA1-96):

default hmac
lifetime

Configure the lifetime of a security association (SA) in seconds.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

lifetime sec

default lifetime

lifetime sec
Default: 86400
Sets the value of the timeout parameter. sec must be an integer from 60 to 86400.

Usage

The secret keys that are used for various aspects of a configuration should only be used for a limited amount of time before timing out. This exposes a limited amount of data to the possibility of hacking. If the SA expires, the options are then to either close the SA and open a new one, or renew the existing SA.

Example

The following command sets the lifetime timeout to be the default value (86400):

default lifetime
prf

Select one of the HMAC integrity algorithms to act as the IKE Pseudo-Random Function. A PRF produces a string of bits that an attacker cannot distinguish from random bit string without knowledge of the secret key. The default is SHA1.

**Product**

PDIF

**Privilege**

Security Administrator, Administrator

**Syntax**

```
prf { md5 | sha1 }
```

**Default prf**

```
md5
```

MD5 uses a 128-bit secret key and produces a 128-bit authenticator value.

```
sha1
```

SHA-1 uses a 160-bit secret key and produces a 160-bit authenticator value. SHA-1 is considered cryptographically stronger than MD5, but it takes more CPU cycles to compute. This is the default setting for this command.

**Usage**

The prf is used for generating keying material for all the cryptographic algorithms used in both the IKE_SA and the CHILD_SAs.

**Example**

This configuration sets the prf to be the default value (sha1):

```
default prf
```
Chapter 121
IMS Authorization Service Configuration Mode Commands

IP Multimedia Sub-system (IMS) authorization service is used to configure authorization parameters to manage policy control functions and Gx and Ty interface support with Diameter based procedures for flow based charging within a context. The system uses Gx/Gy and Tx/Ty functionality based on the charging policy and rules configured to flow based charging for a subscriber session.

---

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the IMS Authorization Configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to change to the Exec mode.
exit

Exits the current configuration mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
exit
```

Usage
Use this command to return to the parent configuration mode.
p-cscf discovery

This command defines the method of Proxy-Call Session Control Function (P-CSCF) discovery to be used.

Product
GGSN

Privilege
Security Administrator, Administrator

Syntax

```plaintext
p-cscf discovery { table { 1 | 2 } [ algorithm { ip-address-modulus | msisdn-modulus | round-robin } ] | diameter-configured }
[ default | no ] p-cscf discovery
```

---

default
Sets the P-CSCF discovery to default parameter.

---

no
Removes/deletes configured parameters for P-CSCF discovery.

---

```plaintext
table { 1 | 2 }
```

This keyword specifies that which P-CSCF table is to be used to obtain the primary and secondary P-CSCF addresses. Total 2 tables can be configured for P-CSCF discovery.

---

```plaintext
algorithm { ip-address-modulus | msisdn-modulus | round-robin }
```

This keyword specifies the algorithm to select the row from the P-CSCF table to be used for P-CSCF discovery.

- **ip-address-modulus**: This algorithm divides the IP address, in binary, of the subscriber by the number of rows in the table, and the remainder is used as an index into the specified table to select the row.
- **msisdn-modulus**: This algorithm divides the MSISDN value in binary without the leading “+” of the subscriber by the number of rows in the table, and the remainder is used as an index in the specific table to select the row.
- **round-robin**: This algorithm rotates all rows in the active table for selection of the row in round-robin way. If no algorithm is specified this is the default behavior.

Default: round-robin.

---

diameter-configured
This option enables the table number and algorithm specified by the `diameter host-select table` configuration in Policy Control Configuration mode. If the primary host in that configuration is down it assumes that the primary P-CSCF in the row of P-CSCF table is also down, and it does not return that IP address in the create PDP context response. This option also performs the deactivation processing of the PDP contexts when Diameter Policy Control Application (DPCA) switches, host tables as detailed in the `diameter host-select` command description in Policy Control Configuration mode.
Usage
Use this command to configure the table and row selection methods to select IP address/host address for P-CSCF discovery.

Example
The following command specifies table 1 with round-robin algorithm to select the rows with IP address for P-CSCF discovery.

```
p-cscf discovery table 1 algorithm round-robin
```
p-cscf table

This command adds/appends rows with primary and/or secondary IPv4/IPv6 address to a P-CSCF discovery table with precedence for Proxy-Call Session Control Function (P-CSCF) discovery.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
p-cscf table { 1 | 2 } row-precedence precedence_value { address ip_address | ipv6-address ipv6_address } [ secondary { address ip_address | ipv6-address ipv6_address } ]
```

```
no p-cscf table { 1 | 2 } row-precedence precedence_value
```

no
Removes/deletes configured row with precedence in specified table for P-CSCF discovery address.

```
{ 1 | 2 }
```
Specifies which P-CSCF table is to be used to add/append the primary and secondary P-CSCF addresses. Two tables can be configured for P-CSCF discovery address.

```
row-precedence precedence_value
```
This keyword adds/appends the row with the specified row-precedence to the P-CSCF address table. In StarOS 8.1 and later, `precedence_value` must be an integer from 1 through 128, and a maximum of 128 rows can be added to a table. In StarOS 8.0, `precedence_value` must be an integer from 1 through 100, and a maximum of 16 rows can be added to a table.

```
secondary
```
Specifies the secondary IPv4/IPv6 address to be entered in P-CSCF table rows.

```
address ip_address
```
Specifies the primary and/or secondary IPv4 address for P-CSCF discovery table. This keyword, if used with `secondary` keyword, specifies the secondary IPv4 address. `ip_address` must be an IPv4 IP address entered using dotted decimal notation.

```
ipv6-address ipv6_address
```
Specifies the primary and/or secondary IPv6 address for P-CSCF discovery table. This keyword, if used with `secondary` keyword, specifies the secondary IPv6 address. `ipv6_address` must be an IPv6 IP address entered using colon (:) separated notation.

Usage
Use this command to add rows with primary and/or secondary IP addresses for P-CSCF discovery. The row is added with the specified row-precedence. The operator can add/remove rows to the table that is not currently selected by the `diameter host-select table` command in Policy Control Configuration Mode.

**Example**
The following command adds a row in table 2 with primary IP address 1.2.3.4, secondary IP address as 5.6.7.8, and row-precedence value as 20 for P-CSCF discovery.

```
p-cscf table 2 row-precedence 20 address 1.2.3.4 secondary 5.6.7.8
```
policy-control

This command enters the Policy Control Configuration mode for Diameter Policy Control Application (DPCA) to configure Diameter authorization and policy control parameter for IMS authorization.

Product
All

Privilege
Security Administrator, Administrator

Syntax

[ no ] policy-control

---

no
Disables the pre-configured policy control parameters for IMS authorization in this IMS authorization service.

---

Usage
Use this command to enter the Policy Control Configuration Mode to configure the policy control parameters for Diameter authorization and charging policy in IMS Authorization Service.

---

Example

policy-control
qos-update-timeout

This command sets the Quality of Service update timeout for a subscriber in IMS authorization service.

Product
GGSN

Privilege
Security Administrator, Administrator

Syntax
qos-update-timeout timeout_duration
[ no ] qos-update-timeout

no
Disables the pre-configured QoS update timeout parameter in this IMS authorization service.

timeout_duration
Specifies the duration of timeout in seconds, and must be an integer from 0 through 3600. Default: 60

Usage
Use this command to set the maximum time to wait for a subscriber to initiate the update QoS procedure in IMS authorization service.

Example
The following command sets the QoS update timeout to 90 seconds.

qos-update-timeout 90
signaling-flag

This command specifies whether a request for a PDP context dedicated to signaling (for IMS sessions) should be granted or denied.

Product
GGSN

Privilege
Security Administrator, Administrator

Syntax

    signaling-flag { deny | permit }

    [ default ] signaling-flag

    default
    Sets the signaling flag to default mode of deny.

    deny
    When specified this keyword denies the request for a signaling PDP context for IMS session and keeps signaling co-existed with other traffic on PDP contexts.
    Default: Enabled

    permit
    When specified this keyword permit the request for a signaling PDP context for IMS session and a separate signaling context activated.
    Default: Disabled

Usage

Use this command to allow or deny the activation of dedicated PDP context for signaling. The user equipment (UE) may indicate that the PDP context should be dedicated for IP multimedia (IM) signaling by setting the IP Multimedia Core Network (IM CN) signaling flag in the Protocol Configuration Options (PCO).

The deny option causes the system to inform the UE that the PDP context will not be dedicated for IM signaling and signaling will co-exist with other traffic on PDP context.

The permit option is used to activate the signaling context for signal traffic and the other traffic uses other PDP context for traffic with the following destinations:
  ● Towards the DHCP and DNS servers for the IMS domain.
  ● Towards the P-CSCF(s).

The UE is not trusted to follow these restrictions, and the system monitors and restricts the traffic from the dedicated PDP context. The signaling-flow class-map command is used to configure the restrictions.

Example

The following command denies the request for a signaling PDP context for IMS session.
default signaling-flag
signaling-flow permit

This command specifies the packet filters and policy servers for bandwidth control and singling context enforcement that define the traffic that is allowed through the dedicated signaling context.

Product
GGSN

Privilege
Security Administrator, Administrator

Syntax

```
signaling-flow permit server-address ip_address [ server-port { port_num | range start_port to end_port } ] [ description STRING ]
[ no ] signaling-flow permit server-address ip_address [ server-port { port_num | range start_port to end_port } ]
```

no
Disables the signaling flow option configured with this command.

`server-address ip_address`

The server address `ip_address` refers to the destination IP address in uplink packets, and the source IP address in downlink packets.

- `ip_address` is IPv4/IPv6 address in standard notation and can be used with sub-net mask.
- A maximum of 16 signaling server address can be configured per IMS Authorization service.

`server-port { port_num | range start_port to end_port }`

Specifies the TCP/UDP port number(s) of the server and to be used for communication.

- `port_num` must be an integer from 1 through 65535.
- `range start_port to end_port` provides the option to configure the range of ports on server for communication.

- `start_port` must be an integer from 1 through 65535 but lesser than `end_num`, and `end_port` must be an integer from 1 through 65535 but greater than `start_num`.

`description STRING`

Specifies the customized description for configured signaling server.

- `STRING` must be an alpha and/or numeric string with maximum of 64 characters.

Usage
Traffic that matches any instance of the signaling-flow command will be forwarded via the signaling PDP context. In addition, the policy server gives policy gates to use for the signaling PDP context.

Example
The following command sets the packet filter server address to `1.2.3.4` with port number `1234` for packet filtering.
signaling-flow server-address 1.2.3.4 server-port 1234
**traffic-policy general-pdp-context**

This command specifies the action on packets which do not match any policy gates in the general purpose PDP context.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
traffic-policy general-pdp-context no-matching-gates direction { downlink | uplink } { forward | discard }

default traffic-policy general-pdp-context no-matching-gates direction { downlink | uplink }
```

- **default**
  Sets the default traffic policy for packets without any policy gate match in general purpose PDP context. By default packets which do not have any matching policy gate are forwarded.

- **no-matching-gates**
  This keyword applies traffic policy for packets which do not match any policy gate.

- **direction { downlink | uplink }**
  Specifies the direction of traffic to apply this traffic policy in general PDP context.

  - **downlink**
    Specifies the traffic from system to MN. Default is set to forward.

  - **uplink**
    Specifies the traffic from MN to system. Default is set to forward.

- **forward**
  This option forward the packets which do not match any policy gates.
  Default: Enabled

- **discard**
  This option discards the packets which do not match any policy gates.
  Default: Disabled

**Usage**

This command provides configuration on traffic policy applied on packets which are not matching any policy gate in general PDP context. Packets can either forwarded or discarded on the basis of operators configuration.

This command needs to be configured once for downlink and once for uplink separately.

**Example**

The following command discard uplink packets which do not match any policy gate in general purpose PDP context.
traffic-policy general-pdp-context no-matching-gates direction uplink discard
Chapter 122
IMS Sh Service Configuration Mode Commands

The IMS Sh Interface Configuration Mode is used to configure various Diameter parameters in order for:
PDIF to communicate with the HSS server. HSS server is used for MAC address validation in the IKEv2 exchanges to set up SAs and for storing part of the user profile. SCM to communicate with the HSS server. HSS server is used for retrieval and update of call feature parameters and call restriction data.

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
diameter

This command configures Diameter parameters.

Product
PDIF, SCM

Privilege
Administrator

Syntax

diameter { dictionary { custom1 | standard } | endpoint string }
default diameter { dictionary | endpoint }
no diameter endpoint

no
Removes previously configured endpoint.

default
Configures parameters to the default value.

dictionary
Specifies the dictionary to use.
• custom1: A custom dictionary
• standard: The standard dictionary

Important: SCM uses only the standard dictionary.

endpoint string
Selects an endpoint to use in the configuration.
string must be the endpoint name, and must be an alpha and/or numeric string of 1 through 63 characters in length.

Usage
The Diameter endpoint contains information on the peer names and IP addresses and port, and the local IP address to use for Diameter.
You can have more than one Diameter endpoint configured on the chassis and the ims-sh-service needs to know which Diameter endpoint to use. This command is to select the appropriate Diameter endpoint, even if only one has been configured.

Example
The following example selects a diameter endpoint diam1:
diameter endpoint diam1
end

Exits the current mode and returns to the Exec Mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to change to the Exec Mode.
exit

Exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

exit

Usage
Use this command to return to the parent configuration mode.
**failure-handling**

This command configures the action to take in the event of an HSS server request failure.

**Product**
PDIF, SCM

**Privilege**
Administrator

**Syntax**

```plaintext
default failure-handling { profile-update-request | user-data-request } { { diameter-result-code result_code [ to result_code ] } | timeout } action { continue | retry-and-terminate | terminate } }
```

**default**
Resets configuration for the specified keyword to the default setting.

**profile-update-request**
Configures failure-handling as a result of a profile update request error.

**user-data-request**
Configures failure-handling as a result of a user data request.

**diameter-result-code result_code [ to result_code ]**
The Result-Code data field contains a space representing errors. Diameter provides the following classes of errors, all identified by the thousands digit in the decimal notation:
- 3xxx (Protocol Errors)
- 4xxx (Transient Failures)
- 5xxx (Permanent Failure)

`result_code` specifies either a result code value (`diameter-result-code 3001`) or a range of result code values (`diameter-result-code 3000 to 9999`) to which the failure-handling applies.

**action**
Configures the action to take depending on the diameter-result-code:
- Continue the session
- Retry and then terminate
- Terminate the session

**request-timeout action**
Configures the action to take as a result of a request timeout error:
- Continue the session
- Retry and then terminate
- Terminate the session
Usage

Configures all failure-handling parameters.

Example

The following command configures profile-update-request failure-handling using a result-code configuration with the terminate session option:

```
failure-handling profile-update-request diameter-result-code 3005 to 3600 action terminate
```
**request**

Configures application request timeout.

**Product**

PDIF, SCM

**Privilege**

Administrator

**Syntax**

```
request timeout secs
```

```
[ no | default ] request timeout
```

- **no**
  Disables a configured timeout request.

- **default**
  Default: 300 seconds
  Resets configuration to the default setting.

```
request timeout secs
```

Configures the request timeout in seconds.

*secs* must be an integer from 1 through 300.

**Usage**

Specifies the session request timeout period in seconds after which the request is deemed to have failed.

**Example**

The following example configures the default timeout request of 300 seconds:

```
default request timeout
```
Chapter 123
IPMS Client Configuration Mode Commands

The IPMS Client Configuration Mode is used to enable the IPMS client service on an Access Gateway and to set basic service wide options in a context.

**Important:** This is a license enabled external application support. For more information on this product, refer to the IPMS Installation and Administration Guide.

```
Exec Mode
  configure
    Global Configuration Mode
      context name
        Context Configuration Mode
          ipms
            IPMS Configuration Mode
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Change the mode back to the Exec mode.
exit

Exits the current mode and returns the CLI session to the previous parent mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the parent CLI mode.
export keys

This command enables the encryption key export in specific key exchange events to IPMS server from IPMS-enabled AGW.

**Important:** This is a license enabled customer specific command.

**Product**
IPMS

**Privilege**
Security Administrator, Administrator

**Syntax**

```
no
```

Removes the configured source IP address from this context for IPMS client communication with IPMS server.

```
ikev2
```

This keyword enables the security association (SA) key export for Internet Key Exchange (IKEv2) protocol to IPMS server.

**Usage**
Monitor subscribers which have complaints of service availability or to monitor a test user for system verification.

**Example**
The following command assigns the IP address 1.2.3.4 to the IPMS client service in context to communicate with IPMS server. This is the IP address allocated for IPMS client service on chassis.

```
source address 1.2.3.4
```
heartbeat

This command configures the IPMS heartbeating between IPMS-enabled AGW and IPMS server.

Product
IPMS

Privilege
Security Administrator, Administrator

Syntax

```
heartbeat period dur [ permitted-failure no_of_failures ]
[ no | default ] heartbeat
```

default
Configures the heartbeat period and permitted number of failure to default value of 10 seconds and 1 failure respectively.

no
Disables/removes the configured heartbeat period and permitted number of failure.

period dur
Default: 10
Specifies the periodicity in seconds of heartbeat messages.

dur is the duration in second between two heartbeat messages and must be an integer value from 1 through 3600.

permitted-failure no_of_failures
Default: 1
Specifies the number of errors/failures allowed before declaring an IPMS server as dead/unreachable.

no_of_failures is the number of errors/failure of heartbeat message response and must be an integer value from 1 through 10.

Usage

Use this command to configure the heartbeat message periodicity and permissible failure of heartbeat message response before declaring an IPMS server as dead or unreachable. When an IPMS server is declared down an SNMP trap is sent.

Example

Following command configures the heartbeat message periodicity to 5 second and number of failures allowed as 3 to determine an IPMS server as dead.

```
heartbeat period 5 permitted-failure 3
```
server

This command configures the IPMS server address and ports on which IPMS client on IPMS-enabled AGW communicates. This is the IP address and port range of IPMS server.

Product
IPMS

Privilege
Security Administrator, Administrator

Syntax

server address ip_address [ secondary ] [ start-port start_port [ end-port end_port ] ] [ secondary ]

no server address ip_address

no
Removes the configured IPMS server IP address and port range from this context.

address ip_address
Specifies the IP address of the IPMS server to which the IPMS client service communicates. This is the address which is used by IPMS client service to locate the IPMS server.
A maximum of 4 IPMS servers can be configured with this command in one context.
ip_address must be an IP v4 address in dotted decimal notation.

[start-port start_port [ end-port end_port ] ]
Default: 45001 source port
45005 end port
Specifies the range of UDP ports on which IPMS client communicates with IPMS server.
start-port start_port is the starting port number and must be an integer value in the range from 1 through 65535 but less than end_port if end-port is specified.
end-port end_port is the end port number and must be an integer value in the range from 1 through 65535 but more than start_port.

secondary
The secondary keyword is used to configure the specified server address as secondary IP address on the IPMS client interface.

Usage
Use this command to configure/remove the IPMS servers. Up to 4 different IPMS servers can be configured with this command. UDP port number can also be configured with this command. IPMS client will search for this IP address to push the event and traffic logs.

Example
The following command configures IPMS server having IP address 1.2.3.4 in the IPMS client service export the event and traffic logs for intelligent packet monitoring functionality. It also specifies the UDP port range from 48000 to 48005 for communication.

```
server address 1.2.3.4 start-port 48000 end-port 48005
```
source

This command configures the source address of IPMS client in this context to communicate with IPMS server. This is the IP address for IPMS client on the chassis.

Product
IPMS

Privilege
Security Administrator, Administrator

Syntax

```
source address ip_address
```

```
address ip_address
```

Specifies the IP address of the IPMS client on the AGW in this context. This is the address which is bound to the IPMS client service in this context.

```
 ip_address
```

must be an IP v4 address in dotted decimal notation.

Usage
Monitor subscribers which have complaints of service availability or to monitor a test user for system verification.

Example
The following command assigns the IP address 1.2.3.4 to the IPMS client service in context to communicate with IPMS server. This is the IP address allocated for IPMS client service on chassis.

```
source address 1.2.3.4
```
Chapter 124
IPSec Transform Set Configuration Mode Commands

The IPSec Transform Set Configuration Mode is used to configure IPsec security parameters. There are two core protocols, the Authentication Header (AH) and Encapsulating Security Payload (ESP). AH may be considered redundant as ESP can provide the same authentication services that AH does.

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
default

Set or restore the default mode for a given parameter

Product
PDIF

Privilege
Security Administrator, Administrator

Syntax

default { encryption | group | hmac | mode }

default { encryption | group | hmac | mode }

Set the defaults for the IPSec transform-set as follows:

• encryption: Default Child SA IPSec ESP algorithm is AES-CBC-128.
• group: Default Diffie-Hellman group algorithm is none. This also deactivates PFS.
• hmac: Default Child SA IPSec hashing algorithm is SHA1-96.
• mode: Default Child SA IPSec Mode is Tunnel.

Usage
Defines the default values for the Child SA IPSec transform-set.

Example
Use the following configuration to set the default mode to Tunnel:

default mode
encryption

Configures the appropriate IPsec ESP encryption algorithm and encryption key length. AES-CBC-128 is the default.

Product
PDIF

Privilege
Security Administrator, Administrator

Syntax

encryption { 3des-cbc | aes-cbc-128 | aes-cbc-256 | des-cbc | null }

default encryption

3des-cbc
Data Encryption Standard Cipher Block Chaining encryption applied to the message three times using three different cypher keys (triple DES).

aes-cbc-128
Advanced Encryption Standard Cipher Block Chaining with a key length of 128 bits. This is the default setting for this command.

aes-cbc-256
Advanced Encryption Standard Cipher Block Chaining with a key length of 256 bits.

des-cbc

null
The NULL encryption algorithm represents the optional use of applying encryption within ESP. ESP can then be used to provide authentication and integrity without confidentiality.

Usage
In cipher block cryptography, the plaintext is broken into blocks usually of 64 or 128 bits in length. In cipher block chaining (CBC) each encrypted block is chained into the next block of plaintext to be encrypted. A randomly generated vector is applied to the first block of plaintext in lieu of an encrypted block. CBC provides confidentiality, but not message integrity.
Because RFC 4307 calls for interoperability between IPsec and IKEv2, the IKEv2 confidentiality algorithms must be the same as those configured for IPsec in order for there to be an acceptable match during the IKE message exchange. In IKEv2, there is no NULL option.

Example
The following command configures the encryption to be the default aes-cbc-128:
default encryption
end

Exits the current mode and returns to the Exec Mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
end
```

Usage

Change the mode back to the Exec Mode.
exit

Exits the current mode and returns to the previous mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Returns to the previous mode.
group

Configure the appropriate key exchange cryptographic strength and activate Perfect Forward Secrecy by applying a Diffie-Hellman group.

Product
PDIF

Privilege
Security Administrator, Administrator

Syntax

group { 1 | 2 | 5 | 14 | none }

default group

default group
Configures the default crypto strength to be none and disables Perfect Forward Secrecy.

1
Configures crypto strength at the Group 1 level. Lowest security.

2
Configures crypto strength at the Group 2 level. Medium security.

5
Configures crypto strength at the Group 5 level. Higher security.

14
Configures crypto strength at the Group 14 level. Highest security.

none
Applies no group and disables Perfect Forward Secrecy. This is the default.

Usage

Diffie-Hellman groups are used to determine the length of the base prime numbers used during the key exchange process. The cryptographic strength of any key derived depends, in part, on the strength of the Diffie-Hellman group upon which the prime numbers are based. Group 1 provides 768 bits of keying strength, Group 2 provides 1024 bits, Group 5 provides 1536 bits and Group 14 2048 bits. Selecting a group automatically activates Perfect Forward Secrecy. The default value is none, which disables PFS

Example
This command configures security at Group 2 and activates PFS:
group 2
**hmac**

Configures the IPsec ESP integrity algorithm.

**Product**
PDIF

**Privilege**
Security Administrator, Administrator

**Syntax**

```
hmac { md5-96 | sha1-96 | null }
default hmac
```

---
```
default
Configures the default hmac value of sha1-96.
```

---
```
md5-96
MD5-96 uses a 128-bit secret key and produces a 128-bit authenticator value.
```

---
```
sha1-96
SHA-1 uses a 160-bit secret key and produces a 160-bit authenticator value.
This is the default setting for this command.
```

---
```
null
Configures the hmac value to be null. The NULL encryption algorithm represents the optional use of applying encryption within ESP. ESP can then be used to provide authentication and integrity without confidentiality.
```

---

**Usage**

HMAC is an encryption technique used by IPsec to make sure that a message has not been altered. A keyed-Hash Message Authentication Code, or HMAC, is a type of message authentication code (MAC) calculated using a cryptographic hash function in combination with a secret key to verify both data integrity and message authenticity. A hash takes a message of any size and transforms it into a message of a fixed size: the authenticator value. This is truncated to 96 bits and transmitted. The authenticator value is reconstituted by the receiver and the first 96 bits are compared for a 100 percent match. Because RFC 4306 calls for interoperability between IPsec and IKEv2, the IKEv2 integrity algorithms must be the same as those configured for IPsec in order for there to be an acceptable match during the IKE message exchange.

---

**Example**
The following command configures the default HMAC value (SHA1-96):

```
default hmac
```
IPSec Transform Set Configuration Mode Commands

hmac
mode

Configures the security of IP datagrams based on header placement. Tunnel mode applies security to a completely encapsulated IP datagram, while Transport does not. Default is Tunnel mode.

Product
PDIF

Privilege
Security Administrator, Administrator

Syntax

```
mode { transport | tunnel }

default mode
```

**transport**

In Transport mode, the IPSec header is applied only over the IP payload, not over the IP header in front of it. The AH and/or ESP headers appear between the original IP header and the IP payload, as follows:
Original IP header, IPSec headers (AH and/or ESP), IP payload (including transport header).
Transport mode is used for host-to-host communications and is generally unsuited to PDIF traffic.

**tunnel**

In Tunnel mode, the original IP header is left intact, so a complete IP datagram is encapsulated, forming a virtual tunnel between IPSec-capable devices. The IP datagram is passed to IPSec, where a new IP header is created ahead of the AH and/or ESP IPSec headers, as follows:
New IP header, IPSec headers (AH and/or ESP), old IP header, IP payload.
Tunnel mode is used for network-to-network communications (secure tunnels between routers) or host-to-network and host-to-host communications over the Internet.
This is the default setting for this command.

**Usage**

IPSec modes are closely related to the function of the two core protocols, the Authentication Header (AH) and Encapsulating Security Payload (ESP). Both of these protocols provide protection by adding to a datagram a header (and possibly other fields) containing security information. The choice of mode does not affect the method by which each generates its header, but rather, changes what specific parts of the IP datagram are protected and how the headers are arranged to accomplish this.

**Example**

The following command configures the default Tunnel mode:

```
default mode
```
Chapter 125
IPSG RADIUS Server Configuration Mode Commands

The IP Services Gateway (IPSG) RADIUS Server Configuration Mode is used to create and configure IPSG services in
the current system context. The IPSG RADIUS Server Mode configures the system to receive RADIUS accounting
requests as if it is a RADIUS Accounting Server, and reply after accessing those requests for user information.

Important: The commands or keywords/variables that are available are dependent on platform type, product
version, and installed license(s).
bind

This command binds the IPSG RADIUS Server service to a logical AAA interface and specifies the number of allowed subscriber sessions.

Product
IPSG

Privilege
Security Administrator, Administrator

Syntax

```
bind { accounting-proxy address ip_address | address ip_address } [ max-subscribers max_sessions | port port_number | source-context source_context ]
bind authentication-proxy address ip_address [ acct-port port_number | auth-port port_number | max-subscribers max_sessions | source-context source_context ]
```

no bind

no

Removes the binding for the service.

```
accounting-proxy address ip_address | address ip_address } [ max-subscribers max_sessions | port port_number | source-context source_context ]
```

- **accounting-proxy address ip_address**: Specifies IP address of the interface where accounting proxy requests are received by this service.
  
  `ip_address` must be specified using standard IPv4 or IPv6 dotted decimal notation.

- **address ip_address**: Specifies IP address of the interface where accounting requests are received by this service.
  
  `ip_address` must be specified using standard IPv4 or IPv6 dotted decimal notation.

- **max-subscribers max_sessions**: Specifies the maximum number of subscriber sessions allowed for the service. If this option is not configured, the system defaults to the license limit.
  
  On an ST16 chassis, in Release 8.x and later, `max_sessions` must be an integer from 0 through 1000000.
  
  On an ASR 5000 chassis, in Release 8.x, `max_sessions` must be an integer from 0 through 3000000. In Release 9.x and later, `max_sessions` must be an integer from 0 through 4000000.

- **port port_number**: Specifies the port number of the interface where accounting requests are received by this service.
  
  `port_number` must be an integer from 0 through 65535.
  
  Default: 1813

- **source-context source_context**: Specifies the source context where RADIUS accounting requests are received.
  
  `source_context` must be an alpha and/or numeric string of 1 through 79 characters in length.
This keyword should be configured if the source of the RADIUS requests is in a different context than the IPSG service. If this keyword is not configured, the system will default to the context in which the IPSG service is configured.

```
authentication-proxy address ip_address [ acct-port port_number | auth-port port_number | max-subscribers max_sessions | source-context source_context ]
```

- **authentication-proxy address ip_address**: Specifies IP address of the interface where authentication proxy requests are received by this service.
  - `ip_address` must be specified using standard IPv4 or IPv6 dotted decimal notation.

**Important**: Enabling authentication proxy also enables accounting proxy.

- **acct-port port_number**: Specifies the port number of the interface where accounting proxy requests are received by this service.
  - `port_number` must be an integer from 0 through 65535.
  - Default: 1813

- **auth-port port_number**: Specifies the port number of the interface where authentication proxy requests are received by this service.
  - `port_number` must be an integer from 0 through 65535.
  - Default: 1812

- **max-subscribers max_sessions**: Specifies the maximum number of subscriber sessions allowed for the service. If this option is not configured, the system defaults to the license limit.
  - On an ST16 chassis, in Release 8.x and later, `max_sessions` must be an integer from 0 through 1000000.
  - On an ASR 5000 chassis, in Release 8.x, `max_sessions` must be an integer from 0 through 3000000. In Release 9.0 and later, `max_sessions` must be an integer from 0 through 4000000.

- **source-context source_context**: Specifies the source context where RADIUS accounting requests are received.
  - `source_context` must be an alpha and/or numeric string of 1 through 79 characters in length.
  - This keyword should be configured if the source of the RADIUS requests is in a different context then the IPSG service. If this keyword is not configured, the system will default to the context in which the IPSG service is configured.

**Usage**

Use this command to bind the IPSG RADIUS Server service to a logical AAA interface and specify the number of allowed subscriber sessions. If the AAA interface is not located in this context, configure the `source-context` parameter.

Use the accounting and authentication proxy settings to enable RADIUS proxy server functionality on the IPSG. These commands are used when the NAS providing the RADIUS request messages is incapable of sending them to two separate devices. The IPSG in RADIUS Server mode proxies the RADIUS request and response messages while performing the user identification task in order to provide services to the session.
Example
The following command binds the service to a AAA interface with and IP address of `1.2.3.4` located in the source context named `aaa_ingress`:

```plaintext
bind address 1.2.3.4 source-context aaa_ingress
```
connection authorization

This command configures the RADIUS authorization password that must be matched by the RADIUS accounting requests received by this service.

Product
IPSG

Privilege
Security Administrator, Administrator

Syntax

connection authorization { [ encrypted ] password password }

no connection authorization

no

Removes the RADIUS authorization for the IPSG RADIUS server service.

[ encrypted ] password password

encrypted: Specifies that the RADIUS authorization password is encrypted.

password password: Specifies the password that must be matched by incoming RADIUS accounting requests.

password must be an alpha and/or numeric string of 1 through 63 characters in length.

Usage

The IPSG RADIUS server service does not terminate RADIUS user authentication so the user password is unknown.

Use this command to configure the authorization password that the RADIUS accounting requests must match in order for the service to examine and extract user information.

Example

The following command sets the RADIUS authorization password that must be matched by the RADIUS accounting requests sent to this service. The password must be encrypted and the example provided is the word “secret”.

connection authorization encrypted password secret
end

This command exits the IPSG RADIUS Server Configuration Mode and returns the CLI prompt to the Exec Mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
end

**Usage**
Use this command to change to the Exec Mode.
exit

This command exits the IPSG RADIUS Server Configuration Mode and returns the CLI prompt to the Context Configuration Mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

exit

Usage
Use this command to return to the Context Configuration Mode.
profile

This command configures the service to use APN or subscriber profiles.

Product
IPSG

Privilege
Security Administrator, Administrator

Syntax

profile { APN | subscriber }

default profile

default
Configures the default setting for this command.
Default: APN

APN
Sets the service to support APN configuration required to enable Gx support.

subscriber
Sets the service to support subscriber profile lookup.

Usage
Use this command to set the service to support APN profiles (supporting Gx through the enabling of `ims-auth-service`) or for basic subscriber profile lookup.
radius accounting

Specifies the IP address and shared secret of the RADIUS accounting client from which RADIUS accounting requests are received. The RADIUS client can be either the access gateway or the RADIUS accounting server depending on which device is sending accounting requests.

Product
IPSG

Privilege
Security Administrator, Administrator

Syntax

```bash
radius accounting { { client { ip_address | ip_address/mask } [ encrypted ] key secret [ dictionary dictionary ] } | { interim create-new-call } }

no radius accounting client { ip_address | ip_address/mask }

default radius accounting interim create-new-call
```

- **no**
  - Removes the RADIUS accounting client address identifier from the service.

  ```bash
  ip_address | ip_address/mask
  ```
  - Specifies the IP address and, optionally, subnet mask of the RADIUS client from which RADIUS accounting requests are received. `ip_address` and `ip_address/mask` must be specified using standard IPv4 or IPv6 dotted decimal notation. Up to 16 addresses can be configured.

- **dictionary dictionary**
  - Specifies what dictionary database to use. The possible values for `dictionary` are described in the following table:

**Table 24.**

<table>
<thead>
<tr>
<th>Dictionary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3gpp2</td>
<td>This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835-A.</td>
</tr>
<tr>
<td>3gpp2-835</td>
<td>This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835.</td>
</tr>
<tr>
<td>custom(x)</td>
<td>These are dictionaries that can be customized to fit your needs. Customization information can be attained by contacting your local service representative. (x) is the integer value of the custom dictionary.</td>
</tr>
<tr>
<td>standard</td>
<td>This dictionary consists only of the attributes specified in RFC 2865, RFC 2866, and RFC 2869.</td>
</tr>
</tbody>
</table>
### Dictionary Description

<table>
<thead>
<tr>
<th>Dictionary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>starent</td>
<td>This dictionary consists of all of the attributes in the starent-vsa1 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the dictionaries supported by the system.</td>
</tr>
<tr>
<td>starent-835</td>
<td>This dictionary consists of all of the attributes in the starent-vsa1-835 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the -835 dictionaries supported by the system.</td>
</tr>
<tr>
<td>starent-vsa1</td>
<td>This dictionary consists not only of the 3gpp2 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0 - 255). This is the default dictionary.</td>
</tr>
<tr>
<td>starent-vsa1-835</td>
<td>This dictionary consists not only of the 3gpp2-835 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0 - 255). This is the default dictionary.</td>
</tr>
</tbody>
</table>

```
[ encrypted ] key secret
  • encrypted: Specifies that the shared key between the RADIUS client and this service is encrypted.
  • key secret: Specifies the shared key between the RADIUS client and this service.
    secret must be an alpha and/or numeric string of 1 through 127 characters in length, and is case sensitive.

interim create-new-call
Enables the ability to create a new session upon receipt of a RADIUS interim message.
Default: Disabled
```

**Usage**

Use this command to configure the communication with the RADIUS client from which RADIUS accounting requests are received.

**Example**

The following command configures the service to communicate with a RADIUS client with an IP address of 1.2.3.4 and an encrypted shared secret of `secret_1234`:

```
radius accounting client 1.2.3.4 encrypted key secret_1234
```
radius dictionary

Configures the RADIUS database dictionary to use for the IPSG service.

Product
IPSG

Privilege
Security Administrator, Administrator

Syntax

radius dictionary dictionary

default radius dictionary

dictionary dictionary

Default: starent-vsa1

Specifies what dictionary database to use. The possible values for dictionary are described in the table that follows:

<table>
<thead>
<tr>

This is the default dictionary.</td>
</tr>
</tbody>
</table>
**radius dictionary**

**Usage**

Use this command to specify the RADIUS database dictionary to use for the IPSG service.

**Example**

The following command configures the IPSG service to use the `custom10` RADIUS database dictionary:

```
radius dictionary custom10
```
**setup-timeout**

Configures a timeout value for IPSG session set up attempts.

**Product**
IPSG

**Privilege**
Security Administrator, Administrator

**Syntax**

```
setup-timeout seconds
```

```
default setup-timeout
```

`seconds`
Specifies the time period, in seconds, the IPSG session setup is allowed to continue before the set up attempt is terminated.

`seconds` must be an integer from 1 through 100000.
Default: 60

**Usage**
Use this command to prevent IPSG session set up attempts from continuing without termination.

**Example**
The following command sets the session setup timeout to 20 seconds:

```
setup-timeout 20
```
Chapter 126
IPSG RADIUS Snoop Configuration Mode Commands

The IP Services Gateway (IPSG) RADIUS Snoop Configuration Mode is used to create and configure IPSG services within the current context. The IPSG RADIUS Snoop Mode configures the system to inspect RADIUS accounting requests on the way to the RADIUS accounting server and extract user information.

Exec Mode

configure

Global Configuration Mode

context name

Context Configuration Mode

ipsg-service name mode
radius-snoop

IPSG RADIUS Snoop Config Mode

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
bind

Configures the service to accept data on any interface configured in the context. Optionally allows the system to limit the number of sessions processed by this service.

**Product**

IPSG

**Privilege**

Security Administrator, Administrator

**Syntax**

```
bind [ max-subscribers max_sessions ]
```

```
no bind
```

```
no
```

Removes the binding for the service.

```
max-subscribers max_sessions
```

Specifies the maximum number of subscriber sessions allowed for the service. If this option is not configured, the system defaults to the license limit.

On an ST16 chassis, in Release 8.x and in Release 9.x and later, `max_sessions` must be an integer from 0 through 1000000.

On an ASR 5000 chassis, in Release 8.x, `max_sessions` must be an integer from 0 through 3000000. In Release 9.0 and later, `max_sessions` must be an integer from 0 through 4000000.

**Usage**

Use this command to initiate the service and begin accepting data on any interface configured in the context.

**Example**

The following command prepares the system to receive subscriber sessions on any interface in the context and limits the sessions to 10000:

```
bind max-subscribers 10000
```
connection authorization

Sets the RADIUS authorization password that must be matched by the RADIUS accounting requests “snooped” by this service.

Product
IPSG
Privilege
Security Administrator, Administrator
Syntax

connection authorization [ encrypted ] password password

no connection authorization

no
Removes the RADIUS authorization for the IPSG RADIUS snoop service.

[ encrypted ] password password

- **encrypted**: Specifies that the received RADIUS authorization password is encrypted.
- **password**: Specifies the password that must be matched by incoming RADIUS accounting requests.

password must be an alpha and/or numeric string of 1 through 63 characters in length.

Usage
RADIUS accounting requests being examined by the IPSG RADIUS snoop service are destined for a RADIUS Accounting Server. Since the “snoop” service does not terminate user authentication, the user password is unknown.
Use this command to configure the authorization password that the RADIUS accounting requests must match in order for the service to examine and extract user information.

Example
The following command sets the RADIUS authorization password that must be matched by the RADIUS accounting requests “snooped” by this service. The password must be encrypted and the example provided is the word “secret”.

```
connection authorization encrypted password secret
```
end

This command exits the IPSG RADIUS Snoop Configuration Mode and returns to the Exec Mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to change to the Exec Mode.
exit

This command exits the IPSG RADIUS Snoop Configuration Mode and returns to the Context Configuration Mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
exit
```

Usage
Use this command to return to the Context Configuration Mode.
radius

Specifies RADIUS accounting servers where accounting requests are sent after being “inspected” by this service.

Product
IPSG

Privilege
Security Administrator, Administrator

Syntax

```
[ no ] radius { accounting server ip_address [ port port_number | source-context name ] | dictionary { 3gpp2 | 3gpp2-835 | custom XX | standard | starent | starent-835 | starent-vs1 | starent-vs1-835 } }
```

**no**
Removes the RADIUS accounting server identifier from this service.

**radius accounting server ip_address**
Specifies the IP address of a RADIUS Accounting Server where accounting requests are sent after being “snooped” by this service.

- `ip_address` must be specified using standard IPv4 or IPv6 dotted decimal notation and must be a valid IP address.
- Up to 16 addresses can be configured.

**port port_number**
Specifies the port number of the RADIUS Accounting Server where accounting requests are sent after being “snooped” by this service.

- `port_number` must be an integer from 0 through 65535.
- Default: 1813

**source-context name**
Specifies the source context where RADIUS accounting requests are received.

- `name` must be an alpha and/or numeric string of 1 through 79 characters in length.
- If this keyword is not configured, the system will default to the context in which the IPSG service is configured.

**dictionary { 3gpp2 | 3gpp2-835 | custom XX | standard | starent | starent-835 | starent-vs1 | starent-vs1-835 }**
Specifies what dictionary to use. The possible values are described in the following table:

<table>
<thead>
<tr>
<th>Dictionary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3gpp2</td>
<td>This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in 3GPP 32.015.</td>
</tr>
</tbody>
</table>
**Dictionary** | **Description**
--- | ---
3gpp2 | This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835-A.
3gpp2-835 | This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835.
customXX | These are dictionaries that can be customized to fit your needs. Customization information can be attained by contacting your local service representative. XXX is the integer value of the custom dictionary.
standard | This dictionary consists only of the attributes specified in RFC 2865, RFC 2866, and RFC 2869.
starent | This dictionary consists of all of the attributes in the starent-vsa1 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the dictionaries supported by the system.
starent-835 | This dictionary consists of all of the attributes in the starent-vsa1-835 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the -835 dictionaries supported by the system.
starent-vsa1 | This dictionary consists not only of the 3gpp2 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0 - 255). This is the default dictionary.
starent-vsa1-835 | This dictionary consists not only of the 3gpp2-835 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0 - 255). This is the default dictionary.

**Usage**

Use this command to specify the RADIUS Accounting Servers where accounting requests are sent after being snooped by this service.

**Example**

The following command specifies the IP address (1.2.3.4) of a RADIUS Accounting Server whose accounting requests are to be “snooped”, and the source context (aaa_ingress) where the requests are received on the system:

```
radius accounting server 1.2.3.4 source-context aaa_ingress
```
setup-timeout

Configures a timeout value for IPSG session setup attempts.

Product
IPSG

Privilege
Security Administrator, Administrator

Syntax

```
setup-timeout setup_timeout
```

default setup-timeout

```
setup_timeout

Specifies the period of time, in seconds, the IPSG session setup is allowed to continue before the setup attempt is terminated.

`setup_timeout` must be an integer from 1 through 100000.
Default: 60
```

Usage
Use this command to prevent IPSG session setup attempts from continuing without termination.

Example
The following command configures the session setup timeout setting to 20 seconds:

```
setup-timeout 20
```
Chapter 127
IPSP Configuration Mode Commands

The IPSP Configuration Mode is used to configure properties for the IP pool sharing protocol (IPSP).

Important: For information on configuring and using IPSP refer to the System Administration and Configuration Guide.
**dead-interval**

Configures the retry time to connect to the remote system for the IP Pool Sharing Protocol.

**Product**

PDSN, HA

**Privilege**

Security Administrator, Administrator

**Syntax**

```
dead-interval seconds
```

```
[ no | default ] dead-interval
```

- **no**
  - Disables the dead interval. On loss of connectivity to the remote system, no retries are attempted and the remote system is marked dead immediately on failure.

- **default**
  - Resets the dead interval to the default of 3600 seconds.

- **seconds**
  - Default: 3600 seconds
  - The amount of time in seconds to wait before retrying the remote system. `seconds` must be an integer from 25 through 259200.

**Usage**

Use this command to set the amount of time to wait before retrying to connect with the remote system for the IP pool sharing protocol.

**Example**

Use the following command to set the interval to 180 seconds (3 minutes):

```
dead-interval 180
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
PDSN, HA

**Privilege**
Security Administrator, Administrator

**Syntax**
end

**Usage**
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the context configuration mode.

**Product**
PDNS, HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the context configuration mode.
reserved-free-percentage

This command is used to set the amount of free addresses reserved for use on the primary HA.

Product
PDSN, HA

Privilege
Security Administrator, Administrator

Syntax
reserved-free-percentage value

default reserved-free-percentage

value
Default: 100
value specifies the percentage of free addresses reserved for the use on the primary HA for IP pool sharing during upgrade.

Usage
This command is used with pool-sharing-protocol active mode on primary HA. Before using this command, pool-sharing-protocol in Ethernet Interface Configuration Mode must be configured.
For more information, refer to the Ethernet Interface Configuration Mode Commands chapter in this guide.

Example
To reserve 40 percent of free addresses in primary HA for IP pool sharing, enter the following command:

reserved-free-percentage 40
The IPv6 Access Control List Configuration Mode is used to create and manage IPv6 access privileges.
deny/permit (by source IP address masking)

Used to filter subscriber sessions based on the IPv6 address mask sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
{ deny | permit } [ log ] source_address source_wildcard
after { deny | permit } [ log ] source_address source_wildcard
before { deny | permit } [ log ] source_address source_wildcard
no { deny | permit } [ log ] source_address source_wildcard
```

- **after**
  Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
  This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

- **before**
  Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
  This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

- **no**
  Removes the rule which exactly matches the options specified.

- **deny | permit**
  Specifies the rule is either block (deny) or an allow (permit) filter.
  - **deny**: Indicates the rule, when matched, drops the corresponding packets.
  - **permit**: Indicates the rule, when matched, allows the corresponding packets.

- **log**
  Default: packets are not logged.
  Indicates all packets which match the filter are to be logged.
IPv6 ACL Configuration Mode Commands

deny/permit (by source IP address masking)

source_address

The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then
be configured using the source_wildcard parameter.

source_wildcard

This option is used in conjunction with the source_address option to specify a group of addresses for
which packets are to be filtered.
The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the source_address
  parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the source_address
  parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore,
allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and
0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

Usage

Define a rule when any packet from the IP addresses which fall into the group of addresses matching the IP
address masking. This allows the reduction of filtering rules as it does not require a rule for each source and
destination pair.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is
to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

Example

The following command defines two rules with the second logging filtered packets:

`permit 1:1:1:1:1:1:1`

`deny log 1:1:1:1:1:1:1`

The following sets the insertion point to before the first rule defined above:

`before permit 1:1:1:1:1:1:1`

The following command sets the insertion point after the second rule defined above:

`after deny log 1:1:1:1:1:1:1`

The following deletes the first rule defined above:

`no permit 1:1:1:1:1:1:1`
deny/permit (any)

Used to filter subscriber sessions based on any packet received. This command is also used to set the access control list insertion point.

Product
All

Privilege
Security Administrator, Administrator

Syntax

{ deny | permit } [ log ] any
after { deny | permit } [ log ] any
before { deny | permit } [ log ] any
no { deny | permit } [ log ] any

after
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no
Removes the rule which exactly matches the options specified.

deny | permit
Specifies the rule is either block (deny) or an allow (permit) filter.

• deny: Indicates the rule, when matched, drops the corresponding packets.
• permit: Indicates the rule, when matched, allows the corresponding packets.

log
Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

**any**
Indicates all packets will match the filter regardless of source and/or destination.

**Usage**
Define a catch all rule to place at the end of the list of rules.

**Important:** It is suggested that any rule which is added to be a catch all should also have the *log* option specified. The logged packets may be used to determine if the current list of rules is adequate or needs modification to ensure proper security. The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Example**
The following command defines two rules with the second logging filtered packets:

```
permit any
deny log any
```

The following sets the insertion point to before the first rule defined above:

```
before permit any
```

The following command sets the insertion point after the second rule defined above:

```
after deny log any
```

The following deletes the first rule defined above:

```
no permit any
```
deny/permit (by host IP address)

Used to filter subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
{ deny | permit } [ log ] host source_host_address
after { deny | permit } [ log ] host source_host_address
before { deny | permit } [ log ] host source_host_address
no { deny | permit } [ log ] host source_host_address
```

- **after**
  Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
  This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

- **Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

- **before**
  Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
  This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

- **Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

- **no**
  Removes the rule which exactly matches the options specified.

- **deny | permit**
  Specifies the rule is either block (deny) or an allow (permit) filter.
  - **deny:** Indicates the rule, when matched, drops the corresponding packets.
  - **permit:** Indicates the rule, when matched, allows the corresponding packets.

- **log**
  Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

**Usage**

Define a rule when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rules to be very clear and concise.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Example**

The following command defines two rules with the second logging filtered packets:

```plaintext
permit host 1::1:1:1:1:1:1
deny log host 1::1:1:1:1:1:1
```

The following sets the insertion point to before the first rule defined above:

```plaintext
before permit host 1::1:1:1:1:1:1:1
```

The following command sets the insertion point after the second rule defined above:

```plaintext
after deny log host 1::1:1:1:1:1:1:1
```

The following deletes the first rule defined above:

```plaintext
no permit host 1::1:1:1:1:1:1:1
```
deny/permit (by source ICMP packets)

Used to filter subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
{ deny | permit } [ log ] icmp { source_address source_wildcard | any | host
source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ icmp_type [ icmp_code ] ]

after { deny | permit } [ log ] icmp { source_address source_wildcard | any | host
source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ icmp_type [ icmp_code ] ]

before { deny | permit } [ log ] icmp { source_address source_wildcard | any | host
source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ icmp_type [ icmp_code ] ]

no { deny | permit } [ log ] icmp { source_address source_wildcard | any | host
source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ icmp_type [ icmp_code ] ]
```

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

after
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no
Removes the rule which exactly matches the options specified.
deny | permit
Specifies the rule is either block (deny) or an allow (permit) filter.
  • deny: Indicates the rule, when matched, drops the corresponding packets.
  • permit: Indicates the rule, when matched, allows the corresponding packets.

log
Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

source_address
The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the source_wildcard parameter.

source_wildcard
This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
  • Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
  • One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

any
Specifies that the rule applies to all packets.

host
Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

**deny/permit (by source ICMP packets)**

**destWildcard**

This option is used in conjunction with the **destAddress** option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the **destAddress** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **destAddress** parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

**icmpType**

Specifies that all ICMP packets of a particular type are to be filtered. The type can be any integer value between 0 and 255.

**icmpCode**

Specifies that all ICMP packets of a particular code are to be filtered. The type can be any integer value between 0 and 255.

**Usage**

Define a rule to block ICMP packets which can be used for address resolution and possible be a security risk. The IP filtering allows flexible controls for pairs of individual hosts or groups by IP masking which allows the filtering of entire subnets if necessary.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Example**

The following command defines two rules with the second logging filtered packets:

```
permit icmp host 1.2.3.4 any 168
deny log icmp 1.2.3.0 0.0.0.31 host 1.2.4.16 168 11
```

The following sets the insertion point to before the first rule defined above:

```
before permit icmp host 1.2.3.4 any 168
```

The following command sets the insertion point after the second rule defined above:

```
after deny log icmp 1.2.3.0 0.0.0.31 host 1.2.4.16 168 11
```

The following deletes the first rule defined above:

```
no permit icmp host 1.2.3.4 any 168
```
deny/permit (by source ICMP packets)
deny/permit (by IP packets)

Used to filter subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
{ deny | permit } [ log ] ip { source_address source_wildcard | any | host
  source_host_address } { dest_address dest_wildcard | any | host
  dest_host_address } [ fragment ] [ protocolnum ]
```

```
after { deny | permit } [ log ] ip { source_address source_wildcard | any | host
  source_host_address } { dest_address dest_wildcard | any | host
  dest_host_address } [ fragment ] [ protocolnum ]
```

```
before { deny | permit } [ log ] ip { source_address source_wildcard | any | host
  source_host_address } { dest_address dest_wildcard | any | host
  dest_host_address } [ fragment ] [ protocolnum ]
```

```
no { deny | permit } [ log ] ip { source_address source_wildcard | any | host
  source_host_address } { dest_address dest_wildcard | any | host
  dest_host_address } [ fragment ] [ protocolnum ]
```

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.
deny | permit
 Specifies the rule is either block (deny) or an allow (permit) filter.
 • deny: indicates the rule, when matched, drops the corresponding packets.
 • permit: indicates the rule, when matched, allows the corresponding packets.

log
 Default: packets are not logged.
 Indicates all packets which match the filter are to be logged.

source_address
 The IP address(es) form which the packet originated.
 This option is used to filter all packets from a specific IP address or a group of IP addresses.
 When specifying a group of addresses, the initial address is configured using this option. The range can then
 be configured using the source_wildcard parameter.

source_wildcard
 This option is used in conjunction with the source_address option to specify a group of addresses for
 which packets are to be filtered.
 The mask must be entered as a complement:
 • Zero-bits in this parameter mean that the corresponding bits configured for the source_address
   parameter must be identical.
 • One-bits in this parameter mean that the corresponding bits configured for the source_address
   parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore,
allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and
0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

any
 Specifies that the rule applies to all packets.

host
 Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address
 The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address
 The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address
 The IP address(es) to which the packet is to be sent.
 This option is used to filter all packets to a specific IP address or a group of IP addresses.
 When specifying a group of addresses, the initial address is configured using this parameter. The range can
 then be configured using the dest_wildcard parameter.
deny/permit (by IP packets)

---

**dest_wildcard**

This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.

---

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

---

**fragment**

Indicates packet filtering is to be applied to IP packet fragments only.

---

**protocol num**

Indicates that the packet filtering is to be applied to a specific protocol number. 

**num** can be any integer ranging from 0 to 255.

---

**Usage**

Block IP packets when the source and destination are of interest.

---

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

---

**Example**

The following command defines two rules with the second logging filtered packets:

```plaintext
permit ip host 1.2.3.4 any fragment
deny log ip 1.2.3.0 0.0.0.31 host 1.2.4.16
```

The following sets the insertion point to before the first rule defined above:

```plaintext
before permit ip host 1.2.3.4 any fragment
```

The following command sets the insertion point after the second rule defined above:

```plaintext
after deny log ip 1.2.3.0 0.0.0.31 host 1.2.4.16
```

The following deletes the first rule defined above:

```plaintext
no permit ip host 1.2.3.4 any fragment
```
deny/permit (by TCP/UDP packets)

Used to filter subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```plaintext
{ deny | permit } [ log ] { tcp | udp } { { source_address sourceWildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address destWildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port ] }

after { deny | permit } [ log ] { tcp | udp } { { source_address sourceWildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address destWildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port ] }

before { deny | permit } [ log ] { tcp | udp } { { source_address sourceWildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address destWildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port ] }

no { deny | permit } [ log ] { tcp | udp } { { source_address sourceWildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address destWildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port ] }
```

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

---

**after**

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

---

**before**

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
deny/permit (by TCP/UDP packets)

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no
Removes the rule which exactly matches the options specified.

deny | permit
Specifies the rule is either block (deny) or an allow (permit) filter.
  • deny: Indicates the rule, when matched, drops the corresponding packets.
  • permit: Indicates the rule, when matched, allows the corresponding packets.

log
Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

tcp | udp
Specifies the filter is to be applied to IP based transmission control protocol or the user datagram protocol.
  • tcp: Filter applies to TCP packets.
  • udp: Filter applies to UDP packets.

source_address
The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the source_wildcard parameter.

source_wildcard
This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
  • Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
  • One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

any
 Specifies that the rule applies to all packets.

host
Specifies that the rule applies to a specific host as determined by its IP address.
source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv6 colon notation.

eq source_port
Specifies a single, specific source TCP port number to be filtered.
source_port must be configured to any integer value from 0 to 65535.

gt source_port
Specifies that all source TCP port numbers greater than the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

lt source_port
Specifies that all source TCP port numbers less than the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

neq source_port
Specifies that all source TCP port numbers not equal to the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

dest_address
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

dest_wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

eq dest_port
Specifies a single, specific destination TCP port number to be filtered.
dest_port must be configured to any integer value from 0 to 65535.
deny/permit (by TCP/UDP packets)

<table>

</tbody>
</table>

**Usage**

Block IP packets when the source and destination are of interest but for only a limited set of ports.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

**Example**

The following command defines four rules with the second and fourth rules logging filtered packets:

```
permit tcp host 1.2.3.4 any
deny log udp 1.2.3.0 0.0.0.31 host 1.2.4.16
permit tcp host 1.2.3.64 gt 1023 any
```

The following sets the insertion point to before the first rule defined above:

```
before permit tcp host 1.2.3.4 any
```

The following command sets the insertion point after the second rule defined above:

```
after deny log udp 1.2.3.0 0.0.0.31 host 1.2.4.16
```

The following deletes the third rule defined above:

```
no permit tcp host 1.2.3.64 gt 1023 any
```
end

Exits the ACL configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
end
```

**Usage**
Change the mode back to the Exec mode.

**Example**

```plaintext
end
```
exit

Exits the ACL configuration mode and returns to the context configuration mode.

Privilege
Security Administrator, Administrator

Product
All

Syntax

```
exit
```

Usage
Return to the context configuration mode.

Example

```
exit
```
readdress server

Alter the destination address and port number in TCP or UDP packet headers to redirect packets to a different server.

Product
All

Privilege
Security Administrator, Administrator

Syntax

after
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no
Removes the rule which exactly matches the options specified.

redirect_address
The IP address to which the IP packets are redirected. TCP or UDP packet headers are rewritten to contain the new destination address. This must be an IPv6 address specified in either : or :: notation.

port port_no
The number of the port at the redirect address where the packets are sent. TCP or UDP packet headers are rewritten to contain the new destination port number.

tcp | udp
Specifies the redirect is to be applied to the IP based transmission control protocol or the user datagram protocol.
  • tcp: Redirect applies to TCP packets.
  • udp: Redirect applies to UDP packets.
source_address
The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the source wildcard parameter.

any
Specifies that the rule applies to all packets.

host
Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv6 colon notation.

eq source_port
Specifies a single, specific source TCP port number to be filtered. source_port must be configured to any integer value from 0 to 65535.

gt source_port
Specifies that all source TCP port numbers greater than the one specified are to be filtered. source_port must be configured to any integer value from 0 to 65535.

lt source_port
Specifies that all source TCP port numbers less than the one specified are to be filtered. source_port must be configured to any integer value from 0 to 65535.

neq source_port
Specifies that all source TCP port numbers not equal to the one specified are to be filtered. source_port must be configured to any integer value from 0 to 65535.

dest_address
The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest wildcard parameter.

eq dest_port
Specifies a single, specific destination TCP port number to be filtered. dest_port must be configured to any integer value from 0 to 65535.

gt dest_port
Specifies that all destination TCP port numbers greater than the one specified are to be filtered.
IPv6 ACL Configuration Mode Commands

readdress server

... must be configured to any integer value from 0 to 65535.

lt dest_port
Specifies that all destination TCP port numbers less than the one specified are to be filtered.

neq dest_port
Specifies that all destination TCP port numbers not equal to the one specified are to be filtered.

Usage
Use this command to define a rule that redirects packets to a different destination address. The TCP and UDP packet headers are modified with the new destination address and destination port.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example
The following command defines a rule that redirects packets to the server at 192.168.10.4, UDP packets coming from any host with a destination of any host are matched:

readdress server 192.168.10.4 udp any any

The following sets the insertion point to before the rule defined above:

before readdress server 192.168.10.4 udp any any

The following deletes the rule defined above:

no readdress server 192.168.10.4 udp any any
redirect context (by IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
redirect context context_id [ log ] source_address source_wildcard
after redirect context context_id [ log ] source_address source_wildcard
before redirect context context_id [ log ] source_address source_wildcard
no redirect context context_id [ log ] source_address source_wildcard
```

- **after**
  Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
  This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

- **before**
  Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
  This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

- **no**
  Removes the rule which exactly matches the options specified.

- **context context_id**
  The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

- **log**
  Default: packets are not logged.
  Indicates all packets which match the redirect are to be logged.
source_address

The IP address(es) from which the packet originated. 
This option is used to filter all packets from a specific IP address or a group of IP addresses. 
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the source_wildcard parameter.

source_wildcard

This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered. 
The mask must be entered as a complement:
  •Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
  •One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

Usage

Define a rule when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of redirect rules as it does not require a rule for each source and destination pair.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the context with the context ID of 23 and the source IP and wildcard of 198.162.22.0 and 0.0.0.31:

    redirect context 23 198.162.22.0 0.0.0.31

The following sets the insertion point to before the first rule defined above:

    before redirect context 23 198.162.22.0 0.0.0.31

The following command sets the insertion point after the second rule defined above:

    after redirect context 23 198.162.22.0 0.0.0.31

The following deletes the first rule defined above:

    no redirect context 23 198.162.22.0 0.0.0.31
redirect context (any)

Used to redirect subscriber sessions based on any packet received. This command is also used to set the access control list insertion point.

Product
All

Privilege
Security Administrator, Administrator

Syntax

redirect context context_id [ log ] any
after redirect context context_id [ log ] any
before redirect context context_id [ log ] any
no redirect context context_id [ log ] any

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.

**context context_id**
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the show context all command to display context names and context IDs.

**log**
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.
IPv6 ACL Configuration Mode Commands

**redirect context (any)**

any

Indicates all packets will match the redirect regardless of source and/or destination.

**Usage**

Define a catch all rule to place at the end of the list of rules to provide explicit handling of rules which do not fit any other criteria.

**Important:** It is suggested that any rule which is added to be a catch all should also have the log option specified. The logged packets may be used to determine if the current list of rules is adequate or needs modification to ensure proper security. The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule that redirects packets to the context with the context ID of 23 and any source IP:

```
redirect context 23 any
```

The following sets the insertion point to before the first rule defined above:

```
before redirect context 23 any
```

The following command sets the insertion point after the second rule defined above:

```
after redirect context 23 any
```

The following deletes the first rule defined above:

```
no redirect context 23 any
```
redirect context (by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

Product: All

Privilege: Security Administrator, Administrator

Syntax:

redirect context context_id [ log ] host source_ip_address
after redirect context context_id [ log ] host source_ip_address
before redirect context context_id [ log ] host source_ip_address
no redirect context context_id [ log ] host source_ip_address

- **after**
  Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
  This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

- **Important**: If the options specified do not exactly match an existing rule, the insertion point does not change.

- **before**
  Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
  This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

- **Important**: If the options specified do not exactly match an existing rule, the insertion point does not change.

- **no**
  Removes the rule which exactly matches the options specified.

- **context context_id**
  The context identification number of the context to which packets are redirected. At the executive mode prompt, use the show context all command to display context names and context IDs.

- **log**
  Default: packets are not logged.
  Indicates all packets which match the redirect are to be logged.
host
Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

Usage
Define a rule when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rules to be very clear and concise.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example
The following command defines a rule that redirects packets to the context with the context ID of 23 and a host IP address of 192.168.200.11:

```
redirect context 23 host 192.168.200.11
```

The following sets the insertion point to before the first rule defined above:

```
before redirect context 23 host 192.168.200.11
```

The following command sets the insertion point after the second rule defined above:

```
after redirect context 23 host 192.168.200.11
```

The following deletes the first rule defined above:

```
no redirect context 23 host 192.168.200.11
```
redirect context (by source ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

Product
- All

Privilege
- Security Administrator, Administrator

Syntax

redirect context context_id [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

after redirect context context_id [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

before redirect context context_id [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

no redirect context context_id [ log ] icmp { source_address source_wildcard | any | host source_host_address } { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]

**after**

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**

Removes the rule which exactly matches the options specified.
context context_id

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the show context all command to display context names and context IDs.

log

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the sourceWildcard parameter.

sourceWildcard

This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
  • Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
  • One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

any

Specifies that the rule applies to all packets.

host

Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address

The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the destWildcard parameter.
redirect context (by source ICMP packets)

This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

Specifies that all ICMP packets of a particular type are to be filtered. The type can be any integer value between 0 and 255.

Specifies that all ICMP packets of a particular code are to be filtered. The type can be any integer value between 0 and 255.

**Usage**

Define a rule to block ICMP packets which can be used for address resolution and possibly be a security risk. The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule that redirects packets to the context with the context ID of 23, and ICMP packets coming from the host with the IP address 198.162.100.25:

```
redirect context 23 icmp host 198.162.100.25
```

The following sets the insertion point to before the first rule defined above:

```
before redirect context 23 icmp host 198.162.100.25
```

The following command sets the insertion point after the second rule defined above:

```
after redirect context 23 icmp host 198.162.100.25
```

The following deletes the first rule defined above:
no redirect context 23 icmp host 198.162.100.25
redirect context (by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

Product

```
    no
    Removes the rule which exactly matches the options specified.
```
context context_id

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the show context all command to display context names and context IDs.

log

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the sourceWildcard parameter.

sourceWildcard

This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
•Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
•One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

any

Specifies that the rule applies to all packets.

host

Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address

The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the destWildcard parameter.
**redirect context** (by IP packets)

This option is used in conjunction with the `dest_address` option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**fragment**

Indicates packet redirection is to be applied to IP packet fragments only.

**protocol** `num`

Indicates that the packet filtering is to be applied to a specific protocol number. `num` can be any integer ranging from 0 to 255.

### Usage

Block IP packets when the source and destination are of interest.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

### Example

The following command defines a rule that redirects packets to the context with the context ID of 23, and IP packets coming from the host with the IP address 198.162.100.25, and fragmented packets for any destination are matched:

```
redirect context 23 ip host 198.162.100.25 any fragment
```

The following sets the insertion point to before the first rule defined above:

```
before redirect context 23 ip host 198.162.100.25 any fragment
```

The following command sets the insertion point after the second rule defined above:

```
after redirect context 23 ip host 198.162.100.25 any fragment
```

The following deletes the first rule defined above:

```
no redirect context 23 ip host 198.162.100.25 any fragment
```
redirect context (by TCP/UDP packets)

Used to redirect subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
redirect context context_id [ log ] { tcp | udp } { { source_address
source wildcard | any | host source_host_address } [ eq source_port | gt
source_port | lt source_port | neq source_port ] } { { dest_address
dest wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port |
lt dest_port | neq dst_port ] }
```

```plaintext
after redirect context context_id [ log ] { tcp | udp } { { source_address
source wildcard | any | host source_host_address } [ eq source_port | gt
source_port | lt source_port | neq source_port ] } { { dest_address
dest wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port |
lt dest_port | neq dst_port ] }
```

```plaintext
before redirect context context_id [ log ] { tcp | udp } { { source_address
source wildcard | any | host source_host_address } [ eq source_port | gt
source_port | lt source_port | neq source_port ] } { { dest_address
dest wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port |
lt dest_port | neq dst_port ] }
```

```plaintext
no redirect context context_id [ log ] { tcp | udp } { { source_address
source wildcard | any | host source_host_address } [ eq source_port | gt
source_port | lt source_port | neq source_port ] } { { dest_address
dest wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port |
lt dest_port | neq dst_port ] }
```

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.
Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no
Removes the rule which exactly matches the options specified.

context context_id
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the show context all command to display context names and context IDs.

log
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

tcp | udp
Specifies the redirect is to be applied to IP based transmission control protocol or the user datagram protocol.
  - tcp: Redirect applies to TPC packets.
  - udp: Redirect applies to UDP packets.

source_address
The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the source_wildcard parameter.

source_wildcard
This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

any
Specifies that the rule applies to all packets.

host
Specifies that the rule applies to a specific host as determined by its IP address.
source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv6 colon notation.

eq source_port
Specifies a single, specific source TCP port number to be filtered.
source_port must be configured to any integer value from 0 to 65535.

gt source_port
Specifies that all source TCP port numbers greater than the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

lt source_port
Specifies that all source TCP port numbers less than the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

neq source_port
Specifies that all source TCP port numbers not equal to the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

dest_address
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

dest_wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

eq dest_port
Specifies a single, specific destination TCP port number to be filtered.
dest_port must be configured to any integer value from 0 to 65535.
**gt dest_port**
Specifies that all destination TCP port numbers greater than the one specified are to be filtered. `dest_port` must be configured to any integer value from 0 to 65535.

**lt dest_port**
Specifies that all destination TCP port numbers less than the one specified are to be filtered. `dest_port` must be configured to any integer value from 0 to 65535.

**neq dest_port**
Specifies that all destination TCP port numbers not equal to the one specified are to be filtered. `dest_port` must be configured to any integer value from 0 to 65535.

**Usage**
Block IP packets when the source and destination are of interest but for only a limited set of ports.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**
The following command defines a rule that redirects packets to the context with the context ID of 23, and UDP packets coming from any host are matched:

```
redirect context 23 udp any
```

The following sets the insertion point to before the rule defined above:

```
before redirect context 23 udp any
```

The following command sets the insertion point after the rule defined above:

```
after redirect context 23 udp any
```

The following deletes the rule defined above:

```
no redirect context 23 udp any
```
redirect css delivery-sequence

This is a restricted command. In StarOS 9.0 and later, this command is obsoleted.
redirect css service (any)

Used to redirect subscriber sessions based on any packet received. This command is also used to set the access control list insertion point.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
redirect css service svc_name [ log ] any
after redirect css service svc_name [ log ] any
before redirect css service svc_name [ log ] any
no redirect css service svc_name [ log ] any
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>redirect</code></td>
<td>Indicates all rule definitions defined subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.</td>
</tr>
<tr>
<td><code>after</code></td>
<td>Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definitions which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.</td>
</tr>
<tr>
<td><code>before</code></td>
<td>If the options specified do not exactly match an existing rule definition, the insertion point does not change.</td>
</tr>
<tr>
<td><code>no</code></td>
<td>Removes the rule definition which exactly matches the options specified.</td>
</tr>
<tr>
<td><code>css service</code></td>
<td>The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the <code>show active-charging service all</code> command to display the names of all configured charging services. <code>svc_name</code> must be a string of 1 through 15 characters in length.</td>
</tr>
</tbody>
</table>

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.
**log**
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**any**
Indicates all packets will match the redirect regardless of source and/or destination.

**Usage**
Define a catch all rule definitions to place at the end of the list of rule definitions to provide explicit handling of rule definitions which do not fit any other criteria.

**Important:** It is suggested that any rule definition which is added to be a catch all should also have the **log** option specified. The logged packets may be used to determine if the current list of rule definitions is adequate or needs modification to ensure proper security.

**Important:** A maximum of 16 rule definitions can be configured per ACL.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**
The following command defines a rule definition that redirects packets to the charging service with the name *chgsvc1* and any source IP:

```
redirect css service chgsvc1 any
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service chgsvc1 any
```

The following command sets the insertion point after the second rule definitions above:

```
after redirect css service chgsvc1 any
```

The following deletes the first rule definition above:

```
o redirect css service chgsvc1 any
```
redirect css service (by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Syntax

redirect css service svc_name [ log ] host source_host_address
after redirect css service svc_name [ log ] host source_host_address
before redirect css service svc_name [ log ] host source_host_address
no redirect css service svc_name [ log ] host source_host_address

after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no
Removes the rule definition which exactly matches the options specified.

css service svc_name
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the show active-charging service all command to display the names of all configured charging services.
svc_name must be a string of 1 through 15 characters in length.
IPv6 ACL Configuration Mode Commands

redirect css service (by host IP address)

---

### log

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

### host

Specifies that the rule definition applies to a specific host as determined by its IP address.

---

**source_host_address**

The IP address of the source host to filter against expressed in IPv6 colon notation.

---

### Usage

Define a rule definition when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rule definitions to be very clear and concise.

---

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

---

### Example

The following command defines a rule definition that redirects packets to the charging service with the name *chgsvc1* and a host IP address of 198.162.200.11:

```
redirect css service chgsvc1 host 198.162.200.11
```

The following sets the insertion point to before the first rule definition above:

```
befo re redirect css service chgsvc1 host 198.162.200.11
```

The following command sets the insertion point after the second rule definition above:

```
aft er redirect css service chgsvc1 host 198.162.200.11
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 host 198.162.200.11
```
redirect css service (by ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [icmp_type [ icmp_code ]]
```

```
after redirect css service svc_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [icmp_type [ icmp_code ]]
```

```
before redirect css service svc_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [icmp_type [ icmp_code ]]
```

```
o redirect css service svc_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [icmp_type [ icmp_code ]]
```

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**after**
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.
IPv6 ACL Configuration Mode Commands

redirect css service (by ICMP packets)

no
Removes the rule definition which exactly matches the options specified.

css service svc_name
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the show active-charging service all command to display the names of all configured charging services. svc_name must be a string of 1 through 15 characters in length.

log
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

source_address
The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the source wildcard parameter.

source wildcard
This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

any
Specifies that the rule definition applies to all packets.

host
Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv6 colon notation.
**redirect css service (by ICMP packets)**

- **dest_address**
  
  The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the `dest_wildcard` parameter.

- **dest_wildcard**
  
  This option is used in conjunction with the `dest_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
  
  - Zero-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be identical.
  
  - One-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

- **icmp_type**
  
  Specifies that all ICMP packets of a particular type are to be filtered. The type can be any integer value between 0 and 255.

- **icmp_code**
  
  Specifies that all ICMP packets of a particular code are to be filtered. The type can be any integer value between 0 and 255.

**Usage**

Define a rule definition to block ICMP packets which can be used for address resolution and possibly be a security risk. The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the charging service named `chgsvc1`, and ICMP packets coming from the host with the IP address `198.162.100.25`:

```
redirect css service chgsvc1 icmp host 198.162.100.25
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service chgsvc1 icmp host 198.162.100.25
```
The following command sets the insertion point after the second rule definition above:

    after redirect css service chgsvc1 icmp host 198.162.100.25

The following deletes the first rule definition above:

    no redirect css service chgsvc1 icmp host 198.162.100.25
redirect css service (by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

after redirect css service svc_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

before redirect css service svc_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]

no redirect css service svc_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]
```

**after**

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**

Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.
no
Removes the rule definition which exactly matches the options specified.

css service svc_name
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the show active-charging service all command to display the names of all configured charging services.
svc_name must be a string of 1 through 15 characters in length.

log
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

source_address
The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the sourceWildcard parameter.

sourceWildcard
This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
•Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
•One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

any
Specifies that the rule definition applies to all packets.

host
Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv6 colon notation.
The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

Indicates packet redirection is to be applied to IP packet fragments only.

Usage
Block IP packets when the source and destination are of interest.

Important: A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example
The following command defines a rule definition that redirects packets to the charging service named chgsvc1, and IP packets coming from the host with the IP address 198.162.100.25, and fragmented packets for any destination are matched:

```plaintext
redirect css service chgsvc1 ip host 198.162.100.25 any fragment
```

The following sets the insertion point to before the first rule definition above:

```plaintext
before redirect css service chgsvc1 ip host 198.162.100.25 any fragment
```

The following command sets the insertion point after the second rule definition above:

```plaintext
after redirect css service chgsvc1 ip host 198.162.100.25 any fragment
```

The following deletes the first rule definition above:

```plaintext
no redirect css service chgsvc1 ip host 198.162.100.25 any fragment
```
IPv6 ACL Configuration Mode Commands

redirect css service (by IP packets)
redirect css service (by source IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Syntax

redirect css service svc_name [ log ] source_address source_wildcard
after redirect css service svc_name [ log ] source_address source_wildcard
before redirect css service svc_name [ log ] source_address source_wildcard
no redirect css service svc_name [ log ] source_address source_wildcard

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no
Removes the rule definition which exactly matches the options specified.

css service svc_name
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the show active-charging service all command to display the names of all configured charging services.
svc_name must be a string of 1 through 15 characters in length.
IPv6 ACL Configuration Mode Commands

**log**
Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

**source_address**
The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important**: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**Usage**
Define a rule definition when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rule definitions as it does not require a rule definition for each source and destination pair.

**Important**: A maximum of 16 rule definitions can be configured per ACL.

**Example**
The following command defines a rule definition to redirect packets to a charging service named `chgsvc1`:

```
redirect css service chgsvc1 1:1:1:1:1:1:1
```
redirect css service (by TCP/UDP packets)

Used to redirect subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Syntax

redirect css service svc_name [ log ] { tcp | udp } { { source_address source_port | it source_port | neq source_port | range start_source_port end_source_port } { { dest_address dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port } } { { dest_address dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port } }

after redirect css service svc_name [ log ] { tcp | udp } { { source_address source_port | it source_port | neq source_port | range start_source_port end_source_port } } { { dest_address dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port } }

after redirect css service svc_name [ log ] { tcp | udp } { { source_address source_port | it source_port | neq source_port | range start_source_port end_source_port } } { { dest_address dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port } }{ { dest_address dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port } }

no redirect css service svc_name [ log ] { tcp | udp } { { source_address source_port | it source_port | neq source_port | range start_source_port end_source_port } } { { dest_address dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port } }

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.
IPv6 ACL Configuration Mode Commands

**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**
Removes the rule definition which exactly matches the options specified.

**css service svc_name**
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services. `svc_name` must be a string of 1 through 15 characters in length.

**log**
Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

**tcp | udp**
Specifies the redirect is to be applied to IP based transmission control protocol or the user datagram protocol.
- **tcp:** Redirect applies to TPC packets.
- **udp:** Redirect applies to UDP packets.

**source_address**
The IP address(es) form which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

IPv6 ACL Configuration Mode Commands

redirect css service (by TCP/UDP packets)

- Zero-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

```
eq dest_port
  Specifies a single, specific destination TCP port number to be filtered.
  `dest_port` must be configured to any integer value from 0 to 65535.
```

```
lt dest_port
  Specifies that all destination TCP port numbers less than the one specified are to be filtered.
  `dest_port` must be configured to any integer value from 0 to 65535.
```

```
gt dest_port
  Specifies that all destination TCP port numbers greater than the one specified are to be filtered.
  `dest_port` must be configured to any integer value from 0 to 65535.
```

```
neq dest_port
  Specifies that all destination TCP port numbers not equal to the one specified are to be filtered.
  `dest_port` must be configured to any integer value from 0 to 65535.
```

```
rage start_dest_port end_dest_port
  Specifies that all destination TCP ports within a specific range are to be filtered.
  `start_dest_port` is the initial port in the range and `end_dest_port` is the final port in the range.
  Both `start_dest_port` and `end_dest_port` can be configured to any integer value from 0 to 65535.
```

**Usage**
Block IP packets when the source and destination are of interest but for only a limited set of ports.

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**
The following command defines a rule definition that redirects packets to the charging service named `chgsvc1`, and UDP packets coming from any host are matched:

```
redirect css service chgsvc1 udp any
```

The following sets the insertion point to before the rule definition above:

```
before redirect css service chgsvc1 udp any
```
The following command sets the insertion point after the rule definition above:

```
after redirect css service chgsvc1 udp any
```

The following deletes the rule definition above:

```
no redirect css service chgsvc1 udp any
```
redirect css service (for downlink, any)

Used to redirect subscriber sessions based on any packet received in the downlink (from the Mobile Node) direction. This command is also used to set the access control list insertion point.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
redirect css service svc_name [ log ] downlink any
after redirect css service svc_name [ log ] downlink any
before redirect css service svc_name [ log ] downlink any
no redirect css service svc_name [ log ] downlink any
```

*after*
Indicates all rule definitions defined subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important**: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

*before*
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important**: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

*no*
Removes the rule definition which exactly matches the options specified.

*css service svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services.

*svc_name* must be a string of 1 through 15 characters in length.
**redirect css service (for downlink, any)**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>downlink</td>
<td>Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.</td>
</tr>
<tr>
<td>log</td>
<td>Default: packets are not logged. Indicates all packets which match the redirect are to be logged.</td>
</tr>
<tr>
<td>any</td>
<td>Indicates all packets will match the redirect regardless of source and/or destination.</td>
</tr>
</tbody>
</table>

**Usage**

Define a catch all rule definition to place at the end of the list of rule definitions to provide explicit handling of rule definitions which do not fit any other criteria.

**Important:** It is suggested that any rule definition which is added to be a catch all should also have the `log` option specified. The logged packets may be used to determine if the current list of rule definitions is adequate or needs modification to ensure proper security.

**Important:** A maximum of 16 rule definitions can be configured per ACL.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the charging service with the name `chgsvcl` and any source IP:

```
redirect css service chgsvcl downlink any
```

The following sets the insertion point to before the first rule definition above:

```
before redirect service chgsvcl downlink any
```

The following command sets the insertion point after the second rule definition above:

```
after redirect service chgsvcl downlink any
```

The following deletes the first rule definition above:

```
no redirect service chgsvcl downlink any
```
redirect css service (for downlink, by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address in the downlink (from the Mobile Node) direction.

Product
All

Privilege
Security Administrator, Administrator

Syntax

redirect css service svc_name [ log ] downlink host source_host_address
after redirect css service svc_name [ log ] downlink host source_host_address
before redirect css service svc_name [ log ] downlink host source_host_address
no redirect css service svc_name [ log ] downlink host source_host_address

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before
Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no
Removes the rule definition which exactly matches the options specified.

css service svc_name
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the show active-charging service all command to display the names of all configured charging services.
svc_name must be a string of 1 through 15 characters in length.
redirect css service (for downlink, by host IP address)

IPv6 ACL Configuration Mode Commands

downlink
Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

log
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

host
Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

Usage
Define a rule definition when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rule definitions to be very clear and concise.

Important: A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example
The following command defines a rule definition that redirects packets to the charging service with the name chgsvc1 and a host IP address of 198.162.200.11:

   redirect service chgsvc1 downlink host 198.162.200.11

The following sets the insertion point to before the first rule definition above:

   before redirect service chgsvc1 downlink host 198.162.200.11

The following command sets the insertion point after the second rule definition above:

   after redirect service chgsvc1 downlink host 198.162.200.11

The following deletes the first rule definition above:

   no redirect service chgsvc1 downlink host 198.162.200.11
redirect css service (for downlink, by ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets in the downlink (from the Mobile Node) direction.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] downlink icmp { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]
```

```
after redirect css service svc_name [ log ] downlink icmp { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]
```

```
before redirect css service svc_name [ log ] downlink icmp { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]
```

```
no redirect css service svc_name [ log ] downlink icmp { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]
```

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

```
after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.
```

```
before
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.
```

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.
no
Removes the rule definition which exactly matches the options specified.

css service svc_name
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

downlink
Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

log
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

source_address
The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the sourceWildcard parameter.

sourceWildcard
This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

any
Specifies that the rule definition applies to all packets.

host
Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.
IPv6 ACL Configuration Mode Commands

The IP address of the destination host to filter against expressed in IPv6 colon notation.

**dest_address**

The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the **dest_wildcard** parameter.

**dest_wildcard**

This option is used in conjunction with the **dest_address** option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the **dest_address** parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**icmp_type**

Specifies that all ICMP packets of a particular type are to be filtered. The type can be any integer value between 0 and 255.

**icmp_code**

Specifies that all ICMP packets of a particular code are to be filtered. The type can be any integer value between 0 and 255.

**Usage**

Define a rule definition to block ICMP packets which can be used for address resolution and possibly be a security risk.
The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**
The following command defines a rule definition that redirects packets to the charging service named chgsvc1, and ICMP packets coming in the downlink (from the Mobile Node) direction from the host with the IP address 198.162.100.25:

```
redirect css service chgsvc1 downlink icmp host 198.162.100.25
```
redirect css service (for downlink, by ICMP packets)

The following sets the insertion point to before the first rule definition above:

```
before redirect css service chgsvc1 downlink icmp host 198.162.100.25
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service chgsvc1 downlink icmp host 198.162.100.25
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 downlink icmp host 198.162.100.25
```
redirect css service (for downlink, by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets in the downlink (from the Mobile Node) direction.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
redirect css service svc_name [ log ] downlink ip { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ fragment ]
```

```plaintext
after redirect css service svc_name [ log ] downlink ip { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ fragment ]
```

```plaintext
before redirect css service svc_name [ log ] downlink ip { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ fragment ]
```

```plaintext
no redirect css service svc_name [ log ] downlink ip { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ fragment ]
```

**after**
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important**: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important**: If the options specified do not exactly match an existing rule definition, the insertion point does not change.
redirect css service (for downlink, by IP packets)

no
Removes the rule definition which exactly matches the options specified.

css service svc_name
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the show active-charging service all command to display the names of all configured charging services.
svc_name must be a string of 1 through 15 characters in length.

downlink
Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

log
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

source_address
The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the sourceWildcard parameter.

sourceWildcard
This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

any
Specifies that the rule definition applies to all packets.

host
Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.
**redirect css service (for downlink, by IP packets)**

- `dest_host_address`
  The IP address of the destination host to filter against expressed in IPv6 colon notation.

- `dest_address`
  The IP address(es) to which the packet is to be sent.
  This option is used to filter all packets to a specific IP address or a group of IP addresses.
  When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the `dest_wildcard` parameter.

- `dest_wildcard`
  This option is used in conjunction with the `dest_address` option to specify a group of addresses for which packets are to be filtered.
  The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be ignored.

**Important:**
The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

- `fragment`
  Indicates packet redirection is to be applied to IP packet fragments only.

**Usage**
Block IP packets when the source and destination are of interest.

**Important:**
A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**
The following command defines a rule definition that redirects packets to the charging service named `chgsvc1`, and downlink IP packets coming from the host with the IP address `198.162.100.25`, and fragmented packets for any destination are matched:

```
redirect css service chgsvc1 downlink ip host 198.162.100.25 any fragment
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service chgsvc1 downlink ip host 198.162.100.25 any fragment
```

The following command sets the insertion point after the second rule definition above:
redirect css service (for downlink, by IP packets)

```
after redirect css service chgsvc1 downlink ip host 198.162.100.25 any fragment
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 downlink ip host 198.162.100.25 any fragment
```
redirect css service (for downlink, by source IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source in the downlink (from the Mobile Node) direction.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] downlink source_address source_wildcard
after redirect css service svc_name [ log ] downlink source_address source_wildcard
before redirect css service svc_name [ log ] downlink source_address source_wildcard
no redirect css service svc_name [ log ] downlink source_address source_wildcard
```

**after**
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**
Removes the rule definition which exactly matches the options specified.
**css service svc_name**

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services. 

*svc_name* must be a string of 1 through 15 characters in length.

**downlink**

Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

**log**

Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

**source_address**

The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**Usage**

Define a rule definition when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rule definitions as it does not require a rule definition for each source and destination pair.

**Important:** A maximum of 16 rule definitions can be configured per ACL.

**Example**

The following command defines a rule definition to redirect packets to a charging service named *chgsvc1*:

```
redirect css service chgsvc1 downlink 1:1:1:1:1:1:1
```
redirect css service (for downlink, by source IP address masking)
redirect css service (for downlink, by TCP/UDP packets)

Used to redirect subscriber sessions to a charging service based on the transmission control protocol/user datagram protocol packets in the downlink (from the Mobile Node) direction.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] downlink { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }
```

```
after redirect css service svc_name [ log ] downlink { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }
```

```
no redirect css service svc_name [ log ] downlink { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }
```

```
after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.
```

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.
before
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no
Removes the rule definition which exactly matches the options specified.

css service svc_name
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the show active-charging service all command to display the names of all configured charging services.
svc_name must be a string of 1 through 15 characters in length.

downlink
Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

log
Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

tcp | udp
Specifies the redirect is to be applied to IP based transmission control protocol or the user datagram protocol.
  - tcp: Redirect applies to TPC packets.
  - udp: Redirect applies to UDP packets.

source_address
The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the source wildcard parameter.

source wildcard
This option is used in conjunction with the source address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the source address parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the source address parameter must be ignored.
**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**any**
Specifies that the rule definition applies to all packets.

**host**
Specifies that the rule definition applies to a specific host as determined by its IP address.

**source_host_address**
The IP address of the source host to filter against expressed in IPv6 colon notation.

**dest_host_address**
The IP address of the destination host to filter against expressed in IPv6 colon notation.

**eq source_port**
Specifies a single, specific source TCP port number to be filtered.
source_port must be configured to any integer value from 0 to 65535.

**gt source_port**
Specifies that all source TCP port numbers greater than the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

**lt source_port**
Specifies that all source TCP port numbers less than the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

**neq source_port**
Specifies that all source TCP port numbers not equal to the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

**range start_source_port end_source_port**
Specifies that all source TCP ports within a specific range are to be filtered.
start_source_port is the initial port in the range and end_source_port is the final port in the range.
Both start_source_port and end_source_port can be configured to any integer value from 0 to 65535.

**dest_address**
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest wildcard parameter.
**dest_wildcard**

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

---

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is *not* acceptable since the one-bits are not contiguous.

**eq dest_port**

Specifies a single, specific destination TCP port number to be filtered. *dest_port* must be configured to any integer value from 0 to 65535.

**gt dest_port**

Specifies that all destination TCP port numbers greater than the one specified are to be filtered. *dest_port* must be configured to any integer value from 0 to 65535.

**lt dest_port**

Specifies that all destination TCP port numbers less than the one specified are to be filtered. *dest_port* must be configured to any integer value from 0 to 65535.

**neq dest_port**

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered. *dest_port* must be configured to any integer value from 0 to 65535.

**range start_dest_port end_dest_port**

Specifies that all destination TCP ports within a specific range are to be filtered. *start_dest_port* is the initial port in the range and *end_dest_port* is the final port in the range. Both *start_dest_port* and *end_dest_port* can be configured to any integer value from 0 to 65535.

---

**Usage**

Block IP packets when the source and destination are of interest but for only a limited set of ports.

---

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

---

**Example**

The following command defines a rule definition that redirects packets to the charging service named *chgsvc1*, and UDP packets coming from any host are matched:
**redirect css service** `chgsvc1 downlink udp any`

The following sets the insertion point to before the rule definition above:

```
before redirect css service chgsvc1 downlink udp any
```

The following command sets the insertion point after the rule definition above:

```
after redirect css service chgsvc1 downlink udp any
```

The following deletes the rule definition above:

```
no redirect css service chgsvc1 downlink udp any
```
redirect css service (for uplink, any)

Used to redirect subscriber sessions based on any packet received in the uplink (to the Mobile Node) direction. This command is also used to set the access control list insertion point.

Product
All

Privilege
Security Administrator, Administrator

Syntax

redirect css service svc_name [ log ] uplink any
after redirect css service svc_name [ log ] uplink any
before redirect css service svc_name [ log ] uplink any
no redirect css service svc_name [ log ] uplink any

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

css service svc_name

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the show active-charging service all command to display the names of all configured charging services.
svc_name must be a string of 1 through 15 characters in length.
IPv6 ACL Configuration Mode Commands

**redirect css service (for uplink, any)**

- **uplink**
  Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

- **log**
  Default: packets are not logged.
  Indicates all packets which match the redirect are to be logged.

- **any**
  Indicates all packets will match the redirect regardless of source and/or destination.

**Usage**
Define a catch all rule definition to place at the end of the list of rule definitions to provide explicit handling of rule definitions which do not fit any other criteria.

**Important:** It is suggested that any rule definition which is added to be a catch all should also have the `log` option specified. The logged packets may be used to determine if the current list of rule definitions is adequate or needs modification to ensure proper security.

**Important:** A maximum of 16 rule definitions can be configured per ACL.

**Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**
The following command defines a rule definition that redirects packets to the charging service with the name `chgsvc1` and any source IP:

```
redirect css service chgsvc1 uplink any
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service chgsvc1 uplink any
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service chgsvc1 uplink any
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 uplink any
```
redirect css service (for uplink, by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address in the uplink (to the Mobile Node) direction.

**redirect css service (for uplink, by host IP address)**

IPv6 ACL Configuration Mode Commands

```plaintext
redirect css service svc_name

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services.

`svc_name` must be a string of 1 through 15 characters in length.

**uplink**

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

**log**

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

**host**

Specifies that the rule definition applies to a specific host as determined by its IP address.

```plaintext
source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.
```

**Usage**

Define a rule definition when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rule definitions to be very clear and concise.

> **Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the charging service with the name `chgsvc1` and a host IP address of `192.168.200.11`:

```plaintext
redirect service chgsvc1 uplink host 192.168.200.11
```

The following sets the insertion point to before the first rule definition above:

```plaintext
before redirect service chgsvc1 uplink host 192.168.200.11
```

The following command sets the insertion point after the second rule definition above:

```plaintext
after redirect service chgsvc1 uplink host 192.168.200.11
```

The following deletes the first rule definition above:

```plaintext
no redirect service chgsvc1 uplink host 192.168.200.11
```
redirect css service (for uplink, by ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets in the uplink (to the Mobile Node) direction.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```plaintext
redirect css service svc_name [ log ] uplink icmp { any | host source_host_address | source_address sourceWildcard } { any | host dest_host_address | dest_address destWildcard } [ icmp_type [ icmp_code ] ]
```

```
after
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.
```

```
before
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.
```

```
no
Removes the rule definition which exactly matches the options specified.
```

```
css service svc_name
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the show active-charging service all command to display the names of all configured charging services.
svc_name must be a string of 1 through 15 characters in length.
```

```
uplink
Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.
```
**Log**
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**source_address**
The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**
This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**any**
Specifies that the rule definition applies to all packets.

**host**
Specifies that the rule definition applies to a specific host as determined by its IP address.

**source_host_address**
The IP address of the source host to filter against expressed in IPv6 colon notation.

**dest_host_address**
The IP address of the destination host to filter against expressed in IPv6 colon notation.

**dest_address**
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the `dest_wildcard` parameter.

**dest_wildcard**
This option is used in conjunction with the `dest_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.

One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

```plaintext
icmp_type
```

Specifies that all ICMP packets of a particular type are to be filtered. The type can be any integer value between 0 and 255.

```plaintext
icmp_code
```

Specifies that all ICMP packets of a particular code are to be filtered. The type can be any integer value between 0 and 255.

**Usage**

Define a rule definition to block ICMP packets which can be used for address resolution and possibly be a security risk.

The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

**Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

**Example**

The following command defines a rule definition that redirects packets to the charging service named chgsvc1, and ICMP packets in the uplink (to the Mobile Node) direction from the host with the IP address 198.162.100.25:

```
redirect css service chgsvc1 uplink icmp host 198.162.100.25
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service chgsvc1 uplink icmp host 198.162.100.25
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service chgsvc1 uplink icmp host 198.162.100.25
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 uplink icmp host 198.162.100.25
```
redirect css service (for uplink, by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets in the uplink (to the Mobile Node) direction.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
redirect css service svc_name [ log ] uplink ip { any | host source_host_address | source_address source wildcard } { any | host dest_host_address | dest_address dest wildcard } [ fragment ]
```

```
after redirect css service svc_name [ log ] uplink ip { any | host source_host_address | source_address source wildcard } { any | host dest_host_address | dest_address dest wildcard } [ fragment ]
```

```
before redirect css service svc_name [ log ] uplink ip { any | host source_host_address | source_address source wildcard } { any | host dest_host_address | dest_address dest wildcard } [ fragment ]
```

```
no redirect css service svc_name [ log ] uplink ip { any | host source_host_address | source_address source wildcard } { any | host dest_host_address | dest_address dest wildcard } [ fragment ]
```

**after**
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

**no**
Removes the rule definition which exactly matches the options specified.
**css service** `svc_name`

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services.

`sfdcme _name_` must be a string of 1 through 15 characters in length.

**uplink**

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

**log**

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

**source_address**

The IP address(es) form which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

**source_wildcard**

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**any**

Specifies that the rule definition applies to all packets.

**host**

Specifies that the rule definition applies to a specific host as determined by its IP address.

**source_host_address**

The IP address of the source host to filter against expressed in IPv6 colon notation.

**dest_host_address**

The IP address of the destination host to filter against expressed in IPv6 colon notation.
redirect css service (for uplink, by IP packets)

dest_address
The IP address(es) to which the packet is to be sent. This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest wildcard parameter.

dest wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

fragment
Indicates packet redirection is to be applied to IP packet fragments only.

Usage
Block IP packets when the source and destination are of interest.

Example
The following command defines a rule definition that redirects packets to the charging service named chgsvc1, and uplink IP packets going to the host with the IP address 198.162.100.25, and fragmented packets for any destination are matched:

```
redirect css service chgsvc1 uplink ip host 198.162.100.25 any fragment
```

The following sets the insertion point to before the first rule definition above:

```
redirect css service chgsvc1 uplink ip host 198.162.100.25 any fragment
```

The following command sets the insertion point after the second rule definition above:

```
before redirect css service chgsvc1 uplink ip host 198.162.100.25 any fragment
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 uplink ip host 198.162.100.25 any fragment
```
redirect css service (for uplink, by source IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source in the uplink (to the Mobile Node) direction.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
redirect css service svc_name [ log ] uplink source_address
source_wildcard
```

**after**
Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

**before**
Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

**no**
Removes the rule definition which exactly matches the options specified.

**css service svc_name**
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the `show active-charging service all` command to display the names of all configured charging services.
`svc_name` must be a string of 1 through 15 characters in length.

**uplink**
Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

**log**
Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

**source_address**
The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
IPv6 ACL Configuration Mode Commands

**redirect css service** (for uplink, by source IP address masking)

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source_wildcard` parameter.

```
source_wildcard
```

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Usage**

Define a rule definition when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rule definitions as it does not require a rule definition for each source and destination pair.

**Example**

The following command defines a rule definition to redirect packets to a charging service named `chgsvc1`:

```
redirect css service chgsvc1 uplink 1::1
```
redirect css service (for uplink, by TCP/UDP packets)

Used to redirect subscriber sessions to a charging service based on the transmission control protocol/user datagram protocol packets in the uplink (to the Mobile Node) direction.

Product
All

Privilege
Security Administrator, Administrator

Syntax

redirect css service svc_name [ log ] uplink { tcp | udp } { { source_address source_wildcard | any | source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

after redirect css service svc_name [ log ] uplink { tcp | udp } { { source_address source_wildcard | any | source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

before redirect css service svc_name [ log ] uplink { tcp | udp } { { source_address source_wildcard | any | source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

no redirect css service svc_name [ log ] uplink { tcp | udp } { { source_address source_wildcard | any | source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port | range start_source_port end_source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port | range start_dest_port end_dest_port ] }

---

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.
IPv6 ACL Configuration Mode Commands

redirect css service (for uplink, by TCP/UDP packets)

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

no
Removes the rule definition which exactly matches the options specified.

css service svc_name
The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the show active-charging service all command to display the names of all configured charging services. svc_name must be a string of 1 through 15 characters in length.

uplink
Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

log
Default: packets are not logged. Indicates all packets which match the redirect are to be logged.

tcp | udp
Specifies the redirect is to be applied to IP based transmission control protocol or the user datagram protocol.
- tcp: Redirect applies to TPC packets.
- udp: Redirect applies to UDP packets.

source_address
The IP address(es) from which the packet originated. This option is used to filter all packets from a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the source wildcard parameter.

source wildcard
This option is used in conjunction with the source_address option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the source_address parameter must be ignored.

any
Specifies that the rule definition applies to all packets.

host
Specifies that the rule definition applies to a specific host as determined by its IP address.
source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address
The IP address of the destination host to filter against expressed in IPv6 colon notation.

eq source_port
Specifies a single, specific source TCP port number to be filtered.
source_port must be configured to any integer value from 0 to 65535.

gt source_port
Specifies that all source TCP port numbers greater than the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

lt source_port
Specifies that all source TCP port numbers less than the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

neq source_port
Specifies that all source TCP port numbers not equal to the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

range start_source_port end_source_port
Specifies that all source TCP ports within a specific range are to be filtered.
start_source_port is the initial port in the range and end_source_port is the final port in the range.
Both start_source_port and end_source_port can be configured to any integer value from 0 to 65535.

dest_address
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest_wildcard parameter.

dest_wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

eq dest_port
Specifies a single, specific destination TCP port number to be filtered.
**redirect css service (for uplink, by TCP/UDP packets)**

**dest_port** must be configured to any integer value from 0 to 65535.

**gt dest_port**

Specifies that all destination TCP port numbers greater than the one specified are to be filtered. 
**dest_port** must be configured to any integer value from 0 to 65535.

**lt dest_port**

Specifies that all destination TCP port numbers less than the one specified are to be filtered. 
**dest_port** must be configured to any integer value from 0 to 65535.

**neq dest_port**

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered. 
**dest_port** must be configured to any integer value from 0 to 65535.

**range start_dest_port end_dest_port**

Specifies that all destination TCP ports within a specific range are to be filtered.
**start_dest_port** is the initial port in the range and **end_dest_port** is the final port in the range. 
Both **start_dest_port** and **end_dest_port** can be configured to any integer value from 0 to 65535.

**Usage**

Block IP packets when the source and destination are of interest but for only a limited set of ports.

**Example**

The following command defines a rule definition that redirects packets to the charging service named **chgsvc1**, and UDP packets coming from any host are matched:

```
redirect css service chgsvc1 uplink udp any
```

The following sets the insertion point to before the rule definition above:

```
before redirect css service chgsvc1 uplink udp any
```

The following command sets the insertion point after the rule definition above:

```
after redirect css service chgsvc1 uplink udp any
```

The following deletes the rule definition above:

```
no redirect css service chgsvc1 uplink udp any
```
**redirect nexthop (by IP address masking)**

Used to redirect subscriber sessions based on the IP address mask sent by the source to the mobile node or the network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] source_address source_wildcard

after redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] source_address source_wildcard

before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] source_address source_wildcard

no redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] source_address source_wildcard
```

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed. This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed. This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.

**nexthop nexthop_addr**
The IP address to which the IP packets are redirected.
**redirect nexthop (by IP address masking)**

context context_id

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

interface interface_name

The name of the logical interface to which the packets should be redirected. `interface_name` must be an alpha and/or numeric string from 1 to 79 characters in length.

log

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `sourceWildcard` parameter.

sourceWildcard

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

Usage

Define a rule when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of redirect rules as it does not require a rule for each source and destination pair.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the next hop host at 192.168.10.4, the context with the context ID of 23 and the source IP and wildcard of 198.162.22.0 and 0.0.0.31:
The following sets the insertion point to before the first rule defined above:

`before redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31`

The following command sets the insertion point after the second rule defined above:

`after redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31`

The following deletes the first rule defined above:

`no redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31`
redirect nexthop (any)

Used to redirect subscriber sessions based on any packet received. This command is also used to set the access control list insertion point.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] any
after redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] any
before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] any
no redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] any
```

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**
Removes the rule which exactly matches the options specified.

**nexthop nexthop_addr**
The IP address to which the IP packets are redirected.
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

The name of the logical interface to which the packets should be redirected. `interface_name` must be an alpha and/or numeric string from 1 to 79 characters in length.

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

Indicates all packets will match the redirect regardless of source and/or destination.

Usage
Define a catch all rule to place at the end of the list of rules to provide explicit handling of rules which do not fit any other criteria.

**Important:** It is suggested that any rule which is added to be a catch all should also have the `log` option specified. The logged packets may be used to determine if the current list of rules is adequate or needs modification to ensure proper security. The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example
The following command defines a rule that redirects packets to the next hop host at 192.168.10.4, the context with the context ID of 23 and any source IP:

```
redirect next-hop 192.168.10.4 context 23 any
```

The following sets the insertion point to before the first rule defined above:

```
between redirect next-hop 192.168.10.4 context 23 any
```

The following command sets the insertion point after the second rule defined above:

```
after redirect next-hop 192.168.10.4 context 23 any
```

The following deletes the first rule defined above:

```
no redirect next-hop 192.168.10.4 context 23 any
```
redirect nexthop (by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Syntax

redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] host source_ip_address

after redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] host source_ip_address

before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] host source_ip_address

no redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] host source_ip_address

---

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

---

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

---

no

Removes the rule which exactly matches the options specified.

nexthop nexthop_addr

The IP address to which the IP packets are redirected.
context context_id
The context identification number of the context to which packets are redirected. At the executive mode prompt, use the show context all command to display context names and context IDs.

interface interface_name
The name of the logical interface to which the packets should be redirected. interface_name must be an alpha and/or numeric string from 1 to 79 characters in length.

log
Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

host
Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address
The IP address of the source host to filter against expressed in IPv6 colon notation.

Usage
Define a rule when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rules to be very clear and concise.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example
The following command defines a rule that redirects packets to the next hop host at 192.168.10.4, the context with the context ID of 23 and a host IP address of 192.168.200.11:

```plaintext
redirect nexthop 192.168.10.4 context 23 host 192.168.200.11
```

The following sets the insertion point to before the first rule defined above:

```plaintext
before redirect nexthop 192.168.10.4 context 23 host 192.168.200.11
```

The following command sets the insertion point after the second rule defined above:

```plaintext
after redirect nexthop 192.168.10.4 context 23 host 192.168.200.11
```

The following deletes the first rule defined above:

```plaintext
no redirect nexthop 192.168.10.4 context 23 host 192.168.200.11
```
redirect nexthop (by source ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] icmp { source_address source wildcard | any | host source_host_address } { dest_address dest wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]
```

```
after redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] icmp { source_address source wildcard | any | host source_host_address } { dest_address dest wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]
```

```
before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] icmp { source_address source wildcard | any | host source_host_address } { dest_address dest wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]
```

```
norem redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] icmp { source_address source wildcard | any | host source_host_address } { dest_address dest wildcard | any | host dest_host_address } [ icmp_type [ icmp_code ] ]
```

**after**
Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**
Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.
redirect nexthop (by source ICMP packets)

- **no**
  Removes the rule which exactly matches the options specified.

- **nexthop** nexthop_addr
  The IP address to which the IP packets are redirected.

- **context** context_id
  The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

- **interface** interface_name
  The name of the logical interface to which the packets should be redirected. `interface_name` must be an alpha and/or numeric string from 1 to 79 characters in length.

- **log**
  Default: packets are not logged.
  Indicates all packets which match the redirect are to be logged.

- **source_address**
  The IP address(es) form which the packet originated.
  This option is used to filter all packets from a specific IP address or a group of IP addresses.
  When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source wildcard` parameter.

- **source wildcard**
  This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.
  The mask must be entered as a complement:
  - Zero-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
  - One-bits in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.

- **Important**: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

- **any**
  Specifies that the rule applies to all packets.

- **host**
  Specifies that the rule applies to a specific host as determined by its IP address.

- **source_host_address**
  The IP address of the source host to filter against expressed in IPv6 colon notation.
redirect nexthop (by source ICMP packets)

dest_host_address
The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address
The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the dest wildcard parameter.

dest wildcard
This option is used in conjunction with the dest address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
• Zero-bits in this parameter mean that the corresponding bits configured for the dest address parameter must be identical.
• One-bits in this parameter mean that the corresponding bits configured for the dest address parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

icmp_type
Specifies that all ICMP packets of a particular type are to be filtered. The type can be any integer value between 0 and 255.

icmp_code
Specifies that all ICMP packets of a particular code are to be filtered. The type can be any integer value between 0 and 255.

Usage
Define a rule to block ICMP packets which can be used for address resolution and possible be a security risk.
The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example
The following command defines a rule that redirects packets to the next hop host at 192.168.10.4, the context with the context ID of 23, and ICMP packets coming from the host with the IP address 192.168.100.25:

    redirect nexthop 192.168.10.4 context 23 icmp host 192.168.100.25
The following sets the insertion point to before the first rule defined above:

```
before redirect nexthop 192.168.10.4 context 23 icmp host 192.168.100.25
```

The following command sets the insertion point after the second rule defined above:

```
after redirect nexthop 192.168.10.4 context 23 icmp host 192.168.100.25
```

The following deletes the first rule defined above:

```
no redirect nexthop 192.168.10.4 context 23 icmp host 192.168.100.25
```
redirect nexthop (by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] ip { source_address sourceWildcard | any | host source_host_address } { dest_address destWildcard | any | host dest_host_address } [ fragment ] [ protocol num ]
```

**after**

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.
This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**before**

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.
This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**

Removes the rule which exactly matches the options specified.

**nexthop nexthop_addr**

The IP address to which the IP packets are redirected.

**context context_id**

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.
**IPv6 ACL Configuration Mode Commands**

---

**redirect nexthop (by IP packets)**

**interface interface_name**

The name of the logical interface to which the packets should be redirected. *interface_name* must be an alpha and/or numeric string from 1 to 79 characters in length.

**log**

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

**source_address**

The IP address(es) form which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

**source_wildcard**

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:
- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

**any**

Specifies that the rule applies to all packets.

**host**

Specifies that the rule applies to a specific host as determined by its IP address.

**source_host_address**

The IP address of the source host to filter against expressed in IPv6 colon notation.

**dest_host_address**

The IP address of the destination host to filter against expressed in IPv6 colon notation.

**dest_address**

The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.
IPv6 ACL Configuration Mode Commands

redirect nexthop (by IP packets)

dest_wildcard
This option is used in conjunction with the dest_address option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the dest_address parameter must be ignored.

**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is not acceptable since the one-bits are not contiguous.

fragment
Indicates packet redirection is to be applied to IP packet fragments only.

protocol num
Indicates that the packet filtering is to be applied to a specific protocol number.
num can be any integer ranging from 0 to 255.

Usage
Block IP packets when the source and destination are of interest.

**Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.
redirect nexthop (by TCP/UDP packets)

Used to redirect subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

Product
All

Privilege
Security Administrator, Administrator

Syntax

redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }

after redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }

before redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }

no redirect nexthop nexthop_addr { context context_id | interface interface_name } [ log ] { tcp | udp } { { source_address source_wildcard | any | host source_host_address } [ eq source_port | gt source_port | lt source_port | neq source_port ] } { { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }

---

**Important:** If the options specified do not exactly match an existing rule, the insertion point does not change.

---

**after**

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.
IPv6 ACL Configuration Mode Commands

redirect nexthop (by TCP/UDP packets)

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

![Important:](image)

If the options specified do not exactly match an existing rule, the insertion point does not change.

**no**

Removes the rule which exactly matches the options specified.

**nexthop nexthop_addr**

The IP address to which the IP packets are redirected.

**context context_id**

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the `show context all` command to display context names and context IDs.

**interface interface_name**

The name of the logical interface to which the packets should be redirected. `interface_name` must be an alpha and/or numeric string from 1 to 79 characters in length.

**log**

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

**tcp | udp**

Specifies the redirect is to be applied to IP based transmission control protocol or the user datagram protocol.

- **tcp**: Redirect applies to TCP packets.
- **udp**: Redirect applies to UDP packets.

**source_address**

The IP address(es) form which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the `source wildcard` parameter.

**source wildcard**

This option is used in conjunction with the `source_address` option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- **Zero-bits** in this parameter mean that the corresponding bits configured for the `source_address` parameter must be identical.
- **One-bits** in this parameter mean that the corresponding bits configured for the `source_address` parameter must be ignored.
**Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

---

**any**

Specifies that the rule applies to all packets.

**host**

Specifies that the rule applies to a specific host as determined by its IP address.

**source_host_address**

The IP address of the source host to filter against expressed in IPv6 colon notation.

**dest_host_address**

The IP address of the destination host to filter against expressed in IPv6 colon notation.

**eq source_port**

Specifies a single, specific source TCP port number to be filtered. `source_port` must be configured to any integer value from 0 to 65535.

**gt source_port**

Specifies that all source TCP port numbers greater than the one specified are to be filtered. `source_port` must be configured to any integer value from 0 to 65535.

**lt source_port**

Specifies that all source TCP port numbers less than the one specified are to be filtered. `source_port` must be configured to any integer value from 0 to 65535.

**neq source_port**

Specifies that all source TCP port numbers not equal to the one specified are to be filtered. `source_port` must be configured to any integer value from 0 to 65535.

**dest_address**

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses. When specifying a group of addresses, the initial address is set using this parameter. The range can then be set using the `dest_wildcard` parameter.

**dest_wildcard**

This option is used in conjunction with the `dest_address` option to specify a group of addresses for which packets are to be filtered. The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the `dest_address` parameter must be identical.
• One-bits in this parameter mean that the corresponding bits configured for the \textit{dest\_address} parameter must be ignored.

\textbf{Important:} The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is \textbf{not} acceptable since the one-bits are not contiguous.

\textbf{eq} \ dest\_port

Specifies a single, specific destination TCP port number to be filtered. \textit{dest\_port} must be configured to any integer value from 0 to 65535.

\textbf{gt} \ dest\_port

Specifies that all destination TCP port numbers greater than the one specified are to be filtered. \textit{dest\_port} must be configured to any integer value from 0 to 65535.

\textbf{lt} \ dest\_port

Specifies that all destination TCP port numbers less than the one specified are to be filtered. \textit{dest\_port} must be configured to any integer value from 0 to 65535.

\textbf{neq} \ dest\_port

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered. \textit{dest\_port} must be configured to any integer value from 0 to 65535.

\textbf{Usage}

Block IP packets when the source and destination are of interest but for only a limited set of ports.

\textbf{Important:} The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that "redirect" rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

\textbf{Example}

The following command defines a rule that redirects packets to the next hop host at 192.168.10.4, the context with the context ID of 23, and UDP packets coming from any host are matched:

\texttt{redirect nexthop 192.168.10.4 context 23 udp any}

The following sets the insertion point to before the rule defined above:

\texttt{before redirect nexthop 192.168.10.4 context 23 udp any}

The following command sets the insertion point after the rule defined above:

\texttt{after redirect nexthop 192.168.10.4 context 23 udp any}

The following command deletes the first rule defined above:
no redirect next-hop 192.168.10.4 context 23 udp any
Chapter 129
IPv6 to IPv4 Tunnel Interface Configuration Mode
Commands

The IPv6 to IPv4 Tunnel Interface Configuration Mode is used to create and manage the IP interfaces for addresses, address resolution options, etc.

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
redirect nexthop (by TCP/UDP packets)
destination address

Configures the destination of the tunneled packets for a manual tunnel.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
  destination address address
  no destination
```

```
  no
  Removes configuration for the specified keyword.
```

```
  text
  Specifies the descriptive text to use. `text` must be 0 to 79 alpha and/or numeric characters with no spaces or a quoted string of printable characters
```

Usage
Set the description to provide useful information on the interface’s primary function, services, end users, etc. Any information useful may be provided.

Example
```
description sampleInterfaceDescriptiveText
```
end

Exits the interface configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
```
end
```

Usage
Change the mode back to the Exec mode.
exit

Exits the Interface Configuration Mode and returns to the Context Configuration Mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Return to the context configuration mode.
mode

Configures the mode of IPv6 to IPv4 tunneling. The default is set to manual mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
mode ( 6to4 | manual )
default mode
```

---

**6to4**
Configures automatic 6to4 IPv6 to IPv4 tunnels as specified in RFC 3056.

---

**manual**
Configures point-to-point manual IPv6 to IPv4 tunnels by specifying IPv4 address of the tunnel remote end.

---

**default**
Resets the mode of IPv6 to IPv4 tunneling to manual mode.

**Usage**

There can be only one 6to4 tunnel possible in a context. Once a 6to4 tunnel is configured, all subsequent tunnels will be configured as manual tunnels.

**Example**
The following command configures the mode to 6to4.

```
mode 6to4
```

The following command configures the mode to 6to4.

```
mode manual
```
source

Configures the source of tunneled packets.

Product
PDSN, HA

Privilege
Security Administrator, Administrator

Syntax

source { address ip_address /interface interface_name}
no source

address ip_address
Specifies the IPv4 address to use as the source address of the tunnel.
ip_address is the IP address in dotted-decimal notation.

interface interface_name
Specifies the name of a non-tunnel IPv4 interface, whose address is used as the source address of the tunnel.

no
Removes configuration for the specified keyword.

Usage
Configures the source IPv4 address of the tunnel by either specifying the IP address (host address) or by specifying another configured non-tunnel IPv4 interface. The source address must be an existing interface address before it is used. State of source address will affect the operational state of the tunnel.

Example
The following command configures the source address of the tunnel.
source address 1.2.3.4
The following command specifies the source interface as testsOURCE.
source interface testsOURCE
tos

Configures the type of service (TOS) settings of the outer IPv4 header of the tunneled packets.

Product
PDSN, HA

Privilege
Security Administrator, Administrator

Syntax

tos {copy | value tos_value }
default tos

copy
Copies the DC octet of IPv6 packet to the TOS octet of IPv4 packet.

default
Configures default setting for the specified keyword.

value
Configures the raw TOS value ranging from 0 to 255. The default is 0.

Usage
Sets the TOS parameter to be used in the tunnel transport protocol or instructs to copy TOS value from the original IPv6 DC byte to the TOS value of the encapsulating IPv4 header.

Example
The following command sets the tos value to 1:
tos value 1
**ttl**

Configures the TTL (Time to live) value of the outer IPv4 header of the tunneled packets.

**Product**
PDSL, HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
ttl value ttl_value
```

- **default**
  Configures default setting for the specified keyword.

- **value**
  **value** is a range from 1 to 255. The default is 16.

**Usage**
Configures the TTL parameter to be used in the tunnel transport protocol.

**Example**
The following command sets the TTL value to 25.
```plaintext
ttl value 25
```
The IP Virtual Routing and Forwarding Context Configuration Mode is used to create and manage the VRF context instance for GRE tunneling interfaces for addresses, address resolution options, etc.

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the interface configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

end

Usage
Change the mode back to the Exec mode.
exit

Exits the Interface Configuration Mode and returns to the Context Configuration Mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
exit
```

Usage

Return to the context configuration mode.
ip maximum-routes

This command configures the maximum number of routes in an IP VRF routing table configured in this context.

Product
All

Privilege
Security Administrator, Administrator

Syntax

ip maximum-routes max_routes

no ip maximum-routes

Usage
Use this command to configure the maximum number of routes in a particular VRF routing table. When the number of routes in the VRF is more than the maximum limit configured, a critical log is generated indicating that the number of routes is over the limit. Once the number of routes in the VRF goes under the limit, a clear log is generated.

The maximum routes configured using this command will be sent to the threshold configuration logic for appropriate action. For more information on threshold configuration, refer to threshold route-service bgp-routes and threshold poll route-service interval commands in Global configuration mode.

Example
The following command sets 1000 routes as a maximum limit for specific VRF context:

   ip maximum-routes 1000
**mpls map-dscp-to-exp**

This command provides mapping of final differentiated services code point (DSCP) bit value in IP packet header to final Experimental (EXP) bit value in MPLS header for incoming traffic.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
mpls map-dscp-to-exp dscp dscp_bit_value exp exp_bit_value
```

**dscp dscp_bit_value**
This keyword specifies the final DSCP bit value which is to map with the final EXP bit value in MPLS header for incoming traffic.

*dscp_bit_value* specifies the value of DSCP bit values separated in 8 groups and represented with integers between 0 through 7.

The default representation of DSCP value in 8 groups is given in the following table:

<table>
<thead>
<tr>
<th>DSCP Marking Value</th>
<th>DSCP Map Group</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-7</td>
<td>0</td>
</tr>
<tr>
<td>8-15</td>
<td>1</td>
</tr>
<tr>
<td>16-23</td>
<td>2</td>
</tr>
<tr>
<td>24-31</td>
<td>3</td>
</tr>
<tr>
<td>32-39</td>
<td>4</td>
</tr>
<tr>
<td>40-47</td>
<td>5</td>
</tr>
<tr>
<td>48-55</td>
<td>6</td>
</tr>
<tr>
<td>56-63</td>
<td>7</td>
</tr>
</tbody>
</table>

**exp exp_bit_value**
This keyword specifies the final EXP bit value in MPLS header to which the final DSCP bit value 0 to 7 (represented in 8 values) coming from incoming traffic will be mapped.

*exp_bit_value* is the value of EXP bit in MPLS header and must be an integer between 0 through 7.

**Usage**
Use this command to map the final DSCP value coming from incoming IP traffic to a final EXP value in MPLS header. This mapping determines the QoS and service parameters to which the packet is assigned.

**Example**
The following command maps the DSCP value 3 (24 to 31) to EXP bit 3 in MPLS header:

```
mpl map-dscp-to-exp dscp 3 exp 3
```
**mpls map-exp-to-dscp**

This command provides mapping of incoming Experimental (EXP) bit value in MPLS header to internal differentiated services code point (DSCP) bit value in IP packet header for outgoing traffic.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
mpls map-exp-to-dscp exp exp_bit_value dscp dscp_bit_value
```

- **exp exp_bit_value**
  This keyword specifies the incoming EXP bit value in MPLS header to which the internal DSCP bit value 0 to 7 (represented in 8 values) in IP traffic will be mapped.
  *exp_bit_value* is the value of EXP bit in MPLS header and must be an integer between 0 through 7.

- **dscp dscp_bit_value**
  This keyword specifies the DSCP bit value is to be mapped with the incoming EXP bit value in MPLS header.
  *dscp_bit_value* specifies the value of DSCP bit values separated in 8 groups and represented with integers between 0 through 7.
  The default representation of DSCP value in 8 groups is given in the following table:

<table>
<thead>
<tr>
<th>DSCP Marking Value</th>
<th>DSCP Map Group</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-7</td>
<td>0</td>
</tr>
<tr>
<td>8-15</td>
<td>1</td>
</tr>
<tr>
<td>16-23</td>
<td>2</td>
</tr>
<tr>
<td>24-31</td>
<td>3</td>
</tr>
<tr>
<td>32-39</td>
<td>4</td>
</tr>
<tr>
<td>40-47</td>
<td>5</td>
</tr>
<tr>
<td>48-55</td>
<td>6</td>
</tr>
<tr>
<td>56-63</td>
<td>7</td>
</tr>
</tbody>
</table>

**Usage**
Use this command to map the incoming EXP bit value in MPLS header to DSCP bit value in IP traffic. This mapping determines the QoS and service parameters to which the packet is assigned.

**Example**

Use this command to map the incoming EXP bit value in MPLS header to DSCP bit value in IP traffic. This mapping determines the QoS and service parameters to which the packet is assigned.
The following command maps the EXP bit value 4 to DSCP value 6 (48 to 55) in IP header:

```
mpl map-exp-to-dscp exp 4 dscp 6
```
Chapter 131
ISAKMP Configuration Mode Commands

The ISAKMP Configuration Mode is used to configure Internet Security Association Key Management Protocol (ISAKMP) policies that are used to define Internet Key Exchange (IKE) security associations (SAs).

Modification(s) to an existing ISAKMP policy configuration will not take effect until the related security association has been cleared. Refer to the clear crypto security-association command located in the Exec Mode Commands chapter of the Command Line Interface Reference for more information.

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
authentication

Configures the ISAKMP policy authentication mode.

Product
PDSN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

```plaintext
authentication preshared-key
[ default | no ] authentication
```

(default)
Restores the default setting of this parameter. The command is enabled by default.

(no)
Disables the preshared key authentication mode.

(preshared-key)
Specifies that the policy will be authenticated through the use of the pre-shared key.

Usage
When the system is configured to use ISAKMP-type crypto maps for establishing IPSec tunnels, this command is used to indicate that the policy will be authenticated through the use of the pre-shared key configured in the ISAKMP crypto map.

Example
The following command sets policy authentication mode to use a pre-shared key:

```plaintext
authentication preshared-key
```
encryption

Configures the encryption protocol to use to protect subsequent IKE SA negotiations.

**Product**

PDSN, HA, GGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
encryption { 3des-cbc | des-cbc }
[ default | no ] encryption
```

- **default**
  Restores the default setting of this parameter.

- **no**
  Removes a previously configured encryption type.

- **3des-cbc**
  Specifies that the encryption protocol is Triple Data Encryption Standard (3DES) in chain block (CBC) mode.

- **des-cbc**
  Specifies that the encryption protocol is DES in CBC mode. This is the default setting.

**Usage**

Once the D-H exchange between the system and the security gateway has been successfully completed, subsequent IKE SA negotiations will be protected using the protocol specified by this command.

**Example**

The following command sets the IKE encryption method to 3des-cbc:

```
encryption 3des-cbc
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
PDSN, HA, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Returns to the Exec mode.
exit

Exits the current configuration mode and returns to the Context configuration mode.

**Product**

PDSN, HA, GGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the Context Configuration mode.
group

Configures the Oakely group (also known as the Diffie-Hellman (D-H) group) in which the D-H exchange occurs.

Product
PDSN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

group { 1 | 2 | 5 }

[ default | no ] group

---

default
Restores the default setting of this parameter.

no
Removes a previously configured group.

---

{ 1 | 2 | 5 }
Default: 1
The number of the Oakley group. The following groups are allowed:

- **1**: Enables Oakley Group 1 using a 768-bit modp as defined in RFC 2409.
- **2**: Enables Oakley Group 2, using a 1024-bit modp as defined in RFC 2409.
- **5**: Enables Oakley Group 5, using a 1536-bit modp as defined in RFC 3526.

---

Usage
Specifies the Oakley group that determine the length of the base prime numbers that are used during the key exchange process.

---

Example
The following command sets the group to 5 which specifies 1536-bit base prime numbers:

`group 5`
hash

Configures the IKE hash protocol to use during IKE SA negotiations.

**Product**
PDSN, HA, GGSN

**Privilege**
Security Administrator, Administrator\n
**Syntax**

```
hash { md5 | sha1 }
[ default | no ] hash
```

---

**default**
Restores the default setting of this parameter.

---

**no**
Removes a previously configured hash algorithm.

---

**md5**
Specifies that the hash protocol is Message Digest 5 truncated to 96 bits.

---

**sha1**
Specifies that the hash protocol is Secure Hash Algorithm-1 truncated to 96 bits. This is the default setting for this command.

---

**Usage**
Use this command to configure the hash algorithm used during key negotiation.

---

**Example**
Set the hash algorithm to Message-Digest 5 by entering the following command:

```
hash md5
```
**lifetime**

Configures the lifetime of the IKE Security Association (SA).

**Product**
PDSN, HA, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
lifetime seconds
```

```
default lifetime
```

**Usage**

Use this command to set the time that an ISAKMP SA will be valid. The lifetime is negotiated with the peer and the lowest configured lifetime duration is used.

**Example**
The following command sets the SA lifetime to 100 seconds:

```
lifetime 100
```
Chapter 132
IuPS Service Configuration Mode Commands

The IuPS Service configuration mode is used to define properties for the IuPS service which controls the Iu-PS interface connections to Radio Network Controllers (RNCs) of the UMTS Terrestrial Radio Access Network (UTRAN). In this mode, the prompt will appear similar to:

```
[<context_name>]hostname(config-ctx-iups-service)#
```

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
access-protocol

This command configures the access protocol parameters for the IuPS service.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

[ no ] access-protocol scgp-network scgp_net_id

no
Removes a previously configured access protocol value.

scgp-network scgp_net_id
Specifies the Signaling Connection Control Part (SCCP) for this IuPS service to use.
scgp_net_id must be an integer from 1 to 16.

Usage
Use this command to configure access protocol parameters for the current IuPS service.

Example
The following command specifies that the current Iu-PS service should use SCCP 1:

access-protocol scgp-network 1
blacklist-timeout-gtpu-bind-addresses

This command specifies the time period that a GTP-U bind address (loopback address) will not be used (is blacklisted) in RAB-Assignment requests after a RAB assignment request, with that GTP-U bind address, has been rejected by an RNC with the cause - Unspecified Error. This is a failure at the RNC’s GTP-U IP interface.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

blacklist-timeout-gtpu-bind-addresses  seconds

default blacklist-timeout-gtpu-bind-addresses

**default**
Resets the blacklist time to 60 seconds.

**seconds**
Number of seconds that the GTP-U bind (loopback) address will not be used in a RAB-Assignment request.  
seconds: Must be an integer from 1 to 1800.

Usage
Use this command to configure the blacklist period.

Example
The following command specifies a 15 minutes blacklist period.

```
blacklist-timeout-gtpu-bind-addresses seconds 460
```
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the previous configuration mode, the context configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the context configuration mode.
gtpu

This commands configures parameters for the GTP user (GTP-U) dataplane.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
gtpu { bind ip_addr | echo-interval seconds | max-retransmissions number | retransmission-timeout seconds }
no gtpu { bind address ip_addr | echo-interval | max-retransmissions | retransmission-timeout }
default gtpu { echo-interval | max-retransmissions | retransmission-timeout }
```

- **no**
  Removes the configured parameter value.

- **default**
  Sets the specified parameter to its default setting.

- **bind address ip_addr**
  This command binds the specified IP address to the Iu-PS GTP-U endpoint.
  `ip_addr`: Must be an IP v4 IP address in dotted decimal notation.

- **echo-interval seconds**
  Default: 60
  Configures the rate, in seconds, at which GTP-U echo packets are sent to the UTRAN over the Iu-PS interface.
  `seconds`: Must be an integer from 60 through 3600.

- **max-retransmissions number**
  Default: 5
  Configures the maximum number of transmission retries for GTP-U packets.
  `number`: Must be an integer from 0 through 15.

- **retransmission-timeout seconds**
  Default: 5
  Configures the retransmission timeout for GTPU packets in seconds.
  `seconds`: Must be an integer from 1 through 20.

**Usage**
Use this command to configure GTP-U parameters for the Iu-PS interface.

Example
The following command binds the IP address 192.168.0.10 to the Iu-PS interface for communication with the UTRAN:

```
gtpu bind address 192.168.0.10
```
iu-hold-connection

Defines the type and duration of the Iu hold connection.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
iu-hold-connection ( always [ hold-time time ] | requested-by-ms [ hold-time time ] )

[ default | no ] iu-hold-connection
```

- **default**
  Resets the Iu hold connection parameters to requested-by-ms and 100 second duration.

- **no**
  Removes the configuration information for the specified Iu hold connection parameter.

- **always**
  Specifies that there is always to be an Iu hold connection procedure.

- **requested-by-ms**
  Specifies that there is only an Iu hold connection procedure if requested by the MS/UE. This is the default setting for Iu-hold-connection.

- **hold-time time**
  This variable configures the interval (in seconds) that the SGSN holds the Iu connection. `time` must be an integer from 10 to 3600. Default is 100.

**Usage**
Define the amount of time the Iu connection will be held open.

**Example**

```
iu-hold-connection always hold-time 120
```
iu-recovery

This command enables the Iu recovery function.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
iu-recovery
no iu-recovery

Usage
Enable or disable Iu recovery function that should be used whenever sessions are recovered.

Example
The following command disables the Iu Recovery function:
no iu-recovery
iu-release-complete-timeout

Configures the SGSN’s timer for waiting for an Iu Release Complete message from the RNC.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

      iu-release-complete-timeout time

    default iu-release-complete-timeout

        default
        Resets the timer to its default setting.

        time
        This variable defines the amount of time (in seconds) that the SGSN waits to receive an ‘Iu Release Complete’ message from the RNC.
        Default: 10.
        time: Must be an integer from 1 to 60.

Usage
Configure the number of seconds that the SGSN waits to receive the Iu Release Complete message.

Example

      iu-release-complete-timeout 20
loss-of-radio-coverage ranap-cause

This command sets the detection cause included in the Iu Release message. This command is unique to releases 9.0 and higher.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

loss-or-radio-coverage ranap-cause cause_number

default loss-of-radio-coverage ranap-cause

default
This keyword resets the configuration to the default cause ID number.

ranap-cause cause_number
This number identifies the reason the SGSN has detected, from Iu Release messages, for the loss of radio coverage (LORC). This value is included in the IE messages the SGSN sends to either the GGSN or the GGSN and the peer SGSN to indicate LORC state. The range of reasons is a part of the set defined by 3GPP 25413.

cause_number: Must be an integer from 1 to 512.
Default: 46 (MS/UE radio connection lost)

Usage
By defining a cause code, the SGSN knows to detect the LORC state of the mobile from Iu Release messages it receives for the subscriber. This configuration also instructs the SGSN to include the defined cause code for the LORC state in the IE portion of various messages sent to the GGSN and optionally the peer SGSN. This command is one of the two commands required to enable the SGSN to work with the GGSN and, optionally the peer SGSN, to implement the Overcharging Protection feature (see the SGSN Overview in the SGSN Administration Guide for feature details. The other command needed to implement the Overcharging Protection feature is the gtp private extension command explained in the SGSN APN Policy Configuration Mode chapter of the Command Line Interface Reference.

Example
Use the following command to set the cause code to indicate that there are no radio resources available in the target cell, cause 53.

loss-or-radio-coverage ranap-cause 53
**plmn**

Configures the PLMN (public land mobile network) related parameters for the IuPS service. This command is applicable to releases 8.1 and higher.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
plmn id mcc mnc_num mnc mnc_num [ network-sharing common-plmn mcc mnc_num mnc mnc_num [ plmn-list mcc mnc_num mnc mnc_num [ mcc mnc_num mnc mnc_num+ ] ] ]

no plmn id
```

**no**

Removes the PLMN ID from the configuration.

**id**

Creates a PLMN configuration instance based on the PLMN ID (comprised of the MCC and MNC). In accordance with TS 25.413, the SGSN supports up to 32 PLMN configurations for shared networks.

```plaintext
mcc mnc_num
```

Specifies the mobile country code (MCC) portion of the PLMN’s identifier. 

- `mcc_num`: The PLMN MCC identifier and can be configured to any integer value between 100 and 999.

```plaintext
mnc mnc_num
```

Specifies the mobile network code (MNC) portion of the PLMN’s identifier. 

- `mnc_num`: The PLMN MNC identifier and can be configured to any 2-digit or 3-digit value between 00 and 999.

```plaintext
network-sharing common-plmn mcc mnc_num mnc mnc_num
```

When network sharing is employed, this set of keywords is required to define the PLMN ID of the common PLMN. The common PLMN is usually not the same as the local PLMN.

```plaintext
plmn-list mcc mnc_num mnc mnc_num
```

When network sharing is employed and more than two PLMNs are available, then use the `plmn-list` keyword to begin a list of all additional PLMNs.

**Usage**

Use this command to configure the PLMN associated with the SGSN. There can only be one PLMN associated with an SGSN unless one of the following features is enabled and configured: network sharing or multiple PLMN.

For network sharing, use of the `network-sharing` keywords make it possible to identify more than one PLMN. Including the PLMN identified initially. None have precedence. They are all treated equally but they
must each be unique. In a MOCN configuration, the PLMN list will not be used as there would only be one local PLMN.

For multiple PLMN support, the SGSN can support up to 8 Iu-PS configurations for PLMNs. These Iu-PS service configurations must be associated with the SGSN via the `ran-protocol` command in the SGSN Service configuration mode.

**Example**

Use the following command to identify a PLMN and instruct the SGSN to perform network sharing with a single PLMN:

```
plmn id mcc 313 mnc 23 network-sharing common-plmn mcc 404 mnc 123
```
rab-assignment-response-timeout

Configures the RAB assignment timer.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

rab-assignment-response-timeout time

default rab-assignment-response-timeout

default
Resets the timer to its default setting.

time
This variable configures the amount of time (in seconds) that the SGSN waits to receive a RAB assignment from the RNC.
time: must be an integer from 1 to 60.
Default: 8.

Usage
This command defines time the SGSN waits for the completion of the RAB assignment procedure.

Example
Change the timer setting to 11 seconds.

rab-assignment-response-timeout
radio-network-controller

This command creates an instance of an RNC configuration to associate with the IuPS service for the SGSN. This command is only available in release 8.0; use the rnc command for releases 8.1 and higher.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

radio-network-controller id rnc_id mcc mcc_num mnc mnc_num
no radio-network-controller id rnc_id mcc mcc_num mnc mnc_num

no
Removes the configuration information for the specified RNC.

id rnc_id
Define the instance number of the RNC configuration.

rnc_id: Must be an integer from 0 to 4095.

mcc mcc_num
Specifies the mobile country code (MCC).
mcc_num: Must be an integer between 100 and 999.

mnc mnc_num
Specifies the mobile network code (MNC).
mnc_num: Must be an integer between 00 and 999.

Usage
Use this command to configure information for the IuPS service to use to contact specific RNCs. This command also provides access to the RNC configuration mode.

Example
The following command creates or accesses an instance of an RNC configuration.

radio-network-controller id 1 mcc 131 mnc 22
relocation-complete-timeout

This command specifies the maximum time for the SGSN to wait for a Relocation Completion from the core network.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

relocation-complete-timeout timeout_value

default relocation-complete-timeout

default
Reset the configuration to a 5 second wait time.

timeout_value
Time in seconds that the SGSN waits for relocation to be completed.

timeout_value: Must be an integer from 1 to 60.
Default: 5 seconds.

Usage
Use this command to configure the number of seconds the SGSN will wait for a relocation to be completed. This timeout needs to be set with sufficient time so that SRNS procedure aborts can be avoided if the peer fails to respond in a timely fashion in the case of a hard handoff.

Example
The following command sets the wait time for 10 seconds.

relocation-complete-timeout 10
reset

Defines the configuration specific to the RESET procedure.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
reset ( ack-timeout time | guard-timeout time | max-retransmissions retries | sgsn-initiated )
```

```
default reset ( ack-timeout | guard-timeout | max-retransmissions | sgsn-initiated )
```

```
no reset sgsn-initiated
```

---

**default**
Returns to the default settings for the Reset procedure.

---

**no**
Removes the SGSN-initiated reset procedure from the configuration.

---

**ack-timeout time**
Configures the interval (in seconds) for which the SGSN waits for RESET-ACK from the RNC.
*time* must be an integer from 5 to 10.
Default: 10.

---

**guard-timeout**
Configures the interval (in seconds) after which the SGSN sends RESET-ACK to the RNC.
*time* must be an integer from 5 to 10.
Default: 10

---

**max-retransmissions**
Configures maximum retries for RESET message.
*retries* must be an integer from 0 to 2.
Default: 1.

---

**sgsn-initiated**
Enables SGSN initiated RESET procedure.
Default: disabled.

---

**Usage**
Configures the parameters that determine a RESET.
Example
Use the following to have the SGSN initiate the RESET procedure:

```
reset sgsn-initiated
```
**rnc**

This command creates or accesses an instance of an RNC (radio network controller) configuration.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
 rnc id rnc_id

no rnc id rnc_id
```

- **no**
  - Removes the configuration information for the specified RNC.

- **id rnc_id**
  - Set the identification number of the RNC configuration instance.
  - *rnc_id*: Must be an integer from 0 to 4095 for 8.1 releases. Must be an integer from 0 to 65535 for releases 9.0 and higher.

**Usage**

Use this command to configure information for the IuPS service to use to contact specific RNCs. This command also provides access to the RNC configuration mode.

**Example**

The following command creates an RNC configuration instance

```
rnc id 1
```
security-mode-complete-timeout

This command configures the security mode timer.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

security-mode-complete-timeout time

default security-mode-complete-timeout

default
Resets the timer configuration to the default settings.

time
Configures the interval (in seconds) the SGSN waits for the security mode from the MS to complete.

*time* must be an integer from 1 to 60.
Default is 5

Usage
Use this command to configure the timer that determines how long the SGSN waits for a Security Mode Complete message from the MS (mobile station).

Example

security-mode-complete-timeout 7
srns-context-response-timeout

This command configures the SGSN context response timer.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

srns-context-response-timeout time

default srns-context-response-timeout

default
Resets the timer configuration to the default setting.

time
Configures the interval (in seconds) for which the SGSN waits for an SRNS Context Request message. time must be an integer from 1 to 60. Default: 5.

Usage
Configures the time to wait before the SGSN sends a response to the SRNS ‘context request’ message.

Example

srns-context-response-timeout 7
**tigoc-timeout**

This command configures the TigOc interval.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
tigoc-timeout time
```

```
default tigoc-timeout
```

**default**

Resets the timer configuration to the default setting.

```
time
```

This command sets the time in seconds.

*time*: Must be an integer from 1 to 10.
Default: 5.

**Usage**

Define the amount of time that the SGSN ignores any overload messages for TigOc interval after receiving one overload message from the RNC.

**Example**

Use the following command to change the default TigOc interval:

```
tigoc-timeout 4
```
tintc-timeout

This command configures the TinTc interval.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

tintc-timeout time

default tintc-timeout

default
Resets the timer configuration to the default setting.

time
Set the number of seconds to wait.
time: Must be an integer from 1 to 10.
Default: 5.

Usage
Define the number of seconds that the SGSN waits before decrementing (by one) the traffic level of the RNC.

Example

tintc-timeout 4
Chapter 133
LAC Service Configuration Mode Commands

The LAC Service Configuration Mode is used to create and manage L2TP services within contexts on the system. L2TP Access Concentrator (LAC) services facilitate tunneling to peer L2TP Network Servers (LNSs).

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
allow

This command configure the system to allow different attributes in the LAC Hostname AVP and Called-Number AVP for L2TP messages exchanged between LAC and LNS.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax
allow {aaa-assigned-hostname | called-number value apn}
[
no | default ] allow {aaa-assigned-hostname | called-number value apn}

no
Disable the configured attribute and returns to the behavior that uses the LAC-Service name as the HostName AVP.

aaa-assigned-hostname
When enabled if AAA assigns a valid Tunnel-Client-Auth-ID attribute for the tunnel, it is used as the HostName AVP in the L2TP tunnel setup message.
This keyword works in conjunction with local-hostname hostname keyword applied with tunnel 12tp command in APN configuration mode.
When Tunnel parameters are not received from the RADIUS Server, Tunnel parameters configured in APN are considered for the LNS peer selection. When APN configuration is selected, local-hostname configured with tunnel 12tp command in the APN for the LNS peer will be used as a LAC Hostname.

called-number value apn
This keyword configure the system to send APN name in Called-Number AVP as a part of ICRQ message sent to the LNS. If this keyword is not configured, Called-Number AVP will not be included in ICRQ message sent to the LNS.

Usage
Use this command to configure the attribute for the HostName AVP for L2TP messages exchanged between LAC and LNS.
LAC Hostname will be different for the subscribers corresponding to the different corporate APNs. In the absence of a AAA assigned HostName, the LAC-Service name is used as HostName. By default the LAC-Service name is used as the HostName AVP.

Example
The following command enables the use of the value of Tunnel-Client-Auth-ID attribute for the HostName AVP:

allow aaa-assigned-hostname
Use the following command to reset the behavior so that the LAC-Service uses the LAC-Service name as the HostName AVP:

```
no allow aaa-assigned-hostname
```
bind

This command assigns a local end point address to the LAC service in the current context.

**Product**
PDSN, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
bind ip_address [max-subscribers]
no bind ip_address
```

**Usage**

Use this command to bind a local end point IP address to the LAC service.

**Example**

The following command binds the local end point IP address 10.10.10.100 to the LAC service in the current context:

```bash
bind 10.10.10.100
```

The following command removes the binding of the local end point to the LAC service:

```bash
no bind
```
**data sequence-number**

Enables data sequence numbering for sessions that use the current LAC service. Data sequence numbering is enabled by default.

**Product**
PDSN, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
data sequence-number
no data sequence-number
```

- **no**
  Disables data sequence numbering for sessions.

**Usage**
An L2TP data packet header has an optional data sequence numbers field. The data sequence number may be used to ensure ordered delivery of data packets. This command is used to re-enable or disable the use of the data sequence numbers for data packets.

**Example**

Use the following command to disable the use of data sequence numbering:

```plaintext
no data sequence-number
```

Use the following command to re-enable data sequence numbering:

```plaintext
data sequence-number
```
default

This command sets the specified LAC service parameter to its default value or setting.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

default {data sequence-number | hide-attributes | keepalive-interval | load-balancing | local-receive-window | max-retransmission | max-session-per-tunnel | max-tunnel-challenge-length | max-tunnels | proxy-lcp-authentication | retransmission-timeout-first | retransmission-timeout-max | trap all | tunnel-authentication}

data sequence-number

Enables data sequence numbering for sessions.

hide-attributes

Disables hiding attributes in control messages sent from the LAC to the LNS.

keepalive-interval

Sets the interval for send L2TP Hello keepalive if there is no control or data transactions to the default value of 60 secs.

load-balancing

Sets the load balancing algorithm to be used when many LNS peers have been configured to the default of round robin.

local-receive-window

Sets the window size to be used for the local side for the reliable control transport to the default of 16.

max-retransmission

Sets the maximum number of retransmissions to the default of 5.

max-session-per-tunnel

Sets the maximum number of sessions per tunnel at any point in time to the default of 512.

max-tunnel-challenge-length

Sets the maximum length of the tunnel challenge to the default of 16 bytes.

max-tunnels

Sets the maximum number of tunnels for this service to the default of 32000.
proxy-lcp-authentication
Sets sending of proxy LCP authentication parameters to the LNS to the default state of enabled.

retransmission-timeout-first
Sets the first retransmit interval to the default of 1 second.

retransmission-timeout-max
Sets the maximum retransmit interval to the default of 8 seconds.

trap all
Generates all supported SNMP traps.

tunnel-authentication
Sets tunnel authentication to the default state of enabled.

Usage
Use the default command to set LAC service parameters to their default states.

Example
Use the following command to set the keep alive interval to the default value of 60 seconds:

    default

    keepalive-interval

Use the following command to set the maximum number of sessions per tunnel to the default value of 512:

    default max-session-per-tunnel
hide-attributes

Enables hiding certain attributes (such as proxy-auth-name and proxy-auth-rsp) in control messages sent from the LAC to the LNS. The LAC hides such attributes only if tunnel authentication is enabled between the LAC and the LNS.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax

hide-attributes

no hide-attributes

Usage
Use this command to hide certain attributes from control messages when tunnel authentication is enabled between the LAC and the LNS.

Example
The following command enables hiding attributes:

hide-attributes
keepalive-interval

This command specifies the amount of time to wait before sending a Hello keep alive message.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax
keepalive-interval seconds

no keepalive-interval

no
Disables the generation of Hello keep alive messages on the tunnel.

seconds
Default: 60
The number of seconds to wait before sending a Hello keep alive message. The number can be configured to any integer value from 30 to 2147483648.

Usage
Use this command to set the amount of time to wait before sending a Hello keep alive message or disable the generation of Hello keep alive messages completely. A keep alive mechanism is employed by L2TP in order to differentiate tunnel outages from extended periods of no control or data activity on a tunnel. This is accomplished by injecting Hello control messages after a specified period of time has elapsed since the last data or control message was received on a tunnel. As for any other control message, if the Hello message is not reliably delivered then the tunnel is declared down and is reset. The transport reset mechanism along with the injection of Hello messages ensures that a connectivity failure between the LNS and the LAC is detected at both ends of a tunnel.

Example
Use the following command to set the Hello keep alive message interval to 120 seconds:

    keepalive-interval 120

Use the following command to disable the generation of Hello keep alive messages:

    no keepalive-interval
load-balancing

Configures how LNSs are selected for this LAC service.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax

load-balancing {balanced | prioritized | random}

| balanced
LNS selection is made without regard to prioritization, but in a sequential order that balances the load across the total number of LNS nodes available.

| prioritized
LNS selection is made based on the priority assigned in the Tunnel-Preference attribute. An example of this method is three LNS nodes, with preferences of 1, 2, and 3 respectively. In this example, the RADIUS server always tries the tunnel with a preference of 1 before using any of the other LNS nodes.

| random
Default: Enabled
LNS selection is random in order, wherein the RADIUS server does not use the Tunnel-Preference attribute in determining which LNS to select.

Usage
Use this command to configure the load-balancing algorithm that defines how the LNS node is selected by the LAC when there are multiple peer LNSs configured in the LAC service.

Example

The following command sets the LAC service to connect to LNSs in a sequential order;

    load-balancing balanced

The following command sets the LAC service to connect to LNSs according to the priority assigned through the Tunnel-Preference attribute:

    load-balancing prioritized
local-receive-window

Specifies the number of control messages the remote peer LNS can send before waiting for an acknowledgement.

**Product**

PDSN, GGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
local-receive-window integer
```

- **integer**
  - Default: 4
  - The number of control messages to send before waiting for an acknowledgement. The number can be configured to any integer value from 1 to 256.

**Usage**

Use this command to set the size of the control message receive window being offered to the remote peer LNS. The remote peer LNS may send the specified number of control messages before it must wait for an acknowledgment.

**Example**

The following command sets the local receive window to 10 control messages:

```
local-receive-window 10
```
max-retransmission

Sets the maximum number of retransmissions of a control message to a peer before the tunnel and all sessions within it are cleared.

**Product**
PDSN, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
max-retransmission integer
```

- **integer**
  - Default: 5
  - The maximum number of retransmissions of a control message to a peer. This value must be an integer in the range of 1 to 10.

**Usage**

Each tunnel maintains a queue of control messages to be transmitted to its peer. After a period of time passes without acknowledgement, a message is retransmitted. Each subsequent retransmission of a message employs an exponential backoff interval. For example; if the first retransmission occurs after 1 second, the next retransmission occurs after 2 seconds has elapsed, then the next after 4 seconds. If no peer response is detected after the number of retransmissions set by this command, the tunnel and all sessions within are cleared.

Use this command to set the maximum number of retransmissions that the LAC service sends before closing the tunnel and all sessions within it.

**Example**

The following command sets the maximum number of retransmissions of a control message to a peer to 7:

```
max-retransmissions 7
```
max-session-per-tunnel

Sets the maximum number of sessions that can be facilitated by a single a tunnel at any time.

**Product**
PDSN, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
max-sessions-per-tunnel integer
```

<table>
<thead>
<tr>
<th>integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 512</td>
</tr>
<tr>
<td>The maximum number of sessions. This value must be in the range of 1 to 65535.</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to set the maximum number of sessions you want to allow in a tunnel.

**Example**

The following command sets the maximum number of sessions in a tunnel to 5000:

```
max-sessions-per-tunnel 5000
```
max-tunnel-challenge-length

Sets the maximum length of the tunnel challenge in bytes. The challenge is used for tunnel authentication purposes during tunnel creation.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax

max-tunnel-challenge-length bytes

bytes
Default: 16
The number of bytes to set the maximum length of the tunnel challenge. This must be a value from 4 to 32.

Usage
Use this command to set the maximum length, in bytes, for the tunnel challenge that is used during tunnel creation.

Example
The following command sets the maximum length of the tunnel challenge to 32 bytes:

max-tunnel-challenge-length 32
max-tunnels

The maximum number of tunnels that the current LAC service can support.

**Product**
PDSN, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
max-tunnels integer
```

`integer`

Default: 32000

The maximum number of tunnels. This value must be an integer from 1 to 32000.

**Usage**

Use this command to set the maximum number tunnels that this LAC service can support at any on time.

**Example**

Use the following command to set the maximum number of tunnels for the current LAC service to 20000:

```
max-tunnels 20000
```
peer-lns

Adds a peer LNS address for the current LAC service. Up to 8 peer LNSs can be configured for each LAC service.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax

peer-lns ip_address [encrypted] secret secret [crypto-map map_name { [encrypted] isakmp-secret secret } ] [ description text ] [ preference integer]

no peer-lns ip_address

no peer-lns ip_address
Deletes the peer LNS at the IP address specified by ip_address. ip_address must be entered in standard IPv4 dotted decimal notation.

ip_address
The IP address of the peer LNS for the current LAC service. ip_address must be entered in standard IPv4 dotted decimal notation.

[encrypted] secret secret
Designates the secret which is shared between the current LAC service and the peer LNS. secret must be a string from 1 to 256 alpha and/or numeric characters and is case sensitive.

encrypted secret secret: Specifies that encryption should be used when communicating the secret with the peer LNS.

crypto-map map_name { [encrypted] isakmp-secret secret }
map_name is the name of a crypto map that has been configured in the current context. map_name must be a string from 1 to 127 alpha and/or numeric characters and is case sensitive.

isakmp-secret secret: The pre-shared key for IKE. secret must be a string from 1 to 127 alpha and/or numeric characters and is case sensitive.

encrypted isakmp-secret secret: The pre-shared key for IKE. Encryption must be used when sending the key. secret must be a string from 1 to 127 alpha and/or numeric characters.

description text
Specifies the descriptive text to use to describe the specified peer LNS. text must be 0 to 79 alpha and/or numeric characters with no spaces or a quoted string of printable characters.

preference integer
This sets the priority of the peer LNS if multiple peer LNSs are configured. integer must be a value ranging from 1 to 128.
Usage
Use this command to add a peer LNS address for the current LAC service.

Example
The following command adds a peer LNS to the current LAC service with the IP address of 10.10.10.100, sets encryption on, specifies the shared secret to be 1b34nnf5d and sets the preference to 3:

```
peer-lns 10.10.10.100 encrypted secret 1b34nnf5d preference 3
```

The following command removes the peer LNS with the IP address of 10.10.10.200 for the current LAC service:

```
no peer-lns 10.10.10.200
```
proxy-lcp-authentication

Enables and disables the sending of proxy LCP authentication parameters to the LNS.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax

proxy-lcp-authentication

no proxy-lcp-authentication

no
Disables the sending of proxy LCP authentication parameters to the LNS.

proxy-lcp-authentication
Default: Enabled
Enables the sending of proxy LCP authentication parameters to the LNS.

Usage
Use this feature in situations where the peer LNS does not understand the proxy LCP Auth AVPs that the system sends and does not do an LCP renegotiation and tears down the call.

Example
Use the following command to disable the sending of proxy LCP authentication parameters to the LNS:

no proxy-lcp-authentication

Use the following command to re-enable the sending of proxy LCP authentication parameters to the LNS:

proxy-lcp-authentication
retransmission-timeout-first

Each tunnel maintains a queue of control messages to transmit to its peer. After a period of time passes without acknowledgement, a message is retransmitted. This command sets the initial timeout for retransmission of control messages.

Privilege
Security Administrator, Administrator

Syntax

retransmission-timeout-first integer

integer
Default: 1
The amount of time to wait before sending the first control message retransmission. This value is measured in seconds and must be an integer from 1 to 100.

Usage
Use this command to set the initial timeout before retransmitting control messages to the peer.

Example
The following command sets the initial retransmission timeout to 3 seconds:

retransmission-timeout-first 3
retransmission-timeout-max

This command configures maximum amount of time between two retransmission of control messages.

Privilege
Security Administrator, Administrator

Syntax
```
retransmission-timeout-max integer
```

`integer`
Default: 8
`integer` is the maximum time in seconds to wait before retransmitting control messages and must be an integer between 1 through 100.

Usage
Use this command to set the maximum amount of time that can elapse before retransmitting control messages.
Each tunnel maintains a queue of control messages to transmit to its peer. After a period of time passes without acknowledgement, a message is retransmitted. Each subsequent retransmission of a message employs an exponential backoff interval.

Example
The following command sets the maximum retransmission time-out to 10 seconds:
```
retransmission-timeout-max 10
```
single-port-mode

This command enables/disables the L2TP LAC service always to use standard L2TP port 1701 as source port for all L2TP control and data packets originated from LAC node.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax
[no | default] single-port-mode

no
Disables the configured single source port configuration from this LAC service.

default
Default: Enabled
Sets this command to default state of disabled. By default single source port configuration for L2TP LAC packets is disabled.

Usage
Use this command to enable or disable the single port mode for L2TP LAC service.
If this feature is enabled, then L2TP LAC service will always use standard L2TP port 1701 as source port for all L2TP control/data packets originated from LAC (instead of the default scheme in which each L2TPMgr uses a dynamic source port). L2TPMgr instance 1 will handle all L2TP calls for the service.

⚠️ Caution: Changing this configuration, while the service is already running, will cause restart of the service.

Example
The following command enables the LAC service to use port 1701 as source port for all L2TP control and data packets:
single-port-mode
**snoop framed-ip-address**

When enabled, this feature allows the LAC to detect IPCP packets exchanged between the mobile node and the LNS and extract the framed-ip-address assigned to the mobile node. The address will be reported in accounting start/stop messages and will be displayed for subscriber sessions.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
[no | default] snoop framed-ip-address
```

- **no**
  Disables the feature. Accounting start/stop will occur before the PPP session is established and the framed IP address field will be reported as 0.0.0.0.

- **default**
  Disabled.

**Usage**

This feature is available to address simple IP roaming scenarios. If this feature is enabled, the accounting start will be sent only after the framed-ip-address is detected. If the framed-ip-address is not detected within 16 seconds, an accounting start will be sent for the session with the 0.0.0.0 address. If the session is disconnected during the detection attempt, accounting start/stop will be sent for the session. If the session renegotiates IPCP, an accounting stop will be generated with a framed-ip-address from the old session and an accounting start will be generated with an IP address for the new session. IPv6 address detection is not supported.

**Important:** When this feature is enabled and the show subscribers all command is invoked, the framed-IP-address is displayed for the PDSN Simple IP subscriber in the output display.
trap

This command generates SNMP traps.

**Product**

PDSN, GGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
[no] trap all
```

  ```
no
Disables SNMP traps.
  ```

**Usage**

Use this command to enable/disable all supported SNMP traps.

**Example**

To enable all supported SNMP traps, enter the following command:

```
trap all
```
tunnel-authentication

Enables tunnel authentication. When tunnel authentication is enabled, a configured shared secret is used to ensure that the LAC service is communicating with an authorized peer LNS. The shared secret is configured by the peer-lns command in the LAC service configuration mode, the tunnel 12tp command in the subscriber configuration mode, or the Tunnel-Password attribute in the subscribers RADIUS profile.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax

[no] tunnel-authentication

no

Disables tunnel authentication.
Tunnel authentication is enabled by default.

Usage
Disable or enable the usage of secrets to authenticate a peer LNS when setting up a tunnel.

Example
To disable tunnel authentication, use the following command:

no tunnel-authentication

To re-enable tunnel authentication, use the following command:

tunnel-authentication
tunnel selection-key

This command enables the support to create tunnels between L2TP service and an LNS server on the basis of value of attribute “Tunnel-Server-Auth-ID” received from AAA server.

Privilege
Security Administrator, Administrator

Syntax

tunnel selection-key { tunnel-server-auth-id | none }

[default] tunnel selection-key

default
This keyword disables the creation of tunnel between LAC service and LNS based on key value received in attribute, “Tunnel-Server-Auth-ID” from AAA server.

tunnel-server-auth-id
Default: Enabled
This keyword enables the creation of tunnels between LAC service on GGSN and an LNS server on the basis of domain attribute, “Tunnel-Server-Auth-ID”, value received from AAA server.

none
Default: Enabled
This keyword disables the creation of multiple tunnels between a pair of LAC service on GGSN and LNS server. LAC will not make use of key to choose a tunnel with LNS in this setup.

Usage
Use this command to enable or disable the creation of additional L2TP tunnels between LAC service on GGSN and LNS server on the basis of “Tunnel-Server-Auth-ID” attribute value received from AAA Server in Access-Accept message. This value of attribute is treated as a key for tunnel selection and creation.
When the LAC needs to establish a new L2TP session, it would first check if there is already an existing L2TP tunnel with the peer LNS based on the value of key configured. If no such tunnel exists for the key, it will create a new Tunnel with the LNS.
Default configuration have selection-key as none. Hence, LAC will not make use of key to choose a tunnel with LNS, in default setup.
Maximum number of session as configured with max-sessions-per-tunnel command will be applicable for each tunnel created through this command. By default each tunnel supports 512 sessions.
If LAC service needs to establish a new tunnel for new L2TP session with LNS and the tunnel create request fails because maximum tunnel creation limit is reached, LAC will try other LNS addresses received from AAA server in Access-Accept message for the APN/subscriber. If all available peer-LNS are exhausted, LAC service will reject the call.

Example
The following command enables the use of “Tunnel-Server-Auth-ID” attribute value received from AAA Server in Access-Accept message as a key for tunnel selection and creation:
tunnel selection-key tunnel-server-auth-id
Chapter 134
Line Configuration Mode Commands

The Line Configuration Mode is used to manage the terminal line characteristics for output formatting.

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
default

Restores the default length or width for the output to the display terminal.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
default { length | width }
```

- **length | width**
  - **length**: restores the default value for the number of rows (length) of the output for display.
  - **width**: restores the default value for the number of columns (width) of the output for display as the number of characters.

Usage
Reset the output display properties if they had been changed during a session.

Example

```
default length

default width
```
end

Exits the line configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

end

Usage
Change the mode back to the Exec mode.
exit

Exits the line configuration mode and returns to the global configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Return to the global configuration mode.
**length**

Configures the output for the displays length (number of rows).

**Privilege**
Security Administrator, Administrator

**Syntax**

```
length number
```

- **number**
  Specifies the number of rows (lines) of output that can be displayed at one time for the display (output) terminal. *number* must have a value of 0 or be in the range from 5 through 512 where the special value 0 implies an infinite number of rows.

**Usage**
Set the current session’s display terminal has different display characteristics than the defaults. The special infinite value (0) is typically used when logging the output of a session from a remote machine since this will result in no pagination of output.

**Example**
The following commands set the length of the display to infinite and 33, respectively.

```
length 0
length 33
```
width

Configures the output for the display's width (number of columns/characters wide).

Privilege

Security Administrator, Administrator

Syntax

width number

number

Specifies the number of columns (characters) of output that can be displayed at one time for the display (output) terminal. number must have a value in the range from 5 through 512.

Usage

Set the current session's display terminal has different display characteristics than the defaults.

Example

width 160
Chapter 135
Link Configuration Mode Commands

The Link configuration mode defines the MTP3 link parameters for a specific link in a linkset of an SS7 routing domain instance.

In this mode, the prompt will be similar to:

```
[local]hostname(config-ss7-rd-linkset-<#>-link-<#>)#`
```
**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
arbitration

This command configures link arbitration.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

arbitration { active | passive }

no arbitration

Usage
Sets the configuration to initiate transmission of PDUs.

Example

arbitration active
end

Exits the current mode and returns to the Exec Mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Change the mode back to the Exec Mode.
exit

Exits the current mode and returns to the previous mode.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Returns to the previous mode.
mtp2-issu-len

This command sets the length of the link status signal unit (LSSU) which carries link status information used to manage link alignment and indicate the status of the signaling points to each other.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

mtp2-issu-len #_octets

default mtp2-issu-len

default
Using this keyword with the command resets the length to the default of 1 octet.

#_octets
Sets the number of octets for the length of the LSSU.
#_octets: Must be either 1 or 2.

Usage
Use this command to define the maximum amount of link status information that is to be shared between signaling points.

Example
You can use the following command to set the LSSU length to 2 octets - the maximum length:

mtp2-issu-len 2
**mtp3-discard-priority**

Configure MTP3 message discard priority.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
set mtp3-discard-priority priority
```

**Usage**
Use this command to manage MTP3 messaging.

**Example**
```
mtp3-discard-priority 2
```
mtp3-max-slt-try

Configure maximum number of times to retry SLT (signaling link test).

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

mtp3-max-slt-try retries

default mtp3-max-slt-try

default
Resets the number of retries to the default value.

retries
retries: must be an integer between 1 to 65535.
Default is 10.

Usage
Use this command to troubleshoot MTP3 link mismatch.

Example

mtp3-max-slt-try 35
**mtp3-msg-priority**

Configures the priority for sending MTP3 management messages.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```bash
mtp3-msg-priority priority
```

```bash
default mtp3-msg-priority
```

- **default**
  - Resets the number of priority to the default value.

- **priority**
  - `priority`: must be an integer from 0 to 3. Default: 0

**Usage**
Use this command to set the priority for sending MTP3 management messages.

**Example**
Use the following to set the message priority to 3:

```bash
mtp3-msg-priority 3
```
mtp3-msg-size

Configures the size of messages from layer 3 to layer 2.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

mtp3-msg-size size

default mtp3-msg-size

default
Resets the size to the default value which is 4096 (for q.2140) or 272 (for MTP2)

size
size: must be an integer from 1 to 4096.

Usage
Use this command to set the maximum message size, in bytes.

Example
Use this command to set the MTP3 message size to 4096 bytes:

mtp3-msg-size 4096
**mtp3-p1-qlen**

Configure the size for the MTP3 p1 queue length.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
 mtp3-p1-qlen size

 default mtp3-p1-qlen
```

**default**

Resets the number of size of the priority 1 queue to the default value.

**size**

- **size**: integer from 1 to 65535. Size should be less than MTP3 p2 qlen and p3 qlen.
- **Default**: 1024

**Usage**

Use this command to configure the queue length threshold for raising the congestion priority to level 1.

**Example**

Use this command to set the queue length priority to 128:

```
 mtp3-p1-qlen 128
```
mtp3-p2-qlen

Configure the size of the priority 2 queue.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
resets the number of size of the priority 2 queue to the default value.

size

size: integer from 1 to 65535. Size should be less than MTP3 p3 qlen and greater than p1 qlen.
Default: 1024
```

Usage
Use this command to configure the queue length threshold for raising the congestion priority to level 2.

Example
Use this command to set the queue length threshold to 256:

```
mtp3-p2-qlen 256
```
mtp3-p3-qlen

Configure the size of the priority 3 queue.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
mtp3-p3-qlen size
```

default mtp3-p3-qlen

- **default**
  Resets the number of size of the priority 3 queue to the default value.

- **size**
  `size`: integer from 1 to 65535. Size should be greater than MTP3 p1 qlen and p2 qlen. 
  Default: 1024

Usage
Use this command to configure the queue length threshold for raising the congestion priority to level 3.

Example
```
mtp3-p3-qlen 1024
```
mtp3-test-pattern

Configures the character string for the test message.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

mtp3-test-pattern pattern

default mtp3-test-pattern

default
Resets the pattern to the default value.

pattern

pattern: 1 to 15 alphanumeric characters.
Default: SGSN-ORIGINATED

Usage
Use this command to define a test pattern string for the signalling link test match (SLTM).

Example

mtp3-test-pattern TEST1-HomeOffice
**priority**

Configures the MTP3 Link Priority.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
priority pri_value
no priority
```

**Usage**
Use this command to configure the link priority within the MTP3 link set.

**Example**
```
priority 2
```
signaling-link-code

Configures the signaling link code (SLC).

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
signaling-link-code code

no signaling-link-code
```

- `no`  Removes the SLC configuration.
- `code`  integer from 0 to 15.

**Usage**
Use this command to uniquely identify the signaling link to be used for MTP3 management messages.

**Example**

```
signaling-link-code 4
```
**sscf-nni-n1**

Configures the SSCF NNI N1.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
sscf-nni-n1 value

no scsf-nni-n1
```

- **default**
  Removes the sscf-nni-n1 configuration.

- **value**
  value: integer from 1 to 65535.
  Default: 1000

**Usage**
Use this command to identify the network-to-node interface (NNI) between the MTP3 and SSCOP layers.

**Example**

```plaintext
sscf-nni-n1 4064
```
**sscop-max-cc**

Configure the maximum value for the SSCOP connection control (CC) state variable.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
sscop-max-cc value

no sscop-max-cc
```

<table>
<thead>
<tr>
<th><strong>default</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Removes the sscop-max-cc configuration.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>value</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>value</code>: integer from 1 to 65535.</td>
</tr>
<tr>
<td>Default: 4</td>
</tr>
</tbody>
</table>

**Usage**

Use this command as part of the configuration responsible for managing the SSCOP connection. This command sets the number of times retries.

**Example**

```
sscop-max-cc 256
```
**sscop-max-pd**

Configures the maximum acceptable value for the SSCOP state variable VT(PD).

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
sscop-max-pd value

no scopp-max-pd
```

**default**

Removes the **sscop-max-pd** configuration.

**value**

- **value**: integer from 1 to 65535.
- **Default**: 500

**Usage**

Use this command to define the maximum number of data PDUs transmitted between POLL PDUs.

**Example**

```plaintext
sscop-max-pd 2500
```
**sscop-max-stat**

Configures the maximum number of elements included in a status PDU.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
sscop-max-stat value
```

```
no sscop-max-stat
```

```
default

Removes the sscop-max-stat configuration.
```

```
value

value: integer from 3 to 65535. This parameter should be an odd integer greater than or equal to 3. Default: 67
```

**Usage**

Received in response to a POLL PDU, the STAT PDU includes information about the number of SD PDUs that have been received.

**Example**

```
sscop-max-stat 56000
```
timeout

This command enables configuration of an array of signaling and flow control timers - for MTP, SSCF, and SSCOP.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
[ no ] timeout timer
```

---

no

Adding `no` to the `timeout` command removes the timer configuration.

---

timer

Repeat the command as needed to configure all required timers.

- `mtp3-tmr-t1` - mtp3 t1 timer, default value is 500ms
- `mtp3-tmr-t12` - mtp3 t12 timer, default value is 800ms
- `mtp3-tmr-t13` - mtp3 t13 timer, default value is 800ms
- `mtp3-tmr-t14` - mtp3 t14 timer, default value is 2000ms
- `mtp3-tmr-t17` - mtp3 t17 timer, default value is 800ms
- `mtp3-tmr-t2` - mtp3 t2 timer, default value is 700ms
- `mtp3-tmr-t22` - mtp3 t22 timer, default value is 180s
- `mtp3-tmr-t23` - mtp3 t23 timer, default value is 180s
- `mtp3-tmr-t24` - mtp3 t24 timer, default value is 500ms
- `mtp3-tmr-t3` - mtp3 t3 timer, default value is 500ms
- `mtp3-tmr-t31` - mtp3 t31 timer, default value is 5s
- `mtp3-tmr-t32` - mtp3 t32 timer, default value is 10s
- `mtp3-tmr-t33` - mtp3 t33 timer, default value is 20s
- `mtp3-tmr-t34` - mtp3 t34 timer, default value is 60s
- `mtp3-tmr-t4` - mtp3 t4 timer, default value is 500ms
- `mtp3-tmr-t5` - mtp3 t5 timer, default value is 500ms
- `mtp3-tmr-t7` - mtp3 t7 timer, default value is 1000ms
- `sscf-nni-tmr-t1` - sscf nni t1 timer. default value is 5s
- `sscf-nni-tmr-t2` - sscf nni t2 timer. default value is 30s
- `sscf-nni-tmr-t3` - sscf nni t2 timer. default value is 10ms
- `sscop-tmr-cc` - sscop cc timer. default value is 200ms
- `sscop-tmr-idle` - sscop idle timer (UNI 3.1 only). default value is 100ms
• \textit{sscop-tmr-keep-alive} - sscop keep alive timer. Default value is 100ms. For stability purposes, \( \text{tmrKeepAlive} \geq \text{tmrPoll} \) and \( \text{tmrKeepAlive} < \text{tmrNoResponse} \)

• \textit{sscop-tmr-no-rsp} - sscop no response timer. Default value is 1.5s. For stability purposes, \( \text{tmrNoResponse} > \text{tmrKeepAlive} \)

• \textit{sscop-tmr-poll} - sscop poll timer. Default value is 100ms. For stability purposes, \( \text{tmrPoll} \leq \text{tmrKeepAlive} \)
Chapter 136
Linkset Configuration Mode Commands

The Linkset configuration mode defines the MTP3 linkset parameters for a specific SS7 routing domain instance. In this mode, the prompt will appear similar to:

```
[local]hostname(config-ss7-rd-linkset-<#>)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
adjacent-point-code

This command defines the point-code for the adjacent (next) network element in the SS7 network.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
adjacent-point-code  point-code
no  adjacent-point-code
```

**point-code**

Point-code is an SS7 address for an element in the SS7 network. Point-codes must be defined in dotted-decimal format in a string of 1 to 11 digits. Format options include:
- 0.0.1 to 7.255.7 for point-code in the ITU range.
- 0.0.1 to 255.255.255 for point-code in the ANSI range.
- 0.0.1 to 15.31.255 for point-code in the TTC range.
- A string of 1 to 11 digits in dotted-decimal to represent a point-code in a different range.

**no**

Removes the adjacent-point-code configuration for this linkset in the SS7 routing domain

**Important:** Removing the linkset configuration will result in the termination of all of the links within the linkset.

**Usage**
Use this command to define the point-code for the adjacent element in the SS7 network.

**Example**

```
adjacent-point-code  6.202.7
```
end

Exits the current mode and returns to the Exec Mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Change the mode back to the Exec Mode.
exit

Exits the current mode and returns to the previous mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Returns to the previous mode.
**Link**

This command creates an MTP3 link configuration for the SS7 linkset and enters the Link configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
link id id [ link-type [ atm-broadband | highspeed-narrowband | lowspeed-narrowband ] ]
no link id id
```  

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>no</strong></td>
<td>Disables the specified link configuration.</td>
</tr>
</tbody>
</table>

**Important:** Removing the link configuration will result in the termination of traffic on the specified link.

```
#=octets
```

Sets the number of octets for the length of the LSSU.

```
id
```

This number uniquely identifies the link in the linkset.

*id*: an integer between 1 and 16.

```
link-type
```

**Important:** This keyword is not yet functional - the feature is still in development.

This keyword is applicable only to releases 8.1 and higher. Identifies the signalling type for this link; options include:

- atm-broadband
- high speed-narrowband
- low speed-narrowband

**Usage**

Access the Link configuration mode to make changes to the configuration for a link.

**Example**

Access configuration for link 4:
link id 4
self-point-code

This command defines the SS7 network point-code to identify this SGSN.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

self-point-code point-code
no self-point-code

point-code
Point-code is an SS7 address for an element in the SS7 network. Point-codes must be defined in dotted-decimal format in a string of 1 to 11 digits. Format options include:

- 0.0.1 to 7.255.7 for point-code in the ITU range.
- 0.0.1 to 255.255.255 for point-code in the ANSI range.
- 0.0.1 to 15.31.255 for point-code in the TTC range.
- a string of 1 to 11 digits in dotted-decimal to represent a point-code in a different range.

no
Removes the self-point-code configuration for this linkset in the SS7 routing domain.

Important: Removing the self-point-code will result in the termination of all traffic on this link.

Usage
Use this command to define the SS7 point-code to identify this system.

Example

self-point-code 6.192.7
Chapter 137
LMA Service Configuration Mode Commands

The LMA Service Configuration Mode is used to create and manage the Local Mobility Anchor configuration supporting Proxy Mobile IP on a PDN Gateway in an eHRPD and E-UTRAN/EPC network.

```
Exec Mode
  configure
    Global
      Configuration
        Mode
          context name
            Context
              Configuration
                  Mode
                    lma-service
                        name
                          LMA Service
                              Configuration
                                Mode
```
aaa accounting

Enables the LMA to send AAA accounting information for subscriber sessions.

Product
P-GW

Privilege
Administrator

Syntax

[ default | no ] aaa accounting

default
Sets the command to the default condition of enabled.

no
Disables the ability of the LMA to send AAA accounting information.

Usage

Use this command to enable the LMA service to send all accounting data (start, stop, and interim) to the configured AAA servers.

Important: In order for this command to function properly, AAA accounting must be enabled for the context in which the LMA service is configured using the aaa accounting subscriber radius command.

Example
The following command disables aaa accounting for the LMA service:

no aaa accounting
**bind address**

Binds the LMA service to a logical IP interface serving as the S2a (HSGW) or S5/S8 (S-GW) interface and specifies the maximum number of subscribers that can access this service over the configured interface.

**Product**
P-GW

**Privilege**
Administrator

**Syntax**

```
bind address ip_address [ max-subscribers num ]
no bind address
```

**no**

Removes the interface binding from this service.

**ip_address**

Specifies the IPv6 address of the interface configured as the S2a or S5/S8 interface. *ip_address* is specified in colon separated notation.

**max-subscribers num**

Default: 3000000

Specifies the maximum number of subscribers that can access this service on this interface. *num* must be configured to an integer between 0 and 3,000,000.

![Important:](image.png) The maximum number of subscribers supported is dependant on the license key installed and the number of active PSCs in the system. A fully loaded system with 13 active PSCs can support 3,000,000 total subscribers. Refer to the license key command and the Usage section (below) for additional information.

**Usage**

Associate the LMA service to a specific logical IP address. The logical IP address or interface takes on the characteristics of an S2a or S5/S8 interface that provides the session connectivity to an HSGW (S2a) or S-GW (S5/S8). Only one interface can be bound to a service. The interface should be configured prior to issuing this command.

This command also sets a limit as to the number of simultaneous subscribers sessions that can be facilitated by the service/interface at any given time.

When configuring the **max-subscribers** option, be sure to consider the following:

- The total number of S2a or S5/S8 interfaces you will configure
- The total number of subscriber sessions that all of the configured interfaces may handle during peak busy hours
- An average bandwidth per session multiplied by the total number of sessions
- The type of physical port (10/100Base-T or 1000Base-Tx) that these interfaces will be bound to
Taking these factors into account and distributing your subscriber session across all available interfaces will allow you to configure your interfaces to optimally handle sessions without degraded performance.

Example
The following command would bind the logical IP interface with the address of 4551:0db0:85a3:08d3:3319:8a2e:0370:1344 to the LMA service and specifies that a maximum of 300,000 simultaneous subscriber sessions can be facilitated by the interface/service at any given time:

```
bind address 4551:0db0:85a3:08d3:3319:8a2e:0370:1344 max-subscribers 300000
```
end

Exits the current mode and returns to the Exec Mode.

**Product**
All

**Privilege**
Administrator

**Syntax**
end

**Usage**
Change the mode back to the Exec mode.
exit

Exits the current mode and returns to the previous mode.

**Product**
All

**Privilege**
Administrator

**Syntax**
exit

**Usage**
Return to the previous mode.
refresh-advice-option

Configures inclusion of a refresh advice option in the binding acknowledgement message sent by the LMA.

**Product**

P-GW

**Privilege**

Administrator

**Syntax**

```
[ default | no ] refresh-advice-option
```

- **default**
  Returns the command setting to the default setting of disabled.

- **no**
  Disables the inclusion of the refresh advice option in the binding acknowledgement message sent by the LMA

**Usage**

Use this command to enable the LMA to include this option in a binding acknowledgement sent to the requesting MAG. The option provides a “hint” to the MAG of when it should refresh the binding. As defined in RFC 3775 “Mobility Support in IPv6”, the binding refresh advice option can only be present in the binding acknowledgement sent from the mobile node's home agent in reply to a registration request. A refresh interval parameter determines the amount of time until the mobile node must send a new registration to the home agent to avoid de-registration and loss of session.

**Important:** Refer to the refresh-interval-percent and reg-lifetime commands for a complete understanding of registration (binding) lifetimes and refresh intervals.
refresh-interval-percent

Configures percentage of the granted registration lifetime to be used in the refresh interval mobility option in a binding acknowledgement message sent by the LMA service.

Product
P-GW

Privilege
Administrator

Syntax

```
refresh-interval-percent number
default refresh-interval-percent
```

**default**

Resets the command value to the default setting of 75.

**number**

Default: 75

Sets the percent value for session lifetimes for this service.

*number* must be an integer value from 1 to 99.

**Usage**

Use this command to configure the amount of the granted registration lifetime to be used in the refresh interval mobility option in the binding acknowledgement message sent by the LMA service to the requesting MAG.

Refreshing a binding or registration is based on the granted registration lifetime. Since a refresh request must be within the granted range of a registration lifetime, this command provides a method of setting the interval of when a refresh request is sent.

As described in RFC 3775 “Mobility Support in IPv6”, if a binding refresh advice option is present in the binding acknowledgement, the refresh interval field in the option must be a value less than the binding lifetime (also returned in the binding acknowledgement). The mobile node then should attempt to refresh its registration at the shorter refresh interval. The home agent will still honor the registration for the lifetime period, even if the mobile node does not refresh its registration within the refresh period.

**Important:** Refer to the refresh-advice-option and reg-lifetime commands for a complete understanding of registration (binding) lifetimes and refresh intervals.

**Example**

The following command sets the refresh interval percent to 90:

```
refresh-interval-percent 90
```
**reg-lifetime**

Configures the Mobile IPv6 session registration lifetime for this service.

**Product**
P-GW

**Privilege**
Administrator

**Syntax**

```
reg-lifetime seconds
```

```
default reg-lifetime
```

- **default**
  - Resets the command value to the default setting of 600.

- **seconds**
  - Default: 600
  - Sets the time value for session lifetimes for this service.
  - *seconds* must be an integer value from 1 to 262140.

**Usage**

Use this command to limit PMIPv6 lifetime on this service. If the PBU contains a lifetime shorter than what is specified, it is granted. If the lifetime is longer, then HA service will limit the granted lifetime to the configured value.

**Important:** Refer to the refresh-interval-percent and refresh-advice-option commands for a complete understanding of registration (binding) lifetimes and refresh intervals.

**Example**
The following command sets the registration lifetime for Mobile IPv6 sessions using this service to 1200 seconds (20 minutes):

```
reg-lifetime 1200
```
revocation

Enables the MIP revocation feature and configures revocation parameters.

Product
P-GW

Privilege
Administrator

Syntax

revocation { enable | max-retransmission number | retransmission-timeout msecs }
default revocation { enable | max-retransmission | retransmission-timeout }
no revocation enable

default
Resets the keyword to its default value.

no
Disables revocation for this service.

enable
Default: disabled
Enables the MIP registration revocation feature for the LMA service. When enabled, if revocation is negotiated with a MAG and a MIP binding is terminated, the LMA can send a Revocation message to the MAG. This feature is disabled by default.

max-retransmission number
Default: 3
The maximum number of retransmissions of a Revocation message before the revocation fails. number must be an integer value from 0 through 10.

retransmission-timeout msecs
Default: 3000
The number of milliseconds to wait for a Revocation Acknowledgement from the MAG before retransmitting the Revocation message. msecs must be an integer value from 500 through 10000.

Usage
Use this command to enable or disable the MIP revocation feature on the LMA or to change settings for this feature.

Example
The following command sets the maximum number of retries for a Revocation message to 6:

revocation max-retransmission 6

The following command sets the timeout between retransmissions to 10:

revocation retransmission-timeout 10
sequence-number-validate

Configures sequence number validation of the received MIPv6 control packets by the LMA service according to RFC 3775.

Product
P-GW

Privilege
Administrator

Syntax

[ default | no ] sequence-number-validate

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resets the command value to the default setting of enabled.</td>
</tr>
</tbody>
</table>

| no |
| Disables the feature. |

Usage

Use this command to configure the sequence number validation of the received MIPv6 control packets (PBUs) by the LMA service. This feature validates MIPv6 control packets and insures that any incoming packets with a sequence number prior to the last number received is consider invalid. If this service has no cache entry of the home address included in the PBU, it will accept any sequence value in the initial PBU from the mobile node.
setup-timeout

The maximum amount of time allowed for session setup.

Product
P-GW

Privilege
Administrator

Syntax

setup-timeout seconds

default setup-timeout

default

Resets the command value to the default setting of 60.

seconds

Default: 60 seconds
The maximum amount of time, in seconds, to allow for setup of a session in this service. seconds must be an integer value from 1 through 1000000.

Usage
Use this command to set the maximum amount of time allowed for setting up a session.

Example
The following command sets the maximum time allowed for setting up a session to 5 minutes (300 seconds):

setup-timeout 300
timestamp-replay-protection

Designates timestamp replay protection scheme as per RFC 4285.

Product
P-GW

Privilege
Administrator

Syntax

`timestamp-replay-protection tolerance seconds`

```
[ default | no ] timestamp-replay-protection tolerance

default
Resets the command value to the default setting of 7.

no
Disables the timestamp replay protection feature.

seconds
Default: 7
Defines the acceptable difference in timing (between timestamps) before rejecting packet, in seconds. `seconds` must be an integer value between 0 and 65535.
```

Usage
Use this command to define the acceptable difference in timing (between timestamps) before rejecting packet.

Example
The following command sets the acceptable difference for timestamps to 10 seconds:

```
timestamp-replay-protection tolerance 10
```
Chapter 138
LNS Service Configuration Mode Commands

The LNS Service Configuration Mode is used to create and manage L2TP services within contexts on the system. LNS services facilitate tunneling with peer LACs.

```
Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
```
aaa accounting

Enables the sending of AAA accounting information by the LNS.

**Product**
PDSN, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[no] aaa accounting
```

- **no**
  - Disables this option.

**Usage**

Use this command to enable the sending of AAA accounting information by the LNS. By default this is enabled.

**Example**

The following command enables the sending of AAA accounting information by the LNS:

```
aaa accounting
```
**authentication**

Configures the type of subscriber authentication for PPP sessions terminated at the current LNS.

**Product**
PDSN, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
authentication { [ allow-noauth ] [ chap chap_priority ] [ mschap mschap_priority ] [ pap pap_priority ] } | msid-auth
```

---

**allow-noauth**

Default: Disabled

This option configures the LNS to allow PPP sessions access even though they have not been authenticated. This command issued by itself causes the LNS to not attempt authentication for any PPP sessions. When the allow-noauth option is used in conjunction with commands specifying other authentication protocols and priorities to use, then if attempts to use those protocols fail, the system will treat the allow-noauth option as the lowest priority.

If no authentication is allowed, then NAI construct will be implemented in order to provide accounting records for the PPP session.

---

**chap chap_priority**

Default: 1

This option configures the LNS to attempt to use the Challenge Handshake Authentication Protocol (CHAP) to authenticate the PPP session. A `chap_priority` must be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on. `chap_priority` must be an integer from 1 through 1000. The lower the integer, the higher the preference. CHAP is enabled by default as the highest preference.

---

**mschap mschap_priority**

Default: Disabled

This option configures the LNS to attempt to use the Microsoft Challenge Handshake Authentication Protocol (MSCHAP) to authenticate the PP session. A `mschap_priority` must be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on. `mschap_priority` must be an integer from 1 through 1000. The lower the integer, the higher the preference.

---

**pap pap_priority**

Default: 2

This option configures the LNS to attempt to use the Password Authentication Protocol (PAP) to authenticate the PPP session. A `pap_priority` must be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on.
**authentication**

pap_priority must be an integer from 1 through 1000. The lower the integer, the higher the preference. PAP is enabled by default as the second highest preference.

**msid-auth**

Default: Disabled
This option configures the LNS to attempt to authenticate the PPP session based on the Mobile Station Identity (MSID).

**Usage**

Use to specify how the LNS service should handle authentication and what protocols to use. The flexibility is given to configure this option to accommodate the fact that not every mobile will implement the same authentication protocols.

The chassis is shipped from the factory with the LNS authentication options set as follows:
- allow-noauth disabled
- chap enabled with a priority of 1
- mschap disabled
- msid-auth disabled
- pap enabled with a priority of 2

**Important:** At least one of the keywords must be used to complete the command.

**Example**

The following command configures the LNS service to allow no authentication for PPP sessions and would perform accounting using the default NAI-construct of username@domain:

```
authentication allow-noauth
```

The following command configures the system to attempt authentication first using CHAP, then MSCHAP, and finally PAP. If the allow-noauth command was also issued, when all attempts to authenticate the subscriber using these protocols failed, then the subscriber would be allowed access:

```
authentication chap 1 mschap 2 pap 3
```
avp map called-number apn

This command maps an incoming AVP to a GGSN APN for authentication and authorization of the call.

Product
GGSN

Privilege
Security Administrator, Administrator

Syntax

{ default | no } avp map called-number apn

- default
  Disables mapping.

- no
  Disables mapping.

Usage
For LNS calls received through a LAC, the ICRQ message includes an APN name in the Called Number AVP. This mapping function enables a GGSN system to provide RADIUS authentication/authorization via a defined APN in place of an LNS configuration. If the mapped APN has not been defined within the GGSN configuration then the call will be rejected.

Example
Enter the following command to enable mapping:

    avp map called-number apn

Enter the following command to disable mapping:

    no avp map called-number apn
bind

This command assigns the IP address of an interface in the current context to the LNS service.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax

bind ip_address  [max-subscribers max_value ]
no bind ip_address

no
Unassign, or unbind, the local end point to the LNS service.

ip_address
The IP address of an interface in the current context. This must be a valid IPv4 address, using dotted-decimal notation.

max-subscribers max_value
Default: 10000
The maximum number of subscribers that can be connected to this service at any time. max_value must be an integer from 1 through 2500000.

Usage
Use this command to bind the IP address of an interface in the current context to the LNS service.

Example
The following command binds the current context interface IP address 192.168.100.10 to the current LNS service:

    bind 192.168.100.10

The following command removes the binding of the IP address from the LNS service:

    no bind
data sequence-number

Enables data sequence numbering for sessions that use the current LNS service. Data sequence numbering is enabled by default.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax

[no] data sequence-number

Usage
An L2TP data packet header has an optional data sequence numbers field. The data sequence number may be used to ensure ordered delivery of data packets. This command is used to re-enable or disable the use of the data sequence numbers for data packets.

Example
Use the following command to disable the use of data sequence numbering:

    no data sequence-number

Use the following command to re-enable data sequence numbering:

    data sequence-number
default

This command sets the specified LAC service parameter to its default value or setting.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax

```
default { authentication | data sequence-number | ip source-violation | keepalive-interval | load-balancing | local-receive-window | max-retransmission | max-session-per-tunnel | max-tunnel-challenge-length | max-tunnels | proxy-lcp-authentication | retransmission-timeout-first | retransmission-timeout-max | setup-timeout | single-port-mode | subscriber | trap all tunnel-authentication}
```

---

**authentication**
Sets the authentication parameters for PPP sessions to the following defaults:

- allow-noauth disabled
- chap enabled with a priority of 1
- mschap disabled
- msid-auth disabled
- pap enabled with a priority of 2

---

**data sequence-number**
Enables data sequence numbering for sessions.

---

**ip source-violation**
Sets the IP source violation parameters to the following defaults:

- drop-limit 10
- period 120 seconds
- reneg-limit 5

---

**keepalive-interval**
Sets the interval for send L2TP Hello keepalive if there is no control or data transactions to the default value of 60 secs.

---

**local-receive-window**
Sets the window size to be used for the local side for the reliable control transport to the default of 4.

---

**max-retransmission**
Sets the maximum number of retransmissions to the default of 5.
max-session-per-tunnel
Sets the maximum number of sessions per tunnel at any point in time to the default of 65535.

max-tunnel-challenge-length
Sets the maximum length of the tunnel challenge to the default of 16 bytes.

max-tunnels
Sets the maximum number of tunnels for this service to the default of 32000.

proxy-lcp-authentication
Sets sending of proxy LCP authentication parameters to the LNS to the default state of enabled.

retransmission-timeout-first
Sets the first retransmit interval to the default of 1 second.

retransmission-timeout-max
Sets the maximum retransmit interval to the default of 8 seconds.

setup-timeout
Sets the maximum time allowed for session setup to the default of 60 seconds.

single-port-mode
Disables assignment of only port 1107 for incoming tunnels and allows dynamic assignment of ports.

subscriber
Sets the name of the default subscriber configuration to use.

tunnel-authentication
Sets tunnel authentication to the default state of enabled.

trap all
Generates all supported SNMP traps.

tunnel-switching
Sets the ability of the LNS to create subsequent tunnels to the default of enabled.

Usage
Use the default command to set LAC service parameters to their default states.

Example
Use the following command to set the keep alive interval to the default value of 60 seconds:

default keepalive-interval
Use the following command to set the maximum number of sessions per tunnel to the default value of 512:

```
default max-session-per-tunnel
```
ip source-violation

This command configures settings related to IP source-violation detection.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax

ip source-violation { clear-on-valid-packet | drop-limit num | period secs | reneg-limit num }

no ip source-violation clear-on-valid-packet

clear-on-valid-packet
Default: disabled
Configures the service to reset the reneg-limit and drop-limit counters after receipt of a properly addressed packet.

drop-limit num
Default: 10
Sets the number of allowed source violations within a detection period before forcing a call disconnect. If num is not specified, the value is set to the default.
num can be any integer value from 1 to 1000000.

period secs
Default: 120
The length of time, in seconds, for a source violation detection period to last. drop-limit and reneg-limit counters are decremented each time this value is reached.
The counters are decremented in this manner: reneg-limit counter is reduced by one (1) each time the period value is reached until the counter is zero (0); drop-limit counter is halved each time the period value is reached until the counter is zero (0). If secs is not specified, the value is set to the default.
secs can be any integer value from 1 to 1000000.

reneg-limit num
Default: 5
Sets the number of allowed source violations within a detection period before forcing a PPP renegotiation. If num is not specified, the value is set to the default.
num can be any integer value from 1 to 1000000.

Usage
This function is intended to allow the operator to configure a network to prevent problems such as when a user gets handed back and forth between two PDSNs a number of times during a handoff scenario.
This function operates in the following manner:
When a subscriber packet is received with a source address violation, the system increments both the IP source-violation reneg-limit and drop-limit counters and starts the timer for the IP-source violation period. Every subsequent packet received with a bad source address during the IP-source violation period causes the reneg-limit and drop-limit counters to increment.

For example, if reneg-limit is set to 5, then the system allows 5 packets with a bad source address (source violations), but on the 5th packet, it re-negotiates PPP.

If the drop-limit is set to 10, the above process of receiving 5 source violations and renegotiating PPP occurs only once. After the second 5 source violations, the call is dropped. The period timer continues to count throughout this process.

If at any time before the call is dropped, the configured source-violation period is exceeded, the counters for drop-limit is decremented by half and reneg-limit is decremented by 1. See period definition above.

**Example**

To set the maximum number of source violations before dropping a call to 100, enter the following command:

```
ip source-violation drop-limit 100
```
keepalive-interval

This command specifies the amount of time to wait before sending a Hello keep alive message.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax

keepalive-interval seconds

no keepalive-interval

no
Disables the generation of Hello keep alive messages on the tunnel.

seconds
Default: 60
The number of seconds to wait before sending a Hello keep alive message. The number can be configured to any integer value from 30 to 2147483648.

Usage
Use this command to set the amount of time to wait before sending a Hello keep alive message or disable the generation of Hello keep alive messages completely. A keep alive mechanism is employed by L2TP in order to differentiate tunnel outages from extended periods of no control or data activity on a tunnel. This is accomplished by injecting Hello control messages after a specified period of time has elapsed since the last data or control message was received on a tunnel. As for any other control message, if the Hello message is not reliably delivered then the tunnel is declared down and is reset. The transport reset mechanism along with the injection of Hello messages ensures that a connectivity failure between the LNS and the LAC is detected at both ends of a tunnel.

Example
Use the following command to set the Hello keep alive message interval to 120 seconds:

   keepalive-interval 120

Use the following command to disable the generation of Hello keep alive messages:

   no keepalive-interval
local-receive-window

Specifies the number of control messages the remote peer LAC can send before waiting for an acknowledgement.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax

local-receive-window integer

integer
Default: 4
The number of control messages to send before waiting for an acknowledgement. The number can be configured to any integer value from 1 through 256.

Usage
Use this command to set the size of the control message receive window being offered to the remote peer LAC. The remote peer LAC may send the specified number of control messages before it must wait for an acknowledgment.

Example
The following command sets the local receive window to 10 control messages:

local-receive-window 10
**max-retransmission**

Sets the maximum number of retransmissions of a control message to a peer before the tunnel and all sessions within it are cleared.

**Product**
PDSN, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
max-retransmission integer
```

*integer*

Default: 5

The maximum number of retransmissions of a control message to a peer. This value must be an integer from 1 through 10.

**Usage**

Each tunnel maintains a queue of control messages to be transmitted to its peer. After a period of time passes without acknowledgement, a message is retransmitted. Each subsequent retransmission of a message employs an exponential backoff interval. For example; if the first retransmission occurs after 1 second, the next retransmission occurs after 2 seconds has elapsed, then the next after 4 seconds. If no peer response is detected after the number of retransmissions set by this command, the tunnel and all sessions within are cleared.

Use this command to set the maximum number of retransmissions that the LAC service sends before closing the tunnel and all sessions within it.

**Example**

The following command sets the maximum number of retransmissions of a control message to a peer to 7:

```
max-retransmissions 7
```
max-session-per-tunnel

Sets the maximum number of sessions that can be facilitated by a single tunnel at any time.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax

```
max-sessions-per-tunnel integer
```

integer
Default: 512
The maximum number of sessions. This value must be from 1 through 65535.

Usage
Use this command to set the maximum number of sessions you want to allow in a tunnel.

Example
The following command sets the maximum number of sessions in a tunnel to 5000:

```
max-sessions-per-tunnel 5000
```
max-tunnel-challenge-length

Sets the maximum length of the tunnel challenge in bytes. The challenge is used for tunnel authentication purposes during tunnel creation.

**Product**
PDSN, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
max-tunnel-challenge-length bytes
```

**bytes**
Default: 16
The number of bytes to set the maximum length of the tunnel challenge. This must be a value from 4 through 32.

**Usage**
Use this command to set the maximum length, in bytes, for the tunnel challenge that is used during tunnel creation.

**Example**
The following command sets the maximum length of the tunnel challenge to 32 bytes:

```
max-tunnel-challenge-length 32
```
max-tunnels

The maximum number of tunnels that the current LNS service can support.

**Product**

PDSN, GGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
max-tunnels integer
```

- **integer**

  Default: 32000
  The maximum number of tunnels. This value must be an integer from 1 to 32000.

**Usage**

Use this command to set the maximum number tunnels that this LNS service can support at any one time.

**Example**

Use the following command to set the maximum number of tunnels for the current LNS service to 20000:

```
max-tunnels 20000
```
nai-construction domain

Designates the alias domain name to use for Network Access Identifier (NAI) construction.

**Product**
PDSN, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
nai-construction domain domain_name { @ | % | - | \ | # | / }

no nai-construction domain
```

**no**
Deletes the NAI construction domain alias.

```
domain_name { @ | % | - | \ | # | / }
```

The desired domain name alias followed immediately by a separator from the valid list. `domain_name` must be a string of from 1 through 79 alphanumeric characters.

**Usage**
Use this command to specify the domain alias and separator to use for NAI construction. The specified domain name must be followed by a valid separator (@ | % | - | \ | # | /).

**Example**
To specify a domain alias of mydomain with a separator of @, enter the following command:

```
nai-construction domain mydomain@
```

To delete the current setting for the NAI construction domain alias, enter the following command:

```
no nai-construction domain
```
peer-lac

Adds a peer LAC address for the current LNS service. Up to 8 peer LACs can be configured for each LNS service.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax

```plaintext
peer-lac { ip_address | ip_address/mask } [ encrypted ] secret secret [ description text ]
```

```plaintext
no peer-lac ip_address
```

`no peer-lac ip_address`

Deletes the peer LAC IP address specified by `ip_address`. `ip_address` must be entered in standard IPv4 dotted decimal notation.

`ip_address`

The IP address of a specific peer LAC for the current LNS service. `ip_address` must be entered in standard IPv4 dotted decimal notation.

`ip_address/mask`

A network prefix and mask enabling communication with a group of peer LACs. `ip_address` is the network prefix expressed in dotted decimal notation. `mask` is the number of bits that defines the prefix.

`[encrypted]`

Specifies the encrypted shared key between the LAC and the LNS service. This keyword is intended only for use by the system while saving configuration scripts. The system displays the encrypted keyword in the configuration file as a flag that the variable following the secret keyword is the encrypted version of the plain text secret. Only the encrypted secret is saved as part of the configuration file.

`secret secret`

Designates the secret which is shared between the current LNS service and the peer LAC. `secret` must be a string from 1 to 127 alpha and/or numeric characters and is case sensitive.

`description text`

Specifies the descriptive text to use to describe the specified peer LAC. `text` must be 0 to 79 alpha and/or numeric characters with no spaces or a quoted string of printable characters.

Usage

Use this command to add a peer LAC address for the current LNS service.
Specific peer LACs can be configured by specifying their individual IP addresses. In addition, to simplify configuration, communication with a group of peer LACs can be enabled by specifying a network prefix and a mask.

**Example**
The following command adds a peer LAC to the current LNS service with the IP address of 10.10.10.100, and specifies the shared secret to be \(1b34nnf5d\):

```
peer-lac 10.10.10.100 secret 1b34nnf5d
```

The following command enables communication with up to 16 peer LACs on the 192.168.1.0 network each having a secret of \(abc123\):

```
peer-lac 192.168.1.0/28 secret abc123
```

The following command removes the peer LAC with the IP address of 10.10.200 for the current LNS service:

```
no peer-lac 10.10.10.200
```
proxy-lcp-authentication

Enables/disables proxy LCP authentication.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax

[no] proxy-lcp-authentication

no
Disables the processing of proxy LCP authentication parameters from the LAC.

proxy-lcp-authentication
Default: Enabled
Enables the processing proxy LCP authentication parameters from the LAC.

Usage
When enabled, if proxy LCP authentication parameters are received from the LAC and are acceptable, the LNS resumes the PPP session from the authentication phase and goes to the IPCP phase. When disabled, PPP is always started from the LCP phase, ignoring and discarding any proxy LCP authentication parameters received from the LAC. Disable this feature in situations where accept proxy LCP Auth AVPs that the peer LAC sends should not be expected.

Example
Use the following command to disable the processing of proxy LCP authentication parameters from the LAC:

    no proxy-lcp-authentication

Use the following command to re-enable the processing of proxy LCP authentication parameters from the LAC:

    proxy-lcp-authentication
retransmission-timeout-first

Configures the initial timeout for the retransmission of control messages to the peer LAC.

Privilege
Security Administrator, Administrator

Syntax

```
retransmission-timeout-first integer
```

- `integer`:
  - Default: 1
  - The amount of time to wait before sending the first control message retransmission. This value is measured in seconds and must be an integer from 1 to 100.

Usage
Each tunnel maintains a queue of control messages to transmit to its peer. After a period of time passes without acknowledgement, a message is retransmitted.

Example
The following command sets the initial retransmission timeout to 3 seconds:
```
retransmission-timeout-first 3
```
retransmission-timeout-max

Configures the maximum amount of time that can elapse before retransmitting control messages to the peer LAC.

**Privilege**

Security Administrator, Administrator

**Syntax**

```
retransmission-timeout-max integer
```

<table>
<thead>
<tr>
<th>integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 8</td>
</tr>
<tr>
<td>The maximum time to wait before retransmitting control messages. If this limit is reached, the tunnel, and all sessions within it, is cleared. This value is measured in seconds and must be an integer in the range of 1 to 100.</td>
</tr>
</tbody>
</table>

**Usage**

Each tunnel maintains a queue of control messages to transmit to its peer. After a period of time passes without acknowledgement, a message is retransmitted. Each subsequent retransmission of a message employs an exponential backoff interval. For example; if the first retransmission occurs after 1 second, the next retransmission occurs after 2 seconds has elapsed, then the next after 4 seconds. This continues until the limit set by this command is reached. If this limit is reached, the tunnel, and all sessions within it, is cleared.

**Example**

Use the following command to set the maximum retransmission time-out to 10 seconds:

```
retransmission-timeout-max 10
```
**setup-timeout**

Configures the maximum amount of time, in seconds, allowed for session setup.

**Product**
PDSN, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
setup-timeout seconds
```

- **seconds**
  
  Default: 60
  
  The maximum time to wait, in seconds, for the setup of a session. `seconds` must be an integer from 1 through 1000000.

**Usage**

This command controls the amount of time allowed for tunnel establishment with a peer LAC. If this timer is exceeded the tunnel setup is aborted.

**Example**

The following command configures a maximum setup time of 120 seconds:

```
setup-timeout 120
```
**single-port-mode**

When enabled, this command sets the LNS to use only the default local UDP port (port 1701) for the life of a tunnel.

**Product**

PDSN, GGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
[no | default] single-port-mode
```

- **no**
  
  Disable single port mode

**Usage**

Use this command to control the L2TP LNS tunnel local UDP port assignment mode. If single-port-mode is enabled, the LNS-service uses the standard UDP port (port 1701) for the life of the incoming tunnel. Otherwise, it assigns a new local UDP port number for a tunnel when it responds to a tunnel create request received on the standard port number. This is done for load distributing the tunnel processing between multiple tasks within the system to increase the capacity and performance. Even though all L2TP LACs are required to support such dynamic port assignments during tunnel establishments, there exist some LACs that do not support port assignment other than port 1701. This single-port-mode feature can be enabled to support such LAC peers. This configuration must be applied for the LNS-Service before the `bind` command is executed.

**Example**

The following command enables single port mode for the current LNS service:

```
single-port-mode
```
**trap**

This command generates SNMP traps.

**Product**
PDSN, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[no] trap all
```

- `no`
  Disables SNMP traps.

**Usage**
Use this command to enable/disable all supported SNMP traps.

**Example**
To enable all supported SNMP traps, enter the following command:

```
trap all
```
tunnel-authentication

Enables/disables L2TP tunnel authentication for the LNS service.

**Product**
- PDSN, GGSN

**Privilege**
- Security Administrator, Administrator

**Syntax**

```plaintext
[no] tunnel-authentication
```

- `no`
  - Disables tunnel authentication
  - Tunnel authentication is enabled by default.

**Usage**

When tunnel authentication is enabled, a configured shared secret is used to ensure that the LNS service is communicating with an authorized peer LAC. The shared secret is configured by the `peer-lac` command, the `tunnel l2tp` command in the Subscriber Configuration mode, or the **Tunnel-Password** attribute in the subscribers RADIUS profile.

**Example**

To disable tunnel authentication, use the following command:

```plaintext
no tunnel-authentication
```

To re-enable tunnel authentication, use the following command:

```plaintext
tunnel-authentication
```
tunnel-switching

Enables/disables the LNS service from creating tunnels to another LAC for an existing tunnel.

**Product**
PDSN, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[no] tunnel-switching
```

- **no**
  - Disable tunnel switching.
  - Tunnel switching is enabled by default.

**Usage**
Tunnel switching is when the LNS has a tunnel connected to a LAC and creates a tunnel to a different LAC and routes the data from the original LAC through the new tunnel to the other LAC.

**Example**
To disable tunnel switching in the LNS, enter the following command;

```
no tunnel-switching
```
Chapter 139
Loopback Interface Configuration Mode Commands

Use the Loopback Interface Configuration mode to create and manage loopback interfaces that provide IP addresses that are always available and reachable from any interface within a given context.

```
Exec Mode
  configure
  Global Configuration Mode
    context name
    Context Configuration Mode
      interface name
      loopback
        Loopback Interface Config Mode
```

**Important**: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
description

Use this command to configure the descriptive text for the current interface.

Product
All

Privilege
Security Administrator, Administrator

Syntax

description text

description textno description

no
Clears the description for the interface.

text
Specifies the descriptive text to use. For text, enter 0 to 79 alpha and/or numeric characters with no spaces, or a string of printable characters within quotes.

Usage
Set the description to provide any useful information on the interface’s primary function, services, end users.

Example

description sampleInterfaceDescriptiveText
end

Enter this command to exit the interface configuration mode and return to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Change the mode back to the Exec mode.
exit

Enter this command to exit the interface configuration mode and return to the context configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the context configuration mode.
ip address

Use this command to configure the IP options for the current interface.

Product
All

Privilege
Security Administrator, Administrator

Syntax

ip address { ip_address ip_mask | ip_address/bitmask } [ secondary | srp-activate ]

no ip address ip_address

no
Deletes the IP address you specify from the interface configuration.

address {ip_address ip_mask | ip_address/bitmask} [ secondary | srp-activate ]

Configures the IP address and network mask for the interface.
Enter an ip_address ip_mask to specify an IP address and the subnet mask pair that identifies the IP
address of the interface. For ip_address, specify with standard IPv4 dotted decimal notation. Currently,
the only value accepted for ip_mask is 255.255.255.255.
For the network mask, ip_address/net_mask, enter the IP address and the length in bits of the network
mask in dotted decimal notation and a mask (192.168.1.0/32). Currently, the only value accepted for
bit_mask is 32.
Use the secondary keyword to configure a secondary IP address on the interface. This is referred to as
multi-homing of the interface.
Use the srp-activate keyword to activate the IP address for Interchassis Session Redundancy.

Usage
Create and manage loopback interfaces for the current context.

Example
The following command configures IP address to associate with the interface:
ip address 1.2.3.4 255.255.255.255
The following command removes the associated IP address for the interface:
no ip address 1.2.3.4
ip vrf

Use this command to configure the IP VPN routing/forwarding instance for the current interface.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
ip vrf forwarding vrf_name
no vrf forwarding
```

- **no**
  Deletes the IP VPN routing/forwarding instance you specify from the interface configuration.

- **vrf_name**
  Specifies the preconfigured IP VPN routing/forwarding instance name to be used with this interface.
  For **vrf_name**, enter a preconfigured VPN routing/forwarding instance name with the `ip vrf forwarding` command in Context Configuration mode.

Usage
Use this command to associate a preconfigured IP VPN routing/forwarding instance for the current interface.

Example
The following command associates a preconfigured IP routing/forwarding instance named `vrf_1` with this interface:

```
ip vrf forwarding vrf_1
```
**ipv6 address**

Use this command to configure the IPv6 options for the current interface.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
ipv6 address ipv6_address ip_mask [ srp-activate ]
```

```
no ipv6 address ipv6_address
```

Deletes the specified IPv6 address from the interface configuration.

```
address ipv6_address ip_mask [ srp-activate ]
```

Configures the IP address and network mask for the interface. `ipv6_address ip_mask` specifies an IP address and the subnet mask pair that identifies the IPv6 address of the interface. Specify `ipv6_address` in standard IPv6 dotted decimal notation. The `srp-activate` keyword activates the IPv6 address for Session Recovery.

**Usage**
Create and manage loopback interfaces for the current context and enable Session Redundancy Protocol (SRP) when appropriate.

**Example**
The following command configures an IPv6 address to associate with the interface and enables SRP:

```
ipv6 address 2001:268:2008:b::1021/128 srp-activate
```
Chapter 140
MAG Service Configuration Mode Commands

The MAG Service Configuration Mode is used to create and manage a Mobility Access Gateway service in an HSGW (eHRPD network) or a P-MIP S-GW (LTE-SAE network). The MAG is the PMIP client and communicates with the Local Mobility Anchor (LMA) configured on a PDN Gateway.
**bind address**

Binds the service to a logical IP interface serving as the S2a (HSGW) or S5/S8 (S-GW) interface and specifies the maximum number of subscribers that can access this service over the configured interface.

**Product**

HSGW, S-GW

**Privilege**

Administrator

**Syntax**

```
bind address ip_address [ max-subscribers num ]
```

```
no bind address
```

- **no**
  
  Removes the interface binding from this service.

- **ip_address**
  
  Specifies the IPv6 address of the interface configured as the S5/S8 interface. *ip_address* is specified in colon separated notation.

- **max-subscribers num**
  
  Default: 1500000
  
  Specifies the maximum number of subscribers that can access this service on this interface. *num* must be configured to an integer between 0 and 3000000.

**Important:** The maximum number of subscribers supported is dependant on the license key installed and the number of active PSCs in the system. A fully loaded system with 13 active PSCs can support 3,000,000 total subscribers. Refer to the license key command and the Usage section (below) for additional information.

**Usage**

Associate the MAG service to a specific logical IP address. The logical IP address or interface takes on the characteristics of an S2a or S5/S8 interface that provides the session connectivity to/from a PDN gateway. Only one interface can be bound to a service. The interface should be configured prior to issuing this command.

This command also sets a limit as to the number of simultaneous subscribers sessions that can be facilitated by the service/interface at any given time.

When configuring the **max-subscribers** option, be sure to consider the following:

- The total number of S2a or S5/S8 interfaces you will configure
- The total number of subscriber sessions that all of the configured interfaces may handle during peak busy hours
- An average bandwidth per session multiplied by the total number of sessions
- The type of physical port (10/100Base-T or 1000Base-Tx) that these interfaces will be bound to
Taking these factors into account and distributing your subscriber session across all available interfaces will allow you to configure your interfaces to optimally handle sessions without degraded performance.

Example
The following command would bind the logical IP interface with the address of 4551:0db8:85a3:08d3:3319:8a2e:0370:1344 to the MAG service and specifies that a maximum of 300,000 simultaneous subscriber sessions can be facilitated by the interface/service at any given time:

```
bind address 4551:0db8:85a3:08d3:3319:8a2e:0370:1344 max-subscribers 300000
```
encapsulation

Configures data encapsulation type to be used for specific MAG service.

Product
HSGW, S-GW

Privilege
Administrator

Syntax

encapsulation { gre | ipip }

default encapsulation

default

Resets the encapsulation type to be used by this service to the default option of GRE.

{ gre | ipip }

gre: Specifies that GRE encapsulation is to be used for PMIPv6 tunnel data between the MAG and the LMA. This is the default for this command.

ipip: Specifies that IP-in-IP encapsulation is to be used for PMIPv6 tunnel data between the MAG and the LMA.

Usage

Use this command to select the encapsulation type to be used for PMIPv6 tunnel data between the MAG and the LMA.

Example

The following command sets the encapsulation data to IP-in-IP:

encapsulation ipip
end

Exits the current mode and returns to the Exec Mode.

**Product**
All

**Privilege**
Administrator

**Syntax** `end`

**Usage**
Change the mode back to the Exec mode.
exit

Exits the current mode and returns to the previous mode.

Product
All

Privilege
Administrator

Syntax
exit

Usage
Return to the previous mode.
information-element-set

Identifies the information element set of mobility options to be used in Proxy Binding Update (PBU) messages sent by the MAG to the LMA.

Product
HSGW, S-GW

Privilege
Administrator

Syntax

information-element-set { custom1 | standard }

default information-element-set

default
Resets the command to the default value of “standard”.

{ custom1 | standard }
custom1: Specifies that a custom set of mobility options to be used in proxy binding update messages that are sent in Vendor Specific Mobility Options. These options are:
- User Location Info
- Hardware Identifier
- Access Network Charging Identifier

standard: Specifies that a standard set of mobility options are to be used in proxy binding update messages. The 3GPP specification, 29.275 defines these as Protocol Configuration Options.

Usage
Use this command to identify the type of information element set of mobility options to be used in PBU messages sent from the MAG to the LMA. The mobility options can be either standards-based (3GPP 29.275) or custom (vendor-specific as defined by 3GPP 29.275).

Example
The following command identifies the information element set of mobility options to use in PBU messages as custom:

information-element-set custom1
max-retransmissions

Configures maximum number of retransmissions of Proxy MIP control messages to the LMA.

Product
HSGW, S-GW

Privilege
Administrator

Syntax

```
max-retransmissions num

default max-retransmissions
```

default

Rests the maximum number of allowed retransmissions to the default value of 5.

```
um
```

Default: 5
Specifies the maximum number of times the MAG service will attempt to communicate with the LMA before it marks it as unreachable.

```
count can be configured to any integer value between 1 and 4294967295.
```

Usage
Use this command to limit the number of retransmissions to LMA before marking it as unreachable. If the value configured is reached, the call is dropped.

Example
The following command configures the maximum number of retransmissions for the MAG service to 3:

```
max-retransmissions 3
```
reg-lifetime

Configures the Mobile IPv6 session registration lifetime for this service.

Product
HSGW, S-GW

Privilege
Administrator

Syntax

reg-lifetime seconds

default reg-lifetime

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resets the command value to the default setting of 600.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>seconds</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sets the time value for session lifetimes for this service.</td>
</tr>
<tr>
<td>seconds must be an integer value from 1 to 262140.</td>
</tr>
</tbody>
</table>

Usage
Use this command to limit PMIPv6 lifetime on this service. If the PBA from the LMA contains a lifetime shorter or longer than what is specified, it is used instead.

Example
The following command sets the registration lifetime for Mobile IPv6 sessions using this service to 1200 seconds (20 minutes):

reg-lifetime 1200
renew-percent-time

Configures percentage of lifetime at which a registration renewal is sent to the LMA.

Product
HSGW, S-GW

Privilege
Administrator

Syntax

renew-percent-time percent

default renew-percent-time

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resets the command to the default value of 75.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 75</td>
</tr>
<tr>
<td>Specifies the time when the registration renewal is sent to the LMA. percent is a percentage value of the registration lifetime and must be an integer value from 1 to 100.</td>
</tr>
</tbody>
</table>

Usage
Use this command to specify when a registration renewal is sent to the LMA for subscribers using this service.
If the registration lifetime is 600 seconds (10 minutes) and this command is set to 75 (percent), then the registration renewal message is sent after 450 seconds of the registration lifetime has expired.

Example
The following command sets the registration renewal time for subscribers using this service to 90 percent of the registration lifetime:

```plaintext
renew-percent-time 90
```
retransmission-policy

Configures the retransmission policy for Proxy MIP control message retransmissions.

**Product**
HSGW

**Privilege**
Administrator

**Syntax**

```
retransmission-policy { exponential-backoff | normal }
```

```
default retransmission-policy
```

**default**

Returns the command to its default setting of exponential-backoff.

```
{ exponential-backoff | normal }
```

Sets the retransmission timeout behavior for this service.

- **exponential-backoff**: Specifies that the Proxy Binding Update retransmission uses an exponential backoff to increase the retransmission timeout for each retry.
- **normal**: Specifies that the Proxy Binding Update retransmission uses the configured retransmission timeout value for all PBU retransmission retries.

**Usage**

Use this command to specify the retransmission policy for PMIP control messages.

**Example**
The following command sets the retransmission timeout policy for PMIP control packets to “normal”:

```
retransmission-policy normal
```
retransmission-timeout

Configures the maximum allowable time for the MAG service to wait for a response from the LMA before it attempts to communicate with the LMA again (if the system is configured to retry the LMA) or marks the LMA as unreachable.

**Product**
HSGW, S-GW

**Privilege**
Administrator

**Syntax**

```
retransmission-timeout time

{ default | no } retransmission-timeout
```

- **default**
  Resets the timeout setting to the default value of 3.

- **no**
  Deletes a previously configured timeout value.

- **time**
  Default: 3 seconds (300)
  Specifies the maximum allowable time, in milliseconds, for the MAG service to wait for a response from the LMA before it: a) attempts to communicate with the LMA again (if the system is configured to retry the LMA) or b) marks the LMA as unreachable.
  *time* must be an integer value between 100 and 100000.

**Usage**

Use the retransmission timeout command in conjunction with the `max-retransmissions` command in order to configure the MAG services behavior when it does not receive a response from a particular LMA.

**Example**

The following command configures a retransmission timeout value of 5 seconds:

```
retransmission-timeout 5
```
Chapter 141
MAP Service Configuration Mode Commands

The MAP Service Configuration Mode is used to configure properties for Mobile Application Part (MAP) service. Mobile Application Part (MAP) is a protocol which provides an application layer for the various nodes in the core mobile network and GPRS and UMTS core network to communicate with each other in order to provide services to mobile phone users. The MAP service provides the application-layer protocol support used to access the Home Location Register (HLR).

```plaintext
[<context_name>] hostname(config-map-service-<svc_name>)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
access-protocol

Configures access protocol parameters for the MAP service as defined for a specific SCCP network instance.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
access-protocol sccp-network sccp_id
no access-protocol
```

**sccp-network sccp_id**
Specifies the ID number of the SCCP network to use for the SGSN connection.

- `sccp_id`: Must be an integer from 1 to 16.

**no**
Removes the access protocol SCCP network instance ID from the configuration.

**Usage**

Use this command to associate access protocol parameters to a specific instance of the MAP service for an SCCP network.

**Example**

The following command associates the access protocols with the SCCP network ID #10:

```
access-protocol sccp-network 10
```
application-context-name

Configure the operation timer(s) for one or more MAP application contexts.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

application-context-name application operation-timer value

default application-context-name application operation-timer

default
Resets the operation timers for all applications to system defaults.

application
Select one of the following applications to enable the application:
  • authentication-failure-report : Sets the reporting operation timer for authentication failure. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.
  • cancel-location : Sets the cancel location operation timer. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.
  • check-imei : Sets the check-IMEI operation timer. The setting range for this timer is 15 to 30 seconds for releases 8.0 and 8.1 and 1 to 30 seconds for releases 9.0 and higher. The default setting is 15 seconds.
  • delete-subscriber-data : Sets the delete subscriber data operation timer. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.
  • mo-fwd-sm : Sets the operation timer for forwarding mobile-originated SMS. The setting range for this timer is 1 to 10 minutes and the default setting is 1 minute (60 seconds).
  • ms-purge : Sets the operation timer for MS-purge function. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.
  • mt-fwd-sm : Sets the operation timer for forwarding mobile-terminated SMS. The setting range for this timer is 1 to 10 minutes and the default setting is 1 minute (60 seconds).
  • ready-for-sm : Sets the operation timer for the ready for SMS operation. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.
  • send-authentication-info : Sets the operation timer for the sending authentication information operation. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.
  • standalone-insert-subscriber-data : Sets the operation timer for the standalone insert subscriber data operation. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.
Map Service Configuration Mode Commands

• `ugl-insert-subscriber-data` : Sets the operation timer for the insert subscriber data portion of the update GPRS location operation. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.

• `update-gprs-location` : Sets the operation timer for the update GPRS location operation. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.

```plaintext
operation-timer value
```

Configures the operation timer for the selected application. Timer values are indicated above.

Usage

Repeat this command entering a different application each time to enable multiple applications.

Example

```plaintext
application-context-name  stand-alone-insert-subscriber-data  operation-timer  operation-timer  20
```
auth-vectors

Configures the number of authorization vectors to be requested from the home location register (HLR) during call setup to provide subscriber authentication.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```plaintext
auth-vectors number-to-request number

default auth-vectors number-to-request

default
Resets the number of vectors requested from the HLR to the system default.

number-to-request number
number: Must be an integer from 1 to 5 to define the number of authorization vectors be requested from the HLR.
Default is 5.
```

Usage
Set the number of requests to be received from the HLR.

Example

```plaintext
auth-vectors number-to-request 4
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Return to the Exec mode.
equipment-identity-register

Defines the information relevant to the equipment-identity-register (EIR) used by the SGSN.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
equipment-identity-register { isdn E.164_num | point code pt_code } [ source-ssn ssn | checkimei-every-n-events times]
```

```
no equipment-identity-register { isdn E.164_num | point code pt_code }
```

**no**
Deletes the EIR configuration.

**isdn number**
Enter the E.164 number of the EIR.

- **number**: must be a string of 1 to 15 digits.

**point code pt_code**
Enter SS7 point code address of the EIR in dotted-decimal format according to variant settings:
- ITU Range 0.0.1 to 7.255.7
- ANSI Range 0.0.1 to 255.255.255
- TTC Range 0.0.1 to 15.31.255
- or a string of 1 to 11 characters

**source-ssn ssn**
Identifies the subsystem number (SSN) to be used.

- **ssn**: must be an integer from 1 to 255.

**checkimei-every-n-events times**
Configures the frequency with which a ‘check IMEI’ message is sent to the EIR. When set, the SGSN skips sending the ‘check IMEI’ message for the first N-1 where IMEI/IMEISV is received.

- **times**:
  - For releases 8.0 and 8.1, the value must be an integer from 1 to 15.
  - For releases 9.0 and higher, the value must be an integer from 1 to 255.

**Important**: This feature requires the enabling of **verify-equipment-identity** for IMEI or IMEISV as specified with the the **gmm retrieve-equipment-identity imei** command of the SGSN Operator Policy configuration mode.
Usage
Configure the identity of the EIR that the SGSN uses and the interaction parameters. Increasing the `check-imei-every-n-events` frequency enables the EIR to avoid overload as the number of data-only devices attaching to the network increases.

Example
Configure EIR with point code 1.255.1 to perform IMEI check after every 61st received Attach Request message:

```
  equipment-identity-register point code 1.255.1 check-imei-every-n-events
      62
```
exit

Exits the current configuration mode and returns to the global configuration mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Return to the context configuration mode.
**hlr**

This command enters the configuration mode for the home location register (HLR). The HLR is a database containing the subscriber profile information for all mobile stations (MS) / user equipment (UE) connecting to a specific GPRS or UMTS core network.

---

**Important:** The commands and options for this mode are documented in the HLR Configuration Mode chapter.

**Product**
- SGSN

**Privilege**
- Security Administrator, Administrator

**Syntax**

```bash
hlr
```
policy

This command configures the Transaction Capabilities Application Part (TCAP) -specific MAP policy for either ANSI or ITU SS7 variants.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

[ default ] policy tcap { use-received-destination-address | use-received-source-address }

<table>
<thead>
<tr>
<th>use-received-destination-address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Selecting this keyword overwrites stored CG and CD addresses with a new address received in first TC CNT msg</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>use-received-source-address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Selecting this keyword instructs the MAP service to use the received source address for the dialog</td>
</tr>
</tbody>
</table>

Usage
Use this command to determine how TCAP will handle MAP messages.

Example

policy tcap use-received-destination-address
short-message-service

This command enables and disables the short message service (SMS service) and provides access to the SMS service configuration mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

[ no ] short-message-service

    no
    Disables the SMS service.

Usage
Enter the command to access the SMS service configuration mode to fine tune the SMS functionality.

Example

short-message-service
The Mobile IP HA Assignment Table Configuration Mode is used to assign specific HA IP addresses to ranges of Mobile Node IP addresses.
end

Exits the current configuration mode and returns to the Exec mode.

Product
PDSN, HA

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Returns to the Exec mode.
exit

Exits the current configuration mode and returns to the Context configuration mode.

**Product**
PDSN, HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the Context Configuration mode.
**hoa-range**

This command assigns ranges of Mobile Node (MN) IP addresses to specific Home agent IP addresses.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
hoa-range ip_address ip_address2 ha ip_address3
no hoa-range ip_address ip_address2 ha ip_address3
```

- **no**
  Remove the specified Home Agent assignment from the assignment table.

- **ip_address ip_address2**
  Specifies a range of MN IP addresses. `ip_address` and `ip_address2` must be specified in either IPv4 dotted decimal notation or IPv6 colon notation.

- **ha ip_address3**
  Specifies the IP address of the Home Agent to assign to MNs that are within the specified range. `ip_address3` must be specified in either IPv4 dotted decimal notation or IPv6 colon notation.

**Usage**

Use this command to assign ranges of MN IP addresses to specific HAs.

**Important**: A maximum of 8 MIP HA assignment tables can be configured per context with a maximum of 8 MIP HA assignment tables across all contexts.

**Important**: A maximum of 256 non-overlapping hoa-ranges can be configured per MIP HA Assignment table with a maximum of 256 non-overlapping hoa-ranges across all MIP HA Assignment tables.

**Example**

The following command assigns any MN IP address that falls in the range of 192.168.100.0 through 192.168.101.0 to the HA with the IP address of 192.168.200.10:

```
hoa-range 192.168.100.0 192.168.101.0 ha 192.168.200.10
```
Chapter 143
MIPv6HA Service Configuration Mode Commands

The MIPv6 HA Service Configuration Mode is used to create and manage MIPv6 access privileges.

```
Exec Mode

configure

configure context name

Context Configuration Mode

Mipv6ha-service name

MIPv6HA Service Configuration Mode
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
aaa accounting

Configures the sending of subscriber session AAA accounting by the HA service.

**Product**

PDSN, HA

**Privilege**

Security Administrator, Administrator

**Syntax**

```yaml
aaa accounting

no aaa accounting
```

**Usage**

Enabling the HA service will send all accounting data (start, stop, and interim) to the configured AAA servers.

The chassis is shipped from the factory with the AAA accounting enabled.

**Important**: In order for this command to function properly, AAA accounting must be enabled for the context in which the HA service is configured using the `aaa accounting subscriber radius` command.

AAA accounting for the HA service can be disabled using the `no` version of the command.

**Example**

The following command disables aaa accounting for the HA service:

```bash
no aaa accounting
```
bind

Designates the address of the MIPv6HA service and specifies the maximum number of subscribers that can access this service over the interface.

Product
PDSN, HA

Privilege
Security Administrator, Administrator

Syntax

bind address IPv6_address [ max-subscribers count ]

no bind address

address

Specifies the IPv6 address (address) of the MIPv6HA service. The IPv6 address size is 128 bits. The preferred IPv6 address representation is: xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx where each x is a hexadecimal digit representing 4 bits.

max-subscribers count

Default: 3000000

Specifies the maximum number of subscribers that can access this service on this interface. count can be configured to any integer value between 0 and 4000000.
**default**

Restore default values assigned for specified parameter.

**Product**
PDSN, HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
default { aaa | refresh-advice-option | refresh-interval-percent | reg-lifetime | sequence-number-validate | setup-timeout | simul-bindings | subscriber | timestamp-replay-protection }
```

**aaa**
Restores the aaa setting configured by the aaa command to its default of enabled.

**refresh-advice-option**
Restores the refresh-advice-option setting to its default of disabled.

**refresh-interval-percent**
Restores the refresh-interval-percent setting to its default of 75.

**reg-lifetime**
Restores the Mobile IP session registration lifetime setting configured by the reg-lifetime command to its default: 600 seconds.

**sequence-number-validate**
Restores the sequence-number-validate setting to its default of enabled.

**setup-timeout**
Restores the simultaneous bindings setting to its default: 1.

**simul-bindings**
Restores the maximum amount of time allowed for setting up a session to the default: 60 seconds.

**subscriber**
Configures settings for the default subscriber.

**timestamp-replay-protection**
Restores the timestamp-replay-protection scheme according to RFC 4285.
After the system has been modified from its default values, this command is used to set/restore specific parameters to their default values.

**Example**
The following command is used to return the simultaneous bindings setting parameter to it’s default value:

```
default simul-bindings
```
end

Exits the HA service configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Change the mode back to the Exec mode.
exit

Exits the HA service configuration mode and returns to the context configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

exit

**Usage**
Return to the context configuration mode.
refresh-advice-option

Configures inclusion of refresh advice option in Binding Acknowledgement sent by Home Agent (HA).

**Product**

PDSN, HA

**Privilege**

Security Administrator, Administrator

**Syntax**

```
refresh-advice-option
```

**Usage**

Includes the refresh advice option in the binding acknowledgements sent by the home agent. Default is disabled.
refresh-interval-percent

Configures percentage of the granted lifetime to be used in the refresh interval mobility option in Binding Acknowledgement sent by Home Agent (HA).

**Product**
PDSN, HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
refresh-interval-percent value
```

```
value
value represents a percentage, value should be integer between 1 and 99. Default is 75.
```

**Usage**

Use this command to configure the amount of the granted lifetime to be used in the refresh interval mobility option in Binding Acknowledgement sent by Home Agent (HA).

**Example**

The following command sets the refresh-interval-percent value to 50%:

```
refresh-interval-percent 50
```
reg-lifetime

Specifies the longest registration lifetime that the HA service will allow in any Registration Request message from the mobile node.

Product
PDSN, HA

Privilege
Security Administrator, Administrator

Syntax

```
reg-lifetime time
```

```
no
```

Sets the registration lifetime to infinite.

```
time
```

Specifies the registration lifetime. time is measured in seconds and can be configured to any integer value between 1 and 262140. Default is 600.

Usage
Use to limit a mobile nodes lifetime. If the mobile node requests a shorter lifetime than what is specified, it is granted. However, Per RFC 2002, should a mobile node request a lifetime that is longer than the maximum allowed by this parameter, the HA service will respond with the value configured by this command as part of the Registration Reply.

The chassis is shipped from the factory with the registration lifetime set to 600 seconds.

Example
The following command configures the registration lifetime for the HA service to be 2400 seconds:

```
reg-lifetime 2400
```

The following command configures an infinite registration lifetime for MIPv6 calls:

```
no reg-lifetime
```
sequence-number-validate

Configures sequence number validation of the received MIPv6 control packet by the Home Agent (HA) according to RFC 3775.

**Product**

PDSN, HA

**Privilege**

Security Administrator, Administrator

**Syntax**

```
sequence-number-validate
```

**Usage**

Use this command to configure the sequence number validation of the received MIPv6 control packet by the Home Agent (HA) as per RFC 3775. Default is enabled.
**setup-timeout**

The maximum amount of time allowed for session setup.

**Product**
PDSN, HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
setup-timeout seconds
```

*seconds*

Default: 60 seconds
The maximum amount of time, in seconds, to allow for setup of a session. must be an integer from 1 through 1000000. Default is 60 seconds.

**Usage**
Use this command to set the maximum amount of time allowed for setting up a session.

**Example**
To set the maximum time allowed for setting up a session to 5 minutes (300 seconds), enter the following command:

```plaintext
setup-timeout 300
```
simul-bindings

Specifies the maximum number of “care-of” addresses that can simultaneously be bound for the same user as identified by NAI and Home address.

Product
PDSN, HA

Privilege
Security Administrator, Administrator

Syntax

```
simul-bindings number
```

*number*

Configures maximum number of "care of" addresses that can be simultaneously bound for the same user as identified by their NAI and home address. number can be configured to any integer value between 1 and 3. Default is 1.

Usage
The chassis is shipped from the factory with the simultaneous sessions set to 1. Per RFC 2002, the HA service creates a mobile binding record (MBR) for each subscriber session it is facilitating. Each MBR is associated with a care-of address. As the mobile node roams, it is possible that the session will be associated with a new care of address. Typically, the HA service will delete an old binding and create a new one when the information in the Registration Request changes. However, the mobile could request that the HA maintains previously stored MBRs. This command allows you to configure the maximum number of MBRs that can be stored per subscriber if the requested.

Example
The following command configures the service to support up to 2 addresses per subscriber:

```
simul-bindings 2
```
timestamp-replay-protection tolerance

Designates timestamp replay protection scheme as per RFC 4285.

Product
PDSN, HA

Privilege
Security Administrator, Administrator

Syntax

timestamp-replay-protection tolerance

seconds

tolerance seconds

Defines the acceptable difference in timing (between timestamps) before rejecting packet, in seconds. Tolerance must be an integer between 0 and 65535. The default is 7 seconds.

Usage
Use this command to define the acceptable difference in timing (between timestamps) before rejecting packet.
The MME-HSS Service Configuration Mode is used to create and manage the HSS servers on Diameter protocol.
diameter dictionary

Specifies the Diameter Credit Control dictionary for the MME-HSS service.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
diameter dictionary { custom1 | standard }
default diameter dictionary
```

**default**
Sets the dictionary to default for HSS service.

**custom1**
Default: Disabled
This keyword sets the Diameter dictionary to customer specific dictionary. This is a customer specific diameter dictionary.

**standard**
Default: Enabled
This keyword sets the Diameter dictionary to Standard dictionary. This is standard MME-HSS dictionary.

Usage
Use this command to select the Diameter dictionary for MME-HSS service.

Example
The following command sets the Diameter dictionary to IETF RFC 4006 specific:

```
diameter dictionary standard
```
diameter endpoint

This command associates a preconfigured Diameter origin endpoint with this MME-HSS service to manage S6a interface between MME and HSS.

Product
All

Privilege
Security Administrator, Administrator

Syntax

[ no ] diameter endpoint endpoint_name [ -noconfirm ]

- no
Removes previously associated Diameter origin endpoint from this MME-HSS service.

- endpoint_name
This is a preconfigured Diameter endpoint in Context configuration mode. The endpoint must be present in all Diameter messages and is the endpoint that originates the Diameter message.
endpoint_name must be a preconfigured Diameter endpoint name.
If named endpoint is not configured earlier the system will create it and switch to the Diameter Endpoint Configuration mode in Context Configuration mode.

- -noconfirm
Indicates that the command is to execute without any additional prompt and confirmation from the user.

⚠️ WARNING: If this keyword option is used with no diameter endpoint endpoint_name command the Diameter endpoint named endpoint_name will be deleted with all active/inactive subscribers without prompting any warning or confirmation.

Usage
Use this command to associated a Diameter origin endpoint to create Diameter-based S6a interface in this MME-HSS service to provide AAA functionality to EPS bearer context.
If named endpoint is not configured earlier the system will create it and switch to the Diameter Endpoint Configuration mode in Context Configuration mode.
Refer Diameter Endpoint Configuration Mode Commands chapter for more information on Diameter endpoint configuration parameters.

Example
The following command associates the preconfigured Diameter endpoint hss_1 with this MME-HSS service for S6a interface support.

diameter endpoint hss_1
If named endpoint is not configured earlier the system will create it and switch to the Diameter Endpoint Configuration mode in Context Configuration mode and following prompt will appear:

```
[context]host(config-ctx-diameter)#
```
end

Exits the current mode and returns to the Exec Mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Change the mode back to the Exec mode.
exit

Exits the current mode and returns to the previous mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Return to the previous mode.
failure-handling

This command configures the failure handling behavior in the event of a failure with the MME-HSS service. It also defines the action on various error codes on Diameter interface during authentication or session activities.

Product

MME

Privilege

Security Administrator, Administrator

Syntax

failure-handling { authentication-information-request | check-identity-request | notify-request | purge-ue-request | update-location-request } { diameter-result-code start_error_code [ to end_error_code ] | request-timeout } action { continue | retry-and-terminate | terminate }

removes the preconfigured failure handling procedures for MME calls in an MME-HSS service.

default

Sets the default action for failure handling procedure for MME calls in an MME-HSS service.
For default actions on Diameter result/error codes see Usage section of this section.

authentication-information-request

This keyword configures the MME-HSS service to handle the failures in Auth-Information-Request message.

check-identity-request

This keyword configures the MME-HSS service to handle the failures in Check-Identity-Information-Request message.

notify-request

This keyword configures the MME-HSS service to handle the failures in Notify-Request message.

purge-ue-request

This keyword configures the MME-HSS service to handle the failures in Purge-UE-Request message.

update-location-request

This keyword configures the MME-HSS service to handle the failures in Update-Location-Request message.
**diameter-result-code start_error_code [to end_error_code]**

This keyword configures the MME-HSS service to handle the failures for various request messages having specific single or range of Diameter result code in request message.

*start_error_code* specifies the individual error code on Diameter protocol and must be an integer from 3000 through 5999. This will be the starting of code if a range of error codes is specified with optional keyword *to end_error_code*.

*to end_error_code* is used to specify a range of error codes to handle by this command.

*end_error_code* specifies the end error code on Diameter protocol and must be an integer from 3000 through 5999.

**request-timeout**

This keyword configures the MME-HSS service to handle the failures for various request messages if response to that message is not received before timeout duration exhausted.

**action { continue | retry-and-terminate | terminate }**

This keyword specifies the action to be taken on failure of any message as policy of failure handling.

- *continue*: On receipt of any error, this action configuration will allow the MME-HSS service to continue with the session procedure without any interruption.

- *retry-and-terminate*: On receipt of any error, this action configuration will instruct the MME-HSS service to retry with the procedure. System will retry up to the configured number of attempts and terminate the session/procedure if it received subsequent number of errors after retry attempts.

- *terminate*: This action configuration will allow the MME-HSS service to terminate the session procedure without any retry attempt on the event of any failure.

**Usage**

Use this command to configure the failure handling behavior in the event of a communication failure with the MME-HSS service.

Following are the default action for Diameter result codes:

- For all protocol error codes 3000 to 3999 the default action is terminate.
- For all transient error codes 4000, 4001, 4004 to 4180, and 4182 to 4999 the default action is continue.
- For transient error codes 4002, 4003, and 4181 the default action is retry.
- For error code 4001 the default action is terminate.
- For permanent error codes 5000 to 5999 the default action is terminate.

**Example**

The following command will allow MME-HSS service to continue if any failure in Auth-Information-Request message occurred with Diameter error code 3050:

```
failure-handling authentication-information-request diameter-result-code 3050 action continue
```
request timeout

This command configures the application request timeout between MME-HSS service and HSS node. The MME system will wait for this duration before retransmitting the request to corresponding HSS node.

**Product**
MME

**Privilege**
Security Administrator, Administrator

**Syntax**

```
request timeout dur
[n o | default ] request timeout
```

- **no**
  Disables the configured application request timeout value.

- **default**
  Sets the application request time out duration to default value of 300 seconds.

- **dur**
  Default: 300 seconds
  Specifies the application request timeout duration in seconds. The MME will wait for this duration before retrying the request with corresponding HSS.
  `dur` must be an integer from 1 through 300.

**Usage**
Use this command to set the waiting period for MME-HSS service in seconds after which the request is deemed to have failed or system will resend the request.

**Example**
The following example configures the application request timeout duration to 300 seconds:

```
default request timeout
```
test

This command test the configured S6a interface between MME-HSS service and HSS server.

Product
MME

Privilege
Security Administrator, Administrator

Syntax

test s6a_inf_name

[ no | default ] test

no
Removes the configured S6a test interface from this MME-HSS service.

default
Sets the S6a test interface to default interface configured from MME service.

s6a_inf_name
Specifies the name of the S6a interface which is to be used for testing the connectivity between MME and HSS node.

s6a_inf_name is a preconfigured interface for S6a reference on system and must be an alpha and/or numerical string of 1 through 63 characters.

Usage
Use this command to set the S6a interface for testing between MME and HSSS node.

Example
The following command configures S6a test interface to s6a_1:

test s6a_1
Chapter 145
MME Service Configuration Mode Commands

The MME Service Configuration Mode is used to create and manage the LTE Mobility Management Entity (MME) services for LTE/SAE network. This service works in conjunction with MME-HSS Service and eGTP Service.
**associate**

This command associates/disassociates the supportive services like an Evolved GPRS Tunnelling Protocol (eGTP) service or an MME-HSS service with an MME service.

**Product**

MME

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
associate { egtp-service egtp_svc_name | mme-hss-service hss_svc_name} [ context ctx_name ]
no associate { egtp-service | mme-hss-service }
```

**Usage**

Use this command to associate a pre-configured eGTP or MME-HSS service with an MME service. The eGTP service provides eGTP-U and eGTP-C protocol interface support between EPS nodes. For more information on eGTP service and supported interface type, refer eGTP Service Configuration Mode Commands chapter in Command Line Interface Reference.

**Important:** Only one eGTP service can be associated to a service. The eGTP service should be configured prior to issuing this command.
The MME-HSS service provides S6a interface support on Diameter protocol between MME and HSS. For more information on MME-HSS service and other parameters, refer MME-HSS Service Configuration Mode Commands chapter in Command Line Interface Reference.

**Important:** Only one MME-HSS service can be associated to a service in this release. The eGTP service should be configured prior to issuing this command.

**Caution:** This is a critical configuration. The MME service can not be started without this configuration. Any change to this configuration would lead to restarting the MME service and removing or disabling this configuration will stop the MME service.

**Example**
The following command associates a pre-configured eGTP service called `egtp1` in `dst_ctx` context to an MME service:

```
associate egtp-service egtp1 context dst_ctx
```

The following command associates a pre-configured MME-HSS service called `hss1` in the same context as MME service to an MME service:

```
associate mme-hss-service hss1
```
**bind s1-mme**

This command binds the MME service to a logical IP interface serving as the S1-MME interface.

**Product**
MME

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
bind s1-mme address address
no bind address
```

**Usage**

Use this command to associate or tie the MME service to a specific logical IP address that will be used for binding the SCTP socket to communicate with the eNodeB using S1-MME interface. A maximum of one IP address can be configured with this command for one MME service. The MME passes the IP address during setting up the SCTP association with the eNodeB.

**Caution:** This is a critical configuration. The MME service can not be started without this configuration. Any change to this configuration would lead to restarting the MME service and removing or disabling this configuration will stop the MME service.

**Example**

The following command would bind the logical IP interface with the address of 192.168.3.1 to the MME service to interact with eNodeB:

```plaintext
bind s1-mme address 192.168.3.1
```

The following command disables a binding that was previously configured:

```plaintext
no bind s1-mme address
```
dns

This command associates/disassociates the Domain Name System (DNS) client service configured for DNS query in a context to select P-GW and S-GW in an MME service.

Product
MME

Privilege
Security Administrator, Administrator

Syntax

dns { pgw | sgw } [ context ctx_name ]

no dns { pgw | sgw }

no
Disassociates a previously associated context having DNS client service configured for DNS query to select P-GW or S-GW with this MME service.

pgw
This keyword associates the named context with DNS client service for DNS query for selection of P-GW with MME service.

sgw
This keyword associates the named context with DNS client service for DNS query for selection of S-GW with MME service.

context ctx_name
This optional keyword associates the specific context name where DNS client service is configured to select P-GW and/or S-GW for this MME service. If this keyword is omitted DNS client service must be configured in the same context as MME service.

ctx_name is name of the configured context of the DNS client service. This can be from 1 to 63 alpha and/or numeric characters and is case sensitive.

Usage
Use this command to associate a pre-configured context where a DNS client service is configured with an MME service.
The DNS Client service configured in a context provides the DNS query support to locate P-GW or S-GW from and MME service. For more information on DNS Client service and support, refer DNS Client Service Configuration Mode Commands chapter in Command Line Interface Reference.
A maximum of one DNS client service for P-GW and one DNS client service for S-GW can be associated with an MME service.

Example
The following command associates a pre-configured context `dns_ctx1` where a DNS client service is configured for DNS query to P-GW from an MME service:

```
dns pgw context dns_ctx1
```

The following command associates a pre-configured context `dns_ctx2` where a DNS client service is configured for DNS query to S-GW from an MME service:

```
dns sgw context dns_ctx2
```
emm

This command defines the Evolved Mobility Management timer parameters like timeout durations for timers for the NAS message retransmission in MME service.

Product: MME
Privilege: Security Administrator, Administrator

Syntax:

```
default emm { mobile-reachable-timeout | t3412-timeout | T3413-timeout | T3422-timeout | T3423-timeout | T3450-timeout | T3460-timeout | T3470-timeout }

no emm implicit-detach-timeout
```

---

**default**

Resets the specified timer timeout to the system default value.

---

**no**

Removes the specified EMM timeout definition from the configuration.

---

**implicit-detach-timeout detach_dur**

Default: 5640

Sets the timer timeout duration after which subscriber will implicitly detached from the network if there is no activity. Generally this timer value is 240 seconds (4 minutes) more than the timeout value of T3423 timer. This timer starts when mobile reachable timer expires while the network is in EMM-IDLE mode and ISR is activated and stops when NAS signalling connection established.

*detach_dur* is timeout duration in seconds and must be an integer from 1 through 12000.

---

**mobile-reachable-timeout mob_reach_dur**

Default: 5640

Sets the timeout timer duration after which reachability procedure will be discarded and reattempt starts.

*mob_reach_dur* is timeout duration in seconds and must be an integer from 1 through 12000.

---

**t3412-timeout t3412_dur**

Default: 5400

Sets the timeout duration for T3412 timer. This timer is used for periodic tracking area update (P-TAU). When this timer expires, the periodic tracking area updating procedure starts and the timer is set to its initial value for the next start. This timer starts when the UE goes from EMM-CONNECTED to EMM-IDLE mode and stops when the UE enters EMM-CONNECTED mode.

*t3412_dur* is timeout duration in seconds and must be an integer from 1 through 11160.

---

**T3413-timeout t3413_dur**

Default: 10
Sets the timeout duration for T3413 timer. The timer starts when MME initiates the EPS paging procedure to the EMM entity in the network and requests the lower layer to start paging. This timer stops for the paging procedure when a response received from the UE.

t3413_dur is timeout duration in seconds and must be an integer from 1 through 20.

**T3422-timeout t3422_dur**

Default: 10
Sets the timeout duration for T3422 timer. This timer starts when MME initiates the detach procedure by sending a DETACH REQUEST message to the UE and stops upon receipt of the DETACH ACCEPT message.

t3422_dur is timeout duration in seconds and must be an integer from 1 through 20.

**T3423-timeout t3423_dur**

Default: 5400
Sets the timeout duration for T3423 timer. This timer starts when UE enters the EMM-DEREGISTERED state or when entering EMM-CONNECTED mode. It stops while the UE is in EMM-REGISTERED.NO-CELL-AVAILABLE state and Idle mode Signalling Reduction (ISR) is activated.

t3423_dur is timeout duration in seconds and must be an integer from 1 through 11160.

**T3450-timeout t3450_dur**

Default: 6
Sets the timeout duration for T3450 timer. This timer starts when MME initiates the Globally Unique Temporary Identifier (GUTI) reallocation procedure by sending a GUTI REALLOCATION COMMAND message to the UE and stops upon receipt of the GUTI REALLOCATION COMPLETE message. This timer is also used for Tracking area update procedure.

t3450_dur is timeout duration in seconds and must be an integer from 1 through 20.

**T3460-timeout t3460_dur**

Default: 6
Sets the timeout duration for T3460 timer. The timers starts when the network initiates the authentication procedure by sending an AUTHENTICATION REQUEST message to the UE and stops upon receipt of the AUTHENTICATION RESPONSE message.

t3460_dur is timeout duration in seconds and must be an integer from 1 through 20.

**T3470-timeout t3470_dur**

Default: 6
Sets the timeout duration for T3470 timer. The MME starts this timer when the network initiates the identification procedure by sending an IDENTITY REQUEST message to the UE and stops upon receipt of the IDENTITY RESPONSE message.

t3470_dur is timeout duration in seconds and must be an integer from 1 through 20.

**Usage**

Use this command to set EMM timers.
Following tables describe the triggers and states for timers:
### Table 27. EPS mobility management timers – UE side

</tr>
</tbody>
</table>

NOTE 1: The default value of this timer is used if the network does not indicate another value in an EMM signalling procedure.

NOTE 2: The value of this timer is provided by the network operator during the attach and tracking area updating procedures.

NOTE 3: The value of this timer may be provided by the network in the ATTACH ACCEPT message and TRACKING AREA UPDATE ACCEPT message. The default value of this timer is identical to the value of T3412.

NOTE 4: The value of this timer is provided by the network operator when a service request for CS fallback is rejected by the network with EMM cause #39 “CS domain temporarily not available”.

</tbody>
</table>

NOTE 1: Typically, the procedures are aborted on the fifth expiry of the relevant timer. Exceptions are described in the corresponding procedure description.

This command can be repeated to set each timer as needed.
The retransmission of all type of NAS messages can be configured through `nas-max-retransmissions` command.

**Example**
The following command sets the timeout value for EPS paging procedure timer T3413 for 10 seconds.

```
emm t3413-timeout 10
```
encryption-algorithm-lte

This command configures the precedence for LTE encryption algorithms to use for security procedures through this MME service.

Product
MME

Privilege
Security Administrator, Administrator

Syntax

encryption-algorithm-lte priority1 { 128-eaa0 | 128-eel1 | 128-eel2 } [ priority2 { 128-eel0 | 128-eel1 | 128-eel2}] [ priority3 { 128-eel0 | 128-eel1 | 128-eel2 } ]

default encryption-algorithm-lte

default

Sets the default LTE encryption algorithm for security procedures with configured priority value. Default configuration of LTE encryption algorithm is:

- priority1 with 128-eel0 encryption algorithm
- priority2 with 128-eel1 encryption algorithm
- priority3 with 128-eel2 encryption algorithm

priority1

Specifies the preference of integrity algorithm for security procedures on this MME service as priority 1. Least value has highest preference.

priority2

Specifies the preference of integrity algorithm for security procedures on this MME service as priority 2. Least value has highest preference.

priority3

Specifies the preference of integrity algorithm for security procedures on this MME service as priority 3. Least value has highest preference.

128-eel0

Default: Enabled
This keyword sets the Null ciphering algorithm (128-EAA0) for LTE encryption as the encryption algorithm for security procedures.

128-eel1

Default: Disabled
This keyword sets the SNOW 3G synchronous stream ciphering algorithm (128-EEL1) for LTE encryption as the encryption algorithm for security procedures. SNOW 3G is a stream cipher that forms the base of the 3GPP confidentiality algorithm UEA2 and the 3GPP integrity algorithm UIA2.
Default: Disabled
This keyword sets the Advance Encryption Standard (AES) ciphering algorithm (128-EEA2) for LTE encryption as the encryption algorithm for security procedures.

Usage
Use this command to set the LTE encryption algorithms for security procedures to use with this MME service.

⚠️ Caution: When this command is executed, all the existing priority to algorithm mappings will be removed and the newly configured ones will be applicable for security procedures.

⚠️ Caution: Configuration of same algorithm to multiple priorities is prohibited.

Example
The following command sets the 128-EEA1 as the LTE encryption algorithm with priority 2 for security procedures with an MME service:

```
encryption-algorithm-lte priority2 128-ee1
```
### end

Exits the current mode and returns to the Exec Mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
end
```

**Usage**

Change the mode back to the Exec mode.
esm

This command defines the Evolved Session Management timer parameters like timeout durations for timers for the retransmission of NAS messages in MME service.

Product
MME

Privilege
Security Administrator, Administrator

Syntax

default esm { t3485-timeout | T3495-timeout }

default
Resets the specified Evolved Session Management timer timeout to the system default value.

t3485-timeout t3485_dur
Default: 6
Sets the timeout duration for T3485 timer. This timer is used for default EPS bearer context activation procedure.
This timer starts when the MME sends ACTIVATE DEFAULT EPS BEARER CONTEXT REQUEST message to UE and stops when receives ACTIVATE DEFAULT EPS BEARER CONTEXT ACCEPT or ACTIVATE DEFAULT EPS BEARER CONTEXT REJECT message from UE.
t3485_dur is timeout duration in seconds and must be an integer from 1 through 60.

T3495-timeout t3495_dur
Default: 6
Sets the timeout duration for T3485 timer. This timer is used for default EPS bearer context deactivation procedure.
This timer starts when the MME sends DEACTIVATE EPS BEARER CONTEXT REQUEST message to UE and stops when receives DEACTIVATE EPS BEARER CONTEXT ACCEPT or DEACTIVATE EPS BEARER CONTEXT REJECT message from UE.
t3495_dur is timeout duration in seconds and must be an integer from 1 through 60.

Usage
Use this command to set Evolved Session Management timers.
Following tables describe the triggers and states for timers:

Table 31. EPS session management timers – Network side

<table>
<thead>
<tr>
<th>Timer</th>
<th>State</th>
<th>Cause of Start</th>
<th>Normal Stop</th>
<th>On Expiry1st, 2nd, 3rd, 4th EXPIRY (NOTE 1)</th>

<td>BEARER CONTEXT INACTIVE PENDING</td>
<td>DEACTIVATE EPS BEARER CONTEXT REQUEST sent</td>
<td>DEACTIVATE EPS BEARER CONTEXT ACCEPT received</td>
<td>Retransmission of DEACTIVATE EPS BEARER CONTEXT REQUEST</td>
</tr>
</tbody>
</table>

**NOTE 1:** Typically, the procedures are aborted on the fifth expiry of the relevant timer. Exceptions are described in the corresponding procedure description.

This command can be repeated to set each timer as needed. The retransmission of all type of NAS messages can be configured through the `nas-max-retransmissions` command.

**Example**
The following command sets the timeout value for default EPS bearer context activation procedure timer T3485 for 10 seconds.

```
esm t3485-timeout 10
```
exit

Exits the current mode and returns to the previous mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Return to the previous mode.
integrity-algorithm-lte

This command configures the precedence of LTE integrity algorithms to use for security procedures through this MME service. By default integrity algorithm is enabled on MME service, which cannot be disabled.

**Product**
MME

**Privilege**
Security Administrator, Administrator

**Syntax**

```default integrity-algorithm-lte
```

**default**
Removes the preconfigured integrity algorithm and sets the default LTE integrity algorithm for security procedures. Default configuration of LTE integrity algorithm is:

- priority1 with 128-eia1 integrity algorithm
- priority2 with 128-eia2 integrity algorithm

**priority1**
Specifies the preference of integrity algorithm for security procedures on this MME service as priority 1. This is the mandatory and default priority keyword.

**priority2**
Specifies the preference of integrity algorithm for security procedures on this MME service as priority 2.

**128-eia1**
Default: Disabled
This keyword sets the SNOW 3G synchronous stream ciphering algorithm (128-EIA1) for LTE integrity as the integrity algorithm for security procedures. SNOW 3G is a stream cipher that forms the base of the 3GPP confidentiality algorithm UEA2 and the 3GPP integrity algorithm UIA2.

**128-eia2**
Default: Enabled
This keyword sets the Advanced Encryption Standard (AES) ciphering algorithm (128-EIA2) for LTE integrity as the integrity algorithm for security procedures.

**Usage**

Use this command to set the LTE integrity algorithms for security procedures to use with this MME service.

**WARNING:** Integrity algorithm is a mandatory aspect and cannot be disabled in MME service.

**Caution:** When this command is executed, all the existing priority to algorithm mappings will be removed and the newly configured ones will be applicable for security procedures.
Caution: Configuration of same algorithm to multiple priorities is prohibited.

Example
The following command sets the AES ciphering algorithms (128-EIA2) as the LTE integrity algorithm with priority as 1 for security procedures with an MME service:

```
integrity-algorithm-lte priority1 128-eia2
```
location-reporting

This command enables the location reporting functionality for UE on MME service.

**Product**
MME

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no | default ] location-reporting
```

- **default**
  Disables the location reporting feature on MME service.

- **no**
  Disables the location reporting feature on MME service.

**Usage**

Use this command to enable/disable the UE location reporting feature on MME service.

**Example**
The following command sets the MME service to provide the location reporting functionality for UE:

```
location-reporting
```
max-bearers per-subscriber

This command specifies the maximum number of EPS bearers that a subscriber may simultaneously use to access this MME service.

Product
MME

Privilege
Security Administrator, Administrator

Syntax

max-bearers per-subscriber max_bearer

default max-bearers per-subscriber

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configures the maximum EPS bearers for a subscriber to use simultaneously to default value of 11.</td>
</tr>
</tbody>
</table>

| max_bearer |
| Default: 11 |
| Specifies the maximum number of EPS bearers for a subscriber may simultaneously use to access this MME service. |
| max_bearer can be configured to any integer value between 1 and 11. |

Usage
Use this command to set the maximum number of EPS bearers that a subscriber may simultaneously use to access this MME service.

Example
The following command specifies that a maximum of 6 simultaneous EPS bearers can be facilitated for a subscriber at any given time:

max-bearers per-subscriber 6
max-paging-attempts

This command configures the maximum number of paging attempt retransmission allowed for network requested service creation to a subscriber while first attempt failed.

Product
MME

Privilege
Security Administrator, Administrator

Syntax

max-paging-attempt max_paging_retry

default max-paging-attempt

default
Configures the maximum number of retransmission of paging request to default value of 3.

max_paging_retry
Default: 3
Specifies the maximum number of paging attempt retransmission allowed for network requested service creation to a subscriber while first attempt failed.
max_paging_retry can be configured to any integer value between 1 and 10.

Usage
Use this command to set the maximum number of paging attempt retransmission allowed for network requested service creation to a subscriber while first attempt failed.

Example
The following command specifies that a maximum of 6 paging attempt retransmission allowed for network requested service creation to a subscriber while first attempt failed for a subscriber at any given time:

max-paging-attempt 6
max-pdns per-subscriber

This command specifies the maximum number of PDNs that a subscriber may simultaneously access through this MME service.

**Product**
MME

**Privilege**
Security Administrator, Administrator

**Syntax**

```
max-pdns per-subscriber max pdn
```

default max-pdns per-subscriber

```
default
Confirms the maximum PDNs for a subscriber simultaneously access through this MME service to default value of 3 PDNs.
```

```
max pdn
Default: 3
Specifies the maximum number of PDNs that a subscriber may simultaneously access through this MME service.
max pdn can be configured to any integer value between 1 and 11.
```

**Usage**
Use this command to set the maximum number of PDNs that a subscriber may simultaneously access through this MME service.

**Example**
The following command specifies that a maximum of 2 simultaneous PDNs can be accessed by a subscriber at any given time through this MME service:

```
max-pdns per-subscriber 6
```
mme-id

This command configures the MME identifier with an MME service. MME identifier is constructed with MME group ID and MME Code.

**Product**
MME

**Privilege**
Security Administrator, Administrator

**Syntax**

```
mme-id group-id grp_id mme-code mme_code
no mme-id
```

- `no` Removes the configured MME identifier for this MME service.

**Caution:** Removing the MME identifier is a disruptive operation; the MME service shall be removed from the service.

- `group-id grp_id`
  Specifies the group identifier of for the group of which this MME is belongs to. `grp_id` must be an integer value from 0 through 65535.

- `mme-code mme_code`
  Specifies the unique code for this MME service. `mme_code` must be an integer value from 0 through 255.

**Usage**
Use this command to set the MME identifier for this MME service. This MME identifier will be the identity of this MME in network.

**Caution:** Changing or removing the MME identifier is a disruptive operation; the MME service shall be re-started or removed from service.

**Example**
The following command configures the MME identifier with group id as 1025 and MME code as 101 for this MME service:

```
mme-id group-id 1025 mme-code 101
```
nas-max-retransmission

This command sets the retransmission counter for all type of NAS messages in an MME service.

Product
MME

Privilege
Security Administrator, Administrator

Syntax

nas-max-retransmissions nas_retrans_count

default nas-max-retransmissions

default
Resets the retransmission counter to the system default value of 4.

nas_retrans_count
Default: 4
Sets the maximum number of retransmission of NAS messages permitted during any procedure after which activation procedure will be discarded.

Usage
Use this command to set maximum number of retries allowed for any type of NAS messages. NAS Messages send by the MME which require a response from the UE for procedure completion are retransmitted. Retransmission happens based on timer expiry. The timers are configured through emm and esm command. The NAS messages are retransmitted as per configuration, and if no response from the UE is received, the pending transaction is abandoned. If the transaction is a DETACH or PDN DISCONNECT REQUEST, the transaction is completed without further UE signaling. The timeout duration configured through emm and esm command will be applicable between two retries.

Example
The following command sets the maximum number of retries allowed as 4 for all type of NAS messages in an MME service.

  default nas-max-retransmissions
pgw-address

This command configures the PDN Gateway (P-GW) address to use P-MIP protocol for S5 and S8 interface and other parameters with MME service. By default S5 and S8 use GTP protocol for this.

Product
MME

Privilege
Security Administrator, Administrator

Syntax

```
pgw-address address [ s5-s8-protocol pmip ] [ weight value ]
```

```
no pgw-address address [ s5-s8-protocol pmip ]
```

**no**
Removes a previously configured IP address of P-GW along with S5 and S8 interface of P-MIP protocol type and other parameters from this MME service.

**address**
Specifies the IP address of the P-GW.
*address* must be an IP address in IPv4 or IPv6 notation.

**s5-s8-protocol pmip**
Specifies that P-MIP type of protocol to use for S5 and S8 interfaces with P-GW. By default S5 and S8 interface uses GTP protocol.
*pmip* Sets the protocol to Proxy-MIP for S5 and S8 interface as by default GTP is the applicable protocol.

**weight value**
Assigns the weight to P-GW address to use as a preferred P-GW.
*value* must be an integer from 1 through 100. Lowest value has the least preference.

**Usage**
Use this command to configure the PDN Gateway (P-GW) addresses to use with MME service. This command also changes the default protocol or GTP to P-MIP for the S5 and S8 interface and weight to share the load between associated P-GWs. A maximum of 16 P-GW addresses can be configured with this command.
This command only changes the use of protocol in S5 and S8 interface. By default P-GW uses GTP protocol for S5 and S8 interfaces. By this command user can change the protocol to P-MIP for S5 and S8 interface. When weight is used, the weights of the P-GW(s) (that are operational) are totaled and then weighted round-robin selection is used to distribute new default bearer context among the P-GW(s) according to their weights.

**Example**
The following command associates the P-GW IP address of 192.168.3.1 to the MME service with S5 and S8 protocol as P-MIP and weight as 90:

```
pgw-address 192.168.3.1 s5-s8-protocol pmip weight 90
```

The following command removes the above configured P-GW IP address and other parameters:

```
no pgw-address 192.168.3.1 s5-s8-protocol pmip
```
**plmn-id**

This command configures the Public Land Mobile Network (PLMN) identifier for this MME service. PLMN identifier is made of Mobile Country Code (MCC) and Mobile Network Code (MNC). A maximum of 16 PLMN id can be configured in an MME service.

**Product**
MME

**Privilege**
Security Administrator, Administrator

**Syntax**

```
plmn-id mcc mcc_value mnc mnc_value
no plmn-id mcc mcc_value mnc mnc_value
```

- `plmn-id` Removes the configured PLMN identifier for this MME service.
- `no` Removes the configured PLMN identifier for this MME service.

**Usage**

Use this command to set the PLMN identifier for this MME service.

**Caution:** Removing the PLMN identifier is a disruptive operation; the MME service shall be re-started.

```
mcc mcc_value
```

Specifies the mobile country code (MCC) part of PLMN identifier.

- `mcc_value` must be an integer value from 101 through 998.

```
mnc mnc_value
```

Specifies the mobile network code (MNC) part of PLMN identifier.

- `mnc_value` must be an integer value from 01 through 99 or 100 through 998.

**Example**
The following command configures the PLMN identifier with MCC value as 102 and MNC value as 20 for this MME service:

```
plmn-id mcc 102 mnc 20
```
policy idle-mode

This command configures the user-defined policies of session management for LTE subscriber in an MME service.

Product
MME

Privilege
Security Administrator, Administrator

Syntax

policy idle-mode detach { explicit | implicit }

[ default ] policy idle-mode detach

default
Sets the policy of idle mode detach for a subscriber to its default behavior as implicit.

idle-mode detach
This keyword configures the IDLE mode detach behavior of a UE.

detach
This keyword defines the detach procedure while UE is in IDLE mode.

explicit
Default: disabled
This keyword enables the explicit detach while a UE is in IDLE mode. System will page UE before detach procedure started and then perform explicit detach procedure.

implicit
Default: Enabled
This keyword enables the implicit detach while a UE is in IDLE mode. System never send any message to UE before detach and performs explicit detach procedure immediately.

Usage
Use this command to set the user-defined policies for session management in this MME service.

Example
The following command sets the idle mode detach policy to explicit for a user in this MME service:

policy idle-mode detach explicit
policy overload

This command configures the traffic overload policy to control congestion in this service.

**Product**
MME

**Privilege**
Administrator

**Syntax**

```
policy overload { drop | reject }
default policy overload
```

- **default**
  Sets the traffic overload policy action to default behavior of reject.

- **drop**
  Default: Disabled
  Specifies that the system is to drop the incoming packets with new session requests to avoid overload on MME node.

- **reject**
  Default: Enabled
  This keyword configures the system to reject the new session/call request and responds with a reject message when threshold for allowed call session is crossed on MME node.

**Usage**
Use this command to set the user-defined policies for new call connection attempted during overload in an MME service.
Congestion policies at the service-level can be configured for service. When congestion control functionality is enabled at service level, these policies dictate how services respond should the system detect that a congestion condition threshold has been crossed.

**Example**
The following command sets the nw call connect policy to reject the new session/call request in an MME service:

```
policy overload reject
```
policy pdn-reconnection

This command configures the action by MME when a PDN connection request to an already connected APN is being processed by MME service.

**Product**
MME

**Privilege**
Security Administrator, Administrator

**Syntax**
```
policy pdn-reconnection { multiple | reject | restart }
[ default ] policy pdn-reconnection
```

---

**default**
Sets the policy of PDN reconnection to its default behavior of reject.

---

**multiple**
Default: Disabled
This keyword allows multiple connections to a PDN with same APN and PDN Type. In this case, the existing connection is left unchanged, and the MME attempts to establish an additional connection to the PDN.

---

**reject**
Default: Enabled
This keyword configures set the action of MME to deny or reject the request, by sending a PDN connection reject command. This is the default behavior.

---

**restart**
Default: Disabled
This keyword deletes the existing connection and initiate an attempt to establish a new connection.

**Usage**
Use this command to set the user-defined policies for PDN reconnection attempt procedures initiated by UE in an MME service.
While a UE is attached, the UE can request connections to PDNs. The PDNs are identified by APN (Access Point Name) and PDN Type (ipv4, ipv6 or ipv4v6).
If the UE requests connection to a PDN for which a connection with the same APN name and PDN type already exists, the MME can; 1) deny or Reject the request, by sending a PDN connection reject command; 2) allow multiple connections to a PDN with same APN and PDN Type; or 3) delete the existing connection, and attempt to establish a new connection.

**Example**
The following command sets the PDN reconnect policy to delete the existing PDN and start the attempt to establish a new connection in an MME service:
policy pdn-reconnection restart
s1-mme sctp port

This command configures the source SCTP port that will be used for binding the SCTP socket to communicate with the eNodeB using S1AP with this MME service.

Product
MME

Privilege
Security Administrator, Administrator

Syntax

s1-mme sctp port port_num

default s1-mme sctp port

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sets the SCTP port to default value of 699 to communicate with the eNodeBs using S1-MME interface.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>port_num</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the SCTP port number to communicate with the eNodeBs using S1-MME interface. port_num must be an integer between 1 through 65535.</td>
</tr>
</tbody>
</table>

Usage
Use this command to assign the SCTP port with SCTP socket to communicate with the eNodeB using S1AP. A maximum of one SCTP port can be associated with one MME service.

Example
The following command sets the default SCTP port number 699 for to interact with eNodeB using S1AP on S1-MME interface:

default s1-mme sctp port
setup-timeout

This command configures the timeout duration for call setup of MME calls in this MME service.

Product
MME

Privilege
Security Administrator, Administrator

Syntax

setup-timeout <dur>

default setup-timeout

default

Sets the call setup timeout duration to default value of 60 seconds.

dur

Default: 60
Specifies the call setup timeout duration for MME calls after which attempt will be discarded.
<dur> must be an integer between 1 through 10000.

Usage

Use this command to configured the timeout duration in seconds to setup an MME call with an MME service. One this duration exhausted Call setup procedure will be discarded with this MME service.

Example

The following command sets the default setup timeout duration of 60 seconds for MME calls:

default setup-timeout
ue-db

This command configures the UE database which is maintained by MME as cache of EPS context per UE keyed by IMSI/GUTI to allow UE to attach by GUTI and reuse previously established security parameters. This cache will be maintained in each session manager where the first attach occurred for an UE.

Product
MME

Privilege
Security Administrator, Administrator

Syntax

```plaintext
ue-db purge-timeout dur_mins
default ue-db purge-timeout
```

**default**

Resets the UE database purge timer timeout to the system default value of 10080 mins.

**purge-timeout**  

`dur_mins`

Default: 10080
Sets the timeout duration for MME to store UE database in cache memory. This timer starts when UE goes in dormant.
`dur_mins` is timeout duration in minutes and must be an integer from 1 through 20160.

Usage

Use this command to set timeout duration for MME to hold UE database information in cache memory. The MME DB acts as a cache for storing subscriber related information. This subscriber related information helps in reducing signaling traffic. The MME DB is a part of the Session Manager and interfaces between the Session Manager Application and Evolved Mobility Management Manager to provide access to the cached data.

Example

The following command configures the MME database cache timer to hold the UE information up to 7 days (10080 minutes) in MME Database:

```plaintext
default ue-db purge-timeout
```
Chapter 146
Network Service Entity- IP Local Configuration Mode Commands

The Network Service Entity (NSE) - IP Local configuration mode is a sub-mode of the Global Configuration mode. This sub-mode configures the local endpoint for NS/IP with the commands and parameters to define the management functionality for the Gb interface between a BSS and an SGSN over a 2.5G GPRS IP network connection.

Upon entering this mode, the prompt will appear in a manner similar to:

```
[local]hostname(nse-ip-local)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
all-nsvc-failure-action

Configure how the SGSN handles the NSE when all NSVCs go down.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
all-nsvc-failure-action clear-nse
default all-nsvc-failure-action
```

- **default**
  By default, the NSE is not cleared if all NSVCs go down.

- **clear-nse**
  Instructs the SGSN to clear NSEs if all NSVCs to the BSC are down.

**Usage**
Enable the SGSN to clear NSE information when all NSVCs go down.

**Example**
Use the following command to configure the SGSN to clear NSEs when all NSVCs go down.

```
all-nsvc-failure-action clear-nse
```
bssgp-timer

This command has been deprecated.
end

Exits the current configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
```
end
```

Usage
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the global configuration mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Returns to the global configuration mode.
max-ns-retransmissions

This command configures the maximum number of transmission retries counter.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

[ default ] max-ns-retransmissions { alive count | sns-proc count }

---

default
Resets the specified counter configuration to the default value.

---

alive count
Sets the maximum number of alive retries.

*count*: Must be an integer between 0 and 10. Default is 3.

---

sns-proc count
Sets the maximum number of retries for the SNS procedure.

*count*: Must be an integer between 0 and 5. Default is 3.

---

Usage

Sets the maximum for NS transmission retries.

Example

max-ns-retransmission alive 4
ns-timer

This command sets the network service (NS) counters for the SNS procedure and testing.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

ns-timer { sns-prov timeout_val | test timeout_val }

default ns-timer { sns-prov | test }

default
Resets the selected timer configuration to its default value.

sns-prov timeout_val
Sets the SNS procedure timeout value in seconds.
timeout_val: Enter an integer from 1 to 10. Default is 5.

test timeout_val
Sets the test procedure timeout value in seconds.
timeout_val: Enter an integer from 1 to 60. Default is 30 seconds.

Usage
Set NS timers to help manage the NSE-IP connection.

Example
The following example sets the test timer to 4 seconds:

ns-timer test 4
nsvc-failure-action

This command enables and disables the sending of an NS-STATUS message with cause ‘ip-test fail’ when NSVC goes down.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```text
nsvc-failure-action send-ns-status
```

default nsvc-failure-action

---

**default**

Resets the command configuration to its default value. The default action is not to send an NS-STATUS message. This is applicable only to NSVCs that are auto-learned and not configured.

---

**send-ns-status**

Enables the sending of the NS-STATUS message.

---

**Usage**

Use this command to enable or disable sending an NS-STATUS messages when an NSVC goes down.

---

**Example**

Enable sending of the message:

```text
nsvc-failure-action send-ns-status
```
nsvl

This command creates an instance of a network service virtual link (NSVL) and enters the NSVL configuration mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

[ no ] nsvl instance nsvl_id

- **no**
  - Removes the identified NSVL definition from the configuration.

- **instance** nsvl_id
  - Identifies a specific NSVL configuration instance.
  - **nsvl_id**: Must be an integer from 0 to 3.

Usage
Access the NSVL configuration mode.

Example
Enter the NSVL configuration sub-mode to modify the configuration for NSVL instance 2:

```
nsvl instance 2
```
peer-network-service-entity

This command has been replaced by the Network Service Entity - Peer NSEI Frame Relay configuration mode.
retry-count

This command has been replaced by the `max-ns-retransmissions` command.
This command has been replaced by the `ns-timer` command.
Chapter 147
Network Service Entity - Peer NSEI Configuration Mode Commands

The Network Service Entity (NSE) - Peer NSEI configuration mode configures the Frame Relay parameters for the peer NSE. This mode is a sub-mode of the Global Configuration mode. This sub-mode provides the commands and parameters to define the management functionality for the Gb interface between a BSS and an SGSN over a 2.5G GPRS Frame Relay network connection.

Upon accessing this mode, the prompt should be similar to:

   [local]hostname(nse-fr-peer-nsei-<nse_id>)#

---

**Important**: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
bssgp-timer

This command has been deprecated.
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```plaintext
end
```

**Usage**
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the previous configuration mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Return to the global configuration mode.
ns-reset-mode

The command configures automatic NS-Reset for a specific Frame Relay peer NSE (network service entity).

**Product Privilege Syntax**

- **default**
- **active**
  Configures active mode so that the SGSN is enabled to initiate NS-Reset without manual intervention.
- **passive**
  Configures passive mode which means the SGSN continues *not* to initiate NS-Reset. This is the default mode.

**Usage**

Use this command to configure the SGSN for active mode regarding the peer NSE, so that the SGSN will initiate:
- NS-Reset when NSVC-DLCI binding is done.
- NS-Reset when the link goes down and then comes back.
- NS-Unblock upon receipt of NS-Reset-Ack message.

Active mode is useful in the following scenarios:
- If the SGSN detects LMI down but the BSC does not detect any link failure so does not send NS-Reset.
- If the NS layer can go down and the SGSN will mark the link as ‘Blocked-Dead’. If the link comes up later, the NS layer state for that link will remain in the Blocked state.

**Example**

Configure active mode to perform NS-Reset when the link goes down and comes back up:

```
ns-reset-mode active
```
**ns-vc**

This command creates a network service virtual circuit (NSVC) for this frame relay NSE and enters the configuration sub-mode to define the NSVC parameters. These parameters are described in the NSVC Configuration Mode chapter elsewhere in this CLI Reference Guide.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] ns-vc id ns-vc_id
```

- **no**
  Removes the specified NSVC configuration.

- **id ns-vc_id**
  This keyword defines the NSVC configuration identifier.
  
  \textit{ns-vc_id}: Must be an integer from 0 to 65535

**Usage**

Access the NSVC configuration mode.

**Example**

Gain access to the NSVC configuration mode to change the 4th instance.

```
ns-vc id 4
```
Chapter 148
Network Service Virtual Connection Configuration Mode Commands

The Network Service Virtual Connection (NSVC) configuration mode is a sub-mode of the Network Service Entity (NSE) - Peer NSEI (for Frame Relay) configuration mode. The NSVC sub-mode creates a configuration instance for a specific NSVC, within the Gb interface, between a BSS and an SGSN in a 2.5G GPRS Frame Relay network connection.

Upon accessing this mode, the prompt will appear similar to:

```
[local] hostname(nse-fr-peer-nsei-<nse_id>-nsvc<-nsvc_id>)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
```
end
```

Usage
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the previous configuration mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Returns to the network service entity - frame relay configuration mode.
Chapter 149
Network Service Virtual Link Configuration Mode Commands

The Network Service Virtual Link configuration mode is a sub-mode of the Network Service Entity - IP configuration mode. This sub-mode provides the commands and parameters to define the NSVL of the Gb interface between a BSS and an SGSN in a 2.5G GPRS IP network connection.

Upon entering this mode, the prompt should appear similarly to the following:

```
[local]hostname(nse-ip-local-nsvl-<nsvl_id>)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the previous configuration mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```bash
exit
```

Usage

Return to the network service entity - IP configuration mode.
nsvl-address

This command configures the IP address of the NSVL end-point.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
nsvl-address ip-address ip_address context ctxt_name port port_num
```

**Usage**
Use this command to configure the IP address, context name and port number for the NSVL end-point.

**Example**

```
nsvl-address ip-address 1.1.1.1 context sgsn2 port 3735
```
**weight**

This command configures the signaling or data weight for NSVL.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
weight { data data_weight | signaling signaling_weight }
```

**data data_weight**
Defines the data weight for the NSVL.
`data_weight`: Must be an integer from 0 to 255. Default is 1.

**signaling signaling_weight**
Defines the signaling weight for the NSVL.
`signaling_weight`: Must be an integer from 0 to 255. Default is 1.

**Usage**
Configure the weight of the signaling or data for the NSVL.

**Example**

```
weight data 234
```
Chapter 150
NTP Configuration Mode Commands

The Network Timing Protocol Configuration Mode is used to manage the NTP options for the entire system.
enable

Enables the use of the network timing protocol for updating the system clock.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
enable [ context ]
```

**context**
Default: local
Specifies the context for which NTP is to be enabled. name must refer to a previously configured context.

**Usage**
Set the NTP server to be used for the system. Only one NTP server may be active at any given time. If this command were issued in a different context followed by the current context, the prior context’s NTP server would be disabled and the current context’s NTP server would be used.

If any NTP server is enabled, the chassis system clock will be synchronized to the active NTP server which covers all contexts for timing synchronization.

The use of a given context for NTP server assignment is to inherit the domain and IP routing options of the configured context.

**Example**

```plaintext
enable sampleContext
```
end

Exits the NTP configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
end
```

Usage
Change the mode back to the Exec mode.
exit

Exits the NTP configuration mode and returns to the global configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Return to the global configuration mode.
**server**

Configures an NTP server for use by the local NTP client in synchronizing the system clock.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
server ip_address [ prefer ] [ version number ] [ minpoll poll_period ] [ maxpoll poll_period ]
```

```
no server ip_address
```

- **no**
  Indicates the server specified is to be removed from the list of NTP servers for clock synchronization.

- **ip_address**
  Specifies the IP address of the NTP server to allow for clock synchronization. `ip_address` must be specified using the standard IPv4 dotted decimal notation.

- **prefer**
  Indicates the NTP server specified to be the preferred server. Only one server can be set to preferred. The preferred server is first contacted for clock synchronization.

> **Important:** Use of the prefer keyword is not recommended.

- **version number**
  Default: 4
  Specifies the network timing protocol version to use for server communications. `number` must be a value in the range from 1 to 4.

- **minpoll poll_period**
  Default: 6
  Specifies the minimum polling interval for NTP messages, in seconds, as a power of 2. `poll_period` is the power or exponent. For example, if you specify the number 10, the value is $2^{10}$ and the resultant poll period is 1024 seconds. `poll_period` must be an integer from 6 through 17.

- **maxpoll poll_period**
  Default: 10
  Specifies the maximum polling interval for NTP messages, in seconds, as a power of 2. `poll_period` is the power or exponent. For example, if you specify the number 10, the value is $2^{10}$ and the resultant poll period is 1024 seconds. `poll_period` must be an integer from 6 through 17.
**Usage**
Configure the network timing protocol servers in the network as changes occur.

**Important:** Adding, removing, or modifying an NTP server configuration entry causes the NTP client to restart and restart the synchronization process with all configured NTP servers.

**Example**
The following command adds the NTP server with address 1.2.3.4 to the list of NTP servers.

```
server 1.2.3.4
```

The following marks the server with IP address 1.2.3.4 as the preferred NTP server.

```
server 1.2.3.4 prefer
```
Chapter 151
ORBEM Configuration Mode Commands

The ORB Element Manager Configuration Mode is used to manage the ORBEM server options for the current context.

```
Exec Mode
  configure
  Global Configuration Mode
    orbem
    ORBEM Configuration Mode
```
activate

Activates/deactivates a client for the ORB element management system interface.

Product
All

Privilege
Security Administrator, Administrator

Syntax

active client id

no active client id

no
Indicates the client specified is to be deactivated. When omitted, the client is activated.

id name
Specifies the client to be activated. name must refer to a previously configured client.

Usage
Activate clients after they have been configured or deactivated by the system or by configuration.

Example

active client sampleClient

no active client sampleClient
client

Configures/removes a client from the ORB element manager system interface.

Product
All

Privilege
Security Administrator, Administrator

Syntax

client id name [ encrypted ] password pwd

no client id name

no
Indicates the client specified is to be removed from the configuration.

id name
Specifies the client to be configured. name must be from 1 to 10 alpha and/or numeric characters in length.

encrypted
Indicates password specified is encrypted.
The encrypted keyword is intended only for use by the chassis while saving configuration scripts. The system displays the encrypted keyword in the configuration file as a flag that the variable following the password keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file.

password pwd
Specifies the password for the client. pwd must be from 1 to 35 alpha and/or numeric characters.

Usage
Clients for ORB element manager access must be configured prior to being activated.

Example
The following commands set the password for client sampleClient specifying a plain text password and an encrypted password as well.

client id sampleClient password secretPassword
client id sampleClient encrypted password f54gi801sd

The following deletes sampleClient from the configuration.

no client id sampleClient
default

Restores the system default values for the option specified.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
default { event-notif-iiop-port | event-notif-service filter | event-notif-siop-port | iiop-port | iop-address | max-attempt | session-timeout | siop-port }
```

**event-notif-iiop-port**
Restores the port number for the inter-ORB event notifications to the system default: 7778.

**event-notif-service filter**
Restores the ORB Notification Service filter to its default behavior of sending all “error” level and higher events, and “info” level events for the orbs facility, CLI command logs, and license change logs.

**event-notif-siop-port**
Restores the port to use for secure socket layer inter-ORB event communication to the system default: 7777.

**iiop-port**
Restores the port number for the inter-ORB communications to the system default: 14132.

**iop-address**
Restores the IP address for the inter-ORB communications to the system default: IP address of current context.

**max-attempt**
Restores the maximum number of failed login attempts before which the client is deactivated to the system default: 3 attempts.

**session-timeout**
Restores the amount of idle time (no activity) before a session is terminated to the system default: 300 seconds.

**siop-port**
Restores the secure socket layer I/O port for inter-ORB events to the system default: 14131.

**Usage**

Restore the ORB element manager options to a well known values, the system defaults.
Example

    default event-notif-iiop-port
    default max-attempt
end

Exits the ORBEM configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Change the mode back to the Exec mode.
event-notif-iiop-port

Configures the port number for the Internet inter-ORB event notifications.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
event-notif-iiop-port number
```

number
Default: 7778
Specifies the port number to use as a number between 1 and 65535.

Usage
Explicitly set the port number when the default port number is not the desired port value for integrating multiple products together for standardized inter-ORB communications.
Event notification port configured is only used if the Internet inter-ORB transport is enabled via the `iiop-transport` command with the event notification service being enabled as well.

Example

```
event-notif-iiop-port 25466
```
**event-notif-service**

Enables/disables the ORB Notification Service and allows the configuration of filters dictating which event notifications are sent.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```
event-notif-service [ filter { event-id event_id [ to final_event_id ] | facility event_facility level event_level } ]
```

```
no event-notif-service [ filter { event-id event_id [ to final_event_id ] | facility event_facility level event_level } ]
```

```
no
```

Indicates the event notification service is to be disabled.

**filter**

Allows the specification of a filter dictating which events the system sends notifications for.

```
event-id event_id [ to final_event_id ]
```

Specifies an event filter based on event identification (event ID) number.

- `event_id` is a specific event ID to filter or is the initial event ID in range if the `to` keyword is used. It can be configured to any integer value between 1 to 100,000.
- `to` allows the specification of a range of event IDs to filter. When used, `final_event_id` specifies the last event ID in the range to be filtered. It can be configured to any integer value between 1 to 100,000 but should be a value greater than the initial event ID.

```
facility event_facility level event_level
```

Specifies an event filter based on facility type and notification severity level.

- `event_facility` specifies the facility type and can be any one of the following:
  - `a10`: A10 interface facility
  - `a11`: A11 interface facility
  - `a1mgr`: A11 Manager facility
  - `aaa-client`: AAA client facility
  - `aaamgr`: AAA manager logging facility
  - `aaaproxy`: AAA Proxy facility
  - `acl-log`: Access Control List logging facility
  - `acctrl`: Active Charging Service (ACS) Controller facility
  - `acsmgr`: Active Charging Service (ACS) Manager facility
  - `alarmctrl`: Alarm Controller facility
• all: All facilities
• asf: Voice Application Server Framework logging facility
• asfprt: ASF Protocol Task (SIP) logging facility
• asnwmgr: ASN Gateway Manager facility
• asnlrmgr: ASN Paging/Location-Registry Manager facility
• bgp: Border Gateway Protocol (BGP) facility
• cli: CLI logging facility
• cscf: IMS/MMD CSCF
• cscfmgr: SIP CSCF Manager facility
• csp: Card Slot Port controller facility
• css: Content Service Selection (CSS) facility
• css-sig: Content Service Selection (CSS) RADIUS Signaling facility
• dcardctrl: IPSEC Daughtercard Controller logging facility (not used at this time)
• dcardmgr: IPSEC Daughtercard Manager logging facility (Not used at this time)
• dhcp: DHCP facility (GGSN product only)
• dhost: Distributed Host logging facility
• diameter: Diameter endpoint logging facility
• diameter-ecs: ECS Diameter signaling facility
• dpath: IPSEC Data Path facility
• drvctrl: Driver Controller facility
• evlog: Event log facility
• famgr: Foreign Agent manager logging facility
• gss-gcdr: GTPP Storage Server GCDR facility
• gtp: GTP-C protocol logging facility (GGSN product only)
• gtpcmgr: GTP-C protocol Manager logging facility (GGSN product only)
• gtppm: GTP-PRIME protocol logging facility (GGSN product only)
• gtpu: GTP-U protocol logging facility (GGSN product only)
• h248prt: H.248 Protocol logging facility
• hamgr: Home Agent manager logging facility
• hat: High Availability Task (HAT) process facility
• ims-authorizatn: IMS Authorization Service facility
• ip-arp: IP Address Resolution Protocol facility
• ip-interface: IP interface facility
• ip-route: IP route facility
• ipsec: IP Security logging facility
• ipsmgr: IP Services Gateway facility
• ipsp: IP Pool Sharing Protocol logging facility
ORBEM Configuration Mode Commands

- **l2tp-control**: L2TP control logging facility
- **l2tp-data**: L2TP data logging facility
- **l2tpdemux**: L2TP Demux Manager logging facility
- **l2tpmgr**: L2TP Manager logging facility
- **li**: Lawful intercept facility (Logs are visible only to system accounts with li-administrator privileges.)
- **mobile-ip**: Mobile IP processes
- **mobile-ip-data**: Mobile IP data facility
- **multicast-proxy**: Multicast Proxy logging facility
- **netwstrg**: Network Storage facility
- **npuctrl**: Network Processor Unit Control facility
- **npumgr**: Network Processor Unit Manager facility
- **nsctrl**: Charging Service Controller facility (supported in conjunction with ECSv1)
- **nsmgr**: Charging Service Manager facility
- **nsproc**: Charging Service process facility
- **orbs**: Object Request Broker System logging facility
- **ospf**: OSPF logging facility
- **ppp**: PPP link and packet facilities
- **radius-acct**: RADIUS accounting logging facility
- **radius-auth**: RADIUS authentication logging facility
- **radius-coa**: RADIUS change of authorization and radius disconnect
- **rct**: Recovery Control Task logging facility
- **rdt**: Redirect Task logging facility
- **resmgr**: Resource Manager logging facility
- **rip**: RIP logging facility (RIP is not supported at this time.)
- **rohc**: RObust Header Compression facility
- **rsvp**: Reservation Protocol logging facility
- **sct**: Shared Configuration Task logging facility
- **sessctrl**: Session Controller logging facility
- **sessmgr**: Session Manager logging facility
- **sft**: Switch Fabric Task logging facility
- **sipcdprt**: Sip Call Distributor facility
- **sitmain**: System Initialization Task main logging facility
- **snmp**: SNMP logging facility
- **srdb**: Static Rating Database
- **srp**: Service Redundancy Protocol (SRP) logging facility
- **ssh-ipsec**: SSH IP Security logging facility
- **stat**: Statistics logging facility
event-notif-service

- **system**: System logging facility
- **tacacsplus**: TACACS+ Protocol logging facility
- **threshold**: threshold logging facility
- **udr**: User detail record facility (used with the Charging Service)
- **user-data**: User data logging facility
- **user-l3tunnel**: User layer-3 tunnel logging facility
- **vpn**: Virtual Private Network logging facility
- **wimax-data**: WiMAX DATA
- **wimax-r6**: WiMAX R6

`event_level` specifies the severity level of the event notification to filter and can be configured to one of the following:
- **critical**: display critical events
- **error**: display error events and all events with a higher severity level
- **warning**: display warning events and all events with a higher severity level
- **unusual**: display unusual events and all events with a higher severity level
- **info**: display info events and all events with a higher severity level
- **trace**: display trace events and all events with a higher severity level
- **debug**: display all events

**Usage**

This command is used to enable or disable the ORB Notification Service. Additionally, it can be used to configure filters dictating which events are sent. This service is disabled by default.

Filters can be configured for a specific event identification number (event ID), a range of event IDs, or specific severity levels for events for particular facilities.

When no filters are configured and the service is enabled, the ORB Notification Service sends all “error” level and higher events, and “info” level events for the orbs facility, CLI command logs, and license change logs.

Multiple instance of this command can be executed to configure multiple filters.

**Example**

The following command enables the ORB Notification service:

```
   event-notif-service
```

The following command disables the ORB Notification service:

```
   no event-notif-service
```

The following command configures a filter for the ORB Notification Service allowing only event IDs 800 through 805 to be sent:

```
   event-notif-service filter event-id 800 to 805
```
The following command configures a filter for the ORB Notification Service allowing only “critical” level notifications for the A11 facility:

```
event-notif-service filter facility all level critical
```
event-notif-siop-port

Configures the port to use for secure socket layer inter-ORB event communication.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
event-notif-siop-port number
```

*number*
Default: 7777
Specifies the port number to use as a number between 1 and 65535.

**Usage**
Explicitly set the port number when the default port number is not the desired port value for integrating multiple products together for inter-ORB communications using SSL.

**Example**

```
event-notif-siop-port 25466
```
exit

Exits the ORBEM configuration mode and returns to the global configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**
Return to the global configuration mode.
**iiop-port**

Configures the port number for the internet inter-ORB communications.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] iiop-port number
```

- **no**
  Disables the iiop port.

- **number**
  Default: 14132
  Specifies the port number to use as a number between 1 and 65535.

**Usage**
Explicitly set the port number when the default port number is not the desired port value for integrating multiple products together for standardized inter-ORB communications.

Internet inter-ORB port is only used if the Internet inter-ORB transport is enabled via the `iiop-transport` command.

**Example**

```
iiop-port 25466
```
**iiop-transport**

Enables/disables use of the Internet Inter-ORB Protocol for management across the network.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```
iiop-transport
no iiop-transport

no
```

Indicates no internet inter-ORB protocol communication is to take place across the network.

**Usage**

Enable the transport of Internet Inter-ORB Protocol messages to support remote management across the network.

The chassis is shipped from the factory with the Internet Inter-ORB transport disabled.

**Example**

The following commands enable and disable the ORB-based management across the network, respectively.

```
iiop-transport
no iiop-transport
```
iop-address

Enables/disables use of the Internet Inter-ORB Protocol for management across the network.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
iop-address ip_address
```

- `ip_address`
  Specifies the IP address to use for inter-ORB communications for the current context. `ip_address` must be specified using the standard IPv4 dotted decimal notation.

Usage
Change the inter-ORB IP address when the IP address of the current context should not be used. The IP address of the local context may not be appropriate when the ORB configuration across nodes would cause conflicts with the IP addresses. The chassis is shipped from the factory with the inter-ORB IP address defaulted to the IP address of the current context.

Example

```
iop-address 1.2.3.4
```
**max-attempt**

Configures the maximum number of failed login attempts before which the client is deactivated.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
max-attempt count
```

- **count**
  Default: 3 attempts
  Specifies the number of failed login attempts prior to deactivating a client. The value must be within the range of 1 through 10.

**Usage**

Adjust the maximum number of attempts to a smaller value to increase the security level of the system.

**Example**

```
max-attempt 3
```
**session-timeout**

Configures the amount of idle time (no activity) before a client session is terminated.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```
session-timeout seconds
```

*seconds*

Default: 300 seconds

Specifies the number of seconds of idle time before a client session is terminated. The value must be in the range of 1 through 86400.

**Usage**

Reduce the session timeout when the maximum number of sessions allowed is frequently being reached. Setting this to a lower value will help release idle sessions faster to allow use by other clients.

**Example**

```
session-timeout 1800
```
siop-port

Configures the secure socket layer I/O port for inter-ORB events.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
siop-port number
```

- `number`

  Default: 14131
  Specifies the port number to use as a number between 1 and 65535.

**Usage**

Explicitly set the port number when the default port number is not the desired port value for integrating multiple products together for inter-ORB communications.

**Example**

```
siop-port 25466
```
ssl-auth-policy

Configures the secure socket layer peer authentication policy used by the ORBEM server.

Product
All

Privilege
Security Administrator, Administrator

Syntax

ssl-auth-policy { auth-none | auth-once | auth-once-fail | auth-peer | auth-peer-fail }

Default: auth-none

auth-none: ORBEM server does not authenticate the peer
auth-once: ORBEM server authenticates the peer once (no fail)
auth-once-fail: ORBEM server authenticates the peer once (fail if no certificate)
auth-peer: ORBEM server authenticates the peer every time (no fail)
auth-peer-fail: ORBEM server authenticates the peer every time (fail if no certificate)

Usage
Use to configure the peer authentication policy used by the SSL transport of ORBEM.

Example
The following command sets the policy to authenticate the peer once without failure.

ssl-auth-policy auth-once
ssl-certificate

Defines the certificate to be used by the SSL transport of ORBEM.

Product

All

Privilege

Security Administrator, Administrator

Syntax

ssl-certificate { string certificate | file url }

string certificate

Specifies an ORBEM SSL certificate. certificate is a string of up to 4096 alpha and/or numeric characters.

file url

Default: /usr/ssl/certs/orbscert.pem

Specifies an ORBEM SSL certificate file and location. url is a string of up to 1024 alpha and/or numeric characters.

Usage

Use to configure the certificate to be used by the SSL transport of ORBEM. Note that if file option is used, the certificate content is read from the url and converted into quoted string.

Example

The following command defines the certificate cert3.pem file as being located in the /usr/ssl/certs directory:

    ssl-certificate file /usr/ssl/certs/cert3.pem

The following command defines the certificate string (the string shown is abbreviated):

    ssl-certificate string

-----END CERTIFICATE-----
ssl-private-key

Configures the SSL private key used by the ORBEM server.

Product
All

Privilege
Security Administrator, Administrator

Syntax

ssl-private-key { string key | file url }

string key
Specifies an ORBEM SSL private key. key is a string of up to 4096 alpha and/or numeric characters.

file url
Default: /usr/ssl/certs/orbscert.pem
Specifies the ORBEM SSL private key file location. url is a string of up to 1024 alpha and/or numeric characters.

Usage
Use to configure the private key to be used by the SSL transport of ORBEM. Note that if file option is used, the private key is read from the url and converted into quoted string.

Example
The following command defines the private key cert3.pem file as being located in the /usr/ssl/certs directory:

ssl-private-key file /usr/ssl/certs/cert3.pem

The following command defines the private key string (the string shown is abbreviated):

ssl-private-key string

Chapter 152
OSPF Configuration Mode Commands

The OSPF Configuration sub-mode is used to configure the OSPF routing protocol. This mode includes commands that configure OSPF routing parameters.

```
Exec Mode
    configure
    Global Configuration Mode
        context name
        Context Configuration Mode
            router ospf
            OSPF Configuration Mode
```

**Important**: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
area authentication

Enables authentication for the specified OSPF area.

**Product**

PDSN, HA GGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
area { ipaddress|decimal_value} authentication[message-digest]
no area { ipaddress|decimal_value} authentication[message-digest]
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Disables authentication for the specified area.</td>
</tr>
</tbody>
</table>

| ipaddress | IP address in IPv4 dotted-decimal notation of the area where authentication will be enabled. |

| decimal-value | The identification number of the area where authentication will be enabled. This must be an integer from 0 through 4294967295. |

| message-digest | Sets the OSPF authentication type to use the message digest 5 (MD5) authentication method. |

**Usage**

Use this command to enable authentication of OSPF areas.

**Example**

The following command enables authentication for an OSPF area defined by the IP address 192.168.100.10 and the OSPF authentication type to MD5:

```
area 192.168.100.10 authentication message-digest
```
area default-cost

This command configures the default cost for an area.

Product
PDSN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

```
area \{ ipaddress|decimal_value \} default-cost cost_value
no area \{ ipaddress|decimal_value \} default-cost cost_value
```

no
Deletes the default cost for the area.

```
ipaddress
The IP address, in IPv4 dotted-decimal notation, of the area.
```

```
decimal-value
The identification number of the area. This must be an integer from 0 through 4294967295.
```

```
cost_value
The default cost to be configured for the specified area. This must be an integer from 0 through 16777215.
```

Usage
Use this command to configure the default cost for an OSPF area.

Example
The following command sets the default cost for an OSPF area defined by the IP address 192.168.100.10 to 300: area 192.168.100.10 default-cost 300
area nssa

Define an area as an NSSA (Not So Stubby Area) and configure OSPF parameters for it.

Product
PDSN, HA GGSN

Privilege
Security Administrator, Administrator

Syntax

```plaintext
area {ipaddress|decimal_value} nssa [ default-information-originate | no-redistribution | no-summary | translate-always | translate-candidate | translate-never ]
```

- **ipaddress**
The IP address, in IPv4 dotted-decimal notation, of the NSSA area.

- **decimal-value**
The identification number of the NSSA area. This must be an integer from 0 through 4294967295.

- **default-information-originate**
Originate default information to the NSSA area

- **no-redistribution**
Do not redistribute external routes to the NSSA area

- **no-summary**
Do not inject inter-area routes into NSSA

- **translate-always**
Configure NSSA-ABR to always translate

- **translate-candidate**
Configure NSSA-ABR for translate election (This is enabled by default.)

- **translate-never**
Configure NSSA-ABR to never translate
Usage

Use this command to define NSSA areas.

Example

The following command defines the area designated by the IP address 192.168.100.10 as an NSSA area:

```
area 192.168.100.10 nssa
```
area stub

This command defines an area as a stub area.

**Product**
PDSN, HAGGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
area {ipaddress|decimal_value} stub [no-summary]
no area {ipaddress|decimal_value} stub [no-summary]
```

- **ipaddress**
The IP address, in IPv4 dotted-decimal notation, of the stub area.

- **decimal-value**
The identification number of the stub area. This must be an integer from 0 through 4294967295.

- **no-summary**
Disables (stops) the ABR from sending summary LSAs into the stub area.

**Usage**
Use this command to define an OSPF area as a stub area.

**Example**
The following command defines the OSPF area defined by the IP address 192.168.100.10 as a stub area:

```plaintext
area 192.168.100.10 stub
```
area virtual-link

This command configures a virtual link between an area that cannot be physically connected to the network backbone and an area that is physically connected to the network backbone.

**Product**
PDSN, HA, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
area { ip|addr|decimal_value } virtual-link router_id|address
no area { ip|addr|decimal_value } virtual-link router_id|address
```

- `no`
  Disables area virtual-link.

- `ip|address`
  The IP address, in IPv4 dotted-decimal notation, of the transit area.

- `decimal-value`
  The identification number of the transit area. This must be an integer from 0 through 4294967295.

- `router_id|address`
  The router id, in dotted-decimal notation, of the ABR to be linked to.

**Usage**

Use this command to create a virtual link between an area that is connected to the network backbone and an area that cannot be connected to the network backbone.

**Example**

The following command creates a virtual link between the OSPF areas defined by the IP address 192.168.100.10 and the IP address 192.168.200.20:

```
area 192.168.100.10 virtual-link 192.168.200.20
```
area virtual link authentication

This command configures the OSPF authentication method to be used by the virtual link between an area that cannot be physically connected to the network backbone and an area that is physically connected to the network backbone.

**Product**
PDSN, HA, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
area { ipaddress | decimal_value } virtual-link router_id_address
authentication {message-digest | null | text}
no area { ipaddress | decimal_value } virtual-link router_id_address
authentication {message-digest | null | text}
```

**Disables area virtual link authentication**

```
ipaddress
The IP address, in IPv4 dotted-decimal notation, of the transit area.

decimal-value
The identification number of the transit area. This must be an integer from 0 through 4294967295.

router_id_address
The router id, in dotted-decimal notation, of the ABR to be linked to.

message-digest
Set the OSPF authentication type to use the message digest (MD) authentication method.

null
Set the OSPF authentication type to use no authentication, thus disabling either MD or clear text methods.

text
Set the OSPF authentication type to use the clear text authentication method.
```

**Usage**

Use this command to set the authentication method for a virtual link between an area that is connected to the network backbone and an area that cannot be connected to the network backbone.

**Example**
The following command sets the authentication method for a virtual link between the OSPF areas defined by the IP address 192.168.100.10 and the IP address 192.168.200.20 to use no authentication:
area 192.168.100.10 virtual-link 192.168.200.2 null
area virtual-link authentication-key

This command configures the authentication password for the virtual link between an area that cannot be physically connected to the network backbone and an area that is physically connected to the network backbone.

**Product**
PDSN, HA, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
area { ipaddress | decimal_value } virtual-link router_id_address
  authentication-key [encrypted password encrypted_authentication_key]
  password authentication_key

no area { ipaddress | decimal_value } virtual-link router_id_address authentication-key
  [encrypted password encrypted_authentication_key] password authentication_key
```

```
o
```

Disables area virtual link authentication key.

**ipaddress**
The IP address, in IPv4 dotted-decimal notation, of the transit area.

**decimal-value**
The identification number of the transit area. This must be an integer from 0 through 4294967295.

**router_id_address**
The router id, in dotted-decimal notation, of the ABR to be linked to.

**encrypted_password**

`encrypted_authentication_key` is a string variable of size 1 to 523.
Use this if you are pasting a previously encrypted authentication key into the CLI command.

**password authentication_key**
The password to use for authentication. `authentication_key` is a string variable, from 1 through 16 alphanumeric characters, that denotes the authentication password. This variable is entered in clear text format.

**Usage**

Use this command to specify the authentication password for a virtual link between an area that is connected to the network backbone and an area that cannot be connected to the network backbone.

**Example**

---

**Cisco ASR 5000 Series Command Line Interface Reference**

4364
The following command creates an authentication password of 123456 for a virtual link between the OSPF areas defined by the IP address 192.168.100.10 and the IP address 192.168.200.20:

```
area 192.168.100.10 virtual-link 192.168.200.20 authentication-key password 123456
```
area virtual link intervals

This command configures the interval or delay type, and the delay time in seconds, for the virtual link between an area that cannot be physically connected to the network backbone and an area that is physically connected to the network backbone.

**Product**
PDSN, HA, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
area \{ ipaddress|decimal_value \} virtual-link router_id_address[dead-interval value][hello-interval value][retransmit-interval value][transmit-delay value][dead-interval value][hello-interval value][retransmit-interval value][transmit-delay value]
```

```
no area \{ ipaddress|decimal_value \} virtual-link router_id_address[dead-interval value][hello-interval value][retransmit-interval value][transmit-delay value][dead-interval value][hello-interval value][retransmit-interval value][transmit-delay value]
```

**no**
Disables area virtual link intervals.

**ipaddress**
The IP address, in IPv4 dotted-decimal notation, of the area.

**decimal-value**
The identification number of the transit area. This must be an integer from 0 through 4294967295.

**router_id_address**
The router id, in dotted-decimal notation, of the ABR to be linked to.

**dead-interval value**
The interval, in seconds, that the router should wait, during which time no packets are received and after the router considers a neighboring router to be off-line. value must be an integer from 1 through 65535.

**hello-interval value**
The interval, in seconds before sending a hello packet. value must be an integer from 1 through 65535.

**retransmit-interval value**
The interval, in seconds, that router should wait before retransmitting a packet. value must be an integer from 1 through 3600.
transmit-delay value

The interval, in seconds, that the router should wait before transmitting a packet. value must be an integer from 1 through 3600.

Usage

Use this command to set the intervals or delay types for a virtual link between an area that is connected to the network backbone and an area that cannot be connected to the network backbone.

Example

The following command sets the retransmit interval for a virtual link between the OSPF areas defined by the IP address 192.168.100.10 and the IP address 192.168.200.20 to 60 seconds:

area 192.168.100.10 virtual-link 192.168.200.20 retransmit-interval 60
area virtual link message-digest-key

This command enables the use of MD5-based OSPF authentication for the virtual link between an area that cannot be physically connected to the network backbone and an area that is physically connected to the network backbone.

Product
PDSN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

```plaintext
area {ipaddress|decimal_value} virtual-link router_id_address message-digest-key key_id md5 [encrypted password encrypted_authentication_key]
password authentication_key
no area {ipaddress|decimal_value} virtual-link router_id_address message-digest-key key_id md5 [encrypted password encrypted_authentication_key]
password authentication_key
```

no
Disables area virtual link message digest key.

ipaddress
The IP address, in IPv4 dotted-decimal notation, of the transit area.

decimal-value
The identification number of the transit area. This must be an integer from 0 through 4294967295.

router_id_address
The router id, in dotted-decimal notation, of the ABR to be linked to.

message-digest-key key_id
Specifies the key identifier number. key_id must be an integer from 1 through 255.

encrypted password

encrypted_authentication_key is a string variable of size 1 to 523.
Used this if you are pasting a previously encrypted authentication key into the CLI command.

password authentication_key
The password to use for authentication. authentication_key is a string variable, from 1 through 16 alphanumeric characters, that denotes the authentication password. This variable is entered in clear text format.

Usage
Use this command to enable the use of MD5-based OSPF authentication for a virtual link between an area that is connected to the network backbone and an area that cannot be connected to the network backbone.
Example
The following command enables the use of MD5-based OSPF authentication for a virtual link between the OSPF areas defined by the IP address 192.168.100.10 and the IP address 192.168.200.20, sets the MD5 Key ID to 25, and the password to 123456:

area 192.168.100.10 virtual-link 192.168.200.20 message-digest-key 25 md5 password 123456
capability graceful-restart

This command configures graceful-restart. By default, capability is set to enabled.

Product
PDFN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

capability graceful-restart

  no capability graceful-restart

Usage
Use this command to configure graceful-restart.

Example
The following command configure capability graceful-restart:

capability graceful-restart
default-information originate

This command creates a default external route into an OSPF routing domain.

Product
PDSN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

\[\text{default-information originate[always][metric}\ metric\_value][\text{metric-type}\{1|2\}][\text{route-map}\ route\_map\_name]\]

- **always**
  Indicates that the route should always be advertised, regardless of whether the software has a default route or not.

- **metric metric_value**
  Sets the OSPF metric used in creating the default route. This must be an integer from 1 through 16777214.

- **metric-type \{ 1 | 2 \}**
  Sets the default route metric type.
  1 : Sets the OSPF external link type for default routes to Type 1.
  2 : Sets the OSPF external link type for default routes to Type 2.

- **route-map route_map_name**
  Specifies the name of the default route-map to be use. This must be specified as a string of 1 through 79 alphanumeric characters.

Usage

Use this command to set the default external route into an OSPF routing domain.

Example

The following command sets the default external route to originate from the routemap named \textit{rmap1}:

\texttt{default-information originate route-map rmap1}
default metric

This command configures the default metric value for the OSPF routing protocol.

**Product**
PDSN, HA, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
default-metric metric_value
no default-metric
```

*metric-value*

The metric value to set. This must be an integer from 1 through 16777214. The default metric value setting is 26385.

*no*

Enables/Disables the followed option

**Usage**

Use this command to set the default metric for routes.

**Example**

The following command sets the default metric to 235:

default-metric 235
**distance**

This command configures the OSPF route administrative distances for all OSPF route types or based on specific route type.

**Product**
PDSN, HA, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```bash
distance {distance_value|ospf { [external distance_value] [inter-area distance_value] [intra-area distance_value] } }
nodistance {distance_value|ospf { [external distance_value] [inter-area distance_value] [intra-area distance_value] } }
```

- `distance_value` is an integer, ranging from 1 to 255, that sets OSPF route administrative distances. The default distance value is 110.

- `ospf { [external distance_value] [inter-area distance_value] [intra-area distance_value] }`

  Set the distance value for the specified route type.

  - `external distance_value`: Set the OSPF route administrative distance for routes from other routing domains, learned by redistribution. This must be an integer from 1 through 255. The default is 110.
  - `inter-area distance_value`: sets the OSPF route administrative distance for routes from one routing area to another. This must be an integer from 1 through 255. The default is 110.
  - `intra-area distance_value`: sets the OSPF route administrative distance for all routes within an area. This must be an integer from 1 through 255. The default is 110.

- `nodistance {distance_value|ospf { [external distance_value] [inter-area distance_value] [intra-area distance_value] } }`

  Enables/Disables the followed option.

**Usage**

Use this command to set the administrative distance for OSPF routes.

**Example**

The following command sets the administrative distance for all OSPF route types to 30:

```bash
distance 30
```
**distribute-list**

This command enables the filtering of networks in outgoing routing updates.

**Product**
PDSN, HA, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
distribute-list route_access_list out {connected|rip|static}
ndistribute-list route_access_list out {connected|rip|static}
```

- **route_access_list**
The name of the OSPF route access list to use. This is an alphanumeric string up to 63 characters in length.

- **connected**
Filter connected routes.

- **rip**
Filter RIP routes. (RIP is not supported at this time.)

- **static**
Filter static routes.

- **no**
Enables/Disables the followed option.

**Usage**
Use this command to enable the filtering of outgoing route updates by using the specified route access list.

**Example**
The following command uses the route access list named `rall` to filter outgoing routing updates for all connected routes:
```
distribute-list rall out connected
```
end

Exits the NTP configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Change the mode back to the Exec mode.
**exit**

Exits the NTP configuration mode and returns to the global configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the global configuration mode.
ip vrf

This command configures the VRF instances for OSPF routing protocol.

Product
All

Privilege
Security Administrator, Administrator

Syntax

ip vrf vrf_name

no ip vrf vrf_name

no
Disables the VRF instances and removes the configured VRF context association for OSPF routing.

vrf_name
vrf_name is name of a preconfigured virtual routing and forwarding (VRF) context configured in Context configuration mode through ip vrf command.

Usage
Use this command to configure the IP VRF forwarding also to associate the preconfigured VRF context with the specific tunnel interface.
This command creates and enters the OSPF VRF Configuration Mode if required to configure the VRF context instances for OSPF routing.

Example
The following command enables preconfigured VRF context instance ospf_vrf1 for OSPF routing and enters the OSPF VRF Configuration mode:
ip vrf ospf_vrf1
neighbor

This command configures OSPF routers that interconnect to non-broadcast networks.

**Product**

PDSN, HA, GGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
neighbor ip_address[ poll-interval poll_interval_value][ priority priority_value]
```

- **ip_address**
  
  The interface IP address of the OSPF neighbor. This must be an IP address entered in dotted-decimal notation.

- **poll-interval poll_interval_value**
  
  Default: 120
  
  Set the number of seconds in the dead neighbor polling interval. This must be an integer from 1 through 65535

- **priority priority_value**
  
  Default: 0
  
  Set the 8-bit number that represents the router priority value of the non-broadcast neighbor associated with the IP address specified. This must be an integer from 0 through 255. This keyword does not apply to point-to-multipoint interfaces.

**Usage**

Use this command to configure OSPF routers that connect to non-broadcast networks.

**Example**

The following command specifies an OSPF router neighbor with the IP address of 192.168.100.10:

```
neighbor 192.168.100.10
```
network area

This command enables OSPF on an interface and defines the OSPF area for that network.

**Product**
PDSN, HA, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
network network_ip_address/network_mask area_id area_ip_address
```

- `network_ip_address/network_mask`
  The network address and mask that specify the interface on which OSPF will be enabled. This is entered in dotted-decimal notation, followed by the “/” and the mask. Example: 192.168.1.0/24.

- `area_id`
  The OSPF area identification number for the specified network. This must be an integer from 0 through 4294967295.

- `area_ip_address`
  The IP address of the OSPF area for the specified network. This must be entered in dotted-decimal notation.

**Usage**
Use this command to specify the IP address of the network interface that the OSPF router will use.

**Example**
The following command specified that the OSPF router will use the interface at IP address 192.168.1.0 with a netmask of 24:

```
network 192.168.1.0/24
```
**ospf graceful-restart**

This command helps configure graceful-restart specific settings.

**Product**

PDSN, HA, GGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
ospf graceful-restart { grace-period grace_period / helper { never | policy { only-reload | only-upgrade } } }
```

- **grace-period grace_period**
  
  OSPF graceful restart grace period (seconds) is the time in which OSPF restarts, it should be an integer between 1 to 1800. Default grace period is **60** seconds.

- **helper { never | policy }**
  
  Helps configure OSPF helper settings.
  
  - **never**: Specifies never as helper.
  
  - **policy { only-reload | only-upgrade }**: Allows ospf graceful-restart helper policy.
    
    - **only-reload**: Allows ospf graceful-restart helper policy only-reload.
    
    - **only-upgrade**: Allows ospf graceful-restart helper policy only-upgrade.

  Default is ospf graceful-restart grace-period.

**Usage**

Use this command to configure graceful-restart specific settings.

**Example**

The following command sets the graceful restart grace period to **60** seconds:

```plaintext
ospf graceful-restart grace-period 60
ospf graceful-restart helper policy only-reload
ospf graceful-restart helper policy only-upgrade
```
ospf router-id

This command configures the router ID for the OSPF process.

**Product**
PDSN, HA, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
ospf router-id ip_address
no ospf router-id ip_address

ip_address
The router ID for the OSPF process. This must be an IP address entered in dotted-decimal notation

no
Disables the router ID for the OSPF process.
```

**Usage**
Use this command to set the router ID for the current OSPF router process.

**Example**
The following command sets the router ID to `192.168.200.1`:
ospf router-id 192.168.200.1
passive-interface

This command enables the suppression of OSPF routing updates on the specific interface.

Product
PDSN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

```
passive-interface interface_name
no passive-interface interface_name
```

interface_name
The name assigned to a logical interface within the specific context. An interface name can be from 1 through 79 alphanumeric characters.

Usage
Use this command to suppress router updates on an interface in the current context.

Example
The following command suppresses OSPF routing updates on the interface named Intfc1:

```
passive-interface Intfc1
```
redistribute

This command redistributes routes into OSPF. This means that any routes from another protocol are redistributed to OSPF neighbors using the OSPF protocol.

Product
PDSN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

redistribute {bgp | connected|rip|static}[metric metric_value][metric-type {1|2}][route-map route_map_name]
no redistribute {bgp | connected|rip|static}

bgp
Specifies that BGP routes will be redistributed.

Important: BGP routing is only supported for use with the HA.

no
Disables the redistributed.

connected
Specifies that connected routes will be redistributed.

rip
Specifies that RIP routes will be redistributed. (RIP is not supported at this time.)

static
Specifies that static routes will be redistributed.

metric metric_value
Sets the OSPF metric used in the redistributed route. This must be an integer from 1 through 16777214.

metric-type { 1 | 2 }
Default: 2
Sets route metric type that is applied to redistributed routes. 1 : Sets the OSPF external link type for routes to Type 1. 2 : Sets the OSPF external link type for routes to Type 2.

route-map route_map_name
Filter routes through the specified route map before redistribution. route_map_name specifies the name of the route-map to use and must be specified as a string of 1 through 79 alphanumeric characters.
Usage

Use this command to define what routing protocols should have their routes redistributed into OSPF.

Example

The following command defines that BGP routes should be redistributed:

redistribute bgp
refresh timer

This command adjusts the OSPF refresh timer.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

- `refresh timer value`
- `no refresh timer value`

- `no`
  Disables refresh timer.

- `value`
  Default: 10
  The minimum amount of time, in seconds, to wait before refreshing an LSA. This must be an integer from 10 through 1800.

Usage

Use this command to define the amount of time to wait before refreshing an LSA.

Example

The following command sets the refresh timer to 90 seconds:

`refresh timer 90`
**router-id**

This command configures the router ID for the OSPF process.

**Product**
PDSN, HA, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
router-id ip_address
no router-id ip_address

no

Disables router ID for the OSPF process.

ip_address

The router ID for the OSPF process. This must be an IP address entered in dotted-decimal notation.
```

**Usage**
Use this command to set the router ID for the current OSPF router process.

**Example**
The following command sets the router ID to 192.168.200.1:

```plaintext
router-id 192.168.200.1
```
**timers spf**

This command adjusts the SPF timers.

**Product**  
PDSN, HA, GGSN

**Privilege**  
Security Administrator, Administrator

**Syntax**

```
no timers spf
timers spf delay_value hold_time_value
```

**no**  
Disables SPF timers.

**delay_value**  
Default: 5  
The delay time, in seconds, between receiving changes to an SPF calculation. This must be an integer from 0 through 4294967295.

**hold_time_value**  
Default: 10  
The hold time, in seconds, between consecutive SPF calculations. This must be an integer from 0 through 4294967295.

**Usage**  
Use this command to set the SPF delay and hold timers for the current OSPF router process.

**Example**  
The following command sets the delay timer to 15 and the hold timer to 15:

```
timers spf 15 15
```
Chapter 153
OSPF VRF Configuration Mode Commands

The OSPF VRF Configuration sub-mode is used to configure the virtual routing and forwarding (VRF) context instances for OSPF routing protocol. This mode includes commands that configure VRF instance for OSPF routing parameters.

```
Exec Mode

configure

Global Configuration Mode

context name

Context Configuration Mode

router ospf

OSPF Configuration Mode

ip vrf vrf_name

OSPF VRF Configuration Mode
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
area

This command configures the various parameters, including authentication, area identification, virtual link id, delay/interval values for the specified OSPF area using specific VRF instance.

Product
PDSN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

[no] area { decimal_value | ip_address } {authentication [ message-digest ] | default-cost cost_value | nssa [default-information-originate] [no-redistribution] [no-summary] [translate-always] [translate-candidate] [translate-never] | stub [no-summary] | virtual-link router_ip_address [authentication {message-digest | null | text}] | authentication-key {encrypted password encrypted_string | password password_string} | message-digest-key key_id md5 [encrypted password encrypted_string | password password_string} | [dead-interval] [hello-interval] [retransmit-interval] [transmit-delay]

no

Disables/removes configured parameters for the specified OSPF area using specific VRF instance.

ip_address

Specifies the IP address in IPv4 dotted-decimal notation, of the area where authentication will be enabled.

decimal_value

Specifies the identification number of the area where parameters to be configured. This must be an integer from 0 through 4294967295.

message-digest

Sets the OSPF authentication type to use the message digest 5 (MD5) authentication method.

default-cost cost_value

Sets the default cost for an OSPF area.

cost_value is the default cost to be configured for the specified area and must be an integer from 0 through 16777215.

nssa [default-information-originate] [no-redistribution no-summary] [translate-always] [translate-candidate] [translate-never]

Configures and defines an area as an NSSA (Not So Stubby Area) and configures OSPF parameters for it.

default-information-originate: This optional keyword configures the OSPF VRF instances to originate default information to the NSSA area.

no-redistribution: This optional keyword configures the OSPF VRF instance to not to redistribute external routes to the NSSA area.
no-summary: This optional keyword configures the OSPF VRF instance to not to inject the inter-area routes into NSSA.
translate-always: This optional keyword configures the NSSA-ABR always to translate. By default this is disabled.
translate-candidate: This optional keyword configures the NSSA-ABR always to translate election. By default this is enabled.
translate-never: This optional keyword configures the NSSA-ABR never to translate. By default this is disabled.

stub [no-summary]
This keyword specifies an OSPF area as an stub area configures the NSSA-ABR never to translate. By default this is disabled.
no-summary: This optional keyword disables (stops) the ABR from sending summary LSAs into the stub area.

virtual-link router_id
Specifies the router identifier which provides a virtual link between an area that cannot be physically connected to the network backbone and an area that is physically connected to the network backbone. router_id must be an IP address in IPv4 dotted-decimal notation of the ABR to be linked to.

authentication {message-digest | null | text}
Configures the OSPF authentication method to be used by the virtual link between an area that cannot be physically connected to the network backbone and an area that is physically connected to the network backbone.
message-digest: Set the OSPF authentication type to use the message digest (MD) authentication method.
null: Set the OSPF authentication type to use no authentication, thus disabling either MD or clear text methods.
text: Set the OSPF authentication type to use the clear text authentication method.

authentication-key
Configures the authentication password for the virtual link between an area that cannot be physically connected to the network backbone and an area that is physically connected to the network backbone.

message-digest-key key_id
Specifies the MD key identifier number for virtual link connection.
key_id must be an integer from 1 through 255.

md5
Sets the message digest to MD5 for virtual link connection.

[encrypted] password passwd_string
Specifies the password required for virtual link connection authentications. The keyword password is optional and if specified passwd_string must be from 1 to 63 alpha and/or numeric characters. The password specified must be in an encrypted format if the optional keyword encrypted was specified. The encrypted keyword is intended only for use by the system while saving configuration scripts. The system displays the encrypted keyword in the configuration file as a flag that the variable following the password keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file. encrypted_string is a string of size 1 to 523.
dead-interval value
Specifies the dead interval, in seconds, that the router should wait, during which time no packets are received and after the router considers a neighboring router to be off-line. value must be an integer from 1 through 65535.

hello-interval value
Specifies the hello interval, in seconds before sending a hello packet. value must be an integer from 1 through 65535.

retransmit-interval value
Specifies the delay between retransmission, in seconds, that router should wait before retransmitting a packet. value must be an integer from 1 through 3600.

transmit-delay value
Specifies the interval, in seconds, that the router should wait before transmitting a packet. value must be an integer from 1 through 3600.

Usage
Use this command to configure/set the various network/connection/authentication parameters of OSPF areas using specific VRF instance.

Example
The following command enables authentication for an OSPF area defined by the IP address 192.168.100.10 and the OSPF authentication type to MD5:

    area 192.168.100.10 authentication message-digest

The following command sets the default cost for an OSPF area defined by the IP address 192.168.100.10 to 300:
The following command defines the area designated by the IP address 192.168.100.10 as an NSSA area where translation of NSSA candidate is enabled by default:

    area 192.168.100.10 nssa

The following command defines the OSPF area defined by the IP address 192.168.100.10 as a stub area:

    area 192.168.100.10 stub

The following command creates a virtual link between the OSPF areas defined by the IP address 192.168.100.10 and the IP address 192.168.200.20:

    area 192.168.100.10 virtual-link 192.168.200.20

The following command sets the authentication method for a virtual link between the OSPF areas defined by the IP address 192.168.100.10 and the IP address 192.168.200.20 to use no authentication:

    area 192.168.100.10 virtual-link 192.168.200.20 null

The following command creates an authentication password of 123456 for a virtual link between the OSPF areas defined by the IP address 192.168.100.10 and the IP address 192.168.200.20:

    area 192.168.100.10 virtual-link 192.168.200.20 authentication-key password 123456

The following command enables the use of MD5-based OSPF authentication for a virtual link between the OSPF areas defined by the IP address 192.168.100.10 and the IP address 192.168.200.20, sets the MD5 Key ID to 25, and the password to 123456:

    area 192.168.100.10 virtual-link 192.168.200.20 authentication-key md5 password 123456

The following command sets the retransmit interval for a virtual link between the OSPF areas defined by the IP address 192.168.100.10 and the IP address 192.168.200.20 to 60 seconds:
area 192.168.100.10 virtual-link 192.168.200.20 retransmit-interval 60
default-information originate

This command creates a default external route into an OSPF routing domain.

Product
PDSN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

```markdown
default-information originate [always] [ metric metric_value ] [ metric-type { 1 | 2 } ] [ route-map route_map_name]
```

```markdown
nodefault-information originate [always] [ metric metric_value ] [ metric-type { 1 | 2 } ] [ route-map route_map_name]
```

```markdown
no
```

Disables default-information.

```markdown
always
```

Indicates that the route should always be advertised, regardless of whether the software has a default route or not.

```markdown
metric metric_value
```

Sets the OSPF metric used in creating the default route. This must be an integer from 1 through 16777214.

```markdown
metric-type { 1 | 2 }
```

Sets the default route metric type.

1: Sets the OSPF external link type for default routes to Type 1.

2: Sets the OSPF external link type for default routes to Type 2.

```markdown
route-map route_map_name
```

Specifies the name of the default route-map to be use. This must be specified as a string of 1 through 79 alphanumeric characters.

Usage
Use this command to set the default external route into an OSPF routing domain.

Example
The following command sets the default external route to originate from the routemap named `rmap1`:

```bash
default-information originate route-map rmap1
```
default metric

This command configures the default metric value for the OSPF routing protocol.

Product
PDSN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

```
default-metric metric_value

no default-metric
```

- `metric_value`
  The metric value to set. This must be an integer from 1 through 16777214. The default metric value setting is 26385.

- `no`
  Disables `default-metric`.

Usage
Use this command to set the default metric for routes.

Example
The following command sets the default metric to 235:

```
default-metric 235
```
end

Exits the NTP configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Change the mode back to the Exec mode.
exit

Exits the NTP configuration mode and returns to the global configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```bash
exit
```

Usage
Return to the global configuration mode.
neighbor

This command configures OSPF routers that interconnect to non-broadcast networks.

Product
PDSN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

neighbor ip_address [poll-interval poll_inter_value] [ priority priority_value]

no neighbor ip_address [poll-interval poll_inter_value] [ priority priority_value]

no
Disables neighbor IP address.

ip_address
The interface IP address of the OSPF neighbor. This must be an IP address entered in dotted-decimal notation.

poll-interval poll_inter_value
Default: 120
Set the number of seconds in the dead neighbor polling interval. This must be an integer from 1 through 65535

priority priority_value
Default: 0
Set the 8-bit number that represents the router priority value of the non-broadcast neighbor associated with the IP address specified. This must be an integer from 0 through 255. This keyword does not apply to point-to-multipoint interfaces.

Usage
Use this command to configure OSPF routers that connect to non-broadcast networks.

Example
The following command specifies an OSPF router neighbor with the IP address of 192.168.100.10:

neighbor 192.168.100.10
network area

This command enables OSPF on an interface and defines the OSPF area for that network.

Product
PDSN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

```
network ip_address/ip_mask area { area_id | area_ip_address }
no network ip_address/ip_mask area { area_id | area_ip_address }
```

Usage
Use this command to specify the IP address of the network interface that the OSPF router will use.

Example
The following command specified that the OSPF router will use the interface at IP address 192.168.1.0 with a netmask of 24:

```
network 192.168.1.0/24
```
ospf router-id

This command configures the router ID for the OSPF process.

Product
PDSN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

```
ospf router-id ip_address

no ospf router-id ip_address
```

Usage
Use this command to set the router ID for the current OSPF router process.

Example
The following command sets the router ID to 192.168.200.1:

```
ospf router-id 192.168.200.1
```
### passive-interface

This command enables the suppression of OSPF routing updates on the specific interface.

**Product**

PDSN, HA, GGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
passive-interface interface_name
no passive-interface interface_name
```

**Usage**

Use this command to suppress router updates on an interface in the current context.

**Example**

The following command suppresses OSPF routing updates on the interface named `Intfc1`:

```
passive-interface Intfc1
```
redistribute

This command redistributes routes into OSPF. This means that any routes from another protocol are redistributed to OSPF neighbors using the OSPF protocol.

Product
PDSN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

redistribute {connected | rip | static} [metric value] [metric-type {1 | 2}] [route-map route_map_name]

no redistribute {connected | rip | static} [metric value] [metric-type {1 | 2}] [route-map route_map_name]

---

no
Disables redistribute.

connected
Specifies that connected routes will be redistributed.

rip
Specifies that RIP routes will be redistributed. (RIP is not supported at this stage.)

static
Specifies that static routes will be redistributed.

metric value
Sets the OSPF metric used in the redistributed route.
value must be an integer from 1 through 16777214.

metric-type {1 | 2}
Default: 2
Sets route metric type that is applied to redistributed routes.
1: Sets the OSPF external link type for routes to Type 1.
2: Sets the OSPF external link type for routes to Type 2.

route-map route_map_name
Filter routes through the specified route map before redistribution. route_map_name specifies the name of the route-map to use and must be specified as a string of 1 through 79 alphanumeric characters.
Use this command to define what routing protocols should have their routes redistributed into OSPF.

**Example**
The following command defines that static routes should be redistributed in an OSPF area:

```
redistribute static
```
refresh timer

This command adjusts the OSPF refresh timer.

Product
PDSN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

```
refresh timer value
no refresh timer value
```

**no**
Disables `refresh timer`.

**value**
Default: 10
The minimum amount of time, in seconds, to wait before refreshing an LSA. This must be an integer from 10 through 1800.

**Usage**
Use this command to define the amount of time to wait before refreshing an LSA.

**Example**
The following command sets the refresh timer to 90 seconds:

```
refresh timer 90
```
router-id

This command configures the router ID for the OSPF process.

Product
PDSN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

```plaintext
router-id  ip_address
no router-id  ip_address
```

Usage
Use this command to set the router ID for the current OSPF router process.

Example
The following command sets the router ID to 192.168.200.1:

```plaintext
router-id  192.168.200.1
```
timers spf

This command adjusts the Shortest Path First (SPF) timers.

Product
PDSN, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

timers spf delay_value hold_time_value

no timers spf

no
Disables timers spf.

delay_value
Default: 5
The delay time, in seconds, between receiving changes to an SPF calculation. This must be an integer from 0 through 4294967295.

hold_time_value
Default: 10
The hold time, in seconds, between consecutive SPF calculations. This must be an integer from 0 through 4294967295.

Usage
Use this command to set the SPF delay and hold timers for the current OSPF router process.

Example
The following command sets the delay timer to 15 and the hold timer to 15:

   timers spf 15 15
Chapter 154
Out-Address Configuration Mode Commands

The Out-Address configuration mode provides the commands to configure the outgoing addresses for SCCP entities. In this mode, the prompt line will appear similar to:

```
[local]hostname(config-gtt-addrmap-outaddr-<name>)#
```

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
d

Usage
Change the mode back to the Exec mode.
exit

Exits the configuration mode and returns to the Global configuration mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

exit

Usage
Return to the Global configuration mode.
**gt-address**

Configures the SCCP short address.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
gt-address gt_address
```

- **gt_address**
  
  A string of 1 to 15 digits to define the GT-address

**Usage**

Define the GT-address

**Example**

```
gt-address 010405525397
```
gt-format

The GT-format provides four formats that can be used during GTT.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
gt-format format_num
```

- `format_num`
  1: Selects GT-format 1 options which include `nature-of-address` and `odd/even`. Once selected, the system enters GT-Format1 configuration mode.
  2: Selects GT-format2 options which include `translation-type`. Once selected, the system enters GT-Format2 configuration mode.
  3: Selects GT-format3 options which include `encoding-scheme`, `numbering-plan`, and `translation-type`. Once selected, the system enters GT-Format1 configuration mode.
  4: Selects GT-format4 options which include `encoding-scheme`, `nature-of-address`, `numbering-plan`, and `translation-type`. Once selected, the system enters GT-Format4 configuration mode.

Usage
Select the a GT-format that include encoding-scheme as part of the GTT process.

Example

```
gt-format 3
```
ni-indicator

Configures the National and International indicator to use during the GTT process.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

\texttt{ni-indicator \textit{ni\_ind}}

\begin{tabular}{l}
\texttt{ni\_ind} \\
Select one of the following as the appropriate type of national indicator for the address structure: \\
\hspace{1em} \texttt{national} \\
\hspace{1em} \texttt{international}
\end{tabular}

Usage
Select the international indicator to be used for out-going addresses.

Example

\texttt{ni-indicator international}
point-code

Selects and configures the SS7-type point code for use with the out-going address.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
point-code pt_code
```

```
pt_code
Enter 1 to 11 digits in the point code format predefined during variant selection of GTT association.
```

Usage
Define an ITU point code to be used for out-going address processing.

Example

```
point-code 6.255.6
```
**routing-indicator**

Selects the type of routing and the indicator to be included in the out-going message.

**Product**
- SGSN

**Privilege**
- Security Administrator, Administrator

**Syntax**

```
routing-indicator routing_ind
```

**routing_ind**

Select one of the following options:
- **gt**: Inserts an indicator that identifies routing based on global title.
- **ssn**: Inserts an indicator that identifies routing based on the subsystem number.

**Usage**

Select global title as the appropriate routing indicator.

**Example**

```
routing-indicator gt
```
ssf

Selects the subservice field as factor in the out-going address processing. `ssf` sets the network indicator in the subservice field for SS7 Message Signal Units (MSUs). The indicator carried in the message’s routing information typically identifies the structure of the point code as a message from within a nation or as a message coming from outside the national - international.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
ssf sub_svc fld
```

**sub_svc fld**

Select one of the following options:

- **international**: The network indicator identifies the message as international with a point code structure that does not match the national point code structure,

- **national**: The network indicator identifies the messages as having a national point code structure.

- **reserved**: Provides an alternate network indicator for national messages.

- **spare**: Provides an alternate network indicator for international messages.

**Usage**

Select the international NI for inclusion in out-going address subservice fields.

**Example**

```plaintext
ssf international
```
SSN

Selects the subsystem number to be included in the out-going message.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
ssn sub_sys_num
```

sub_sys_num

Enter an integer from 1 to 255.

Usage

Use subsystem number 44 in the out-going address.

Example

```
ssn 44
```
Chapter 155
PDG Service Configuration Mode Commands

The PDG Service Configuration Mode is used to specify the properties required for the UEs in the WLAN (Wireless Local Access Network) to interface with the PDG/TTG.
associate sgtp-service

Identifies the SGTP service to be associated with the PDG service to enable TTG functionality on the PDG/TTG. TTG functionality supports GTP-C (GTP control plane) messaging and GTP-U (GTP user data plane) messaging between the TTG and the GGSN over the Gn’ interface.

Important: This command can be used before the associated service instance is created and configured but care should be used to match the service names.

Product
PDG/TTG

Privilege
Security Administrator, Administrator

Syntax

```
[ no ] associate sgtp-service sgtp_service_name [ context sgtp_context_name ]
```

no
Removes the service association definition from the configuration.

```
sgtp-service sgtp_service_name
```
Specifies which SGTP service configuration, by naming the SGTP service instance, to associate with this PDG service.

*sgtp_service_name* must be a string of 1 through 63 alpha and/or numeric characters with no spaces.

```
context sgtp_context_name
```
Defines the context in which the SGTP service was created. If no context is specified, the current context is used.

*sgtp_context_name* must be a string of 1 through 63 alpha and/or numeric characters with no spaces.

Usage
Use this command to associate the SGTP service to be associated with the PDG service to enable TTG functionality on the PDG/TTG.

Example
The following command associates SGTP service *sgtp_service_1* with this PDG service:

```
associate sgtp-service sgtp_service_1 context sgtp_context_1
```
**certificate-selection**

Configures the PDG/TTG to select the trusted certificate (and the private key for calculating the AUTH payload) to be included in the first IKE_AUTH message from the PDG/TTG based on the APN (Access Point Name). The selected certificate is associated with the APN included in the IDr payload of the first IKE_AUTH message from the UE.

**Product**
PDG/TTG

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
[ no ] certificate-selection apn-based
default certificate-selection
```

- **certificate-selection apn-based**
  Selects a trusted certificate for the first IKE_AUTH message based on the APN.

- **no certificate-selection**
  Disables APN-based certificate selection and resumes sending a certificate bound to a crypto template.

- **default certificate-selection**
  Sets the default certificate selection method to a certificate bound to a crypto template.

**Usage**

Configures the PDG/TTG to select the trusted certificate to be included in the first IKE_AUTH message based on the APN.

**Example**

Use the following example to enable APN-based certificate selection:

```plaintext
certificate-selection apn-based
```
bind

Binds the PDG service IPv4 address to a crypto template and specifies the maximum number of sessions the PDG service supports.

**Product**
PDG/TTG

**Privilege**
Security Administrator, Administrator

**Syntax**

```bash
[ no ] bind address ipv4_address { crypto-template string } mode { ttg | pdg } [ max-sessions number ]
```

- **no**
  Removes a previously configured binding.

- **bind address ipv4_address**
  Specifies the IPv4 address of the PDG service with which the UE attempts to establish an IKEv2/IPSec tunnel. This address must be a valid IP address within the context. This is a mandatory parameter.

- **crypto-template string**
  Specifies the name of the crypto template to be bound to the PDG service. This is the name of the IPSec policy to be used as a template for PDG/TTG subscriber session IPSec policies. The crypto template includes most of the IPSec and IKEv2 parameters for keepalive, lifetime, NAT-T, and cryptographic and authentication algorithms. There must be one crypto template per PDG service. This is a mandatory parameter.

  *string* is any value from 0 - 127 alpha and/or numeric characters.

- **mode { ttg | pdg }**
  Default: There is no default value.

  Specifies whether the PDG service provides TTG or PDG functionality, as follows:
  
  - In TTG mode, PDN connectivity is provided through the GGSN. PDG functionality is provided by the combined TTG and GGSN.
  - In PDG mode, PDN connectivity and PDG functionality are provided directly through the PDG service.

  This is a mandatory parameter.

**Important:** PDG mode is not supported in this software release.

**Dependencies:**

When you configure the PDG service to be in TTG mode, you must also configure the SGTP service using the `associate sgtp-service` command, as the TTG needs to connect with the GGSN to complete the PDG functionality.

The following behaviors occur when the PDG service operates in TTG mode:
• If the SGTP service associated with PDG service is not configured, the PDG service is not started.
• If the SGTP service associated with PDG service is not started, the PDG service is not started.
• If the SGTP service associated with PDG service is stopped, the PDG service is stopped.
• If the SGTP service associated with PDG service is re-started, the PDG service is re-started.
• If the SGTP service is not yet configured, whenever the SGTP service is started, the PDG service is started.

Note that starting or stopping the PDG service has no impact on the SGTP service.

```plaintext
max-sessions number
```

Default: 1000000
Specifies the maximum number of sessions to be supported by the PDG service.
number can be any integer value from 0 - 1000000.
If the max-sessions value is changed on an existing system, the new value takes effect immediately if it is higher than the current value. If the new value is lower than the current value, existing sessions remain established, but no new sessions are permitted until usage falls below the newly-configured value.

Usage
Use this command in PDG Service Configuration Mode to bind the IP address used as the connection point for establishing IKEv2/IPSec sessions to a crypto template. You can also use it to define the maximum number of sessions the PDG service supports.

Example
The following command binds a PDG service with an IP address of 1.2.3.4 to the crypto template crypto_template_1, sets the mode to TTG, and sets the maximum number of sessions to 500000:

```
bind address 1.2.3.4 crypto-template crypto_template_1 mode ttg max-sessions 500000
```
ip gnp-qos-dscp

Configures the quality of service (QoS) differentiated service code point (DSCP) used when sending data packets over the Gn' interface in the uplink direction.

Product
PDG/TTG

Privilege
Security Administrator, Administrator

Syntax

[ no ] ip gnp-qos-dscp { background dscp | conversational dscp | interactive dscp | streaming dscp | interactive [ traffic-handling-priority traffic_priority ] { allocation-retention-priority allocation_retention_priority } } *

default ip gnp-qos-dscp

no

Disables the overriding of the ToS (Type of Service) field and enables the pass-through option.

background dscp

Specifies the DSCP marking to be used for packets of sessions subscribed to the 3GPP background class, in which the data transfer is not time-critical (for example, in e-mail exchanges). This traffic class is the lowest QoS.

dscp: Set the DSCP for the specified traffic class. See the dscp section below.

conversational dscp

Specifies the DSCP marking to be used for packets of sessions subscribed to the 3GPP conversational class, in which there is a constant flow of traffic in both the uplink and downlink direction. This traffic class is the highest QoS.

dscp: Set the DSCP for the specified traffic pattern. See the dscp section below.

interactive [ traffic-handling-priority traffic_priority ]

Specifies the DSCP marking to be used for packets of sessions subscribed to three possible traffic priorities in the 3GPP interactive class, in which there is an intermittent flow of packets in the uplink and downlink direction. This traffic class has a higher QoS than the background class, but not as high as the streaming class.

traffic_priority is the 3GPP traffic handling priority and can be the integers 1, 2 or 3.

allocation-retention-priority allocation_retention_priority

Specifies the DSCP for the interactive class if the allocation priority is present in the QoS profile.

allocation-retention-priority can be the integers 1, 2, or 3.

DSCP uses the values in the following table based on the traffic handling priority and allocation/retention priority if the allocation priority is present in the QoS profile.

<table>
<thead>
<tr>
<th>Allocation Priority</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Traffic Handling Priority</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Important: If you only configure DCSP marking for interactive traffic classes without specifying ARP, it may not properly take effect. The CLI allows this scenario for backward compatibility however, it is recommended that you configure all three values.

<table>
<thead>
<tr>
<th>Allocation Priority</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ef</td>
<td>ef</td>
<td>ef</td>
</tr>
<tr>
<td>2</td>
<td>af21</td>
<td>af21</td>
<td>af21</td>
</tr>
<tr>
<td>3</td>
<td>af21</td>
<td>af21</td>
<td>af21</td>
</tr>
</tbody>
</table>

**Important**: Specifies the DSCP marking to be used for packets of sessions subscribed to the 3GPP streaming class, in which there is a constant flow of data in either in the uplink or downlink direction. This traffic class has a higher QoS than the interactive class, but not as high as the conversational class.

dscp: Set the DSCP for the specified traffic pattern. See the dscp section below.

**dscp**

Default:

- background: be
- interactive
- Traffic Priority 1: ef
- Traffic Priority 1: af21
- Traffic Priority 1: af21
- streaming: af11
- conversational: ef

Specifies the DSCP for the specified traffic pattern. dscp can be configured to any one of the following:

- af11: Assured Forwarding 11 per-hop-behavior (PHB)
- af12: Assured Forwarding 12 PHB
- af13: Assured Forwarding 13 PHB
- af21: Assured Forwarding 21 PHB
- af22: Assured Forwarding 22 PHB
- af23: Assured Forwarding 23 PHB
- af33: Assured Forwarding 33 PHB
- af41: Assured Forwarding 41 PHB
- af42: Assured Forwarding 42 PHB
- af43: Assured Forwarding 43 PHB
- be: Best effort forwarding PHB
- ef: Expedited forwarding PHB
More than one of the above keywords can be entered within a single command.

Usage

DSCP levels can be assigned to specific traffic patterns in order to ensure that data packets are delivered according to the precedence with which they’re tagged. The diffserv markings are applied to the IP header of every subscriber data packet transmitted over the Gn’ interface(s).

The four traffic patterns have the following order of precedence: background (lowest), interactive, streaming, and conversational (highest). Data packets falling under the category of each of the traffic patterns are tagged with a DSCP that further indicate their precedence as shown in the following tables:

<table>
<thead>
<tr>
<th>Drop Precedence</th>
<th>Class 1</th>
<th>Class 2</th>
<th>Class 3</th>
<th>Class 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low</td>
<td>af11</td>
<td>af21</td>
<td>af31</td>
<td>af41</td>
</tr>
<tr>
<td>Medium</td>
<td>af12</td>
<td>af22</td>
<td>af32</td>
<td>af41</td>
</tr>
<tr>
<td>High</td>
<td>af13</td>
<td>af23</td>
<td>af33</td>
<td>af43</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Precedence (low to high)</th>
<th>DSCP</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Best Effort (be)</td>
</tr>
<tr>
<td>2</td>
<td>Class 1</td>
</tr>
<tr>
<td>3</td>
<td>Class 2</td>
</tr>
<tr>
<td>4</td>
<td>Class 3</td>
</tr>
<tr>
<td>5</td>
<td>Class 4</td>
</tr>
<tr>
<td>6</td>
<td>Express Forwarding (ef)</td>
</tr>
</tbody>
</table>

The DSCP level can be configured for multiple traffic patterns within a single instance of this command.

Example

The following command configures the DSCP level for the streaming traffic pattern to be ef: ip gnp-qos-dscp streaming ef

The following command configures the DSCP levels for the conversational, streaming, interactive and background traffic patterns to be ef, ef, af22, and af41, respectively: ip gnp-qos-dscp conversational ef streaming ef interactive af22 background af41
ip qos-dscp

Configures the quality of service (QoS) differentiated service code point (DSCP) used when sending data packets over the Wu interface in the downlink direction.

Product
PDG/TTG

Privilege
Security Administrator, Administrator

Syntax

[ no ] ip qos-dscp { background dscp | conversational dscp | interactive dscp | streaming dscp | interactive [ traffic-handling-priority traffic_priority ] { allocation-retention-priority allocation_retention_priority } } +

default ip qos-dscp

no
Disables the overriding of the ToS (Type of Service) field and enables the pass-through option.

background dscp
Specifies the DSCP marking to be used for packets of sessions subscribed to the 3GPP background class, in which the data transfer is not time-critical (for example, in e-mail exchanges). This traffic class is the lowest QoS.
dscp: Set the DSCP for the specified traffic class. See the dscp section below.

conversational dscp
Specifies the DSCP marking to be used for packets of sessions subscribed to the 3GPP conversational class, in which there is a constant flow of traffic in both the uplink and downlink direction. This traffic class is the highest QoS.
dscp: Set the DSCP for the specified traffic pattern. See the dscp section below.

interactive [ traffic-handling-priority traffic_priority ]
Specifies the DSCP marking to be used for packets of sessions subscribed to three possible traffic priorities in the 3GPP interactive class, in which there is an intermittent flow of packets in the uplink and downlink direction. This traffic class has a higher QoS than the background class, but not as high as the streaming class.
traffic_priority is the 3GPP traffic handling priority and can be the integers 1, 2, or 3.

allocation-retention-priority allocation_retention_priority
Specifies the DSCP for the interactive class if the allocation priority is present in the QoS profile.
allocation-retention-priority can be the integers 1, 2, or 3.
DSCP uses the values in the following table based on the traffic handling priority and allocation/retention priority if the allocation priority is present in the QOS profile.

<table>
<thead>
<tr>
<th>Allocation Priority</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Traffic Handling Priority</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Important:
If you only configure DCSP marking for interactive traffic classes without specifying ARP, it may not properly take effect. The CLI allows this scenario for backward compatibility however, it is recommended that you configure all three values.

<table>
<thead>
<tr>
<th>Allocation Priority</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ef</td>
<td>ef</td>
<td>ef</td>

<td>af21</td>
<td>af21</td>
<td>af21</td>
</tr>
<tr>
<td>3</td>
<td>af21</td>
<td>af21</td>
<td>af21</td>
</tr>
</tbody>
</table>

#### important
If you only configure DCSP marking for interactive traffic classes without specifying ARP, it may not properly take effect. The CLI allows this scenario for backward compatibility however, it is recommended that you configure all three values.

#### streaming dscp
Specifies the DCSP marking to be used for packets of sessions subscribed to the 3GPP streaming class, in which there is a constant flow of data in either in the uplink or downlink direction. This traffic class has a higher QoS than the interactive class, but not as high as the conversational class.

```dscp```: Set the DCSP for the specified traffic pattern. See the dscp section below.

---

#### dscp
Default:
- background: be
- interactive
- Traffic Priority 1: ef
- Traffic Priority 1: af21
- Traffic Priority 1: af21
- streaming: af11
- conversational: ef

Specifies the DCSP for the specified traffic pattern. `dscp` can be configured to any one of the following:

- af11: Assured Forwarding 11 per-hop-behavior (PHB)
- af12: Assured Forwarding 12 PHB
- af13: Assured Forwarding 13 PHB
- af21: Assured Forwarding 21 PHB
- af22: Assured Forwarding 22 PHB
- af23: Assured Forwarding 23 PHB
- af33: Assured Forwarding 33 PHB
- af41: Assured Forwarding 41 PHB
- af42: Assured Forwarding 42 PHB
- af43: Assured Forwarding 43 PHB
- be: Best effort forwarding PHB
- ef: Expedited forwarding PHB
• af31: Assured Forwarding 31 PHB

• af32: Assured Forwarding 32 PHB

More than one of the above keywords can be entered within a single command.

**Usage**

DSCP levels can be assigned to specific traffic patterns in order to ensure that data packets are delivered according to the precedence with which they’re tagged. The diffserv markings are applied to the IP header of every subscriber data packet transmitted over the Wu interface(s). The four traffic patterns have the following order of precedence: background (lowest), interactive, streaming, and conversational (highest). Data packets falling under the category of each of the traffic patterns are tagged with a DSCP that further indicate their precedence as shown in the following tables:

<table>
<thead>
<tr>

</tbody>
</table>

The DSCP level can be configured for multiple traffic patterns within a single instance of this command.

**Example**

The following command configures the DSCP level for the streaming traffic pattern to be ef:

```
ip qos-dscp streaming ef
```

The following command configures the DSCP levels for the conversational, streaming, interactive and background traffic patterns to be ef, ef, af22, and af41, respectively:
ip qos-dscp

ip qos-dscp conversational ef streaming ef interactive af22 background af41
ip source-violation

Sets the parameters for IP source validation. Source validation is useful if packet spoofing is suspected or for verifying packet routing and labeling within the network.

**Product**
PDG/TTG

**Privilege**
Security Administrator, Administrator

**Syntax**

```
ip source-violation { clear-on-valid-packet | drop-limit num period secs }
default ip source-violation { drop-limit num period secs }
no ip source-violation clear-on-valid-packet
```

---

**clear-on-valid-packet**
Default: disabled
Configures the service to reset the drop-limit counters upon receipt of a properly addressed packet.

---

**drop-limit num**
Default: 10
Sets the maximum number of allowed IP source violations within the detection period before dropping a call. If num is not specified, the value is set to the default value.

`num` can be any integer value from 1 to 1000000.

---

**period secs**
Default: 120
Sets the detection period in seconds for IP source violations. If secs is not specified, the value is set to the default value.

`secs` can be any integer value from 1 to 1000000.

---

**default ip source-violation { drop-limit num period secs }**
Sets or restores the IP source violation detection defaults, as follows:

- **drop-limit**: Sets or restores the maximum number of IP source violations within the detection period before dropping the call to the default value of 10.
- **period**: Sets or restores the detection period for IP source violations to the default value of 120 seconds.

---

**no ip source-violation clear-on-valid-packet**
The drop-limit counters are not reset upon receipt of a properly addressed packet.

---

**Usage**
Source validation is useful if packet spoofing is suspected or for verifying packet routing and labeling within the network.
Source validation requires the source address of received packets to match the IP address assigned to the subscriber (either statically or dynamically) during the session.
This function operates in the following manner: When a subscriber packet is received with a source IP address violation, the system increments the IP source violation drop-limit counter and starts the timer for the IP source violation period. Every subsequent packet received with a bad source address during the IP source violation period causes the drop-limit counter to increment. For example, if the drop-limit is set to 10, after 10 source violations, the call is dropped. The detection period timer continues to count throughout this process.

**Example**
The following command sets the drop limit to 15 and leaves the other values at their default values:

```
ip source-violation drop-limit 15
```
max-tunnels-per-ue

The maximum number of IKEv2/IPSec tunnels allowed per UE by the PDG/TTG. This maximum number is specified per PDG service.

Product
PDG/TTG

Privilege
Security Administrator, Administrator

Syntax

```
max-tunnels-per-ue integer
```

```
default max-tunnels-per-ue
```

integer
Default: 11
The maximum number of IKEv2/IPSec tunnels allowed per UE. This value must be an integer from 1 to 11.

```
default max-tunnels-per-ue
```
Sets the maximum number of IKEv2/IPSec tunnels allowed per UE to its default value, which is 11.

Usage
Use this command to set the maximum number of IKEv2/IPSec tunnels allowed per UE.

Example
Use the following command to set the maximum number of IKEv2/IPSec tunnels allowed per UE to 2:

```
max-tunnels-per-ue 2
```
plmn id

Configures location specific mobile network identifiers used to help translate local emergency and service-related numbers. Default is disabled.

Product
PDG/TTG

Privilege
Security Administrator, Administrator

Syntax

plmn id mcc mcc_number mnc mnc_number
no plmn id mcc mcc_number mnc mnc_number

mcc mcc_number
Specifies the mobile country code (MCC) portion of the PLMN’s identifier.

mcc_number is the PLMN MCC identifier and can be configured to any integer value between 200 and 999.

mnc mnc_number
Specifies the mobile network code (MNC) portion of the PLMN’s identifier.

mnc_number is the PLMN MNC identifier and can be configured to any 2 or 3 digit integer value between 00 and 999.

Usage
The PLMN ID is included in the RAI (Routing Area Identity) field of the PDP Create Request messages sent to the GGSN. Multiple PDG services can be configured with the same PLMN identifier. Up to five PLMN IDs can be configured for each PDG service.

Example
The following command configures the PLMN identifier with an MCC of 462 and MNC of 2:

plmn id mcc 462 mnc 02
setup-timeout

Specifies the maximum time allowed to set up a session in seconds.

Product
PDG/TTG

Privilege
Security Administrator, Administrator

Syntax

setup-timeout integer

default setup-timeout

setup-timeout integer
Default: 60
Sets the session setup timeout value. integer is a value in the range of 2 - 300 seconds.

default setup-timeout
Sets or restores the default session setup timer value to 60 seconds.

Usage
The PDG/TTG clears both the user session and tunnels if a call does not initiate successfully before the session setup timer expires.

Example
The following command sets the session setup timeout value to the default value of 60 seconds:

default setup-timeout
Chapter 156
PDIF Service Configuration Mode Commands

The PDIF Service Configuration Mode is used to configure the properties required for a mobile station to interface with a PDIF.

```
Exec Mode
  configure
    Global Configuration Mode
      context name
        Context Configuration Mode
          pdif-service name
            PDIF Service Configuration Mode
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
aaa attribute

Sets the system attributes for AAA messages.

Product
PDIF

Privilege
Security Administrator, Administrator

Syntax

aaa attribute { 3gpp2-bsid string | 3gpp2-service-option integer | calling-station-id integer | 3gpp2-serving-pcf ip-address }

no aaa attribute

default aaa attribute 3gpp2-service-option integer

no
Removes a previously configured AAA attribute.

default
Returns the specified aaa attribute to the original default system settings.

3gpp2-bsid string
Specifies the base-station ID and consists of the SID + NID + CELLID.
string must contain 12 hexadecimal upper-case ASCII characters.

3gpp2-service-option integer
Default: 4095
Specifies the radius attribute value when sending authentication and accounting messages.
integer can be configured to any value in the range 0 - 32767

calling-station-id integer
Calling station phone number.
integer can be configured to any value from 1 - 15 numbers.

3gpp2-serving-pcf ip-address
Use this command to generate attribute values without creating a new ASR 5000 image.

Usage
If the RADIUS protocol is being used, accounting messages can be sent over a AAA interface to the RADIUS server.
3gpp2-serving-pcf attribute value (if configured) is sent in both RADIUS authentication and accounting messages. If the attribute value is not configured (or explicitly 'not configured' using no command), radius
attributes are still included with just type and length. This is because inclusion/exclusion of radius attributes are still controlled through the dictionary, not with CLI.

Example
The following command identifies the base station ID:

```
aaa attribute 3gpp2-bsid ab23289acb3
```
aaa authentication

Sets the aaa authentication for first and second phase authentication when multiple authentication is configured on the system.

Product
PDIF

Privilege
Security Administrator, Administrator

Syntax

aaa authentication { { first-phase | second-phase } | { context-name name aaa-group name } }

no aaa authentication { first-phase | second-phase }

no aaa authentication { first-phase | second-phase }
Removes any existing authentication configuration.

first-phase context-name name aaa-group name
Specifies the context name and the aaa group name configured in the context for the first authentication phase.

• context-name name: Context where aaa server group is defined. name must be a string of size 1-79.

• aaa-group name: Name of the aaa-group to be used for authentication. name must be a string of size 1-63.

second-phase context-name name aaa-group name
Specifies the context name and the aaa group name configured in the context for the second authentication phase.

• context-name name: Context where aaa server group is defined. name must be a string of size 1-79.

• aaa-group name: Name of the aaa-group to be used for authentication. name must be a string of size 1-63.

Usage
Two phase-authentication happens in IKEv2 setup for setting up the IPSec session. The first authentication uses Diameter AAA EAP method and second authentication uses RADIUS AAA authentication. The same AAA context may be used for both authentications. PDIF service allows you to specify only a single AAA group, which could normally be used for the first authentication method.
A given AAA group only supports either Diameter or RADIUS authentication. If the NAI in the first authentication is different from NAI in the second authentication each NAI can point to a different domain profile in the PDIF. Each domain profile may be configured with each AAA group, one for Diameter and the other for RADIUS.
**Example**

Use the following to configure first-phase authentication for an aaa group named `aaa-10` in the pdif context:

```
first-phase context-name pdif aaa-group aaa-10
```
bind

Binds the service IP address to crypto template and configures the number of sessions the PDIF can support.

Product
PDIF

Privilege
Security Administrator, Administrator

Syntax

bind address address { crypto-template string } [ max-sessions number ]

no bind

---

no
Removes a previously configured binding.

address
Specifies the IP address of the service.

crypto-template string
Specifies the name of the crypto template to be bound to the service.
string is any value from 0 - 127 alpha and/or numeric characters.

max-sessions number
Default is 3000000.
Specifies the maximum number of sessions to be supported by the service.
number can be any integer value from 0 to 3000000.

Usage
Binds the IP address used as the connection point for establishing the IKEv2 sessions to the crypto template. It can also define the number of sessions the PDIF can support.

Example
The following command binds a service with the ip address 13.1.1.1 to the crypto template T1 and sets the maximum number of sessions to 2000000:

bind address 13.1.1.1 crypto-template T1 max-sessions 2000000
default

Sets or restores the default condition for the selected parameter.

Product
PDIF

Privilege
Security Administrator, Administrator

Syntax

```
default { ( aaa attribute 3gpp2-service-option ) | duplicate-session-detection | hss { failure-handling mac-address-validation-failure | mac-address-validation | update-profile } | ip source-violation { drop-limit | period } | setup-timeout | subscriber name | username mac-address-stripping ) }
```

</tr>
</thead>
<tbody>
<tr>
<td>Default is to disable stripping the MAC address from the username.</td>
</tr>
</tbody>
</table>
Usage
Configures the default settings for a given parameter.

Example
Use the following example to configure the default call setup time limit:

```plaintext
default setup-timeout
```
duplicate-session-detection

Configures the PDIF to detect duplicate call sessions using old IMSI or NAI addresses and clear old call information.

Product
PDIF

Privilege
Security Administrator, Administrator

Syntax

[ no | default ] duplicate-session-detection { imsi-based | nai-based }

no
Stores duplicate session detection.

default
Configures the default setting, which is NAI-based detection.

imsi-based
Configures the PDIF to detect duplicate call sessions based on the IMSI address.

nai-based
Configures the PDIF to detect duplicate call sessions based on the NAI address. This is the default setting.

Usage

If an MS leaves the Wi-Fi coverage area and subsequently comes back online, it may initiate a new session setup procedure. After both the device authentication with HSS and the subscriber authentication with AAA server are completed, PDIF runs the internal mechanism to see whether there was any other session bound with the same IMSI. If an old session is detected, PDIF starts clearing this old session by sending a proxy-MIP Deregistration request to the HA. PDIF resumes new session setup by sending a proxy-MIP registration request. When the old session is aborted, PDIF sends Diameter STR messages and RADIUS Acct STOP messages to corresponding AAA servers.

PDIF allows duplicate session detection based on either the NAI or IMSI addresses. When detecting based on NAI, it is the first-phase (device authentication) NAI that is used.

Example

The following command configures duplicate session detection to use IMSI addressing:

duplicate-session-detection imsi
**end**

Exits the current mode and returns to the Exec Mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Change the mode back to the Exec Mode.
exit

Exits the current mode and returns to the previous mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
exit
```

Usage
Returns to the previous mode.
**hss**

Configures the HSS server parameters.

**Product**
PDIF

**Privilege**
Security Administrator, Administrator

**Syntax**

```
hss { failure-handling ( { mac-address-validation-failure | update-profile } action ( terminate | continue ) ) | update-profile | mac-address-validation }
```

```
[ no | default ] hss { failure-handling | update-profile | mac-address-validation }
```

---

**no**
Removes a previously configured HSS profile.

**default**
Resets the defaults for this command.

**failure-handling mac-address-validation-failure**
Configures the way the HSS server is to handle errors.
If HSS returns a list of MAC addresses and if PDIF fails to match the subscriber MAC address against the list, then the session is always terminated.

**action { continue | terminate }**
Configures the action to be performed depending on the failure type.

- **continue**: Ignore a mac-address-validation-failure and continue the session.
- **terminate**: Terminate the session on a mac-address-validation-failure.

**mac-address-validation**
Default: disabled.
If mac-address-validation is enabled, the PDIF queries the HSS server for a list of MAC addresses associated with the Mobile Directory Number (MDN).

**update-profile**
Default: disabled.
Update the HSS server with the subscriber profile.

---

**Usage**
An HSS server is used to provide MAC address validation and store part of the subscriber profile. This command enables or disables validation and profile updates, and configures how the system responds to failures: terminate or continue a session. An ims-sh-service and Diameter interface needs to be configured to communicate with the HSS server.

Example
The following example enables mac-address validation:

```
hss mac-address-validation
```
**ims-sh-service**

Associates the IMS-Sh-service parameters.

**Product**
PDIF

**Privilege**
Security Administrator, Administrator

**Syntax**

```
ims-sh-service name name
no ims-sh-service name name
```

**Usage**

This command is used to name the IMS-Sh-service.

**Example**

The following command names the IMS-Sh-service ims1:

```
ims-sh-service name ims1
```
**ip source-violation**

Sets the parameters for IP source validation. Source validation is useful if packet spoofing is suspected or for verifying packet routing and labeling within the network.

Source validation requires the source address of received packets to match the IP address assigned to the subscriber (either statically or dynamically) during the session.

**Product**
PDIF

**Privilege**
Security Administrator, Administrator

**Syntax**

```
ip source-violation { clear-on-valid-packet | drop-limit num | period secs }
no ip source-violation clear-on-valid-packet
```

**clear-on-valid-packet**
Default: disabled
Configures the service to reset the reneg-limit and drop-limit counters after receipt of a properly addressed packet.

**drop-limit num**
Default: 10
Sets the number of allowed source violations within a detection period before forcing a call disconnect. If `num` is not specified, the value is set to the default. `num` can be any integer value from 1 to 1000000.

**period secs**
Default: 120
The length of time, in seconds, for a source violation detection period to last. If `secs` is not specified, the value is set to the default. `secs` can be any integer value from 1 to 1000000.

**Usage**
This function is intended to allow the operator to configure a network to prevent problems such as when a user gets handed back and forth between two PDIFs a number of times during a handoff scenario.
This function operates in the following manner:
When a subscriber packet is received with a source address violation, the system increments the IP source-violation drop-limit counter and starts the timer for the IP-source violation period. Every subsequent packet received with a bad source address during the IP-source violation period causes the drop-limit counter to increment.
For example, if the drop-limit is set to 10, after 10 source violations, the call is dropped. The period timer continues to count throughout this process.

**Example**
The following command sets the drop limit to 15 and leaves the other values at their defaults:
ip source-violation drop-limit 15
mobile-ip

Sets the MIP FA context for the specific PDIF service.

Product
PDIF

Privilege
Security Administrator, Administrator

Syntax

```
mobile-ip foreign-agent context string [ fa-service string ]

no mobile-ip
```

Usage
Shows in which context the FA is located and names the FA service.

Example
This command configures MIP for the FA context named fa1:

```
mobile-ip foreign-agent context fa1
```
**setup-timeout**

Configures the maximum time allowed to set up a session.

**Product**
PDIF

**Privilege**
Security-Administrator, Administrator

**Syntax**

```plaintext
setup-timeout integer

default setup-timeout
```

- **setup-timeout** integer
  This command manually sets the session setup timer. `integer` is a value in the range 2 - 300 seconds.

- **default setup-timeout**
  Default session setup timer: 60 seconds.

**Usage**

PDIF clears both user session and tunnels if a call does not initiate successfully before the timer expires.

**Example**

The following command sets the setup-timeout to the default 30 seconds:

```plaintext
default setup-timeout
```
username

Configures mac-address-stripping on a username coming in from a mobile station session.

Product
PDIF

Privilege
Security Administrator, Administrator

Syntax
username mac-address-stripping

[ default | no ] username mac-address-stripping

username mac-address-stripping
Configures mac-address stripping from the Network Access Identifier (NAI).

default
Configures the parameter default, which is disabled.

no
Returns the configuration to the default condition.

Usage
When enabled, PDIF strips the MAC address from a mobile username NAI before sending to the RADIUS AAA server.

Example
The following example disables mac-address-stripping.

no username mac-address-stripping
Chapter 157
PDSN Service Configuration Mode Commands

The PDSN Service Configuration Mode is used to create and manage PDSN service instances for the current context.
aaa 3gpp2-service-option

Specifies the value for the 3gpp2-service option.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

```
aaa 3gpp2-service-option number
no aaa 3gpp2-service-option number
```

default aaa 3gpp2-service-option

```
no
Disables the aaa 3gpp2-service option configuration.

default
Sets / Restores default value assigned for specified parameter aaa 3gpp2-service-option
```

`number`

Service option `number` is integer and should be between 0 to 32767.

Usage
Allows the configuration of a default service option value to be sent in accounting when service option values are not received from PCF. The PDSN will default the service option value to the configured value if the value is not specified by the PCF.

Example
The following command sets the service option to be 40:

```
aaa 3gpp2-service-option 40
```
access-flow traffic-validation

if **access-flow traffic-validation** is enabled for the service and the subscriber then the flows are checked against the filter rules. If the packets does not match the filter rules, and N violations occur in K seconds, the rp connection is downgraded to best-effort flow, if it is not already a best-effort flow

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
access-flow traffic-validation threshold [ interval seconds | violations limit ]
```

**[no | default] access-flow traffic-validation**

<table>
<thead>
<tr>
<th>no</th>
<th>default</th>
</tr>
</thead>
</table>
| Disable traffic validation for the service.

**threshold { [ violations limit ] [ interval seconds ] }**

violations **limit**: Sets the parameters that determine traffic access violations. This is determined by setting the maximum number of violations within a set time period. must be an integer from 1 through 100000.

interval **seconds**: Sets the time interval, in seconds. must be an integer from 1 through 100000.

**Usage**

Use this command to enable traffic validation for the current PDSN service.

**Example**
The following command enables traffic validation for the current PDSN service and sets the limit allowed to 100 violations within 5 seconds:

```
access-flow traffic-validation threshold violations 100 interval 5
```
access-network

Configures access network parameters.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

```
access-network { accounting identifier | realm realm_name }

no access-network { accounting identifier | realm }
```

no
Disables the `access-network`.

accounting identifier
Configures accounting for the access-network. This value must be a string from 1 to 128 characters in length.

realm realm_name
Configures the realm for the access-network. `realm_name` must be a string from 1 to 128 characters in length.

Usage
Use this command to configure access-network parameters for accounting and realms.

Example
The following command creates an `access-network realm` named `realm2`.

```
access-network realm realm2
```
airlink bad-sequence-number

Configures PDSN behavior for airlink related parameters.

Product
PDSN

Privilege
Security Administrator, Administrator

```
airlink bad-sequence-number { accept | deny [use-deny-code { poorly-formed-request | unsupported-vendor-id}]}[ no | default ] airlink bad-sequence-number

[ no | default ]
```

Disables the deny of bad-sequence number and accept it.
It is the default behavior.

**accept**
Accepts the A11 RRQ messages that have an Airlink Sequence number less than or equal to a previously received sequence number.
It is the default behavior.

**deny**
Rejects the A11 RRQ messages that have an Airlink Sequence number less than or equal to a previously received sequence number.
It uses **poorly-formed-request** option by default to deny a request.

**use-deny-code (poorly-formed-request | unsupported-vendor-id)**
These are optional keywords that used with **deny** sub-command to deny the A11 RRQ messages that have either an unsupported vendor Id or A11 Requests with bad/poor formation.
**unsupported-vendor-id** denies request on the basis of vendor Id.
**poorly-formed-request** will deny the A11 request on the basis of request formation or structure. It is the default deny code for **deny** sub-command.

**Usage**
This command is used to configure the airlink parameters for A11 RRQs.
When configured it denies the A11 RRQ messages that have an Airlink Sequence number less than or equal to a previously received sequence number.

**Example**
The following command would configure the system to deny all A11 RRQ messages having unsupported vendor Id or bad structure of message, including those having airlink sequence number less than or equal to a previously received sequence number:

```
airlink bad-sequence-number deny
```
allow alt-ppp

Allows proprietary modified versions of PPP type sessions to connect this PDSN service.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

allow alt-ppp
no allow alt-ppp

Usage

This command is used to deviate from standard PPP protocol and use a proprietary modified version of PPP with a pre-defined non-negotiable PPP parameters. It is a vendor-specific licensed feature command.
always-on-indication

Enables/disables the inclusion of 3GPP2 Always On Indicators in messages to the PCF.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
always-on-indication

no always-on-indication
```

```
no
```

Disables the sending of 3GPP2 Always On Indication messages.

**Usage**

This command is available when the 3GPP2 Always-On RP Extensions feature-use license is installed. When enabled, this command causes the PDSN service to include the Always On Indicators in the Normal Vendor Specific Extension (NVSE) part of an A11 Session Update message to the PCF. The indicator will only be sent for those subscriber sessions in which Always On functionality is enabled as determined after a successful authentication: the 3GPP2-Always-On attribute is set to a value of 1 (Active) for subscribers configured on a AAA server, or the always-on parameter is set for locally configured subscribers. This functionality is enabled by default.
authentication

Configures the PDSN service authentication parameters.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

```
authentication { { [ allow-noauth ] [ chap chap_priority ] [ mschap mschap_priority ] [ msid-auth ] } | pap pap_priority }
```

default authentication

default

Configures authentication parameters for specific PDSN service.

allow-noauth
Default: Disabled
This option configures the system to provide subscribers with network access even though they have not been authenticated. This command issued by itself would cause the system to not attempt to authenticate subscribers. When the allow-noauth option is used in conjunction with commands specifying other authentication protocols and priorities to use, then if attempts to use those protocols fail, the system will treat the allow-noauth option as the lowest priority. If no authentication is allowed, then NAI construct will be implemented in order to provide accounting records for the subscriber.

chap chap_priority
Default: 1
This option configures the system to attempt to use the Challenge Handshake Authentication Protocol (CHAP) to authenticate the subscriber. A chap_priority must be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on. chap_priority must be an integer from 1 through 1000. The lower the integer, the higher the preference. CHAP is enabled by default as the highest preference.

mschap mschap_priority
Default: Disabled
This option configures the system to attempt to use the Microsoft Challenge Handshake Authentication Protocol (MSCHAP) to authenticate the subscriber. A mschap_priority must be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on. mschap_priority must be an integer from 1 through 1000. The lower the integer, the higher the preference.
**pap pap_priority**

Default: 2  
This option configures the system to attempt to use the Password Authentication Protocol (PAP) to authenticate the subscriber.  
*Pap_priority* must be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on.  
*Pap_priority* must be an integer from 1 through 1000. The lower the integer, the higher the preference.  
PAP is enabled by default as the second highest preference.

**msid-auth**

Default: Disabled  
This option configures the system to attempt to authenticate the subscriber based on their Mobile Station Identity (MSID).

**Usage**

Use to specify how the PDSN service should handle authentication and what protocols to use. The flexibility is given to configure this option to accommodate the fact that not every mobile will implement the same authentication protocols.

The chassis is shipped from the factory with the authentication options set as follows:

- *allow-noauth* disabled
- *chap* enabled with a priority of 1
- *mschap* disabled
- *msid-auth* disabled
- *pap* enabled with a priority of 2

**Important:** At least one of the keywords must be used to complete the command.

**Example**

The following command would configure the system to allow no authentication for subscribers and would perform accounting using the default NAI-construct of `username@domain`:

```
authentication allow-noauth
```

The following command would configure the system to attempt subscriber authentication first using CHAP, then MSCHAP, and finally PAP. If the allow-noauth command was also issued, if all attempts to authenticate the subscriber using these protocols fail, then the subscriber would be allowed access:

```
authentication chap 1 mschap 2 pap 3
```
bind

Binds the PDSN service to a logical IP interface serving as the R-P interface. Specifies the maximum number of subscribers that can access this service over the interface.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

bind address address [ max-subscribers count ]

no bind address address

no
Removes a previously configured binding.

address
Specifies the IP address (address) of the interface configured as the R-P interface. address is specified in dotted decimal notation.

max-subscribers count
Default: 500000
Specifies the maximum number of subscribers that can access this service on this interface.

count can be configured to any integer value between 0 and 2500000.

Important: The maximum number of subscribers supported is dependant on the license key and the number of active PACs/PSCs installed in the system. A fully loaded system with 13 active PACs/PSCs can support 2500000 total subscribers. Refer to the license key command for additional information.

Usage
Associate or tie the PDSN service to a specific logical IP address. The logical IP address or interface takes on the characteristics of an R-P interface. Only one interface can be bound to a service. The interface should be configured prior to issuing this command.

This command also sets a limit as to the number of simultaneous subscribers sessions that can be facilitated by the service/interface at any given time.

When configuring the max-subscribers option, be sure to consider the following:
• The total number of interfaces that you will configure for use as R-P interfaces
• The maximum number of subscriber sessions that all of the interfaces may handle during peak busy hours
• The average bandwidth for each of the sessions
• The type of physical port (10/100Base-Tx or 1000Base-T) to which these interfaces will be bound
Taking these factors into account and distributing your subscriber session across all available interfaces will allow you to configure your interfaces to optimally handle sessions without degraded performance.

Example
The following command would bind the logical IP interface with the address of 192.168.3.1 to the PDSN service and specifies that a maximum of 600 simultaneous subscriber sessions can be facilitated by the interface/service at any given time.

    bind address 192.168.3.1 max-subscribers 600

The following command disables a binding that was previously configured:

    no bind address
**bcmcs**

Sets the BCMCS group username and password for RADIUS access.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
bcmcs [ custom ptt | flow-id value [flow-id-type { flow-id | program-id }] ] [ encrypted ] grppasswd group_passwd | grpusrname group_name | ptt { destination-context dest_name | disconnect-dscp-label dscp_label | mtu transmission_unit | rohc-profile-name rohc_profile_name } ]
```

**Syntax**

```
default bcmcs [ custom ptt | ptt { disconnect-dscp-label | mtu | rohc-profile-name } ]
```

**Syntax**

```
no bcmcs [ custom ptt | flow-id value [flow-id-type { flow-id | program-id }] | grppasswd | grpusrname | ptt { destination-context | disconnect-dscp-label | mtu | rohc-profile-name } ]
```

**Custom**

Customise the BCMCS configuration.

**flow-id value**

Set the BCMCS flow-id. This value must be a hex string between 0x1000 and 0xFFFFF.FF.

Making this entry opens a new mode: bcmcs-flow-id.

rohc-profile name: Configure ROHC parameters name. name should be string of size 1 to 63.

**grpusrname group_name**

Sets the BCMCS group name for RADIUS access requests. This value must be a string from 1 to 127 characters in length.

**[ encrypted ] grppasswd group_passwd**

Set the BCMCS group password for RADIUS access requests. This value must be a string from 1 to 63 characters in length.

Password can be encrypted or clear.

**ptt {destination-context dest_name | disconnect-dscp-label dscp_label | mtu transmission_unit | rohc-profile-name rohc_profile_name}**

**destination-context**: Specify the intended destination context name. This value must be string of 1 to 79 characters in length.
disconnect-dscp-label: Configures the DSCP label to be present in the In Call Signalling packet based on which In Call Signalling and Media Flows will be disconnected. This value must be a Hexadecimal number between 0x0 and 0xFF.

mtu transmission unit: Configures maximum transmission unit. This value must be ranging from 100 to 2000. Default is 1500.

rohc_profile_name rohc_profile_name: Profile name of the ROHC compressor and decompressor. This value should be a string of 1 to 63.

Usage

Use this command to set the BCMCS group username and password for RADIUS access requests.

Example

bcmcs grppassword group_namebcmcs grppassword group_password
data-available-indicator

Enable sending Data Available Indicator extension in R-P Registration Reply.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no | default ] data-available-indicator
```

- **no**
  Default: Disabled
  Disable the sending of the Data Available Indicator extension in R-P Registration Reply.

- **default**
  Sets / Restores default value assigned for specified parameter for `data-available-indicator`.

**Usage**
Use this command to enable or disable the sending of the Data Available Indicator extension in R-P Registration Reply.

**Example**
Use the following command to enable sending the Data Available Indicator extension in R-P Registration Reply:

```
data-available-indicator
```

Use the following command to disable sending the Data Available Indicator extension in R-P Registration Reply:

```
no data-available-indicator
```
data-over-signaling

Enable the data-over-signaling marking feature for A10 packets.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

[ no | default ] data-over signaling

default
Sets / Restores default value assigned for specified parameter for data-over signaling

no
Default: Enabled
Disable the data-over signaling feature for A10 packets.

Usage
Use this command to enable or disable the data-over-signaling feature for A10 packets.

Important: This is a customer-specific command.

Example

no data-over-signaling
default subscriber

Specifies the name of a subscriber profile configured within the same context as the PDSN service from which to base the handling of all other subscriber sessions handled by the PDSN service.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

default subscriber profile_name

no default subscriber profile_name

Enables/Disables the option default subscriber profile_name

profile_name

Specifies the name of the configured subscriber profile. profile_name can be between 1 and 63 alpha and/or number characters and is case sensitive.

Usage
Each subscriber profile specifies “rules” such as permissions, PPP settings, and timeout values. By default, the PDSN service will use the information configured for the subscriber named default within the same context. This command allows for multiple PDSN services within the same context to apply different “rules” to sessions they process. Each set of rules can be configured under a different subscriber name which is pointed to by this command. Use the no default subscriber profile_name command to delete the configured default subscriber.

Example
To configure the PDSN service to apply the rules configured for a subscriber named user1 to every other subscriber session it processes, enter the following command:

default subscriber user1
dormant-transition

Configures the PDSN behavior to terminate A10 session, when the PDSN receives the A11-RRQ (Type 4) before the session for the original MN is established completely.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

[no | default] dormant-transition initial-session-setup

no
Terminates the A10 session, when PDSN receives the A11-RRQ (Type 4) before the original session established completely.

default
Keeps the A10 session live in case of A11-RRQ (Type 4) is received before the original session is established completely.

Usage
When the status of A10 session goes to dormant before the session for the original MN is established completely, the different MN may possibly send the A11-RRQ (Type 4) to the PDSN and PPP renegotiation may start.
This command is used to terminate the A10 session when the PDSN receives the A11-RRQ (Type 4) before the session for original MN is established completely.

Example
Following command is used to release the A10 session in case of receiving A11-RRQ (Type 4) before the original session is established completely

no dormant-transition initial-session-setup
end

Exits the PDSN service configuration mode and returns to the Exec mode.

**Product**

PDSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Change the mode back to the Exec mode.
exit

Exits the PDSN service configuration mode and returns to the context configuration mode.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Return to the context configuration mode.
**fragment**

It enables/disables fragmentation of PPP data.

**Product**

PDSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
[ no | default ] fragment ppp-data
```

- **no**
  - Disables the fragmentation of ppp data.

- **default**
  - Default enables ppp data fragmentation.

**Usage**

This command is to indicate to the RP module to NOT fragment PPP payloads being sent to the PCF, if the total packet size (PPP+GRE+IP) exceeds 1500 bytes. Disabling fragmentation may cause the `sessmgr` to perform outer IP fragmentation of the outgoing packet, if the resulting packet exceeds the MED MTU.
gre

Configures Generic Routing Encapsulation (GRE) parameters for the A10 protocol within the PDSN service.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

gre { checksum | checksum-verify | flow-control [ action { disconnect-session | resume-session } ] [ timeout msecs ] [ action { disconnect-session | resume-session } ] [ timeout msecs ] | ip-header-dscp value { all-control-packets | setup-packets-only } | protocol-type { any | byte-stream | ppp } | reorder-timeout value | segmentation | sequence-mode { none | reorder } | sequence-numbers | threegpp2-ext-header qos-marking }

no gre { checksum | checksum-verify | flow-control | ip-header-dscp | segmentation | sequence-numbers | threegpp2-ext-header qos-marking }

default gre { checksum | checksum-verify | flow-control ip-header-dscp | protocol-type | segmentation | sequence-mode | sequence-numbers | threegpp2-ext-header qos-marking }

---

**no**

Disables the specified functionality.

**default**

Restores the specified parameter to its default setting.

**checksum**

Default: disabled

Enables the introduction of the checksum field in outgoing GRE packets.

**flow-control**

[ action { disconnect-session | resume-session } ] [ timeout msecs ] [ action { disconnect-session | resume-session } ] [ timeout msecs ]

Default: no gre flow-control

Enables 3GPP2 GRE flow control which causes the PDSN to send flow control enabled Normal VendorSpecific Extensions (NVSE) in A11 RRPs.

**disconnect-session**: (default): Ends the session and releases the call.

**resume-session**: Switches flow control to XON and resumes delivery of packets to the RAN.

**msec**: Specifies the amount of time in milliseconds before the timeout is reached. It must be an integer from 1 through 1000000

**checksum-verify**

Default: disabled

Enables verification of the GRE checksum (if present) in incoming GRE packets.
**ip-header-dscp value { all-control-packets | setup-packets-only }**

Default: Disabled

Used to configure the QoS Differentiated Services Code Point (DSCP) marking for GRE packets.

- value: Represents the DSCP setting. It represents the first six most-significant bits of the ToS field. It can be configured to any hex value from 0x0 through 0x3F.
- all-control-packets: Dictates that the DSCP marking is to be provided in all GRE control packets.
- setup-packets-only: Dictates that the DSCP marking is to be provided only in GRE setup packets.

**protocol-type { any | byte-stream | ppp }**

Specifies the protocol used for GRE encapsulation that is acceptable to

- any: Specifies that the PDSN service will accept GRE packets encapsulated using any protocol.
- byte-stream: Specifies that the PDSN service will accept GRE packets only encapsulated using byte stream. Using byte stream encapsulation, PPP packets are framed at different intervals and sent.
- ppp: Specifies that the PDSN service will accept GRE packets only encapsulated using the Point-to-Point Protocol (PPP). Using PPP encapsulation, PPP packets are framed at regular intervals and sent.

**reorder-timeout**

Default: 100

Configures max number of milliseconds to wait before processing reordered out-of-sequence GRE packets. milliseconds must be an integer from 0 through 5000.

**segmentation**

Default: disabled

Enables GRE Segmentation for the PDSN service.

**sequence-mode { none | reorder }**

Default: none

Configures handling of incoming out-of-sequence GRE packets.

- none: Specifies that sequence numbers in packets are ignored and all arriving packets are processed in the order they arrive.
- reorder: Specifies that out of sequence packets are stored in a sequencing queue until one of the conditions is met:
  - The reorder timeout occurs: All queued packets are sent for processing and the accepted sequence number is updated to the highest number in the queue.
  - The queue is full (five packets): All packets in the queue are sent for processing, the reorder timer is stopped and the accepted sequence number is updated to the highest number in the queue.
  - An arriving packet has a sequence number such that the difference between this and the packet at the head of the queue is greater than five. All the packets in the queue are sent for processing, the reorder timer is stopped and the accepted sequence number is updated to the highest number that arrived.
  - A packet arrives that fills a gap in the sequenced numbers stored in the queue and creates a subset of packets whose sequence numbers are continuous with the current accepted sequence number. This subset of packets in the queue is sent for processing. The reorder timer continues to run and the accepted sequence number is updated to the highest number in the subset delivered.
---

**sequence-numbers**

Enables insertion of GRE sequence numbers in data that is about to be transmitted over the A10 interface. Data coming into the system containing sequence numbers but that is out of sequence is not re-sequence.

**threegppp2-ext-headers qos-marking**

When threegppp2-ext-headers qos-marking is enabled and the PCF negotiates capability in the A11 RRQ, the PDSN will include the qos optional data attribute in the GRE 3gpp2 extension header. The **no** keyword, enables qos-marking in the gre header based on the tos value in the header.

---

**Usage**

The `gre protocol-type` command can be used to prevent the PDSN service from servicing PCFs that use a specific form of encapsulation.

Use the `no gre sequence-numbers` command to disable the inclusion of GRE sequence numbers in the A10 data path.

The chassis is shipped from the factory with the authentication options set as follows:

- `protocol-type any`
- `sequence-numbers enabled`

**Example**

Use this command to configure the PDSN service to exclude byte stream encapsulated GRE traffic:

```
gre protocol-type ppp
```
inter-pdsn-handoff mobility-event-indicator

Configures the PDSN to support the Mobility Event Identifier (MEI) during inter-PDSN handoffs. The presence of the Mobility Event Indicator (MEI) and Access Network Identifier (ANID) elements in an A11 handoff request represents an Inter-PDSN handoff.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
inter-pdsn-handoff mobility-event-indicator

no inter-pdsn-handoff mobility-event-indicator

default inter-pdsn-handoff mobility-event-indicator

default

no

Disables support for the MEI during inter-PDSN handoffs.

default

Sets / Restores default value assigned for `inter-pdsn-handoff mobility-event-indicator`. By default it is disabled.
```

**Usage**

Use this command to configure support for the MEI during inter-PDSN handoffs.

**Example**

Use the following command to enable support for the MEI during inter-PDSN handoffs

```plaintext
inter-pdsn-handoff mobility-event-indicator
```
ip header-compression rohc

This command enters PDSN Service ROHC Configuration Mode. The ROHC configuration mode lets you configure ROHC parameters that PDSN conveys to the PCF in the initial A11 RRP message before PPP authentication.

By default, ROHC is disabled for a PDSN service.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

ip header-compression rohc

default ip header-compression rohc

no ip header-compression rohc

Usage

Use this command to enter the PDSN Service ROHC Configuration Mode or disable ROHC for the current PDSN service.

Example

The following command enters PDSN Service ROHC Configuration Mode:

ip header-compression rohc

The following command disables ROHC for the current PDSN service and sets all of the values for commands in PDSN Service ROHC Configuration Mode back to their default settings:

default ip header-compression rohc
**ip local-port**

Configures the local User Datagram Protocol (UDP) port for the R-P interfaces’ IP socket.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
ip local-port number
```

- `number`
  - Default: 699
  - Specifies the UDP port number.
  - `number` can be any integer value between 1 and 65535.

```
default ip local-port
```

- `default`
  - Designates UDP port, default value as 699.

**Usage**
Specify the UDP port that should be used for communications between the Packet Control Function (PCF) and the PDSN.

**Important:** The UDP port setting on the PCF must match the local-port setting for the PDSN service on the system in order for the two devices to communicate.

**Example**
Use the following command to specify a UDP port of 3950 for the PDSN service to use to communicate with the PCF on the R-P interface:

```
ip local-port 3950
```
ip source-violation

Sets the parameters for IP source validation. Source validation is useful if packet spoofing is suspected or for verifying packet routing and labeling within the network.

Source validation requires the source address of received packets to match the IP address assigned to the subscriber (either statically or dynamically) during the session.

Product
PDSN, PDIF

Privilege
Security Administrator, Administrator

Syntax

```
ip source-violation { clear-on-valid-packet | drop-limit num | period secs | reneg-limit num }

no ip source-violation clear-on-valid-packet
default ip source-violation { drop-limit num | period secs | reneg-limit num }
```

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Description</th>

<td>Default: 10</td>
</tr>
<tr>
<td></td>
<td>Sets the number of allowed source violations within a detection period before forcing a call disconnect. If <code>num</code> is not specified, the value is set to the default. The <code>num</code> can be any integer value from 1 to 1000000.</td>
</tr>
<tr>
<td>period secs</td>
<td>Default: 120</td>
</tr>
<tr>
<td></td>
<td>The length of time, in seconds, for a source violation detection period to last. drop-limit and reneg-limit counters are decremented each time this value is reached. The counters are decremented in this manner: reneg-limit counter is reduced by one (1) each time the period value is reached until the counter is zero (0); drop-limit counter is halved each time the period value is reached until the counter is zero (0). If <code>secs</code> is not specified, the value is set to the default. The <code>secs</code> can be any integer value from 1 to 1000000.</td>
</tr>
</tbody>
</table>
PDSN Service Configuration Mode Commands

---

**ip source-violation**

Default: 5
Sets the number of allowed source violations within a detection period before forcing a PPP renegotiation. If `num` is not specified, the value is set to the default.
`num` can be any integer value from 1 to 1000000.

---

**Usage**

This function is intended to allow the operator to configure a network to prevent problems such as when a user gets handed back and forth between two PDIFs PDSNs a number of times during a handoff scenario. This function operates in the following manner:

When a subscriber packet is received with a source address violation, the system increments both the IP source-violation reneg-limit and drop-limit counters and starts the timer for the IP-source violation period. Every subsequent packet received with a bad source address during the IP-source violation period causes the reneg-limit and drop-limit counters to increment.

For example, if reneg-limit is set to 5, then the system allows 5 packets with a bad source address (source violations), but on the 5th packet, it re-negotiates PPP.

If the drop-limit is set to 10, the above process of receiving 5 source violations and renegotiating PPP occurs only once. After the second 5 source violations, the call is dropped. The period timer continues to count throughout this process.

If the configured source-violation period is exceeded at any time before the call is dropped, the reneg-limit counter is checked. If the reneg-limit counter is greater than zero (0), the reneg-limit is decremented by 1. If the reneg-limit counter equals zero, the drop-limit is decremented by half.

---

**Example**

The following command sets the drop limit to 15 and leaves the other values at their defaults:

```
ip source-violation drop-limit 15
```
**lifetime**

Specifies the time that an A10 connection can exist before its registration is considered expired.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
lifetime time
no lifetime

default lifetime
```

**no lifetime**

Specifies that an A10 connection can exist for an infinite amount of time.

**default lifetime**

Sets / Restores default value assigned for *lifetime* as 1800.

**time**

Default: 1800

Specifies the time that an A10 connection can exist before its registration is considered expired. 

*time* is measured in seconds and can be configured to any integer value between 1 and 65534.

**Usage**

Set a limit to the amount of time that a subscriber session can remain up whether or not the session is active or dormant. If the lifetime timer expires before the subscriber terminates the session, their connection will be terminated automatically.

Use the **no lifetime** command to delete a previously configured lifetime setting. If after deleting the lifetime setting you desire to return the lifetime parameter to its default setting, use the **default lifetime** command.

**Example**

The following command specifies a time of 3600 seconds (1 hour) for subscriber sessions on this PDSN service:

```
lifetime 3600
```
max-retransmissions

Configures the maximum number of times the PDSN service will attempt to communicate with a PCF before it marks it as unreachable.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

max-retransmissions count

default max-retransmissions

default

Sets / Restores default value assigned for max-retransmissions as 5.

count

Specifies the maximum number of times the PDSN service will attempt to communicate with a PCF before it marks it as unreachable.

count can be configured to any integer value between 1 and 1,000,000.

Usage

If the value configured for the max-retransmissions is reached the call will be dropped.
The chassis is shipped from the factory with the Internet maximum number of retransmissions set to 5.

Example

The following command configures the maximum number of retransmissions for the PDSN service to 3:

max-retransmissions 3
mobile-ip foreign-agent context

For Mobile IP support, specifies the context in which the FA service(s) are configured.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

```
mobile-ip foreign-agent context context_name [fa-service name]
no mobile-ip foreign-agent context context_name [fa-service name]
```

```
no
Enables/Disables mobile-ip foreign-agent context
```

```
context_name
Specifies the name of the previously configured context that facilitates the FA service(s). context_name must be between 1 and 79 alpha or numeric characters and is case sensitive.
```

```
[fa-service name]
This optional keyword allows you to link the PDSN service to a particular FA service in the specified context. name is the name of the FA service to link to. name is a string of size 1 to 63
```

Usage

FA services on the system can be configured either in the same or different contexts from those facilitating PDSN services. When they are configured in separate contexts, this command configured with a PDSN service instructs the PDSN service to route traffic to the context facilitating the FA service. Use the `no mobile-ip foreign-agent context` to delete a previously configured destination context.

Example

The following command instructs the PDSN service to use the context named FA-destination for FA functionality:

```
mobile-ip foreign-agent context fa-destination
```
msid length

Specifies the allowed configurable Mobile Station IDentifier (MSID) length.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ default ] msid length { min min_length | max } max_length
```

- **default**
  Specifies the default length of MSID (10 to 15) as per standard. By default msid is disabled.

- **min min_length**
  Specifies the minimum length for MSID.
  *min_length* is any Integer value between 10 to 15, but should be less than *max_length* specified with max. Default is 10.

- **max max_length**
  Specifies the maximum length for MSID.
  *max_length* is any Integer value between 10 to 15, but should be more than *min_length* specified with min. Default is 15.

**Usage**
MSID length can be configured either in the standard length or different customized length form. This command is used to specify the allowed length of MSID.

**Example**
The following command specifies an MSID length between 12 and 15:

```
msid length min 12 max 15
```
nai-construction

Specifies a domain alias that will be used to represent the context which the PDSN service should use for AAA functionality.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

nai-construction domain alias
no nai-construction domain

domain alias

alias represents the “domain” name that you would like to associate with the context in which AAA functionality is configured. alias can be between 1 and 79 alpha and/or numeric characters and is case-sensitive.

Usage
Enabling NAI will be constructed for the subscriber in the event that their mobile station (MS) does not negotiate CHAP, PAP, or MSCHAP. If this option is selected, no further attempts will be made to authenticate the user. Instead, the constructed NAI will be used for accounting purposes. The context specified by this command would be used to provide the communication with the RADIUS accounting server.

Use the no nai-constructed domain command to deleted a configured alias.

Important: This command should only be used if the PDSN service is configured to allow no authentication using the authentication allow-noauth command.

Additionally, the aaa constructed-nai command in the Context Configuration mode can be used to configure a password for constructed NALs.

Example
The following command configured a domain alias of aaa_context for the PDSN service to use when an NAI is constructed for a subscriber session:

nai-construction domain aaa_context
new-call conflict

Enable or disable to send A11-RUPD to current PCF, when system receives the A11-RRQ(Type1) from new PCF during the session exists.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

[no | default] new-call conflict terminate-session-old-pcf

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disable to send A11-RUPD to current PCF, when system receives the A11-RRQ(Type1) from new PCF during the session exists.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable to send A11-RUPD to current PCF, when system receives the A11-RRQ(Type1) from new PCF during the session exists.</td>
</tr>
</tbody>
</table>

Usage
This configuration supports to enable or disable to send A11-RUPD to current PCF, when the system receives the A11-RRQ(Type1) from new PCF during the session exists.
If the configuration is no new-call conflict terminate-session-old-pcf system will not send registration update to old PCF on receiving a new call (A11-RRQ(Type1)) request for an existing active/dormant session. The default behavior is to send registration updates.

Example
The following command configured a system to send a registration update on receiving an A11-RRQ (Type 1) request for an existing active/dormant session:

    new-call conflict terminate-session-old-pcf
pcf-monitor

When this is enabled, the PDSN monitors all the PCFs that have sessions associated with it. The PDSN stops monitoring a PCF if it is determined to be down. Once a PCF is determined to be down, the PDSN tears down all sessions that correspond to the PCF and generates AAA Accounting Stop messages. All the PCFs that are connected to the PDSN service are monitored.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
pcf-monitor [ interval seconds | max-inactivity-time seconds | num-retry num | timeout seconds ]
[ no | default ] pcf-monitor
```

- **pcf-monitor**
  Entering the command with no keywords enables the PCF monitoring function with all parameters set to the defaults.

- **no**
  Disables the pcf monitoring function.

- **default**
  Sets / Restores default value assigned for **pcf-monitor**.

- **interval seconds**
  Default: 60 seconds
  Sets the amount of time to wait between ping request messages.
  `seconds` must be an integer in the range from 60 through 3600.

- **max-inactivity-time seconds**
  Default: 120 seconds
  The maximum amount of time (seconds) with no A10 traffic from a PCF before the ICMP-ping mechanism is triggered.
  `seconds` must be an integer from 1 through 3600.

- **num-retry num**
  Default: 5
  Sets the number of times that the PDSN retries to ping the PCF. When num-retry for a given PCF has been exhausted with no response, sessions that correspond to the non-responsive PCF are terminated and Accounting Stop records for each terminated session are generated.
  `num` must be an integer in the range from 0 through 100.
**pcf-monitor**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>timeout seconds</strong></td>
<td>Default: 3 seconds The amount of time to wait for a response before retrying. <code>seconds</code> must be in the range from 1 through 10.</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to enable the PDSN service to monitor the PCFs that have sessions associated with the PDSN service.

**Example**

The following command enables PCF monitoring with parameters set to the defaults:

```
    pcf-monitoring
```

The following command enables PCF monitoring and sets the timeout to 10 seconds:

```
    pcf-monitor timeout 10
```

The following command disables pcf-monitoring:

```
    no pcf-monitor
```
The feature manages current session and PPP renegotiation on GRE-key change without any change in PCF/PANID/CANID. This command disables or enables the PPP renegotiation restart on receiving an RP registration request from the current PCF with GRE key (PCF session Id) change. With this command the PDSN aborts and restarts the call causing PPP renegotiation.

This is enabled by default.

**Product**

PDSN

**Privilege**

Security Administrator, Administrator

**Syntax**

[ no | default ] pcf-session-id-change restart-ppp

- **no**
  Disables the pcf-session-id-change restart-ppp function.
  With this option PDSN does not restart the PPP renegotiation on GRE key change from current PCF in an RP registration request, unless it indicates change in PCF/PANID/CANID.

- **default**
  Set the pcf-session-id-change function to the default state on enabled.

**Usage**

GRE key (PCF session ID) is sued to identify the data packet for a session and is negotiated through the A11 signaling messages between PCF and PDSN. By default PDSN aborts and restart the PPP renegotiation on receipt of any RP registration request with change in GRE key or PCF session Id.

With use of no pcf-session-id-change restart-ppp command PDSN is configured to disable the restart of call or PPP renegotiation on receipt of any RP registration request with changed GRE key, unless it has any PCF/ANID/CANID change. PDSN silently switches the GRE key for the session, retaining the existing PPP session.

**Example**

The following command disables the PPP renegotiation restart action on receipt of any RP RRQ with changed GRE key from same PCF/PANID/CANID.

```
no pcf-session-id-change restart-ppp
```
pdsn type0-tft attempt-inner-match

Configures a type0 traffic flow template (tft) to a type1 traffic flow template.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no | default ] pdsn type0-tft attempt-inner-match
```

- **no**
  Disables `pdsn type0-tft attempt-inner-match`.

- **default**
  Sets / Restores default value assigned for `pdsn type0-tft attempt-inner-match`.

**Usage**

This CLI is used make PDSN match inner IP packets for an AIMS call. When enabled, the PDSN tries to match a type-0 tft to match both outer and inner packet, so that MN can use a Type-0 filter for HoA traffic which are tunneled.

This is disabled by default.

**Example**

The following command enables type0 tft:

```
pdsn type0-tft attempt-inner-match
```
**peer-pcf**

Configures settings for any PCF that has a connection with this PDSN.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
peer-pcf ip_address bcmcs-framing { hdlc-like | segment-based }
```

- `ip_address`

  `ip_address` must be specified using the standard IPv4 dotted decimal notation or colon notation for IPv6.

- `bcmcs-framing { hdlc-like | segment-based }

  Specifies the type of bcmcs-framing to use for this PCF connection.
  - `hdlc-like`: applies HDLC-like framing for all BCMCS flows
  - `segment-based`: applies segment-based framing for all BCMCS flows

**Usage**

Use this command to configure the settings for any PCF that is connected to this PDSN. You can also specify bcmcs framing settings to use for the connection.

**Example**
The following command configures the peer-pcf for an IP address of 131.2.3.4:

```
peer-pcf 131.2.3.4
```
**policy**

Configures PDSN service policies.

**Product**

PDSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
[ no ] policy msid-match msid_with Wildcards { redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ] }

[ default | no ] policy overload { redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ] } | { reject [ use-reject-code { admin-prohibited | insufficient-resources } ] }

[ no ] policy pcf-zone-match zone_number { redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ] }

[ default | no ] policy rrq mei-from-current-pcf suppress-ppp-restart

[ default | no ] policy service-option enforce

[ default | no ] policy unknown-cvse enforce
```

- **no policy { overload [ redirect address [ address2 ... address16 ] ] | rrq mei-from-current-pcf {suppress-ppp-restart} | service-option | unknown-cvse enforce }**

Deletes a previously set policy or removes a redirect IP address.

- **overload**: This keyword without any options deletes the complete overload policy from the PDSN service.

- **overloadredirect address [ address2 ... address16 ]**: deletes up to 16 IP addresses from the overload redirect policy. The IP addresses must be expressed in IP v4 dotted decimal notation.

- **rrq mei-from-current-pcf suppress-ppp-restart**: suppresses the PPP restart, when RRQ containing MEI comes from the current PCF. This is disabled by default.

- **service-option**: Resets the PDSN service to accept calls that do not contain the service option(s) configured using the service option command.

- **unknown-cvse enforce**: When unknown-cvse policy is enforced, PDSN will deny RRQs with unknown CVSEs (unknown vendor id, unknown app type or unknown app subtype) with an error code. When disabled, PDSN will process the CVSE like an NVSE. If an unknown vendor-id, app-type or app-subtype is encountered during the processing of a CVSE, the entire CVSE will be ignored and rest of the RRQ will be processed.

```plaintext
policy overload { redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ] } | { reject [ use-reject-code { admin-prohibited | insufficient-resources } ] }
```

Specifies how a PDSN service should handle an overload condition.
**redirect**: This option enables a redirect policy for overloading conditions. When a redirect policy is invoked, the PDSN service rejects new sessions with an A11 Registration Reply Code of 88H (unknown PDSN address) and provides the IP address of an alternate PDSN. This command can be issued multiple times.

**address**: The IP address of an alternate PDSN expressed in IP v4 dotted decimal notation. Up to 16 IP addresses can be specified either in one command or by issuing the redirect command multiple times. If you try to add more than 16 IP addresses to the redirect policy the CLI issues an error message. If you specify an IP address and weight that already exists in the redirect policy the new values override the existing values.

**weight weight_num**: When multiple addresses are specified, they are selected in a weighted round-robin scheme. Entries with higher weights are more likely to be chosen. If a weight is not specified the entry is automatically assigned a weight of 1. 

**reject**: This option will cause any overload traffic to be rejected. The PDSN will send an A11 Registration Reply Code of 82H (insufficient resources).

**use-reject-code admin-prohibited**: When this keyword is specified and traffic is rejected, the error code admin prohibited is returned instead of the error code insufficient resources. This is the default behavior.

**use-reject-code insufficient-resources**: When this keyword is specified and traffic is rejected, the error code insufficient resources is returned instead of the error code admin prohibited.

```plaintext
policy msid-match msid_with_wildcards { redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ] }
```

Specifies how a PDSN service should handle an incoming call that matches a list of wildcard MSIDs.

**msid_with_wildcards**: An MSID in which up to 16 digits have been replaced with the wildcard ‘$’. This defines the list of possible matches for incoming calls.

**redirect**: This option enables a redirect policy for overloading conditions. When a redirect policy is invoked, the PDSN service rejects new sessions with an A11 Registration Reply Code of 88H (unknown PDSN address) and provides the IP address of an alternate PDSN. This command can be issued multiple times.

**address**: The IP address of an alternate PDSN expressed in IP v4 dotted decimal notation. Up to 16 IP addresses can be specified either in one command or by issuing the redirect command multiple times. If you try to add more than 16 IP addresses to the redirect policy the CLI issues an error message. If you specify an IP address and weight that already exists in the redirect policy the new values override the existing values.

**weight weight_num**: When multiple addresses are specified, they are selected in a weighted round-robin scheme. Entries with higher weights are more likely to be chosen. If a weight is not specified the entry is automatically assigned a weight of 1. 

```plaintext
policy pcf-zone-match zone_number { redirect address [ weight weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ] }
```

Specifies how a PDSN service should handle an incoming call that matches a predefined zone number.

**zone_number**: An integer between 1 and 32 that defines the zone incoming calls must match for redirection.

**redirect**: This option enables a redirect policy for overloading conditions. When a redirect policy is invoked, the PDSN service rejects new sessions with an A11 Registration Reply Code of 88H (unknown PDSN address) and provides the IP address of an alternate PDSN. This command can be issued multiple times.

**address**: The IP address of an alternate PDSN expressed in IP v4 dotted decimal notation. Up to 16 IP addresses can be specified either in one command or by issuing the redirect command multiple times. If you try to add more than 16 IP addresses to the redirect policy the CLI issues an error message. If you specify an IP address and weight that already exists in the redirect policy the new values override the existing values.
**weight** *weight_num* When multiple addresses are specified, they are selected in a weighted round-robin scheme. Entries with higher weights are more likely to be chosen. If a weight is not specified the entry is automatically assigned a weight of 1. *weight_num* must be an integer from 1 through 10.

**Usage**

Policies can be implemented to dictate PDSN service behavior for various conditions such as overloading. The system invokes the overload policy if the number of calls currently being processed exceeds the licensed limit for the maximum number of sessions supported by the system. The system automatically invokes the overload policy when an on-line software upgrade is started.

Use the **no policy** { **overload** | **service-option** } command to delete a previously configured policy. If after deleting the policy setting you desire to return the policy parameter to its default setting, use the **default policy** command.

The chassis is shipped from the factory with the policy options set as follows:

- overload disabled
- sequence-numbers enforced enabled

⚠️ **Caution:** Incorrect configuration of the **policy msid-match** and **policy pcf-zone-match** keywords could result in sessions failing to be established. For example, if PDSN1 is configured to redirect sessions to PDSN2 while PDSN2 is configured to redirect sessions to PDSN1, a loop is created in which all sessions would fail to be connected. In addition, sessions will not be established if the PDSN to which the sessions are being redirected is unavailable.

**Example**

The following command configures the PDSN service to redirect traffic to two different destinations with weights of 1 and 10 respectively:

```
policy overload redirect 192.168.1.100 weight 1 192.168.1.200 weight 10
```
**ppp**

Sets PPP tunneling parameters for subscribers in the current PDSN service.

**Product**

PDSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
ppp { tunnel-context context_name | tunnel-type { l2tp | l2tp-secure | none } }

no ppp tunnel-context
```

**no**

Clears the configured tunnel context entry.

**tunnel-context context_name**

The name of the context that has a LAC service configured to handle all tunnels from this PDSN service.

**tunnel-type { l2tp | l2tp-secure | none }**

- **l2tp**: Force all subscriber sessions in this PDSN service to use L2TP tunneling.
- **l2tp-secure**: Force all subscriber sessions in this PDSN service to use L2TP tunneling and use IPSEC to ensure a secure connection.
- **none**: Do not force L2TP tunneling. This is the default.

**Important:** If the context specified by the `ppp tunnel-context context_name` command does not have a LAC service configured and `tunnel-type` is set to `l2tp` or `l2tp-secure`, the call is rejected.

**Important:** If the PPP tunnel context has not been set or has been cleared with the `no ppp tunnel-context` command and `tunnel-type` is set to `l2tp` or `l2tp-secure`, the context where the current PDSN service resides is used. If that context does not have a LAC service configured the call is rejected.

**Usage**

Use this command to enable or disable forced L2TP tunneling for all subscribers using this PDSN service. Also use this command to define which context defines the L2TP tunneling parameters.

**Example**

To set the tunnel context to the context named `context1` and enable forced L2TP tunneling, use the following commands;

```plaintext
ppp tunnel-context context1
ppp tunnel-type l2tp
```

To enable forced L2TP tunneling with IPSEC security, use the following commands;
**ppp tunnel-type l2tp-secure**

To disable forced tunneling, use the following command;

**ppp tunnel-type none**

To clear the setting for the tunnel context, use the following command;

**no ppp tunnel-context**
qos-profile-id-mapping

This command creates the customized QoS profile identifier to QoS mapping for IMS authorization support through a Ty interface at the PDSN service level.

Product
PDSN, HA

Privilege
Security Administrator, Administrator

Syntax

```bash
qos-profile-id-mapping profile-id id_num { description desc | downlink-bw dl_bw | drop-rate drop_percentage | latency latency_duration | qos-class {class-A | class-B | class-C | class-D | class-E | calss-F } uplink-bw ul_bw }+

[ default | no ] qos-profile-id-mapping profile-id id_num
```

---

**default**

Configures the specified QoS profile ID for QoS mapping with default values in this PDSN service.

**no**

Removes the configured QoS profile ID mapping in this PDSN service.

**profile-id id_num**

Specifies the profile identifier for QoS parameters to be used as the customized profile ID or modifies the QoS parameters in a profile ID (id_num) coming from RAN. id_num must be an integer between 0 and 65535.

**description desc**

Specifies the user defined description for profile identifier. desc must be an alpha and/or numeric string between 1 and 32 characters.

**downlink-bw dl_bw**

Default: 32

Specifies the downlink (towards the MN) data traffic bandwidth in kilo-bits per second for this QoS profile. dl_bw must be an integer value between 0 and 100000.

**drop-rate drop_percentage**

Default: 0

Specifies the permitted packet drop rate in percentage for traffic flow to this QoS profile. drop_percentage must be an integer value between 0 and 1000.

**latency latency_duration**

Default: 1000

Specifies the permitted latency duration in milli-seconds for this QoS profile. latency_duration must be an integer value between 0 and 1000.
qos-class {class-A | class-B | class-C | class-D | class-E | class-F }

Default: Class-C
Specifies the type of QoS class associated with this QoS profile
class-A: Specifies the A type of QoS class.
class-B: Specifies the B type of QoS class.
class-C: Specifies the C type of QoS class.
class-D: Specifies the D type of QoS class.
class-E: Specifies the E type of QoS class.
class-F: Specifies the F type of QoS class.

uplink-bw ul_bw

Default: 32
Specifies the uplink (from the MN) data traffic bandwidth in kilo-bits per second for this QoS profile.
ul_bw must be an integer value between 0 and 100000.

+ More than one of the above keywords can be entered within a single command.

Usage
Use this command to define the values associated with the profile ID on the PDSN. This profile ID is used
during the mapping to and from the authorized QoS to the QoS parameters for the A10 link. This mapping is
required because the PDSN only knows the profile IDs and not the actual configured values for the profile ID
in the RAN. Also this configuration allows the use of custom profile IDs for the subscribers.
If no values are defined with a QoS profile ID, the values from matching QoS profile ID from RAN will be
applicable to the subscriber traffic.

Example
The following command sets the downlink bandwidth to 32 kbps, latency duration as 1000 ms, uplink bandwidth to
32 kbps, and QoS class to Class-C for the QoS profile ID 11 in a PDSN service:

default qos-profile-id-mapping profile-id 11
qos update

Use this command to set QoS update parameters for policy mismatches or wait timeouts.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
qos-update [ policy-mismatch | wait-timeout seconds action [ disconnect-session | downgrade-to-best-effort | drop-packets ] ]
```

[ no | default ] qos-update [ policy-mismatch | wait-timeout]

---

**no**
Enables/Disables the qos-update [policy-mismatch|wait-timeout].

---

**default**
Sets / Restores default value for qos-update [policy-mismatch|wait-timeout].

---

**policy-mismatch**
PDSN raises a TFT violation if there is a QoS policy mismatch.

---

**wait-timeout action [ drop-packets | disconnect-session | downgrade-to-best-effort ]**
Sets the wait for A11 RRQ for QoS changes. seconds must be an integer from 1 through 1000.

**action** configures the action on the wait-timeout

- **disconnect-session**: Drops the call if the A11 RRQ has not been received for the QoS update. This includes all of the IP flows for the session.
- **downgrade-to-best-effort**: Drops packets if the A11 RRQ has not been received for the QoS update. Sends the forward traffic over best effort (flow FF or FE if available).
- **drop-packets**: Drops packets if the A11 RRQ has not been received for the QoS update.

---

**Usage**
This command provides a PDSN service level configurable to configure an action, if the PCF ignores the QoS Update request from PDSN. It sets the amount of time to wait and the action to take, if no RRQ is received before the timeout. The action can be to drop packets for the flow, disconnect the session or to downgrade to best effort.

---

**Example**

```
qos-update policy mismatch
```
The following command sets `wait-timeout` to 60 seconds and invokes `downgrade-to-best-effort` if the A11 RRQ has not been received for the QoS update:

```
qos-update wait-timeout 60 action downgrade-to-best-effort
```
registration-accept

When the PDSN is tearing down a session and the MN moves over to a new PCF and initiates a new session, the PDSN by default does not accept the handoff until it tears down the old session. This command allows the PDSN to accept registration requests when a handoff disconnect is in progress.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
registration-accept handoff session-disconnect-in-progress
```

- **no**
  - Disable accepting of registration requests when a handoff disconnect is still in progress.

- **default**
  - Default is disabled.
  - Sets / Restores default value assigned for `registration-accept handoff session-disconnect-in-progress`.

**Usage**

Use this command to allow the PDSN service to accept registration requests when a handoff disconnect is still in progress.

**Example**

```
registration-accept handoff session-disconnect-in-progress
```
registration-ack-deny terminate-session-on-error

Configure the PDSN service to terminate an A11 session when a Registration ACK received from the PCF has an error status.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

registration-ack-deny terminate-session-on-error

[ no | default ] registration-ack-deny terminate-session-on-error

- no
  Disable terminating A11 sessions on a Registration ACK error from the PCF.

- default
  Sets / Restores default value assigned to registration-ack-deny terminate-session-on-error.

Usage
Use this command to enable the PDSN service to terminate A11 sessions on a Registration ACK error from the PCF.

Example
Use the following command to enable this functionality in the PDSN:

registration-ack-deny terminate-session-on-error
registration-deny

Configures parameters related to registration rejection.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

no registration-deny { handoff { closedrp-rp handoff-in-progress | connection-setup-record-absent } | mismatched-coa-source-address | new-call { connection-setup-record-absent | reverse-tunnel-unavailable } | session-already-active | session-already-closed | session-already-dormant | terminate-session-on-error | use-zero-gre-key

default registration-deny { handoff { closedrp-rp handoff-in-progress | connection-setup-record-absent } | mismatched-coa-source-address | new-call { connection-setup-record-absent | reverse-tunnel-unavailable } | session-already-active | session-already-closed | session-already-dormant | terminate-session-on-error | use-zero-gre-key

default
Sets / Restores default value for registration-deny.

no
Disables the specified option.

handoff { closedrp-rp handoff-in-progress | connection-setup-record-absent [ use-deny-code { poorly-formed-request | reason-unspecified

This command configures the handoff behavior.

closedrp-rp handoff-in-progress: Configures parameters related to denying handoffs from Closed-RP to RP systems. When enabled the PDSN rejects retransmitted handoff R-P requests when a handoff is already in progress from Closed RP to RP. The deny code used is 'Reason Unspecified'. The default is disabled meaning that the PDSN simply discards such requests.

connection-setup-record-absent [ use-deny-code { poorly-formed-request | reason-unspecified }]: When enabled the PDSN denies or discards handoff R-P sessions that do not have an Airlink Connection Setup record in the A11 Registration Request. Default is disabled. Default PDSN behavior is to accept such requests.

{ use-deny-code { poorly-formed-request | reason-unspecified } }: Sets the specified Registration Deny Code when denying a handoff because of a missing connection setup record.
max-deny-reply-limit \textit{num}

Default: 3
Configures max number of retries of erroneous registration request message from PCF for a session before PDSN terminates the session. \textit{num} can be from 1 to 10.

mismatched-coa-source-address

Default: disabled
Denies RP requests which have a care-of-address field that is different from the request source address.

new-call \{ connection-setup-record-absent \[ use-deny-code \{ poorly-formed-request | reason-unspecified \} | reverse-tunnel-unavailable \}

connection-setup-record-absent: Configures the PDSN to reject calls that do not have the airlink connection setup record in the RRQ.
use-deny-code \{ poorly-formed-request | reason-unspecified \}: When rejecting calls that do not have the airlink setup record, use the specified deny code.
reverse-tunnel-unavailable: Configures the PDSN to reject calls if the GRE key for a user collides with that of another user.

session-already-active

PDSN denies Registration requests for sessions that are already active with the error code “poorly formed request”.

session-already-closed

PDSN denies RP renew and dereg requests with error code 0x8E for absent R-P sessions.

session-already-dormant

PDSN denies Registration requests for sessions that are already dormant with the error code “poorly formed request”.

terminate-session-on-error

Default: Disabled.
Configures PDSN to terminate session if erroneous registration request message is received for the session.

use-zero-gre-key

Configures the PDSN to set the GRE key to zero (0) when denying a new R-P session.

Usage

Use this command to configure parameters relating to the rejection of registration requests.

Example

To reject calls that do not have the airlink setup record in the RRQ, enter the following command:

\[
\text{registration-deny new-call connection-setup-record-absent}
\]

To reject calls if the GRE key collides with that of another user, enter the following command:
To set the GRE key to 0 (zero) when a new R-P session is denied, enter the following command:

```
registration-deny new-call use-zero-gre-key
```
registration-discard

Configures the PDSN service to discard any Registration Request message containing multiple information elements of the same type or a different GRE key for existing IMSI session.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
registration-discard { bad-extension | gre-key-change | handoff connection-setup-record-absent }
```

```
no registration-discard { bad-extension | gre-key-change | handoff connection-setup-record-absent }
```

```
default registration-discard { bad-extension | gre-key-change | handoff connection-setup-record-absent }
```

---

**default**

Sets / Restores default value assigned for `registration-discard`.

---

**no**

Disables the discarding of Registration request messages containing multiple information elements or different GRE keys.

---

**bad-extension**

Default: Disabled

Configures the PDSN to discard Registration Request message containing multiple information elements of same type.

---

**gre-key-change**

Default: Disabled

Configures PDSN to discard Registration Request message containing different GRE key for existing IMSI session. Default is disable

---

**handoff connection-setup-record-absent**

Default: Disabled

When enabled, discards A11 Handoff requests that do not contain the Airlink Setup record.

---

**Usage**

Use this command to configure the PDSN service to discard and Registration Requests that contain multiple information elements of the same type or discard Registration Requests that contain GRE keys that have different GRE keys for the existing IMSI session.
Example
To configure the PDSN service to discard Registration Requests that have multiple information elements of the same type, enter the following command:

```
registration-discard bad-extension
```

To configure the PDSN service to discard Registration Requests that contain a GRE key that is different than the existing one for the existing IMSI session, enter the following command:

```
registration-discard gre-key-change
```
registration-update

Configures registration update related parameters for the PDSN.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

registration-update { pdsn-code-nvse | wait-timeout secs }
no registration-update { pdsn-code-nvse | wait-timeout }
default registration-update { pdsn-code-nvse | wait-timeout }

no
If this option is used with the pdsn-code-nvse keyword, then pdsn-code-nvse configuration is disabled.
If this option is used with the wait-timeout keyword, a separate A11 timer is not used. The PDSN waits for the ppp retransmit-timeout and then sends the A11 Update. If a value is provided, then the "ppp retransmit-timeout" is ignored and a separate A11 timeout is started immediately upon sending the LCP Term-Ack. The A11 Update is then sent when the timer expires.
A value of 0 sends the A11 Update immediately after sending the LCP Term-Ack.

default
Sets / Restores default value assigned for registration-update { pdsn-code-nvse | wait-timeout }

pdsn-code-nvse
Adds the PDSN code NVSE in all A11 registration update messages.

secs
The number of seconds to wait. secs must be an integer in the range from 0 through 16.

wait-timeout
After the Mobile Node terminates a PPP session between the PDSN and the Mobile Node, the PDSN service waits for the specified time period to receive an A11 RRQ from the PCF before it sends out a Registration-Update to clear the Session from the PCF.

Usage
Use this command to configure registration update related
The wait-timeout keyword configures the PDSN to wait the specified amount of time before sending out a Registration-Update to clear the Session from the PCF.
Example
Use the following command to set the registration wait-timeout to \( 16 \) seconds:

```
registration-update wait-timeout 16
```
retransmission-timeout

Configures the maximum allowable time for the PDSN service to wait for a response from the PCF before it a) attempts to communicate with the PCF again (if the system is configured to retry the PCF) or b) marks the PCF as unreachable.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

retransmission-timeout  time

no retransmission-timeout

default retransmission-timeout

  no
  Enables/Disables the retransmission-timeout.

  default
  Sets / Restores default value assigned for retransmission-timeout.

  time
  Specifies the maximum allowable time for the PDSN service to wait for a response from the PCF before it a) attempts to communicate with the PCF again (if the system is configured to retry the PCF) or b) marks the PCF as unreachable.
  time is measured in seconds and can be configured to any integer value between 1 and 1,000,000.

Usage

Use the retransmission timeout command in conjunction with the max-retransmissions command in order to configure the PDSN services behavior when it does not receive a response from a particular PCF.
Use the no retransmission-timeout command to delete a previously configured timeout value. If after deleting the lifetime setting you desire to return the lifetime parameter to its default setting, use the default retransmission-timeout command.
The chassis is shipped from the factory with the retransmission timeout set to 3 seconds.

Example

The following command configures a retransmission timeout value of 5 seconds:

  retransmission-timeout 5

The following command deletes a previously configured retransmission-timeout setting:

  no retransmission-timeout
sdb-indication

Configures parameters pertaining to Short Data Burst (SDB) functionality.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

sdb-indication { echo-request | server-address ipaddress/mask packet-length-range min min_range max max_range }

no sdb-indication { echo-request | server-address ipaddress/mask }

no
Disables short-databurst indication.

echo-request
Default: Disabled
Enables the inclusion of the SDB indicator in the LCP Echo Request message(s).

server-address ipaddress/mask
Configures the IP address of the PTT server.
ipaddress is the IP address expressed in dotted decimal notation.
mask is the number of mask bits.

packet-length-range min min_range max max_range
Configures the packet length associated with the specified server.
min min_range configures the minimum packet length as an integer value between 1 and 65535.
max max_range configures the maximum packet length as an integer value between 1 and 65535.

Usage
This command controls the use of Short Data Burst functionality between the PDSN, PCF, and Push-to-Talk (PTT) servers.

Important: This command is for use with a customer-specific implementation and requires a valid Short Data Burst feature-use license to be installed.

Example
The following command configures a PTT server address of 192.168.1.200 with a mask of 16, a minimum packet size of 200, and a maximum packet size of 400:
sdb-indication server-address 192.168.1.200/16 packet-length-range min 200 max 400
**service-option**

If the service option policy is enabled, this command specifies the service options supported by the PDSN service.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
service-option number
no service-option number
default service-option
```

- **no**
  Enables/Disables the `service-option number`

- **default**
  Sets / Restores default value assigned for `service-option`.

- **number**
  Default: 7, 15, 22, 23, 24, 25, 33, 59, 67
  Specifies a specific Service Option (SO) number that this PDSN service is allowed to support. number can be configured to any integer value between 1 and 1000.

**Usage**

Use the service option command in conjunction with the policy service option enforce command to configure specific SO numbers that are supported. If a particular SO number is not configured, then any subscriber session received with that SO number will be rejected and an A11 Registration Reply Code of 86 (poorly formed request) will be sent.

By default, PDSN services are configured to support the following service option numbers:

- 7: PCF specific
- 15: PCF specific
- 22: High Speed Packet Data Service: Internet or ISO Protocol Stack (RS1 forward, RS1 reverse)
- 23: High Speed Packet Data Service: Internet or ISO Protocol Stack (RS1 forward, RS2 reverse)
- 24: High Speed Packet Data Service: Internet or ISO Protocol Stack (RS2 forward, RS1 reverse)
- 25: High Speed Packet Data Service: Internet or ISO Protocol Stack (RS2 forward, RS2 reverse)
- 33: 3G High Speed Packet Data
- 59: High Rate Packet Data
- 67: RP A10 connection
**Important:** Option 67 is used for auxiliary connections for Rev-A calls. PPP encapsulation of data packets does not flow over this service option connection. ROHC can be performed without PPP for this service option.

Use the `no service-option number` command to delete a previously configured service option. If after deleting the service option setting you desire to return the service option parameter to its default setting, use the `default service-option` command.

**Example**
The following command enables a service option of 12:

```
service-option 12
```

The following command disables the default service option 59:

```
no service-option 59
```
setup-timeout

The maximum amount of time allowed for session setup.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

setup-timeout seconds

default setup-timeout

default
Sets / Restores default value assigned for setup-timeout.

seconds
Default: 60 seconds
The maximum amount of time, in seconds, to allow for setup of a session. seconds must be an integer from 1 through 1000000

Usage
Use this command to set the maximum amount of time allowed for setting up a session.

Example
Use the following command to set the maximum time allowed for setting up a session to 300 seconds:

setup-timeout 300
simple-ip allow

This command is used to disable or re-enable SImple-IP sessions from making a connection before authorization takes place.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

[no|default] simple-ip allow

no
When a session attempts PPP authentication, it is assumed that it is a Simple-IP session and it is disconnected before the user is authenticated (RADIUS or local authentication). Also, if allow-noauth is enabled and PPP authentication is not performed, after IPCP the session is disconnected if it is discovered that it is a Simple-IP session.

default
Reset this command to allow Simple-IP sessions to connect.

Usage
Use this command to prevent Simple-IP sessions from connecting to a PDSN service.

Example
The following command configures the PDSN service so that it will reject any Simple-IP sessions:

no simple-ip allow

The following command configures the PDSN service to allow Simple-IP sessions:

simple-ip allow
spi

Configures the security parameter index (SPI) between the PDSN service and the PCF. This command also configures the redirection of call based on PCF zone.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

```
spi remote-address { pcf_ip_address | ip_addr_mask_combo } spi-number
  number { encrypted secret enc_secret | secret secret } [ description string ]
  hash-algorithm { md5 | rfc2002-md5 } [ replay-protection { nonce |
  timestamp } ] [ timestamp-tolerance tolerance ] [ zone zone_id ]
```

```
no spi remote-address pcf_ip_address spi-number number
```

remote-address { pcf_ip_address | ip_addr_mask_combo }

pcf_ip_address: Specifies the IP address of the PCF. pcf_ip_address is an IP address expressed in IP v4 dotted decimal notation.

ip_addr_mask_combo: Specifies the IP address of the PCF and specifies the IP address network mask bits. ip_addr_mask_combo must be specified using the form 'IP Address/Mask Bits' where the IP address must either be an IPv4 address expressed in dotted decimal notation or an IPv6 address expressed in colon notation and the mask bits are a numeric value which is the number of bits in the subnet mask.

spi-number number

Specifies the SPI (number) which indicates a security context between the PCF and the PDSN in accordance with IOS 4.1 and RFC 2002. number can be configured to any integer value between 256 and 4294967295.

encrypted secret enc_secret | secret secret

Configures the shared-secret between the PDSN service and the PCF. The secret can be either encrypted or non-encrypted.

encrypted secret enc_secret: Specifies the encrypted shared key (enc_secret) between the PCF and the PDSN service. enc_secret must be between 1 and 254 alpha and/or numeric characters and is case sensitive.

secret secret: Specifies the shared key (secret) between the PCF and the PDSN services. secret must be between 1 and 127 alpha and/or numeric characters and is case sensitive.

The encrypted keyword is intended only for use by the chassis while saving configuration scripts. The system displays the encrypted keyword in the configuration file as a flag that the variable following the secret keyword is the encrypted version of the plain text secret key. Only the encrypted secret key is saved as part of the configuration file.

description string

This is a description for the SPI. string must be an alpha and or numeric string of from 1 through 31 characters.
hash-algorithm { md5 | rfc2002-md5 }
Default: md5
Specifies the hash-algorithm used between the PDSN service and the PCF.
md5: Configures the hash-algorithm to implement MD5 per RFC 1321.
rfc2002-md5: Configures the hash-algorithm to implement keyed-MD5 per RFC 2002.

replay-protection { nonce | timestamp }
Default: timestamp
Specifies the replay-protection scheme that should be implemented by the PDSN service.
nonce: Configures replay protection to be implemented using NONCE per RFC 2002.
timestamp: Configures replay protection to be implemented using timestamps per RFC 2002.

timestamp-tolerance tolerance
Default: 60
Specifies the allowable difference (tolerance) in timestamps that is acceptable. If the difference is exceeded, then the session will be rejected. If this is set to 0, then time stamp tolerance checking is disabled at the receiving end.
tolerance is measured in seconds and can be configured to any integer value between 0 and 65535.

zone zone_id
Specifies the different PCF zones to configure in PDSN service. Mapping of a zone-number to a set of PDSNs can be done per PDSN service basis.
zone_id must be an integer value between 1 and 32. A maximum of 32 PCF zones can be configured for a PDSN service.

Usage
An SPI is a security mechanism configured and shared by the PCF and the PDSN service. Please refer to IOS 4.1 and RFC 2002 for additional information.
Multiple SPIs can be configured if the PDSN service is communicating with multiple PCFs.

Important: The SPI configuration on the PCF must match the SPI configuration for the PDSN service on the system in order for the two devices to communicate properly.

Use the no version of this command to delete a previously configured SPI.
This command used with zone zone_id redirects all calls on the basis of PCF zone to the specific PDSN on the basis of parameters configured at policy pcf-zone-match command.

Example
The following command configures the PDSN service to use an SPI of 256 when communicating with a PCF with the IP address 192.168.0.2. The key that would be shared between the PCF and the PDSN service is q397F65.

    spi remote-address 192.168.0.2 spi-number 256 secret q397F65

The following command deletes the configured SPI of 400 for an PCF with an IP address of 172.100.3.200:

    no spi remote-address 172.100.3.200 spi-number 400
The following command creates the configured SPI of 400 for an PCF with an IP address of 172.100.3.200 and zone id as 11:

```
spi remote-address 172.100.3.200 spi-number 400 zone 11
```
**spi zone**

Configures the security parameter index (SPI) between the PDSN service and the PCF with mapping between a zone number to a set of PDSNs per PDSN service to redirect call on the basis of PCF zone.

**Product**

PDSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
spi zone zone_id
no spi zone zone_id
```

**Usage**

An SPI is a security mechanism configured and shared by the PCF and the PDSN service. Please refer to IOS 4.1 and RFC 2002 for additional information.

Multiple SPIs can be configured if the PDSN service is communicating with multiple PCFs.

This PCF zone option is used for call redirection on the basis of PCF zone. When a new call arrives the PDSN, it checks whether the PCF, from which the call arrived, belongs to a particular zone. If

**Important:** The SPI configuration on the PCF must match the SPI configuration for the PDSN service on the system in order for the two devices to communicate properly.

Use the `no` version of this command to delete a previously configured SPI.

**Example**

The following command configures the PDSN service to use an SPI of 256 when communicating with a PCF with the IP address 192.168.0.2. The key that would be shared between the PCF and the PDSN service is q397F65.

```plaintext
spi remote-address 192.168.0.2 spi-number 256 secret q397F65
```

The following command deletes the configured SPI of 400 for an PCF with an IP address of 172.100.3.200:

```plaintext
no spi remote-address 172.100.3.200 spi-number 400
```
threshold a11-rrp-failure

Set an alarm or alert based on the number of A11 Registration Response failures for the PDSN service.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
threshold a11-rrp-failure high_thresh [ clear low_thresh ]

no threshold a11-rrp-failure
```

- **no**
  Deletes the alert or alarm.

- **high_thresh**
  Default: 0
  The high threshold number of A11 Registration Response failures that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to any integer value between 0 and 100000.

- **clear low_thresh**
  Default: 0
  The low threshold number of A11 Registration Response failures that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to any integer value between 0 and 100000.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to set an alert or an alarm when the number of A11 Registration Response failures is equal to or greater than a specified number.

Alerts or alarms are triggered for the number of A11 Registration Response failures based on the following rules:

- **Enter condition:** Actual number of A11 Registration Response failures > High Threshold
- **Clear condition:** Actual number of A11 Registration Response failures £ Low Threshold

**Example**
The following command configures a number of A11 Registration Response failures threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```
threshold a11-rrp-failure 1000 clear 500
```
threshold a11-rrq-msg-discard

Set an alarm or alert based on the number of Discarded A11 Registration Requests for the PDSN service.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

```
threshold a11-rrq-msg-discard high_thresh [ clear low_thresh ]

no threshold a11-rrq-msg-discard
```

- **no**

  Deletes the alert or alarm.

- **high_thresh**

  Default: 0
  The high threshold number of Discarded A11 Registration Requests that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to any integer value between 0 and 100000.

- **clear low_thresh**

  Default: 0
  The low threshold number of Discarded A11 Registration Requests that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to any integer value between 0 and 100000.

_Important_: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of Discarded A11 Registration Requests is equal to or greater than a specified number.

Alerts or alarms are triggered for the number of Discarded A11 Registration Requests based on the following rules:

- **Enter condition**: Actual number of Discarded A11 Registration Requests > High Threshold
- **Clear condition**: Actual number of Discarded A11 Registration Requests £ Low Threshold

Example

The following command configures a number of Discarded A11 Registration Requests threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```
threshold a11-rrq-msg-discard 1000 clear 500
```
PDSN Service Configuration Mode Commands

threshold a11-rrq-msg-discard
tft-validation wait-timeout

This command configures the TFT validation wait timeout value for QoS changes. The QoS update timer triggers automatic QoS updates based on dynamic policies.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

\texttt{tft-validation wait-timeout seconds}

\texttt{[ no | default ] tft-validation wait-timeout}

- \texttt{no}
  Removes the wait-timeout timer.

- \texttt{default}
  Sets / Restores default value assigned for \texttt{tft-validation wait-timeout}.

Usage
Detected the TFT validation wait time value for A11 RRQ for QoS changes. \textit{seconds} must be an integer from 1 through 65535.

Example
Use the following command to set the TFT validation wait-timeout to 5 seconds:

\texttt{tft-validation wait-timeout 5}
threshold a11-rac-msg-discard

Set an alarm or alert based on the number of Discarded A11 Registration Acknowledgements for the PDSN service.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
threshold a11-rac-msg-discard high_thresh [ clear low_thresh ]
no threshold a11-rac-msg-discard
```

*no*
Delete the alert or alarm.

*high_thresh*
Default: 0
The high threshold number of Discarded A11 Registration Acknowledgements that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to any integer value between 0 and 100000.

*clear low_thresh*
Default: 0
The low threshold number of Discarded A11 Registration Acknowledgements that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to any integer value between 0 and 100000.

**Important**: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**
Use this command to set an alert or an alarm when the number of Discarded A11 Registration Acknowledgements is equal to or greater than a specified number. Alerts or alarms are triggered for the number of Discarded A11 Registration Acknowledgements based on the following rules:

- **Enter condition**: Actual number of Discarded A11 Registration Acknowledgements > High Threshold
- **Clear condition**: Actual number of Discarded A11 Registration Acknowledgements ≤ Low Threshold

**Example**
The following command configures a number of Discarded A11 Registration Acknowledgements threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:
threshold all-rac-msg-discard 1000 clear 500
threshold all-ppp-send-discard

Set an alarm or alert for the PDSN service based on the number of packets that the PPP protocol processing layer internally discarded on transmit for any reason.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

```
threshold all-ppp-send-discard high_thresh [ clear low_thresh]

no threshold all-ppp-send-discard

no
Delete the alert or alarm.

high_thresh
Default: 0
The high threshold number of discarded PPP send packets that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to any integer value between 0 and 100000.

clear low_thresh
Default: 0
The low threshold number of discarded PPP send packets that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to any integer value between 0 and 100000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage
Use this command to set an alert or an alarm when the number of discarded PPP send packets is equal to or greater than a specified number.
Alerts or alarms are triggered for the number of discarded PPP send packets is based on the following rules:

• Enter condition: Actual number of discarded PPP send packets > High Threshold
• Clear condition: Actual number of discarded PPP send packets ≤ Low Threshold

Example
The following command configures a number of discarded PPP send packets threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```
threshold all-ppp-send-discard 1000 clear 500
```
threshold all-ppp-send-discard
threshold init-rrq-rcvd-rate

Set an alarm or alert based on the average number of calls setup per second for the context.

**Product**
PDSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```bash
threshold init-rrq-rcvd-rate high_thresh [ clear low_thresh ]
no threshold init-rrq-rcvd-rate
```

- `no`
  - Deletes the alert or alarm.

- `high_thresh`
  - **Default:** 0
  - The high threshold average number of calls setup per second must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to any integer value between 0 and 1000000.

- `clear low_thresh`
  - **Default:** 0
  - The low threshold average number of calls setup per second that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to any integer value between 0 and 1000000.

**Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

**Usage**

Use this command to set an alert or an alarm when the average number of calls setup per second is equal to or greater than a specified number of calls per second.

Alerts or alarms are triggered for the number of calls setup per second based on the following rules:

- **Enter condition:** Actual number of calls setup per second > High Threshold
- **Clear condition:** Actual number of calls setup per second £ Low Threshold

**Example**

The following command configures a number of calls setup per second threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```bash
threshold init-rrq-rcvd-rate 1000 clear 500
```
Chapter 158
PDSN Service RoHC Configuration Mode Commands

The PDSN Service RoHC Configuration Mode is used to configure RoHC (Robust Header Compression) parameters the PDSN service conveys to the PCF in the initial A11 RRP message before PPP authentication.

```
Exec Mode
   configure
      Global Configuration Mode
         context name
            Context Configuration Mode
               pd-sn-service name
                  PDSN Service Configuration Mode
                     ip header-compression rohc
                        PDSN Service ROHC Configuration Mode
```

**Important:** The commands, keywords and variables in this mode are available dependent on platform type, product version, and installed license(s).
threshold init-rrq-rcvd-rate
cid-mode

This command enters the RoHC Profile Compression Options Configuration mode. This mode allows you to configure options that apply during RoHC compression for the current RoHC profile.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

cid-mode { large | small } max-cid integer

default cid-mode

default
Reset all options in the RoHC Profile Compression Configuration mode to their default values.

large
Use large packets with optional information for RoHC

small
This is the default packet size. Use small RoHC packets.

max-cid integer
Default: 15
The highest context ID number to be used by the compressor. integer must be an integer from 0 through 15 when small packet size is selected and must be an integer from 0 through 31 when large packet size is selected.

Usage

Use this command to set the RoHC packet size and define the maximum

Example

The following command sets large RoHC packet size and sets the maximum CID to 100:

cid-mode large max-cid 100

The following command sets the cid-mode to the default settings of small packets and max-cid 0:

default cid-mode
end

Returns the CLI prompt to the Exec mode.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

end

Usage
Change the mode back to the Exec mode.
exit

Exits this configuration mode and returns to the PDSN Service configuration mode.

**Product**

PDSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the PDSN Service configuration mode.
mrru

This command sets the size of the largest reconstructed reception unit, in octets, that the decompressor is expected to reassemble from segments. The size includes the CRC. If MRRU is negotiated to be 0, no segment headers are allowed on the channel.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

mrru num_octets

default mrru

default
reset the value of this command to its default setting

num_octets
Default: 0
This is the number of octets for the maximum size of the largest reconstructed reception unit allowed. num_octets must be an integer from 0 through 65535.

Usage
Use this command to set the size, in octets, of the largest reconstructed reception unit, in octets, that the decompressor is expected to reassemble from segments.

Example
The following command sets the largest reconstructed reception unit to 1024 octets:

mrru 1024

The following command resets the mrru size to its default of 0 octets:

default mrru
profile

This command specifies the header compression profiles to use. A header compression profile is a specification of how to compress the headers of a specific kind of packet stream over a specific kind of link. At least one profile must be specified.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

```
profile { [ esp-ip ] [ rtp-udp ] [ udp-ip ] [ uncompressed-ip ] }
```

default profile

```
default
Default: esp-ip rtp-udp udp-ip uncompressed-ip
This command sets the RoHC profile configuration back to its default setting.
```

```
esp-ip
This enables RoHC Profile 0x0003 which is for ESP/IP compression, compression of the header chain up to and including the first ESP header, but not subsequent subheaders.
```

```
rtp-udp
This enables RoHC Profile 0x0001 which is for RTP/UDP/IP compression
```

```
udp-ip
This enables RoHC Profile 0x0002 which is for UDP/IP compression, compression of the first 12 octets of the UDP payload is not attempted.
```

```
uncompressed-ip
This enables RoHC Profile 0x0000 which is for sending uncompressed IP packets.
```

Usage

Use this command to specify the RoHC header compression profiles to use.

Example

The following command sets the profiles to use as esp-ip and rtp-udp:

```
profile esp-ip rtp-udp
```
Chapter 159
Peer-Server Configuration Mode Commands

The Peer-Server configuration mode provides the commands to define and manage the peer server configuration part of the SS7 routing on an SGSN.

In this mode, the prompt line usually appears similar to:

```
[local]hostname(config-ss7-rd-<ss7rd_id>-ps-id-<ps_id>)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
```
end
```

Usage
Change the mode back to the Exec mode.
exit

Exits the configuration mode and returns to the Global configuration mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Return to the Global configuration mode.
**mode**

Configures the operational mode of the peer-server.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
mode ( loadshare | standby )
```

- **loadshare**
  
  Sets the peer-server to load share. This is the default.

- **standby**
  
  Sets the peer-server to be in standby mode.

**Usage**

Configure the operational mode of the peer-server.

**Example**

Configure the peer-server for standby mode.

```plaintext
mode standby
```
**name**

Defines the unique identification - the name - of the peer-server in the SS7 routing domain.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
name name

no name
```

- **no**
  Removes the peer server’s name from this configuration instance.

- **name**
  
  ```
  name: Must be a string of 1 to 64 alphanumeric characters to define a unique identification for the peer-server within the specific SS7 routing domain. Double quotes must be used to create a name that includes spaces.
  ```

**Usage**
Create peer server names that are easy to remember and uniquely identify the PSP.

**Example**
Use this command to create an easily remembered alphanumeric name for the peer-server:

```
name "Berlin West"
```
**PSP**

Creates the peer-server-process (PSP) instance and enters the PSP configuration mode. See the PSP Configuration Mode chapter in this guide for information on the configuration commands.

**Important:** This command configures a mandatory parameter in the configuration of the peer server.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
[ no ] psp instance id
```

- **no**
  Removes the PSP instance from the peer server configuration.

- **id**
  id Uniquely identifies the specific peer-server-process configuration. The Id must be an integer from 1 to 4.

**Usage**

Use this command to define the peer-server-process (PSP) instance ID number for the SGSN configuration.

**Example**

Use this command to create instance #3 for the PSP configuration:

```plaintext
psp instance 3
```
**routing-context**

Defines the ID of the routing context for the peer-server to use.

---

**Important:** This command configures a mandatory parameter in the configuration of the peer server.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
routing-context id
no routing-context
```

**id**

Uniquely identifies a specific routing context for the peer-server-process to use. The Id must be an integer from 1 to 65535.

**no**

Removes the routing-context definition from the peer server configuration.

**Usage**

Use this command to define routing contexts for the peer server.

**Example**

Define routing-context instance 15:

```
    routing-context 15
```
**self-point-code**

This command defines the point-code to identify the SGSN as a peer server.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
self-point-code point-code
no self-point-code
```

---

**point-code**

Point-code is an SS7-type address for an element in the SS7 network. Point-codes must be defined in dotted-decimal format in a string of 1 to 11 digits. Options include:

- 0.0.1 to 7.255.7 for point-code in the ITU range.
- 0.0.1 to 255.255.255 for point-code in the ANSI range.
- 0.0.1 to 15.31.255 for point-code in the TTC Range.
- a string of 1 to 11 digits in dotted-decimal to represent a point-code in a different range.

---

**no**

Removes the self-point-code configuration for this linkset in the peer server.

---

**Important:** Removing the self-point-code will result in the termination of all traffic on this link.

---

**Usage**

Use this command to define the point-code to identify the SGSN.

---

**Example**

Use the following command to remove the self-point-code definition from the peer-server configuration:

```
no self-point-code
```
Chapter 160
P-GW Service Configuration Mode Commands

The P-GW (PDN Gateway) Service Configuration Mode is used to create and manage the relationship between specified services used for either GTP or PMIP network traffic.

```
Exec Mode

configure

Global Configuration Mode

context name

Context Configuration Mode

pgw-service name

P-GW Service Configuration Mode
```
associate

Associates the P-GW service with specific pre-configured services and/or policies configured in the same context.

Product  
P-GW

Privilege  
Administrator

Syntax

```
associate { egtp-service name [ lma-service name ] | lma-service name [ egtp-service name ] | qci-qos-mapping name }

no associate { egtp-service | lma-service | qci-qos-mapping }
```

no

Removes the selected association from this service.

```
{ egtp-service name [ lma-service name ] | lma-service name [ egtp-service name ] }
```

`egtp-service name [ lma-service name ]`: Specifies that the P-GW service is to be associated with an existing eGTP service within this context. `name` must be from 1 to 63 alpha and/or numeric characters and be an existing eGTP service. Configure an associated LMA service name to support handoffs between PMIPv6 and GTP. `name` must be from 1 to 63 alpha and/or numeric characters and be an existing LMA service.

`lma-service name [ egtp-service name ]`: Specifies that the P-GW service is to be associated with an existing LMA service within this context. `name` must be from 1 to 63 alpha and/or numeric characters and be an existing LMA service. Configure an associated eGTP service name to support handoffs between PMIPv6 and GTP. `name` must be from 1 to 63 alpha and/or numeric characters and be an existing eGTP service.

```
qci-qos-mapping name
```

Specifies that the P-GW service is to be associated with an existing QCI-QoS mapping configuration within this context. `name` must be from 1 to 63 alpha and/or numeric characters and be an existing QCI-QoS mapping configuration. QCI-QoS mapping is typically configured in a AAA context. Refer to the QCI-QoS Mapping Configuration Mode Commands chapter for more information.

Usage

Use this command to associate the P-GW service with other pre-configured services and/or policies configured in the same context.

Example

The following command associates this service with an eGTP service called `egtp1`:

```
associate egtp-service egtp1
```
authorize-with-hss

Identifies the function to use for subscriber authorization.

**Product**
P-GW

**Privilege**
Administrator

**Syntax**

```
[ default | no ] authorize-with-hss
```

- **Usage**
  Use this command to specify that the system will use the S6b interface to acquire subscriber authorization from a 3GPP AAA server and the HSS.
**dns-client context**

Specifies the context to use where the DNS client resides to send DNS queries.

**Product**
P-GW

**Privilege**
Administrator

**Syntax**

```powershell
dns-client context name
[ default | no ] dns-client context
```

- **default**
  Returns the command to the default setting of targeting the DNS client in the context where the P-GW service resides.

- **no**
  DNS query is disabled.

- **name**
  Specifies the name of the context where the DNS client is used for the resolution of PCSCF-FQDN received from S6b interface. `name` must be an existing context and be from 1 to 79 alpha and/or numeric characters.

**Usage**
Use this command to specify the context where the DNS client resides to perform P-CSCF-FQDN resolution from the S6b interface.

**Example**
The following command identifies the `egress1` context as the context where the DNS client resides:

```powershell
dns-client context egress1
```
end

Exits the current mode and returns to the Exec Mode.

**Product**
All

**Privilege**
Administrator

**Syntax**
end

**Usage**
Change the mode back to the Exec mode.
exit

Exits the current mode and returns to the previous mode.

Product
All

Privilege
Administrator

Syntax
exit

Usage
Return to the previous mode.
fqdn

Configures a Fully Qualified Domain Name for this P-GW service used in messages between the P-GW and a 3GPP AAA server over the S6b interface.

**Product**
P-GW

**Privilege**
Administrator

**Syntax**

```
fqdn host domain_name realm realm_name
[ default | no ] fqdn
```

<table>
<thead>
<tr>
<th><strong>default</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Returns the command to the default setting of “null”.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>no</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Remove the configured FQDN from this services configuration.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>host domain_name</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the domain name of the P-GW service. <code>domain_name</code> must be from 1 to 255 alpha and/or numeric characters.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>realm realm_name</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the realm name of the P-GW service. <code>realm_name</code> must be from 1 to 255 alpha and/or numeric characters.</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to identify the P-GW service using an FQDN required when sending messages over the S6b interface to a 3GPP AAA server.

**Important:** In order to properly interact with other nodes in the network, the FQDN should be 96 alpha and/or numeric characters or less.

**Topology Matching (eHRPD only)**

You may specify which P-GW you wish an HSGW interface to connect with by enabling topology matching within the FQDNs for both the HSGW service and P-GW service. Topology matching selects geographically closer nodes and reduces backhaul traffic for a specified interface.

The following optional keywords enable or disable topology matching when added to the beginning of an FQDN:

- `<topon><interface_name>`.
Beginning an FQDN with `topon` initiates topology matching with available HSGWs in the network. Once this feature is enabled, the rest of the FQDN is processed from right to left until a matching regional designator is found on a corresponding HSGW FQDN.

```bash
<topoff><interface_name>
```

By default, topology matching is disabled. If you enable topology matching for any interfaces within a node, however, all interfaces not using this feature should be designated with `topoff`.

---

**Example**

The following command configures the FQDN for this P-GW service as `123abc.all.com` with a realm name of `all.com`:

```bash
fqdn host 123abc.all.com realm all.com
```

The following command configures this P-GW service with an FQDN that enables topology matching:

```bash
fqdn host
topon.<interface_name>.pgw01.bos.ma.node.epc.mnc<value>.mcc<value>.3gppnetwork.org realm node.epc.<mnc>.<mcc>.3gppnetwork.org
```

**Important:** The associated HSGW service must have a corresponding FQDN similar to the following:

```bash
topon.<interface_name>.hsgw01.bos.ma.node.epc.mnc<value>.mcc<value>.3gppnetwork.org
```
gx-li context

Configures the name of the context where lawful intercept packets are delivered to the lawful intercept server.

Product
P-GW

Privilege
Administrator

Syntax

gx-li context name

default gx-li context

default
Return the command to the default setting of the P-GW context (where this service resides).

name
Specifies the name of the context where the LI interface is configured for transmitting LI packets to an LI server. name must be from 1 to 79 alpha and/or numeric characters.

Usage
Use this command to specify the name of the context where the LI source address is configured to send packets to a LI server. By default, the P-GW context will be used.

Important: A LI source IP address and interface must be configured in the context specified by this command.

Example
The following command identifies the context to use for LI server traffic as aaa3:

    gx-li context aaa3
newcall

Configures the P-GW to accept or reject requests for a static IP address if the address is already in use by another session.

Product
P-GW

Privilege
Administrator

Syntax

newcall duplicate-subscriber-requested-address { accept | reject }

no newcall duplicate-subscriber-requested-address

no
Returns the command to the default setting of “reject”.

duplicate-subscriber-requested-address { accept | reject }

Default: reject
accept: Specifies that the old session with the requested address will be ended to accept the new session with the same address.
reject: Specifies that the new session requesting the same address will be rejected.

Usage
Use this command to configure the behavior of the P-GW service when receiving requests for static IP address already in use by other sessions.

Important: This command is only applicable to sessions using services supporting duplicate address abort. These services include HA, GGSN, and P-GW.

Example
The following command allows for the acceptance of requests for static IP addresses already in use by other sessions:

newcall duplicate-subscriber-requested-address accept
plmn id

Configures Public Land Mobile Network identifiers used to determine if a mobile station is visiting, roaming, or belongs to this network.

Product
P-GW

Privilege
Administrator

Syntax

plmn id mcc number mnc number [ primary ]

mcc number mnc number

mcc number: Specifies the mobile country code (MCC) portion of the PLMN’s identifier. number is the PLMN MCC identifier and must be an integer value between 100 and 999.
mnc number: Specifies the mobile network code (MNC) portion of the PLMN’s identifier. number is the PLMN MNC identifier and can be configured to any 2 or 3 digit integer value between 00 and 999.

primary

When multiple PLMN IDs are configured, the primary keyword can be used to designate one of the PLMN IDs to be used for the AAA attribute.

Usage

The PLMN identifier is used to aid the P-GW service in the determination of whether or not a mobile station is visiting, roaming, or home. Multiple P-GW services can be configured with the same PLMN identifier. Up to five PLMN IDs can be configured for each P-GW Service.

Example

The following command configures the PLMN identifier with an MCC of 462 and MNC of 02:

plmn id mcc 462 mnc 02
**session-delete-delay**

Configures a delay in terminating a session.

**Product**
P-GW

**Privilege**
Administrator

**Syntax**

```
session-delete-delay timeout [ msec ]
default | no ] session-delete-delay timeout
```

- **default**
  Resets the command to the default setting of 10000 msecs.

- **no**
  Disables the feature.

- **timeout msec**
  Default: 10000
  Specifies the time to retain the session before terminating it. *msec* must be an integer from 1000 to 60000.

**Usage**

Use this command to set a delay to provide session continuity in case of break-before-make scenario.

**Example**

The following command sets the session delete delay to the default setting of 10,000 msecs:

```
session-delete-delay timeout
```
Chapter 161
Policy Control Configuration Mode Commands

Policy Control Configuration mode is used to configure the Diameter dictionary, origin host, host table entry and host selection algorithm for IMS Authorization service.

```
Exec Mode
  configure
    Global Configuration Mode
      context name
        Context Configuration Mode
          ims-auth-service svc_name
            IMS Authorization Configuration Mode
              policy-control
                Policy Control Configuration Mode
```
apn-name-to-be-included

This command configures the APN name to be included in CCR Gx messages.

Product
GGSN, IPSG, P-GW

Privilege
Security Administrator, Administrator

Syntax

```
apn-name-to-be-included { gn | virtual }
```

default apn-name-to-be-included

```
default
Applies the default setting for this command.
Default: gn
```

```
gn | virtual
Specifies which APN name must be sent in the Gx messages.
gn: Send the real APN name.
virtual: Send the virtual APN name if present, else send the real APN name.
```

Usage
Use this command to configure the APN name to be included in the CCR Gx messages to the PCRF—the real APN name or the virtual APN name.

Example
The following command configures sending the real APN name in Gx messages:

```
apn-name-to-be-included gn
```
custom-reauth-trigger

This command enables custom reauth event triggers.

Product
All

Privilege
Security Administrator, Administrator

Syntax

custom-reauth-trigger { none | { preservation-changed | reactivation-changed } + }

default custom-reauth-trigger

default
Configures the default setting for this command.

none
Disables all custom event triggers.
This is the default setting.

preservation-changed
Enables preservation-changed event trigger.

Important: This keyword is for use with a customer-specific implementation, and will be available only if a valid license is installed.

reactivation-changed
Enables reactivation-changed event trigger.

Important: This keyword is for use with a customer-specific implementation, and will be available only if a valid license is installed.

Usage
Use this command to enable/disable custom reauth event triggers.
It is recommended that the preservation-changed and reactivation-changed triggers both be enabled. As, when the bearer goes into preservation mode with the preservation-changed trigger, the reactivation-changed trigger must also be enabled for the bearer to get reactivated subsequently.
If only the preservation-changed trigger is enabled, and the bearer goes into preservation mode, the bearer will never get reactivated. The reactivation triggers will be ignored. If only the reactivation-changed trigger is enabled, reactivation of the already active bearer does not take place, and the reactivation triggers are ignored.
Example
The following command disables all custom event triggers:

```
custom-reauth-trigger none
```
diameter dictionary

Specifies the Diameter Policy Control Application dictionary for the IMS Authorization Service through Gx/Ty interface.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
```

default diameter dictionary

```
default
Sets the Diameter dictionary to standard for Gx or Ty interface.
```

```
dpca-custom1
Custom-defined Diameter dictionary for the Gx interface.
```

```
dpca-custom2
Custom-defined Diameter dictionary for Rel. 7 Gx interface.
```

```
dpca-custom3
Custom-defined Diameter dictionary for the Gx interface in conjunction with IP Services Gateway (IPSG).
```

```
dpca-custom4
Standard Diameter dictionary for 3GPP Rel. 7 Gx interface.
```

```
dpca-custom5
Custom-defined Diameter dictionary for Rel. 7 Gx interface.
```

```
dpca-custom6 ... dpca-custom20
Custom-defined Diameter dictionaries.
```

```
gxa-3gpp2-standard
Gxa 3GPP2 standard dictionary.
```
### diameter dictionary

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>gxc-standard</code></td>
<td>Gxc standard dictionary.</td>
</tr>
<tr>
<td><code>pdsn-ty</code></td>
<td>Custom-defined Diameter dictionary for Ty interface.</td>
</tr>
<tr>
<td><code>r8-gx-standard</code></td>
<td>R8 Gx standard dictionary.</td>
</tr>
<tr>
<td><code>standard</code></td>
<td>Default: Enabled for Gx support in 3GPP networks. Standard Diameter dictionary for the 3GPP Rel. 6 Gx interface.</td>
</tr>
<tr>
<td><code>ty-plus</code></td>
<td>Enhanced custom-defined Diameter dictionary for Ty interface.</td>
</tr>
<tr>
<td><code>ty-standard</code></td>
<td>Specifies standard Diameter dictionary for Ty attributes.</td>
</tr>
</tbody>
</table>

#### Usage

Use this command to specify the Diameter dictionary for IMS Authorization Service.

#### Example

The following command sets the `standard` dictionary for Diameter Policy Control functions in 3GPP network.

```
diameter dictionary standard
```
diameter host-select reselect

This command controls pacing of the reselection or switching of the PCRF after a change occurs in table configuration for an IMS Authorization Service.

Default: Disabled

Product
All

Privilege
Security Administrator, Administrator

Syntax

diameter host-select reselect subscriber-limit subs_limit time-interval duration
{ default | no } diameter host-select reselect

---

default

Applies the default setting for this command.
Sets the PCRF reselection or switching to default state.

---

no

Removes the configured PCRF reselection method and disables the reselection or switching of PCRF.

---

subscriber-limit subs_limit

Specifies the limit of subscribers to switch or reselect the PCRF for subscribers not more than subs_limit in time duration of duration second(s).
subs_limit must be an integer from 1 through 10000000.

---

time-interval duration

Specifies the time duration, in seconds, to reselect PCRF for subscribers not more than subs_limit in time duration of duration second(s).
duration must be an integer from 1 through 3600.

---

Usage

Use this command to specify the pacing of reselection or switching of the PCRF in an IMS authorization service..

In case IMS authorization session have been opened on certain PCRF on the basis of the current selection table, and the current active table configuration is changed, the IMSA starts selection procedure for the PCRF. Existing sessions on current PCRF from earlier table is required to close and reopened on the selected PCRF from the new table. This reselection periodicity is controlled by this command and it indicates the number of subscriber sessions subs_limit to be reselected or moved in duration seconds.

For example, if this command is configured with 100 subscribers and 2 seconds, then the system reselects the PCRF for no more than 100 subscribers per 2 seconds.
Example
The following command sets the system to reselect the new PCRF for no more than 1000 subscriber in 15 seconds:

```
diameter host-select reselect subscriber-limit 1000 time-interval 15
```
diameter host-select row-precedence

This command adds/appends rows with precedence to a Diameter host table or MSISDN prefix range table.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
diameter host-select row-precedence precedence_value table { { 1 | 2 } host host_name [ realm realm_id ] [ secondary host host_name [ realm realm_id ] ] } | { prefix-table { 1 | 2 } msisdn-prefix-from msisdn_prefix_from msisdn-prefix-to msisdn_prefix_to host host_name [ realm realm_id ] [ secondary host sec_host_name [ realm sec.realm_id ] algorithm { active-standby | round-robin } ] } [ -noconfirm ]
```

```
no diameter host-select row-precedence precedence_value table { 1 | 2 } |
prefix-table { 1 | 2 } }
```

```
no diameter host-select row-precedence precedence_value table { 1 | 2 }
```
Removes the row with the specified precedence from the specified Diameter host table.

```
diameter host-select row-precedence precedence_value table { 1 | 2 } host host_name [ realm realm_id ] [ secondary host sec_host_name [ realm sec.realm_id ] ]
```
This command adds/appends a row in the specified Diameter host table.
In StarOS 8.0, a maximum of 16 rows can be added to a table. In StarOS 8.1 and later, a maximum of 128 rows can be added per table.

**row-precedence**:
Specifies precedence of the row in the Diameter host table.

**Important**: In StarOS 8.1 and later, **precedence_value** must be an integer from 1 through 128. In StarOS 8.0 and earlier, **precedence_value** must be an integer from 1 through 100.

```
table { 1 | 2 }: Specifies the Diameter host table to add/append the primary and secondary Diameter host addresses.
host host_name: Specifies the primary host name. host_name must be an alpha and/or numeric string of 1 through 127 characters in length.
realm realm_id: Specifies the primary realm ID. realm_id must be an alpha and/or numeric string of 1 through 127 characters in length.
secondary host sec_host_name [ realm sec.realm_id ]: Specifies the secondary host name and realm ID:
host sec_host_name: Specifies the secondary host name. host_name must be an alpha and/or numeric string of 1 through 127 characters in length.
realm sec.realm_id: Specifies the secondary realm ID. realm_name must be an alpha and/or numeric string of 1 through 127 characters in length.
```
```
no diameter host-select row-precedence precedence_value table prefix-table { 1 | 2 } }
```

Removes the row with the specified precedence from the specified MSISDN prefix range table.

```
diameter host-select row-precedence precedence_value table prefix-table { 1 | 2 }
msisdn-prefix-from msisdn_prefix_from msisdn-prefix-to msisdn_prefix_to host host_name [ realm realm_id ] [ secondary host sec_host_name [ realm sec_realm_id ] algorithm { active-standby | round-robin } ] [ -noconfirm ]
```

Use this command to configure the MSISDN prefix range based PCRF selection mechanism for Rel. 7 Gx interface support, wherein the PCEF is required to discover and select an appropriate PCRF to establish control relationship at primary PDP context activation.

This command adds a row in the specified MSISDN prefix range table. A maximum of 128 rows can be added per prefix range table.

```
row-precedence precedence_value: Specifies precedence of the row in the table.
```

**Important:** In StarOS 8.1 and later, `precedence_value` must be an integer from 1 through 128. In StarOS 8.0 and earlier, `precedence_value` must be an integer from 1 through 100.

```
prefix-table { 1 | 2 }: Specifies the MSISDN prefix range table to add the primary and/or secondary Diameter host addresses.
msisdn-prefix-from msisdn_prefix_from: For a range of MSISDNs, specifies the starting MSISDN.
msisdn-prefix-to msisdn_prefix_to: For a range of MSISDNs, specifies the ending MSISDN.
```

**Important:** To enable the Gx interface to connect to a specific PCRF for a range of MSISDNs/subscribers configure `msisdn_prefix_from` and `msisdn_prefix_to` with the starting and ending MSISDNs respectively. The MSISDN ranges must not overlap between rows. To enable the Gx interface to connect to a specific PCRF for a specific MSISDN/subscriber, configure both `msisdn_prefix_from` and `msisdn_prefix_to` with the same MSISDN.

```
host host_name: Specifies the primary host name. `host_name` must be an alpha and/or numeric string of 1 through 127 characters in length.
realm realm_id: Specifies the primary realm ID. `realm_id` must be an alpha and/or numeric string of 1 through 127 characters in length.
secondary host sec_host_name [ realm sec_realm_id ]: Specifies the secondary host name and realm ID: `sec_host_name` Specifies the secondary host name. `sec_host_name` must be an alpha and/or numeric string of 1 through 127 characters in length.
realm sec_realm_id: Specifies the secondary realm ID. `sec_realm_id` must be an alpha and/or numeric string of 1 through 127 characters in length.
algorithm { active-standby | round-robin }: Specifies the algorithm for selection between primary and secondary servers in the MSISDN prefix range table.
Default: `active-standby`
active-standby: Specifies selection of servers in the Active-Standby fashion.
round-robin: Specifies selection of servers in the Round-Robin fashion.
```

**Important:** The Round Robin algorithm for PCRF selection is effective only over a large number of PCRF selections, and not at a granular level.
Specifies that the command is to execute without any additional prompt and confirmation from the user.

Usage
Use this command to add, update, or delete rows specified with a precedence from a Diameter host table or MSISDN prefix range table.
In the Rel. 7 Gx implementation, when the Gateway interworks with multiple PCRFs, the Gateway can configure the primary and secondary server based on the MSISDN-prefix range in the MSISDN prefix range table. Using this command, you can add a new prefix row into the MSISDN prefix table.
If a row with the precedence that you add already exists in a table, the existing prefix row is removed and the new row is inserted with the same precedence.

Example
The following command adds a row with precedence 12 in table 2 with primary host name as star_ims1 and secondary host name as star_ims2 to Diameter host table.

```
diameter host-select row-precedence 12 table 2 host star_ims1 secondary host star_ims2
```
diameter host-select table

This command selects the Diameter host table or the MSISDN prefix range table, and the algorithm to select rows from the Diameter host table.

Product
All

Privilege
Security Administrator, Administrator

Syntax

diameter host-select table { { 1 | 2 } algorithm { ip-address-modulus [ prefer-ipv4 | prefer-ipv6 ] | msisdn-modulus | round-robin } | prefix-table { 1 | 2 } }

{ default | no } diameter host-select table

default
Applies the default setting for this command.

no
Removes previous configuration.
When no table is selected, the system will not communicate with any PCRF for new sessions.

diameter host-select table { 1 | 2 } algorithm { ip-address-modulus | msisdn-modulus | round-robin }
table { 1 | 2 }: Specifies the Diameter host table to obtain the primary and secondary host name for PCRF.
algorithm { ip-address-modulus[ prefer-ipv4 | prefer-ipv6 ] | msisdn-modulus | round-robin }: Specifies the algorithm to select the row from the Diameter host table.
Default: round-robin
- ip-address-modulus [ prefer-ipv4 | prefer-ipv6 ]: This algorithm divides the IP address, in binary, of the subscriber by the number of rows in the table, and the remainder is used as an index into the specified table to select the row.
- prefer-ipv4: Specifies that IPv4 addresses are to be used, if an IPv4v6 call is received, for selecting the rows in the host table.
- prefer-ipv6: Specifies that IPv6 addresses are to be used, if an IPv4v6 call is received, for selecting the rows in the host table.
- msisdn-modulus: This algorithm divides the MSISDN value in binary without the leading “+” of the subscriber by the number of rows in the table, and the remainder is used as an index in the specific table to select the row.
- round-robin: This algorithm rotates all rows in the active table for selection of the row in round-robin fashion. If no algorithm is specified this is the default behavior.

Important: The Round Robin algorithm is effective only over a large number of selections, and not at a granular level.
diameter host-select table prefix-table { 1 | 2 }

Specifies the MSISDN Prefix Range table to be used in case of MSISDN prefix range based PCRF discovery mechanism.

Usage

Use this command to configure the Diameter host table and row selection methods to select host name or realm for PCRF.

When this command is used to change which table the system should be using, user must re-determine which E-PDF the system should be using for each subscriber. If a different E-PDF results from the configuration change in the table, the system will wait for all of the IMS sessions for the subscriber to be no longer active and then the system either closes/opens Gx sessions with the old/new PDFs respectively, or the system deactivates the PDP contexts of the subscriber.

Here is an example of how row selection is configured for three hosts that the system will use for load-balancing. Operator can configure six rows in a table, as follows.

<table>
<thead>
<tr>
<th>Modulo 6</th>
<th>Primary Host</th>
<th>Secondary Host</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
<td>2</td>
</tr>
</tbody>
</table>

In the above table, the three hosts are named 1, 2, and 3. When all hosts are working, the load will be distributed among all the three hosts. If host 1 fails, then the load will be distributed between the remaining two hosts. In this scenario, the modulo 6 results of 2 and 4 will return rows that have primary hosts but no working back-up host.

In the Rel. 7 Gx implementation, the GGSN/PCEF is required to discover and select an appropriate PCRF to establish control relationship at primary PDP context activation. The ip-address-modulus, msisdn-modulus, and round-robin algorithms are supported by the GGSN/PCEF for PCRF discovery. In addition, the active/standby and round-robin algorithms are used for selection between primary and secondary servers based on the MSISDN Prefix Range Table.

Example

The following command specifies table 1 with round-robin algorithm to select the rows with host name for E-PDF in Diameter host table.

```
diameter host-select table 1 algorithm round-robin
```
**diameter origin endpoint**

This command binds the origin endpoint configured in Context Configuration mode to the IMS Authorization service for Diameter Policy Control Application (DPCA).

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
diameter origin endpoint endpoint_name

no
diameter origin endpoint
```

- **no**
  Removes the binding of Diameter origin endpoint with IMS Authorization service.

- **endpoint endpoint_name**
  `endpoint_name` is the Diameter endpoint configured in Context Configuration Mode to bind with IMS authorization service, and must be an alpha/numeric string of 1 through 63 characters in length.

**Usage**

Use this command to bind a configured Diameter origin endpoint to the IMS Authorization service for DPCA. This IMS authorization service searches all system contexts until it finds one with a matching Diameter origin endpoint name specified.

**Example**

The following command binds a configured endpoint named test to the IMS authorization service:

```plaintext
diameter origin endpoint test
```
diameter request-timeout

This command configures the request-timeout setting for Diameter-IMSA Gx interface.

Product
GGSN

Privilege
Security Administrator, Administrator

Syntax

diameter request-timeout timeout

default diameter request-timeout

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies the default setting for this command.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>timeout</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the timeout period in seconds.</td>
</tr>
<tr>
<td>timeout must be an integer from 1 through 300.</td>
</tr>
<tr>
<td>Default: 10 seconds</td>
</tr>
</tbody>
</table>

Usage
Use this command to configure the request-timeout setting for Diameter-IMSA Gx interface.

Example
The following command configures the Diameter request-timeout setting to 20 seconds:

diameter request-timeout 20
end

Exits the current mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to change to the Exec mode.
**exit**

Exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Use this command to return to the parent configuration mode.
failure-handling

This command configures Diameter failure handling behavior.

Product
All

Privilege
Security Administrator, Administrator

Syntax

In StarOS 8.0:

```
failure-handling { continue | retry-and-terminate | terminate | diameter-result-code { any-error | result_code } ccfh { continue | retry-and-terminate | terminate } [ cc-request-type { initial-request | terminate-request | update-request } ] }
```

```
no failure-handling diameter-result-code { any-error | integer result_code } [ cc-request-type { initial-request | terminate-request | update-request } ]
```

In StarOS 8.1 and later:

```
failure-handling cc-request-type { any-request | initial-request | terminate-request | update-request } { diameter-result-code { any-error | result_code { to end_result_code } } } { continue | retry-and-terminate | terminate }
```

```
no failure-handling cc-request-type { any-request | initial-request | terminate-request | update-request } { diameter-result-code { any-error | result_code { to end_result_code } } }
```

no
Disables previous failure-handling configuration.

continue
Specifies that in the event of a failure the user session continues. DPCA/Diameter will make periodic request and/or connection retry attempts and/or will attempt to communicate with a secondary peer depending on the peer config and session-binding setting.

retry-and-terminate
Specifies that in the event of a failure the user session continues for the duration of one retry attempt with the server. If this retry attempt also fails, the session is terminated.

terminate
Specifies that in the event of a failure the user session be terminated.

diameter-result-code { any-error | result_code { to end_result_code } }
Specifies failure handling behavior for any specific result-code(s) to identify the type of failure and failure handling action for specific credit-control request type.
any-error: Specifies failure handling behavior for those result-codes for which failure-handling behavior has not been specified.
result_code: Specifies a Diameter failure result code. result_code is the code returned for a failure handling action and must be an integer from 3000 through 4999.
to end_result_code: Use to specify a range of Diameter failure result codes. end_result_code must be an integer from 3000 through 4999, and must be greater than result_code.

continue | retry-and-terminate | terminate

As in StarOS 8.1 and later.
Specifies the credit control failure handling action.
  •continue: In the event of a failure the user session continues. DPCA/Diameter will make periodic request and/or connection retry attempts and/or will attempt to communicate with a secondary peer depending on the peer config and session-binding setting.
  •retry-and-terminate: In the event of a failure the user session continues for the duration of one retry attempt with the server. If this retry attempt also fails, the session is terminated.
  •terminate: In the event of a failure the user session is terminated.

ccfh { continue | retry-and-terminate | terminate }

As in StarOS 8.0:
Specifies the credit control failure handling (CCFH) action with or without credit control request type.
  •continue: In the event of a failure the user session continues. DPCA/Diameter will make periodic request and/or connection retry attempts and/or will attempt to communicate with a secondary peer depending on the peer config and session-binding setting.
  •retry-and-terminate: In the event of a failure the user session continues for the duration of one retry attempt with the server. If this retry attempt also fails, the session is terminated.
  •terminate: In the event of a failure the user session is terminated.

cc-request-type

As in StarOS 8.0:
This optional keyword defines the type of credit control request with failure result code and credit control failure handling action for a session.
  •any-request: Specifies the request type as any request for a new session.
  •initial-request: Specifies the request type as initial request for a new session.
  •terminate-request: Specifies the request type as terminate request for a session.
  •update-request: Specifies the request type as update request for an active session.

Usage

Use this command to configure the Diameter Policy Control Application (DPCA) failure handling behavior. When an unknown rulebase comes in CCA, changing of rulebase and failure handling is managed in the following manner:
  •If the new and existing rulebases have the same CCA policy, then switch to the new rulebase is successful.
  •If the new rulebase is valid and has CCA-enabled, in CCA-Initial/Update request, switch to the new rulebase is successful.
• If the new rulebase is valid and does NOT have CCA enabled, whereas the existing rulebase has credit enabled, or vice versa, in CCA-Initial/Update request:
  • CCFH-Continue: Goes offline immediately after sending the CCR-T with termination cause as BAD_ANSWER.
  • CCFH-RETRY&TERMINATE: Goes offline immediately after sending the CCR-T with termination cause as BAD_ANSWER.
  • CCFH-TERMINATE: Goes offline immediately after sending the CCR-T with termination cause as BAD_ANSWER.
• If the new rulebase is invalid, in CCA-Initial/Update request:
  • CCFH-Continue: Goes offline immediately after sending the CCR-T with termination cause as BAD_ANSWER.
  • CCFH-RETRY&TERMINATE: Terminates on successful CCA-T, or terminates after successful/failed retry to secondary.
  • CCFH-TERMINATE: Terminates on successful/failed CCR-T to Primary.

The default failure handling behavior is:

```
failure-handling diameter-result-code any-error ccfh terminate
```

---

**Example**

The following command sets the DPCA failure handling to `retry-and-terminate` and return a result code of 3456 for credit control request type `initial-request`:

As in StarOS 8.0:

```
failure-handling diameter-result-code 3456 ccfh retry-and-terminate cc-request-type initial-request
```

As in StarOS 8.1 and later:

```
failure-handling cc-request-type initial-request diameter-result-code 3456 retry-and-terminate
```
li-secret

This command configures an Lawful Intercept shared secret key value for LI session. This value needs to be the same between PCRF and PCEF for Lawful Interception to happen.

Product
MME, P-GW, S-GW

Privilege
Security Administrator, Administrator

Syntax

[ no ] li-secret [ encrypted ] key key_value

[ no ] li-secret

no
This keywords removes the configured secret key value for LI. This is the default mode.

encrypted
This keyword displays the secret value in an encrypted format and only show configuration showsecrets will make the secret value visible.

key key_value
This keyword configures a secret key value for Lawful Intercept shared secret key.
key_value must be an alphabetic and/or numeric string of size 1 to 128 characters.

Usage
Use this command to configure a shared secret key value with or without encryption. This value needs to be the same between PCRF and PCEF (network function srivice node) for Lawful Interception to happen. It this command is not configured, by default LI secret key will be used.
The command will display the secret value in an encrypted format and only show configuration showsecrets command will make the secret value visible.

Example
Following command sets the encrypted LI secret key to a value for LI session.

    li-secret encrypted key secret_key_value
reauth-trigger

This command specifies the trigger events to initiate re-authorization for a subscriber in IMS authorization service.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ default ] reauth-trigger { all | { an-gw-change | bearer-loss | bearer-recovery | plmn-change | policy-failure | qos-change | rat-change | sgsn-change | tft-change | tft-delete } + }
```

**Default**
Applies the default setting for this command.

**all**
Sets the IMS authorization service to initiate re-authorization process for a subscriber on all events listed in this command.

**an-gw-change**
Sets the IMS authorization service to initiate re-authorization process for a subscriber whose access network gateway changed.

**bearer-loss**
Sets the IMS authorization service to initiate re-authorization process for a subscriber on loss of bearer or service.

**bearer-recovery**
Sets the IMS authorization service to initiate re-authorization process for a subscriber when a bearer or service recovered after loss of bearer or service.

**default-bearer-qos-change**
Sets the IMS authorization service to initiate re-authorization process when QoS is changed and DEFAULT_EPS_BEARER_QOS_CHANGE event triggered for the default EPS bearer context of a subscriber in LTE network.

**plmn-change**
Sets the IMS authorization service to initiate re-authorization process for a subscriber on change in Public Land Mobile Network (PLMN) of subscriber.

**policy-failure**
Sets the IMS authorization service to initiate re-authorization process for a subscriber on failure of credit and charging policy for subscriber.
qos-change
Sets the IMS authorization service to initiate re-authorization process for a subscriber on change in Quality of Service level/rating of subscriber.

rat-change
Sets the IMS authorization service to initiate re-authorization process for a subscriber on change in Radio Access Type (RAT) of subscriber node.

sgsn-change
Sets the IMS authorization service to initiate re-authorization process for a subscriber on change in SGSN for subscriber node.

tft-change
Sets the IMS authorization service to initiate re-authorization process for a subscriber on change in Traffic Flow Template (TFT) of subscriber session.

tft-delete
Sets the IMS authorization service to initiate re-authorization process for a subscriber when Traffic Flow Template (TFT) of subscriber session is deleted by a system administrative user.

Usage
Use this command to set the triggers to initiate QoS re-authorization process for a subscriber in IMS authorization service.

Example
Following command sets the re-authorization trigger to `bearer-loss`, so that re-authorization of subscriber session is initiated on loss of bearer.

```
reauth-trigger bearer-loss
```
Chapter 162
PVC Configuration Mode Commands

The Permanent Virtual Connection (PVC) configuration mode commands bind IP interfaces or SS7-Frame Relay links a PVC as well as configure PVC operational parameters for a specific port.

In this mode, the prompt line should appear similar to:

```
[local]hostname(config-port-<slot#>/<port#>-pvc-<pvc_num>/<vci_num>)#
```

![Diagram of command tree]

**Important**: The commands or keywords/variables that are available are dependent on platform type, version, and installed license(s).
bind

This command binds an IP interface or an SS7 link to the PVC.

**Important:** Prior to attempting the binding, the interface and context or the SS7 routing information and link must have been configured.

<table>
<thead>
<tr>
<th>Product</th>
<th>SGSN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Privilege</td>
<td>Security Administrator, Administrator</td>
</tr>
</tbody>
</table>

**Syntax**

```plaintext
[ no ] bind { interface interface_name context_name | link ss7-routing-domain rd_id linkset-id id link-id id }
```

**no**

Removes the binding from the configuration.

**interface_name**

Defines the name of the virtual interface to be bound to the PVC. *interface_name:* Must be a unique string consisting of 1 to 79 alphanumeric characters.

**context_name**

Specifies the name of the context to be bound to the virtual interface. *context_name:* Must be a unique string consisting of 1 to 79 alphanumeric characters.

**ss7-routing-domain rd_id**

Identifies a specific SS7 routing domain. *rd_id:* must be an integer from 1 to 12

**linkset-id id**

Identifies a specific linkset within the routing domain. *id:* must be an integer from 1 to 33

**link-id id**

Identifies a specific link within the linkset. *id:* must be an integer value 1 - 16

**Usage**

Use this command to bind the PVC to an interface or a specific link.

**Example**

Use a command similar to the following to bind a PVC to a link ID #2:

```plaintext
bind ss7-routing-domain 1 linkset-id 23 link-id 2
```
encapsulation aal5

Specify the data encapsulation type for the ATM adaptation layer 5 (AAL5) frames for the PVC.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
encapsulation aal5 { llc-snap | vc-mux }
```

- **llc-snap**
  Frames protocol is identified in the AAL5 using logical link control (LLC) encapsulation.

- **vc-mux**
  Frames are not encapsulated and use virtual circuit multiplexing (VC-MUX) to identify the protocols used for the AAL5 frames.

Usage
Use this command to identify the protocol type for the circuit.

Example

```
encapsulation aal5 vc-mux
```
end

Exits the PVC configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
```plaintext
end
```

Usage
Change the mode back to the Exec mode.
exit

Exits the PVC configuration mode and returns to the ATM port configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Return to the port configuration mode.
shaping

Specify the type of traffic shaping (rates) for this PVC.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

shaping { cbr pcr pcr_num | ubr pcr pcr_num | ubr+ pcr pcr_num mrc mrc_num | vbr pcr pcr_num scr src_num mbs mbs_num }

**cbr**
Constant bit rate
pcr - peak cell rate = cells per second
pcr_num: Must be an integer from 75 to 1412830

**ubr**
Unspecified Bit Rate
pcr - peak cell rate = cells per second
pcr_num: Must be an integer from 75 to 1412830

**ubr+**
Unspecified Bit Rate with Minimum Cell Rate,
The PCR and MCR values should be set to maintain the following relationship: PCR >= (MCR + minRate),
where the current recommend minRate is 75.
pcr - peak cell rate = cells per second
pcr_num: Must be an integer from 75 to 1412830
mcr - minimum cell rate
mrc_num: Must be an integer from 75 to 1412830

**vbr**
Variable Bit Rate, NRT (not real time) type.
The PCR and MCR values should be set to maintain the following relationship: PCR >= (MCR + minRate),
where the current recommend minRate is 75.
pcr - peak cell rate = cells per second
pcr_num: Must be an integer from 75 to 1412830
scr - sustained cell rate
src_num: Must be an integer from 75 to 1412830
mbs - maximum burst size
mbs_num: Must be an integer from 75 to 1412830

Usage
Use this command to configure the shaping for egress traffic on this PVC.

Example
shaping cbr pcr 56000
**shutdown**

Disables/enables traffic over the current VLAN.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
shutdown
no shutdown
```

no

Enables the VLAN. When omitted the VLAN is non-functional.

**Usage**

Enables/ Disables specified VLAN.
This command is necessary to bring a VLAN into service by enabling it via the **no** keyword.

**Example**

To disable a VLAN from sending or receiving network traffic use the following command:

```
shutdown
```

To enable a VLAN use the following command:

```
no shutdown
```
Chapter 163
PVC Interface Configuration Mode Commands

The PVC (permanent virtual connection) Interface configuration mode is used to create and manage the IP parameters for PVC interface(s) associated with an OLC (ATM-type) for a specific context.

In this mode, the prompt line should appear similar to:

```
[<context_name>]hostname<config-if-pvc>#
```

All configuration information specified with these commands is displayed using the Exec mode.

---

*Important:* The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
description

Defines descriptive text to provide useful information about the current interface.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

description text

no description

no

Erases the port’s description from the configuration file.

text

text: Must be a string of 1 to 79 alphanumeric characters with no spaces or a string within double quotes that includes printable characters. The description is case-sensitive.

Usage
Set the description to provide helpful information, for example the port’s primary function, services, end users. Define any information, the only limit is the number of characters, 79.

Example

description "PVC12 connects server 1 to home office."
end

Exits the PVC interface configuration mode and returns to the Exec mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Change the mode back to the Exec mode.
exit

Exits the interface configuration mode and returns to the context configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the context configuration mode.
The commands in this section are used to configure the IP parameters for the PVC interface.

**Important:** Before configuring the OSPF parameters in this section, you need to enable OSPF using the router command and OSPF configuration sub-mode commands accessed in the Context configuration mode and documented in the Context Configuration Mode chapter of this Command Line Interface Reference.
**ip access-group**

This command identifies the access control list (ACL to be associated with this PVC interface in this context.

---

### Important
Prior to using this command, the access list must be created for this context with the `ip access-list` command in the Context configuration mode and then the ACL must be configured using the commands described in CLI chapter ACL Configuration Mode.

---

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
ip access-group name { in | out }
no ip access-group name { in | out }
```

- **no**
  Indicates the specified access group to be removed from the access list.

- **name**
  Specifies the access control (ACL) rule to be added or removed from the group.

- **name**: Must be a string of 1 to 79 alphanumeric characters with no spaces.

---

### Important
Up to 8 ACLs can be applied to a group provided that the number of rules configured within the ACL(s) does not exceed the 128 rule limit for the interface.

```plaintext
in | out
in: Specifies list is for in-bound access control.
out: Specifies the list is for out-bound access control.
```

---

### Important
Even though “in” or “out” can be specified, context-level ACL rules are automatically applied to both directions.

**Usage**

Use this command to add IP access lists configured for the same context to an IP access-group. The list can be configured to apply to all inbound and/or outbound traffic.

**Example**

```plaintext
```

---

4604
The following adds ACL access-list-1 to the IP access-group associated with this PVC for this context.

```
ip access-group access-list-1 in
```
ip address

Defines the primary IP address and the network mask to be associated with this PVC interface for this context. This command can also be used to configure the secondary IP address.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
iv address ip_address ip_mask [ secondary ]
no iv address ip_address
```

**no**
Removes the IP address information for this PVC from the configuration. It is not necessary to include the subnet mask with the command.
The command must first be issued with the secondary IP address if one exists and then re-issued with the primary IP address.

```
address ip_address ip_mask
```
Configures the IP address and the network mask for this PVC interface. The first time this command is entered, it automatically defines the primary IP address for this interface.

*ip_address* and *ip_mask* must be specified using the standard IPv4 or IPv6 dotted decimal notation.

```
secondary
```
*secondary:* Including this keyword indicates the IP address and subnet mask being defined are to be used as the secondary IP address for this PVC interface. This is referred to as multi-homing of the interface.

**Usage**
Configures or deletes the IPv4 or IPv6 addresses and subnet mask to be associated with this PVC.

**Example**
The following configures the secondary IP address to associate with the interface.

```
iv address 131.2.3.4 255.255.255.0 secondary
```
The following set of commands removes the primary IP address from the PVC interface configuration for this context.

```
no iv address secondary address
no iv address primary address
```
ip mtu

Configures the maximum transmission unit (MTU) to be supported on this interface.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

ip mtu value

no ip mtu

no
Disables and/or restores the option to the system default.

mtu value
Configures the maximum transmission unit in octets.
value: Enter an integer between 576 and 1600. Default is 1500.

Usage
Change the maximum transmission unit size to 1300.

Example

ip mtu 1300
ip ospf authentication-key

This command configures the password or key to be used for OSPF (Open Shortest Path First) authentication with neighboring routers.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

ip ospf authentication-key [ encrypted ] password auth_key

no ip ospf authentication-key

no
Deletes the authentication key.

encrypted
Enter this keyword if you are pasting a previously encrypted authentication key into the password auth_key for this command.

password auth_key
auth_key is a string variable, from 1 through 16 alphanumeric characters, that denotes the authentication key (password). This variable is entered in clear text format.

Usage
Use this command to set the authentication key used when authenticating with neighboring routers.

Example
To set the authentication key to 123abc, use the following command:

ip ospf authentication-key password 123abc

Use the following command to delete the authentication key:

no ip ospf authentication-key
ip ospf authentication-type

This command configures the OSPF authentication method to be used with OSPF neighbors over the logical interface.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
ip ospf authentication-type { message-digest | null | text }
no ip ospf authentication-type { message-digest | null | text }
```

- **no**
  - Disable this function.

- **message-digest**
  - Set the OSPF authentication type to use the message digest (MD) authentication method.

- **null**
  - Set the OSPF authentication type to use no authentication, thus disabling either MD or clear text methods.

- **text**
  - Set the OSPF authentication type to use the clear text authentication method.

Usage

Use this command to set the type of authentication to use when authenticating with neighboring routers.

Example

To set the authentication type to use clear text, enter the following command;

```
ip ospf authentication-type text
```
ip ospf cost

This command configures the cost associated with sending a packet over this logical interface.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

ip ospf cost value
no ip ospf cost

Usage
Use this command to set the cost associated with routes from the interface.

Example
Use the following command to set the cost to 20;

ip ospf cost 20

Use the following command to disable the cost setting;

no ip ospf cost
**ip ospf dead-interval**

This command configures the dead-interval and the delay time in seconds, for OSPF communications.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
ip ospf dead-interval value
no ip ospf dead-interval
```

**Usage**
Use this command to set the dead-intervals or delays for OSPF communications.

**Example**

To set the dead-interval to 100, use the following command;

```
ip ospf dead-interval 100
```

To delete the setting for the dead-interval and reset the dead-interval value to its default of 40, use the following command

```
no ip ospf dead-interval
```
ip ospf hello-interval

This command configures the delay time in seconds, for OSPF hello interval.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

ip ospf hello-interval value
no ip ospf hello-interval

value
The interval, in seconds, between sending hello packets. This value is typically set to be 1/4 of the value of the dead-interval.

Example
To set the hello-interval to 25, use the following command;

ip ospf hello-interval 25

To delete the setting for the hello-interval and reset the hello-interval value to its default of 10, use the following command

no ip ospf hello-interval
ip ospf message-digest-key

This command enables the use of MD5-based OSPF authentication.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
ip ospf message-digest-key key_id md5 [ encrypted ] password authentication_key
```

```
no ip ospf message-digest-key key_id
```

- `no` Deletes the key.

- `message-digest-key key_id` Specifies the key identifier number. `key_id` must be an integer from 1 through 255.

- `encrypted` Use this if you are pasting a previously encrypted authentication key into the CLI command.

- `password authentication_key` The password to use for authentication. `authentication_key` is a string variable, from 1 through 16 alphanumeric characters, that denotes the authentication password. This variable is entered in clear text format.

Usage
Use this command to create an authentication key that uses MD5-based OSPF authentication.

Example
To create a key with the ID of 25 and a password of 123abc, use the following command;

```
ip ospf message-digest-key 25 md5 password 123abc
```

To delete the same key, enter the following command;

```
no ip ospf message-digest-key 25
```
ip ospf network

Configures the OSPF network type.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

ip ospf network { broadcast | non-broadcast | point-to-multipoint | point-to-point }

no ip ospf network

Usage
Use this command to specify the OSPF network type.

Example
To set the OSPF network type to broadcast, enter the following command;

ip ospf network broadcast

To disable the OSPF network type, enter the following command;

no ip ospf network
ip ospf priority

This command designates the OSPF router priority.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

ip ospf priority value

no ip ospf priority value

Usage
Use this command to set the OSPF router priority.

Example
To set the priority to 25, enter the following command:

   ip ospf priority 25

To disable the priority, enter the following command:

   no ip ospf priority
ip ospf retransmit-interval

This command configures the retransmit-interval and the delay time in seconds, for OSPF communications.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```plaintext
ip ospf retransmit-interval value
no ip ospf retransmit-interval
```

Usage
Use this command to set the retransmit-intervals or delays for OSPF communications.

Example
To set the dead-interval to 25, use the following command;

```plaintext
ip ospf retransmit-interval 25
```
ip ospf transmit-delay

This command configures the transmit-delay the OSPF communications parameters.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

ip ospf transmit-delay value

no ip ospf transmit-delay

no
Deletes the value set and returns the value to its default.

transmit-delay value
The interval, in seconds, that the router should wait before transmitting a packet.
value must be an integer from 1 through 65535. Default: 1

Usage
Use this command to set the transmit-delay.

Example
To set the transmit delay to 5 seconds, use the following command;

    ip ospf transmit-delay 5

To delete the setting for the transmit-delay or reset the transmit-delay value to its default of 1, use the following command'

    no ip ospf transmit-delay
Chapter 164
QCI - QoS Mapping Configuration Mode Commands

The QoS Class Index (QCI) to QoS Mapping Configuration Mode is used to map QoS Class Indexes to enforceable QoS parameters. Mapping can occur between the RAN and the Serving Gateway (S-GW), the Mobility Management Entity (MME), and/or the PDN Gateway (P-GW) in an LTE network or between the RAN and the eHRPD Serving Gateway (HSGW) in an eHRPD network.

```
Exec Mode
  configure
    Global Configuration Mode
      qci-qos-mapping name
        QCI – QoS Mapping Config Mode
```
end

Exits the current mode and returns to the Exec Mode.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

dend

**Usage**

Change the mode back to the Exec mode.
exit

Exits the current mode and returns to the previous mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Return to the previous mode.
qci

Creates and maps QCI values to enforceable QoS parameters.

Product
HSGW, P-GW, S-GW

Privilege
Administrator

Syntax

qci num

[ delay-class num precedence-class num reliability-class num

[ downlink { encaps-header { copy-inner | dscp-marking hex } | user-datagram
dscp-marking hex [ encaps-header { copy-inner | dscp-marking hex } ] } ]

[ gbr ]

[ max-packet-delay num max-error-rate num

[ non-gbr ]

[ uplink { encaps-header { copy-inner | dscp-marking hex } | user-datagram dscp-
marking hex [ encaps-header { copy-inner | dscp-marking hex } ] } ]

[ default | no ] qci num

  default
  Resets the default values for the select QCI value.

  no
  Disables the selected QCI value.

  num
  Specifies the QCI value to be enabled. num must be an integer value between 1 and 32.
  QCI values 1 through 9 are standard values. Only undefined values (10 through 32) can be defined.

  Important: QCI values 1 through 9 are defined in the 3GPP Specification TS 23.203 “Policy and charging
  control architecture”.

  delay-class num precedence-class num reliability-class num

  delay-class num: Pre-release 8 value for configuring packet delay. num must be an integer value
  between 1 and 32.

  precedence-class num: Pre-release 8 value for configuring packet precedence. num must be an integer
  value between 1 and 32.
reliability-class num: Pre-release 8 value for configuring packet reliability. num must be an integer value between 1 and 32.

downlink { encaps-header { copy-inner | dscp-marking hex } | user-datagram dscp-marking hex [ encaps-header { copy-inner | dscp-marking hex } ] ] }

Configures parameters for downlink traffic.
encaps-header: Specifies that the DSCP marking must be set on the encapsulation header for IP-in-IP, GRE, or GTP encapsulation.
user-datagram dscp-marking hex: Specifies that the UDP DSCP marking is to be defined by this keyword. hex must expressed as a hexadecimal value from 0x00 through 0x3F.
{ copy-inner | dscp-marking hex }
- copy-inner: Specifies that the DSCP marking is to be acquired from the UDP headers within the encapsulation.
- dscp-marking hex: Specifies that the DSCP marking is to be defined by this keyword. hex must expressed as a hexadecimal value from 0x00 through 0x3F.

gbr
Specifies that this QCI type is Guaranteed Bit Rate (GBR).

max-packet-delay num max-error-rate num

max-packet-delay num: Specifies the maximum packet delay in milliseconds that can be applied to the data with the QCI. num must be an integer value from 10 through 1000. Default is 10ms for QCI values greater than 9.
max-error-rate num: Specifies the maximum error loss rate of non-congestion related packet loss. num must be an integer value from 1 through 6 specifying 10-1 through 10-6. Default is 3 (or 10-3) for QCI values greater than 9.

Important: Defaults for QCI values less than 9 are defined in the 3GPP Specification TS 23.203 “Policy and charging control architecture”.

non-gbr
Specifies that this QCI type is non-Guaranteed Bit Rate (non-GBR).

uplink { encaps-header { copy-inner | dscp-marking hex } | user-datagram dscp-marking hex [ encaps-header { copy-inner | dscp-marking hex } ] ] }

Configures parameters for uplink traffic.
encaps-header: Specifies that the DSCP marking must be set on the encapsulation header for IP-in-IP, GRE, or GTP encapsulation.
user-datagram dscp-marking hex: Specifies that the UDP DSCP marking is to be defined by this keyword. hex must expressed as a hexadecimal value from 0x00 through 0x3F.
{ copy-inner | dscp-marking hex }
- copy-inner: Specifies that the DSCP marking is to be acquired from the UDP headers within the encapsulation.
- dscp-marking hex: Specifies that the DSCP marking is to be defined by this keyword. hex must expressed as a hexadecimal value from 0x00 through 0x3F.
Usage
Use this command to create and map QCI values to enforceable QoS parameters.

Example
The following command creates a QCI value of 15 and defines the uplink encapsulation header as using the DSCP marking from the encapsulated UDP header:

```
qci 15 uplink encaps-header copy-inner
```
Chapter 165
QCI - RAN ID Mapping Configuration Mode Commands

The QoS Class Index (QCI) Mapping Configuration Mode is used to map RAN profile IDs to QoS Class Indexes via the HRPD Serving Gateway (HSGW) in an eHRPD network.
end

Exits the current mode and returns to the Exec Mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Change the mode back to the Exec mode.
exit

Exits the current mode and returns to the previous mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Return to the previous mode.
profile-id

Maps a QCI ID to a RAN profile ID and modifies data flow bit rate ranges.

Product
HSGW

Privilege
Administrator

Syntax

profile-id  id  qci  num  [  uplink  {  gbr  rate  [  mbr  rate  ]  |  mbr  rate  [  gbr  rate  ]  }  
            downlink  {  gbr  rate  [  mbr  rate  ]  |  mbr  rate  [  gbr  rate  ]  }  
            no  profile-id  id

no

Removes the specified profile ID entry from this map.

id

Specifies the profile ID to which a QCI ID will be mapped. id must be an integer value from 1 to 65535.

qci  num

Specifies the QCI number to which the profile ID will be mapped. num must be an integer value from 1 to 255.

uplink

Specifies that the guaranteed bit rate (GBR) and/or maximum bite rate (MBR) setting that follow this
keyword will be applied to the uplink data flow.

downlink

Specifies that the guaranteed bit rate (GBR) and/or maximum bite rate (MBR) settings that follow this
keyword will be applied to the downlink data flow.

gbr  rate

Specifies the guaranteed bit rate for the uplink or downlink data flow. rate must be an integer value from 0
to 4294967295.

mbr  rate

Specifies the maximum bit rate for the uplink or downlink data flow. rate must be an integer value from 0
to 4294967295.

Usage

Use this command to map a QCI ID to a RAN profile ID and, optionally, modify data flow bit rate ranges.
Example
The following command maps a QCI ID (1) to a profile ID (10) and sets the uplink guaranteed bit rate to 10000 and the downlink guaranteed bit rate to 20000:

    profile-id 10 qci 1 uplink gbr 10000 downlink gbr 20000
The Radio Network Controller (for release 8.0) or RNC (for releases 8.1 and higher) configuration mode defines the parameters related to the SGSN connection with an RNC.

The command prompt for this mode will appear similar to:

```
[<context_name>] hostname(config-ctx-iups-service-rnc)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
associate-gtpu-bind-address

This command defines the GTP-U loopback address and associates (binds) this address with a particular interface (non-loopback) address.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

[ no ] associate-gtpu-bind-address ip_address to-interface-address ip_address

no
Removes the loopback address definition and interface association from the current RNC configuration.

ip_address
ip_address: Must be specified using the standard IPv4 dotted decimal notation.

Usage
Use this command to setup associations between loopback GTP-U addresses and a non-loopback addresses.

Example

associate-gtpu-bind-address 123.1.1.1 to-interface-address 222.1.1.1
description

This command defines an alphanumeric string that is intended to provide descriptive information about the radio network controller (RNC). This is used for operator reference only.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

description string

no description

no
Removes the description string from the current RNC configuration.

string
Specifies the alphanumeric string that is stored. must be from 1 through 255 alphanumeric characters. Strings with spaces must be enclosed in double-quotes. See the example below.

Usage
Use this command to set a description for reference by operators.

Example
The following command sets the description to identify a particular RNC and carrier in Uganda:

description "RNC1 Carrier2 Uganda"
**direct-tunnel**

This command enables/disables the direct tunnel feature through the interface to the radio network controller (RNC).

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
direct-tunnel not-permitted-by-rnc

default direct-tunnel
```

**default**

Sets the direct tunnel support on RNC to default mode; i.e. enabling direct tunnel.

**not-permitted-by-rnc**

Default: enabled
Disables the direct-tunnel support on radio network controller (RNC).

**Usage**

Use this command to disable/enable the direct-tunnel function through the interface to the RNC.

**Example**

Following command disables the direct tunnel support to the RNC:

```
direct-tunnel not-permitted-by-rnc
```
end

Exits the configuration mode and returns to the Exec mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Change the mode to the Exec mode.
exit

Exits the current configuration mode and returns to the IuPS Service configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the previous configuration mode.
lac

This command identifies a Local Area Concentrator (LAC) and a Remote Area Concentrator (RAC) and associates them with this RNC definition.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

    [ no ] lac lac_id rac rac_id

    no
    Deletes the LAC and RAC information from the system configuration.

    lac_id
    A unique numeric identifier for the LAC associated with the RNC.
    lac_id must be an integer between 1 and 65535.

    rac_id
    A unique numeric identifier for the RLAC associated with the RNC.
    rac_id must be an integer between 1 and 255.

Usage
Creates an association with a specific LAC and RAC.

Example

    lac 545 rac 23
mbms

Configures RNC options for multimedia broadcast multicast service.

**Important:** This feature and command are currently under development and not yet operational.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
mbms
```

**Usage**
Information will be provided when this command has been fully developed and released.
overload-action disable

This command maps an action to be taken if traffic reaches or exceeds defined levels.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

overload-action disable { activate | attach | auth-challenge | modify-request | paging-downlink-data | ptmsi-reallocation | service-request-data | sms }

traffic-level traffic-level

[ no | default ] overload-action disable { activate | attach | auth-challenge | modify-request | paging-downlink-data | ptmsi-reallocation | service-request-data | sms }

no
Removes the defined overload action from configuration.

default
Resets the traffic level to the default level for the associated overload action.

activate traffic-level traffic-level
The system rejects new requests to activate PDP contexts if the defined traffic-level is exceeded.

traffic-level: An integer 1 to 15.
Default: 14

attach traffic-level traffic-level
The system rejects new requests for GPRS attach if the defined traffic-level is exceeded.

traffic-level: An integer 1 to 15.
Default: 15

auth-challenge traffic-level traffic-level
The system skips performing authentication challenges if the defined traffic-level is exceeded.

traffic-level: An integer 1 to 15.
Default: 4

modify-request traffic-level traffic-level
The system rejects requests to modify a PDP context if the defined traffic-level is exceeded.

traffic-level: An integer 1 to 15.
Default: 12
### Usage

This command defines traffic levels and the actions to take if traffic exceeds the defined levels. The command can be re-entered multiple times to create individual definitions for each type of traffic level and action.

### Example

Use the following to instruct the system to reject service requests to establish new RABs if the traffic level reaches 3: ```

**overload-action disable service-request-data traffic-level 3**

```
paging-non-searching-indication

This command instructs the SGSN to include the non-searching indicator flag in the page-request message.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

paging-non-searching-indication { non-searching | searching }

[ no | default ] paging-non-searching-indication

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>default</td>
</tr>
<tr>
<td>non-searching</td>
<td>Set the non-searching-indication to non-searching in the page-request message.</td>
</tr>
<tr>
<td>searching</td>
<td>Set the non-searching-indication to searching in the page-request message.</td>
</tr>
</tbody>
</table>

Usage
Use this command to determine which type of search indicator flag will be included in the page-request message.

Example
Use this command to include the non-searching flag in page-request messages:

```
paging-non-searching-indication non-searching
```
pointcode

Configures the point code of the RNC.

The access protocol that is part of the IuPS Service configuration mode must be configured prior to defining the RNC’s point code.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

[ no ] pointcode pt_code

- **no**
  - Deletes the RNC’s point code information from the system configuration.

- **pt_code**
  - Point code in dotted-decimal format:
    - ITU Range 0.0.1 to 7.255.7
    - ANSI Range 0.0.1 to 255.255.255
    - TTC Range 0.0.1 to 15.31.255
    - String of 1 to 11 characters

Usage

Use this command to identify the point code of the associated RNC.

Example

pointcode 1.234.2
pooled

Configure an RNC as either ‘pooled’ or ‘non-pooled’.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

pooled

[ default | no ] pooled

<table>
<thead>
<tr>
<th>default</th>
<th>no</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Entering either default or no returns the RNC configuration to the default ‘non-pooled’ state.

Usage
Each RNC, one-at-a-time, can be identified as ‘pooled’ -- as participating within an SGSN pool -- or ‘non-pooled’. Pooled RNCs can co-exist with non-pooled RNCs.

Example
Identify this RNC as being part of an SGSN pool:

pooled
**rab-modify-procedure**

This command configures how the RAB (radio access bearer) assignment procedure will be modified

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
rab-modify-procedure { normal-modify | release-and-establish }
```

- `default rab-modify-procedure`

  Returns the configuration to the default setting for this command parameter.

- `normal-modify`

  Selects the normal RAB modify procedure.

- `release-and-establish`

  Instructs the system to release and establish the RAB procedure.

**Usage**
Set the procedure to establish the radio access bearer (RAB).

**Example**
```
rab-modify-procedure normal-modify
```
**ranap paging-cause-ie**

This command sets the paging cause value and either includes or suppresses the Paging Cause IE in responses to Paging Requests due to various sources. This command is available in releases 8.1 and higher.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```

[ default | no ] ranap { paging-cause-ie { all | background-data | conversational-data | gmm-signalling | gs-signalling | interactive-data | sm-signalling | sms-signalling | streaming-data } }
```

- **default**
  Resets the specific parameters value to default.

- **no**
  Suppresses the Paging Cause IE so that it is not included in responses to Paging Requests from respective sources.

- **all**
  Using **all** sets the action for the Paging Cause IE value for all paging due to all sources.

- **background-data [ value ]**
  Default: 3 (terminating background call)
  Set the Paging Cause IE value for paging due to background data.
  *value*: Must be an integer from 0 to 5. See Paging Cause value mapping in Usage section.

- **conversational-data [ value ]**
  Default: 5 (terminating high priority signaling)
  Set the Paging Cause IE value for paging due to conversational data.
  *value*: Must be an integer from 0 to 5. See Paging Cause value mapping in Usage section.

- **gmm-signalling [ value ]**
  Default: 5 (terminating high priority signaling)
  Set the Paging Cause IE value for paging due to gmm-signaling.
  *value*: Must be an integer from 0 to 5. See Paging Cause value mapping in Usage section.
**Radio Network Controller (RNC) Configuration Mode Commands**

### ranap paging-cause-ie

- **gs-signalling [ value ]**
  - Default: 5 (terminating high priority signaling)
  - Set the Paging Cause IE value for paging due to VLR Paging Request.
  - `value`: Must be an integer from 0 to 5. See Paging Cause value mapping in Usage section.

- **interactive-data [ value ]**
  - Default: 2 (terminating interactive call)
  - Set the Paging Cause IE value for paging due to interactive data.
  - `value`: Must be an integer from 0 to 5. See Paging Cause value mapping in Usage section.

- **sm-signalling [ value ]**
  - Default: 5 (terminating high priority signaling)
  - Set the Paging Cause IE value for paging due to SM signaling.
  - `value`: Must be an integer from 0 to 5. See Paging Cause value mapping in Usage section.

- **sms-signalling [ value ]**
  - Default: 4 (terminating low priority signaling)
  - Set the Paging Cause IE value for paging due to SMS signaling.
  - `value`: Must be an integer from 0 to 5. See Paging Cause value mapping in Usage section.

- **streaming-data [ value ]**
  - Default: 5 (terminating high priority signaling)
  - Set the Paging Cause IE value for paging due to streaming data.
  - `value`: Must be an integer from 0 to 5. See Paging Cause value mapping in Usage section.

### Usage

This command can be used to set the value (meaning) of the Paging Cause IE included in responses to Paging Requests or it can be used to suppress the inclusion of the Paging Cause IE in the responses. These actions can be configured for paging for all sources or for a specified source.

The following values are applicable to all Paging Cause IEs:

- **0**: Terminating conversational call
- **1**: Terminating streaming call
- **2**: Terminating interactive call
- **3**: Terminating background call
- **4**: Terminating low priority signaling
- **5**: Terminating high priority signaling

### Example

Use the following command to set Paging Cause value to 3 for paging due to GMM signaling without affecting cause values for other sources:

```
ranap paging-cause-ie gmm-signalling 3
```

Use the following command to suppress the Paging Cause IE from all Paging Requests to the RNC:

```
no ranap paging-cause-ie all
```
Either of the following commands will cause the Paging Cause IE to be included in Paging Requests with the default value for SM signaling without affecting the cause for other sources:

```plaintext
ranap paging-cause-ie sm-signalling

default ranap paging-cause-ie sm-signalling
```
ranap signalling-indication-ie

This command enables/disables the inclusion of the Signaling Indication IE in either or both the RAB Assignment Request and/or the Relocation Request RANAP messages.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

\[
\text{ranap signalling-indication-ie} \begin{cases} \text{rab-assignment-request} \mid \text{relocation-request} \end{cases} \mid \\
\text{no} \quad \text{ranap signalling-indication-ie} \\
\text{default} \quad \text{ranap signalling-indication-ie}
\]

- \text{no}
  - Sets the configuration so that the SGSN never includes the IE.

- \text{default}
  - Resets the configuration to the default - the SGSN includes the IE in the messages if preconditions are met (see Usage section).

- \text{rab-assignment-request} \mid \text{relocation-request}
  - Including one or both of these keywords configures what type of RANAP message will include the IE.

Usage

The command enables the operator to determine whether the signalling indication information element is included in either or both the RAB Assignment Request and Relocation Request messages during the PDP context setup procedure.

For this command configuration to work so that the IE is included, two preconditions must be met:

- Received QoS traffic class for the context must be interactive
- Received QoS has a signalling indication value as optimized

When an RNC receives this IE, the RNC assumes that the customer is using IMS signaling and allocates massive amounts of bandwidth, potentially causing cell congestion. This command enables the operator to determine the usage of this IE which provides the operator with additional session management control.

Example

Use the following command to include the signalling indication IE in the RAB Assignment Request:

\[
\text{ranap signalling-indication-ie rab-assignment-request}
\]
release-compliance

This command allows the SGSN to support 3GPP release 6 HSPA or release 7 HSPA+.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
release-compliance { pre-release-7 | release-7 }
default release-compliance
```

- **default**
  Returns the configuration to the default value, which is `release-7`.

- **pre-release-7**
  Identifies 3GPP Release 6 (R6) as the release the RNC is compliant with.

- **release-7**
  Identifies 3GPP Release 7 (R7) as the release the RNC is compliant with.

**Usage**
Use this command to match the 3GPP release support by the RNC. As the 3GPP releases each support differing data rate options - R6 supports HSPA and R7 supports HSPA+ - then selecting the compliance is a method of preforming data rate management on a per RNC basis.

**Example**
Enable HSPA fallback to R6 compliance:

```plaintext
release-compliance pre-release-7
```
**reset-resource**

This command enables the operator to control message length by configuring the number of IuConIDs sent in each RANAP Reset Resource messages.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
reset-resource max-iuconid-per-msg number

default reset-resource max-iuconid-per-msg
```

**Usage**
Id numbers for each Iu connection are included in the RANAP Reset Resource messages. Including this potentially long stream of numbers can make the message very long. With this command, the operator can control the size of the messages by controlling the number of Id messages included in the messages.

**Example**
Limit the number of Iu connection Ids to 30:

```
reset-resource max-iuconid-per-msg 30
```
Chapter 167
Remote Address List Configuration Mode Commands

The Remote Address List Configuration Mode is used to configure address lists for the Remote Address-based Accounting feature on a per-context basis.
address

This command configures addresses for the Remote Address List.

Product
PDSN, HA

Privilege
Security Administrator, Administrator

Syntax

`address ip_address netmask subnet`

`no address ip_address netmask subnet`

Usage
Use this command to configure remote address lists for use with the Remote Address-based accounting feature. A maximum of 10 address can be configured per list.

Example
The following command adds an IP address of 192.168.100.1 with a subnet mask of 255.255.255.0 to the list:

`address 192.168.100.1 netmask 255.255.255.0`
**end**

This command exits the current configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Use this command to change to the Exec mode.
exit

This command exits the current mode and returns to the parent configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**
Use this command to return to the parent configuration mode.
Chapter 168
RoHC Profile Common Options Configuration Mode
Commands

The RoHC Profile Common Options Configuration Mode is used to set timers that, upon expiration, release header compression contexts.

```
Exec Mode
  configure
    Global Configuration Mode
    rohc-profile profile-name name
      RoHC Profile Configuration Mode
      common-options
        RoHC Profile Common Options Config Mode
```
delay-release-hc-context-timer

Sets a delay in releasing RoHC contexts allowing for context continuation during intra-gateway handoffs.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

delay-release-hc-context-timer  seconds

no  delay-release-hc-context-timer

no
Removes previously configured value for this command. No value disables the feature.

seconds
Specifies the number of seconds the system delays before releasing the header compression context. seconds must be an integer value from 0 to 65535.

Usage
Use this command to set a delay in releasing a header compression context. This command is necessary when employing RoHC and mobility. Typically, when an RP connection is released, the header compression context is also released immediately. However, in mobility situations, such as intra-PDSN handoffs, the header compression context should be preserved. Adding a delay to cover the handoff time allows the context to be maintained. A header compression context contains the compression/decompression configuration and statistics for the session.

Example
The following command sets the header compression release delay to 20 seconds:

        delay-release-hc-context-timer  20
end

Exits the current mode and returns to the Exec Mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Change the mode back to the Exec mode.
exit

Exits the current mode and returns to the previous mode.

Product
    All

Privilege
    Security Administrator, Administrator

Syntax
    exit

Usage
    Return to the previous mode.
inactive-traffic-release-hc-context-timer

Set an inactivity timer that is checked when inactivity is detected on an SO67 A10 bearer connection with negotiated RoHC parameters. If the inactivity continues to the end of the configured time, the header compression context is released.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

inactive-traffic-release-hc-context-timer seconds

no inactive-traffic-release-hc-context-timer

no
Removes previously configured value for this command. No value disables the feature.

seconds
Specifies the time, in seconds, the system waits for activity on the bearer channel before releasing the header compression context. seconds must be an integer value from 1 to 65535.

Usage
Use this command to set a timer that is started upon detecting inactivity on the bearer channel. Upon expiry, the header compression context is released. Enable this feature to allow for efficient memory utilization.

Example
The following command sets the bearer channel inactivity timer to 60 seconds:

inactive-traffic-release-hc-context-timer 60
Chapter 169
RoHC Profile Compression Configuration Mode Commands

The RoHC Profile Compression Configuration Mode is used to configure RoHC (Robust Header Compression) Compressor parameters. RoHC is not supported on GGSN.

**Important:** The availability of commands, keywords and variables in this mode are dependent on platform type, product version, and installed license(s).
context-timeout

Context timeout in seconds.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

context-timeout seconds

default context-timeout

default

Returns the command to its default value.

seconds

Default: 20 seconds
The context timeout value in seconds. seconds must be an integer from 0 through 100.

Usage

Use this command to set the context timeout.

Example

The following command sets the context timeout to 10 seconds:

context-timeout-period 10
end

Returns the CLI prompt to the Exec mode.

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**
end

**Usage**
Change the mode back to the Exec mode.
exit

Exits this configuration mode and returns to the previous mode.

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**
exit

**Usage**
Return to the previous mode.
ipid-history-size

The number of IP-IDs of previously sent packets to store. An IP ID is a 16-bit header field that stores IPv4 Identification information.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

ipid-history-size number

default ipid-history-size

default
Returns the command to its default value.

number
Default: 8
The number of IP IDs to store. number must be an integer from 1 through 32.

Usage
Use this command to set the number of IP IDs to store in the history.

Example
The following command sets the history size to 24 IP-IDs:

ipid-history-size 24
max-jitter-cd

The upper boundary of jitter expected on the communication channel between the compressor and decompressor.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

max-jitter-cd num_ms

default max-jitter-cd

default
Returns the command to its default value.

num_ms
Default: 150
The number of milliseconds for the maximum jitter setting. num_ms must be an integer from 0 through 999999999.

Usage
Use this command to set the maximum amount of jitter allowed on the communication channel between compressor and decompressor.

Example
The following command sets the jitter limit to 1000ms (1 second):

max-jitter-cd 1000
max-sliding-window

The width of the sliding window for W-LSB (Windows-based Least Significant Bits) encoded values.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

max-sliding-window size

default max-sliding-window

Usage

Use this command to set the size of the sliding window used to compute jitter for W-LSB encoded values.

Example

The following command sets the sliding window size to 500:

max-sliding-window 500
multiple-ts-stride

Enables or disables the use of repeated transmission of RTS_STRIDE for timer-based compression.

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**

```
[ no ] multiple-ts-stride
```

- **no**
  
  Disables the use of repeated transmission of RTS_STRIDE for time-based compression.

- **multiple-ts-stride**
  
  Enables the repeated transmission of RTS_STRIDE for timer-based compression.

**Usage**

Use this command to enable or disable a gateway’s ability to repeatedly transmit RTS_STRIDE for timer-based compression.
new-context-blocking-time

Time period in seconds for blocking the establishment of new contexts after the compressor has received a feedback reject.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

new-context-blocking-time seconds

default context-timeout

default
Returns the command to its default value.

seconds
Default: 20 seconds
The context blocking time in seconds. seconds must be an integer from 0 through 100.

Usage
Use this command to set the context blocking time after the compressor has received a feedback reject.

Example
The following command sets the context blocking time to 10 seconds:

new-context-blocking-time 10
num-pkts-ts

The number packets per RTP timestamp (TS).

Product
HSGW, PDSN

Privilege
Administrator

Syntax

num-pkts-ts num_pkts

default num-pkts-ts

default
Returns the command to its default value.

num_pkts
Default: 6
The number of packets for the timestamp. num_pkts must be an integer from 0 through 999.

Usage
Use this command to set the number of packets for each RTP timestamp (TS).

Example
The following command sets the number of packets per timestamp to 50:

num-pkts-ts 50
num-pkts-u-mode

The number packets sent when operating in U-Mode (unidirectional mode).

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**

```
num-pkts-u-mode num_pkts
default num-pkts-u-mode
```

**default**

Returns the command to its default value.

**num_pkts**

Default: 1
The number of packets sent in U-Mode. num_pkts must be an integer from 0 through 999.

**Usage**

Use this command to set the number of packets sent when in U-Mode.

**Example**

The following command sets the number of packets for U-Mode to 50:

```
num-pkts-u-mode 50
```
num-updates-ir

This command configures the number of IR (Initiation and Refresh state) updates.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

num-updates-ir num_pkts

default num-updates-ir

default
Returns the command to its default value.

num_pkts
Default: 4
The number of packets sent in U-Mode. num_pkts must be an integer from 0 through 999.

Usage
Use this command to set the number of packets sent when in U-Mode.

Example
The following command sets the number of packets for U-Mode to 50:

num-updates-ir 50
optimistic-repeats

For transition from the FO (First Order) to the SO (Second Order) state, the compressor should be confident that the decompressor has all the parameters needed to decompress according to a fixed pattern. The compressor obtains its confidence about decompressor status by sending several packets with the same information according to the lower compression state. If the decompressor receives any of these packets, it is in sync with the compressor. This command defines the number of repeated packets to send to the decompressor.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

```
optimistic-repeats num_pkts

default optimistic-repeats
```

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>default</strong></td>
<td>Returns the command to its default value.</td>
</tr>
</tbody>
</table>
| **num_pkts** | Default: 6  
The number of packets to repeat with the same information to assure synchronization with the decompressor.  
*num_pkts* must be an integer from 0 through 10. |

Usage

Use this command to set the number of packets to repeat to the decompressor to assure synchronization before transition states.

Example

The following command sets the number of repeated packets to 5:

```
optimistic-repeats 5
```
**rtp-sn-p**

The value of p in RTP SN (RTP Sequence Number) calculation. Least Significant Bits (LSB) encoding is used for header fields whose values are usually subject to small changes. With LSB encoding, the k least significant bits of the field value are transmitted instead of the original field value, where k is a positive integer. After receiving k bits, the decompressor derives the original value using a previously received value as reference (v_ref). The scheme is guaranteed to be correct if the compressor and the decompressor each use interpretation intervals as follows:

- In which the original value resides
- And in which the original value is the only value that has the exact same k least significant bits as those transmitted.

The interpretation interval can be described as a function:

\[ f(v_{\text{ref}}, k) = [v_{\text{ref}} - p, v_{\text{ref}} + (2^k - 1) - p] \]

Where p is an integer.

**Product**

HSGW, PDSN

**Privilege**

Administrator

**Syntax**

```
 rtp-sn-p p_value
```

`default rtp-sn-p`

- **default**
  
  Returns the command to its default value.

  ```
  p_value
  
  Default: 6
  The number to use for the value of p in the RTP SN calculation. p_value must be an integer from 0 through 999.
  ```

**Usage**

Use this command to set the value to use for p when performing the RTP SN calculation.

**Example**

The following command sets the value of p to 100:

```
 rtp-sn-p 100
```
rtp-sn-p-override

Allow an override of p in RTP SN calculation. This is disabled by default.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

[ default | no ] rtp-sn-p-override

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
</tr>
<tr>
<td>Returns the command to its default value of disabled.</td>
</tr>
<tr>
<td>no</td>
</tr>
<tr>
<td>Disables overriding p in RTP SN calculation.</td>
</tr>
</tbody>
</table>

Usage

Use this command to enable an override of p in RTP SN calculation.

Example

The following command enables the override of p in the RTP SN calculation:

```
rtp-sn-p-override
```
**rtp-time-stride**

This command sets the time interval used for one TS (RTP Time Stamp) stride. This is used when timer-based encoding is enabled.

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**

```
  rtp-time-stride num_ms

  default rtp-time-stride
```

- **default**
  Returns the command to its default value.

- **num_ms**
  Default: 20
  The number of milliseconds to use for TS_STRIDE. `num_ms` must be an integer from 0 through 999999999.

**Usage**

Use this command to set the length of the TS_STRIDE in milliseconds.

**Example**

The following command sets TS_STRIDE to 100ms:

```
  rtp-time-stride 100
```
rtp-ts-deviation

This command sets the maximum percentage of deviation allowed for input RTP packets for timer-based compression.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

rtp-ts-deviation percentage

default rtp-ts-deviation percentage

default
Returns the command to its default value.

percentage
Default: 25
Specifies the maximum percentage of deviation allowed for input RTP packets for timer-based compression. percentage must be an integer value from 0 through 100.

Usage
Use this command to set the maximum percentage of deviation allowed for input RTP packets for timer-based compression.

Example
The following command sets the time increment to 1000:

rtp-ts-deviation 25
**rtp-ts-stride**

Amount by which TS (RTP time stamp) is incremented. This is used for Scaled RTP TS encoding.

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**

```
 rtp-ts-stride num_ms
 default rtp-ts-stride
```

**default rtp-ts-stride**

- **default**
  Returns the command to its default value.

- **num_ms**
  Default: 160
  The number of milliseconds to use incrementing TS. `num_ms` must be an integer from 0 through 999999999.

**Usage**

Use this command to set the amount by which TS is incremented for Scaled RTP TS encoding.

**Example**

The following command sets amount by which TS is incremented to 100ms:

```
 rtp-ts-stride 100
```
sliding-window-ts

**Description**
The sliding window used to compute jitter.

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**

```
sliding-window-ts size
```

```
default sliding-window-ts
```

**default**

Returns the command to its default value.

```
size
```

Default: 4
Set the size of the sliding window. `size` must be an integer from 1 through 1000.

**Usage**

Use this command to set the size of the sliding window used to compute jitter for the current RoHC profile.

**Example**
The following command sets the sliding window size to 500:

```
sliding-window-ts 500
```
total-jitter-ipv4

The total jitter experienced after compression for IPV4.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

```
total-jitter-ipv4 time
```

```
default total-jitter-ipv4
```

**default**

Returns the command to its default value.

```
time
```

Default: 270
Specifies the time interval to use in milliseconds. *time* must be an integer from 0 through 999999999.

**Usage**

Use this command to set the jitter limit after compression.

**Example**

The following command sets the jitter after compression limit to 900ms:

```
total-jitter-ipv4 900
```
total-jitter-ipv6

The total jitter experienced after compression for IPV6.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

```
total-jitter-ipv6 time

default total-jitter-ipv6
```

**default**

Returns the command to its default value.

```
time
```

Default: 580

Specifies the time interval to use in milliseconds. time must be an integer from 0 through 999999999.

Usage

Use this command to set the jitter limit after compression.

Example

The following command sets the jitter after compression limit to 900 ms:

```
total-jitter-ipv6 900
```
unimode-timeout-to-fo-state

The time period in seconds before falling back to the FO (First Order) state.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

unimode-timeout-to-fo-state num_ms

default unimode-timeout-to-fo-state

default
Returns the command to its default value.

num_ms
Default: 3
Timeout period in seconds. num_ms must be an integer from 0 through 10.

Usage
Use this command to set the timeout before falling back to the FO state when in Unimode.

Example
The following command sets the fall back timeout to 3 seconds:

unimode-timeout-to-fo-state 3
unimode-timeout-to-ir-state

The time period in seconds before falling back to the IR (Initiation and Refresh) state.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

unimode-timeout-to-ir-state num_ms

default unimode-timeout-to-ir-state

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returns the command to its default value.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>num_ms</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 5</td>
</tr>
<tr>
<td>Timeout period in seconds. num_ms must be an integer from 0 through 20.</td>
</tr>
</tbody>
</table>

Usage
Use this command to set the timeout before falling back to the IR state when in Unimode.

Example
The following command sets the fall back timeout to 3 seconds:

```
unimode-timeout-to-ir-state 3
```
use-calculated-rtp-time-stride

This command overrides the configured value of rtp-time-stride with a calculated value.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

\[
\text{\textbf{[ default | no ] use-calculated-rtp-time-stride}}
\]

\begin{verbatim}
default
Returns the command to its default value of enabled.

no
Disables the use of calculated RTP time stride override.
\end{verbatim}

Usage
This command overrides the configured value of rtp-time-stride with a calculated value.

Example
The following command overrides the configured value of rtp-time-stride.

\[
\text{use-calculated-rtp-time-stride}
\]
**use-calculated-rtp-ts-stride**

This command overrides the configured value of rtp-ts-stride with a calculated value.

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**

```
[ default | no ] use-calculated-rtp-ts-stride
```

- **default**
  Returns the command to its default value of enabled.

- **no**
  Disables the use of calculated RTP TS time stride override.

**Usage**

This command overrides the configured value of rtp-ts-stride with a calculated value.

**Example**

The following command overrides the configured value of rtp-ts-stride.

```
use-calculated-rtp-ts-stride
```
use-ipid-overide

Enable and disable overriding the IP-ID (IPv4 Identification header field).

Product
HSGW, PDSN

Privilege
Administrator

Syntax

[ default | no ] use-ipid-overide

default
Returns the command to its default value of disabled.

no
Disables the IP-ID override.

Usage
Use this command to enable overriding the IP-ID.

Example
The following command enables the IP-ID override feature:

use-ipid-overide

The following command disables the IP-ID override feature:

no use-ipid-overide

The following command also disables the IP-ID override feature:

default use-ipid-overide
use-optimized-talkspurt

Disable and enable the use of optimized talkspurt.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

[ default | no ] use-optimized-talkspurt

default
Returns the command to its default value of enabled.

no
Disable the use of optimized talkspurt.

Usage
Use this command to enable and disable the use of optimized talkspurt

Example
The following command enables the use of optimized talkspurt:

use-optimized-talkspurt

The following command disables the use of optimized talkspurt:

no use-optimized-talkspurt
use-optimized-transience

Enable or disable the use of optimized transience.

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**

```bash
[ default | no ] use-optimized-transience
```

- **default**
  - Returns the command to its default value of enabled.

- **no**
  - Disables the use of optimized transience.

**Usage**

Use this command to enable or disable the use of optimized transience.

**Example**

The following command enables the use of optimized transience.

```
use-optimized-transience
```

The following command disables the use of optimized transience.

```
no use-optimized-transience
```
**use-timer-based-compression**

Enables timer-based compression of the RTP time stamp (TS) at the compressor.

**Product**

HSGW, PDSN

**Privilege**

Administrator

**Syntax**

```
[ default | no ] use-timer-based-compression
```

- **default**
  
  Returns the command to its default value of enabled.

- **no**
  
  Disables the use of timer-based compression.

**Usage**

Use this command to enable or disable the use of timer-based compression.

**Example**

The following command enables the use of timer-based compression.

```
use-timer-based-compression
```

The following command disables the use of timer-based compression.

```
no use-timer-based-compression
```
use-uncomp-profile

Uses the Uncompressed Profile (0x0000) if required at the compressor.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

[default | no ] use-uncomp-profile

  default
  Returns the command to its default value of disabled.

  no
  Disables the use of the Uncompressed Profile.

Usage
Use this command to enable or disable the use of the Uncompressed Profile.

Example
The following command enables the use of the Uncompressed Profile.

    use-uncomp-profile

The following command disables the use of the Uncompressed Profile.

    no use-uncomp-profile
Chapter 170
RoHC Profile Configuration Mode Commands

The RoHC Profile Configuration Mode is used to configure RoHC (Robust Header Compression) Compressor and Decompressor parameters. The profiles can then be assigned to specific subscriber sessions when RoHC header compression is configured. RoHC is not supported on GGSN.

```
Exec Mode

configure

Global Configuration Mode

rohc-profile
profile-name name

RoHC Profile Configuration Mode
```

**Important:** The availability of commands, keywords and variables in this mode is dependent on platform type, product version, and installed license(s).
common-options

Enters the RoHC Profile Common Options Configuration Mode where inactivity and delay timers are set to support dynamic header compression contexts and context preservation during handoffs.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

```
[ default ] common-options
```

```
default
Reset all parameters in the RoHC Profile Common Options Configuration Mode to default values.
```

Usage

Use this command to enter the RoHC Profile Common Options Configuration Mode where parameters for maintaining header compression contexts and inactivity timers can be configured. Entering this command results in the following prompt:

```
[context_name]host(config-rohcprofile<-profile_name>-common)#
```

RoHC Profile Common Options Configuration Mode commands are defined in the RoHC Profile Common Options Configuration Mode Commands chapter.
compression-options

Enters the RoHC Profile Compression Options Configuration Mode allowing configuration of options applied during RoHC compression for the current RoHC profile.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

[ default ] compression-options

default
Reset all options in the RoHC Profile Compression Configuration Mode to their default values.

Usage
Use this command to enter RoHC Profile Compression Configuration Mode to set the compression options that are used for subscriber sessions using the current RoHC profile.
Entering this command results in the following prompt:
[context_name]host(config-rohcprofile-<profile_name>-comp)#
RoHC Profile Compression Options Configuration Mode commands are defined in the RoHC Profile Compression Configuration Mode Commands chapter.

Example
The following command enters RoHC Profile Compression Options Configuration Mode:

    compression-options

The following command sets all compression options to their default values:

    default compression-options
decompression-options

Enters the RoHC Profile Decompression Options Configuration Mode allowing configuration of options applied during RoHC decompression for the current RoHC profile.

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**

```
[default ] decomposition-options
```

- `default`
  Reset all options in the RoHC Profile Decompression Options Configuration Mode to their default values.

**Usage**

Use this command to enter RoHC Profile Decompression Options Configuration Mode to set the decompression options used for subscriber sessions using the current RoHC profile.

Entering this command results in the following prompt:

```
[context_name]host(config-rohcprofile-<profile_name>-decomp)#
```

RoHC Profile Decompression Options Configuration Mode commands are defined in the RoHC Profile Decompression Configuration Mode Commands chapter.

**Example**

The following command enters RoHC Profile Decompression Options Configuration Mode:

```
decompression-options
```

The following command sets all decompression options to their default values:

```
default decomposition-options
```
end

Returns the CLI prompt to the Exec mode.

Product
HSGW, PDSN

Privilege
Administrator

Syntax
end

Usage
Change the mode back to the Exec mode.
exit

Exits this configuration mode and returns to the previous mode.

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**
exit

**Usage**
Return to the previous mode.
Chapter 171
RoHC Profile Decompression Configuration Mode

Commands

The RoHC Profile Decompression Configuration Mode is used to configure RoHC (Robust Header Compression) Decompressor parameters.

Important: The availability of commands, keywords and variables in this mode are dependent on platform type, product version, and installed license(s).
accept-delayed-pkts

Accepts delayed packets

Product
HSGW, PDSN

Privilege
Administrator

Syntax

[ default ] accept-delayed-pkts

  default
  Returns the command to its default value of disabled.

Usage
This command helps reduce packet loss during context repair.

Example
Use the following command to enable the system to accept delayed packets:

  accept-delayed-pkts
context-timeout

Ensures that no expired contexts are used for data compression.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

context-timeout seconds

default context-timeout

default
Returns the command to its default value.

seconds
Default: 20 seconds
The context timeout value in seconds. seconds must be an integer from 0 through 100.

Usage
The RoHC stack should periodically clean up expired contexts and release memory in case there is no data activity for the call on this context. The context cleanup period is internally calculated to be set to half of the value of the context-timeout value. This will ensure that no expired contexts are used for data compression.

Example
The following command sets the context-timeout parameter to 30 seconds:

context-timeout 30
**crc-errors-fo**

This command sets the limits for when a NACK message is sent when in the FO (First Order) state. A NACK is sent when out of a specified number of packets a specified number of them have CRC errors.

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**

```
crc-errors-fo-k num_errors

crc-errors-fo-n num_packts

default crc-errors-fo-k

default crc-errors-fo-n

default

```

- **default**
  Returns the command to its default value.

- **crc-errors-fo-k num_errors**
  Default: 1
  The number of received packets within a specified number of received packets that triggers the sending of a NACK. `num_errors` must be an integer from 1 through 10.

**Important:** `num_errors` must be less than or equal to the value specified with the `crc-errors-fo-n` command.

- **crc-errors-fo-n num_packts**
  Default: 1
  The number of packets to check for CRC errors. `num_packts` must be an integer from 1 through 10.

**Usage**

Use this command to set the parameters that trigger sending a NACK message when in the FO state.

**Example**

To configure a NACK to be sent when 4 out of the last 10 packets have CRC errors when in the FO state, use the following commands:

```
crc-errors-fo-k 4

crc-errors-fo-n 10
```
crc-errors-so

This command sets the limits for when a NACK message is sent when in the SO (Second Order) state. A NACK is sent when out of a specified number of packets a specified number of them have CRC errors.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

crc-errors-so-k num_errors

crc-errors-so-n num_packets

default crc-errors-so-k

default crc-errors-so-n

default

Returns the command to its default value.

Default: 1

The number of received packets within a specified number of received packets that triggers the sending of a NACK. num_errors must be an integer from 0 through 10.

Important: num_errors must be less than or equal to the value specified with the crc-errors-so-n command.

Default: 1

The number of packets to check for CRC errors. num_packets must be an integer from 1 through 10.

Usage
Use this command to set the parameters that trigger sending a NACK message when in the SO state.

Example
To configure a NACK to be sent when 4 out of the last 10 packets have CRC errors when in the SO state, use the following commands:

    crc-errors-so-k 4
    crc-errors-so-n 10
end

Returns the CLI prompt to the Exec mode.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.
exit

Exits the this configuration mode and returns to the previous mode.

Product
HSGW, PDSN

Privilege
Administrator

Syntax
exit

Usage
Return to the previous mode.
nack-limit

Sets the number of unsuccessful decompressions allowed before a NACK is sent.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

nack-limit  limit

default nack-limit

default
Returns the command to its default value.

limit
Default: 0
Specifies the number of unsuccessful decompressions allowed. limit must be an integer from 0 through 20.

Usage
Use this command to set the maximum number of unsuccessful decompressions before a NACK message is sent.

Example
The following command sets the number of unsuccessful decompressions allowed to 10:

nack-limit 10
**optimistic-mode-ack**

When this is enabled, if a type 2 IR-DYN packet is successfully decompressed, an optional ACK is sent in U-mode.

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**

```
[ default | no ] optimistic-mode-ack
```

- **default**
  Returns the command to its default value of enabled.

- **no**
  Disables the sending of the optional ACK.

**Usage**
Use this command to enable and disable the sending of an optional ACK in U-mode when a type 2 IR-DYN packet is successfully decompressed.

**Example**
To enable the sending of the optional ACK, enter the following command:

```
optimistic-mode-ack
```

To disable the sending of the optional ACK, enter the following command:

```
no optimistic-mode-ack
```
optimistic-mode-ack-limit

When enabled, this command sets the number of packets to send ACKs for.

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**

```
optimistic-mode-ack-limit num_pkts

default optimistic-mode-ack-limit
```

- **default**
  Returns the command to its default value.

- **num_pkts**
  Default: 3
  The number of packets to send ACKs for. `num_pkts` must be an integer from 0 through 20.

**Usage**
Use this command to set the number of packets to send the optional ACK for when a type 2 IR-DYN packet is successfully decompressed.

**Example**
Enter the following command to set the number of packets to send and ACK for to 6:

```
optimistic-mode-ack-limit 6
```

Use the following command to set the number of packets to send an ACK for back to the default of 3:

```
default optimistic-mode-ack-limit
```
piggyback-wait-time

The time in milliseconds to wait for a feedback packet to be picked up as piggybacked feedback by the associated compressor.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

piggyback-wait-time m_secs

default piggyback-wait-time

default
Returns the command to its default value.

m_secs
Default: 80ms
Specifies the time in milliseconds to wait for a feedback packet to be picked up. m_secs must be an integer value from 0 through 1000.

Usage
Use this command to set the time in milliseconds to wait for a feedback packet to be picked up as piggybacked feedback by the associated compressor.

Example
The following command sets the wait time to 120 ms:

piggyback-wait-time 120
preferred-feedback-mode

Specifies the preferred feedback mode to use between the compressor and the decompressor

Product
HSGW, PDSN

Privilege
Administrator

Syntax

preferred-feedback-mode { bidirectional-optimistic | bidirectional-reliable | unidirectional }

default preferred-feedback-mode

default
Default: bidirectional-optimistic
Returns the command to its default setting.

bidirectional-optimistic
This mode is similar to the Unidirectional mode, with the exception of a feedback channel used to send error recovery requests from the decompressor to compressor.

bidirectional-reliable
Reliable mode makes extensive use of a feedback channel to avoid packet loss from context invalidation. A secure reference model is used instead of the optimistic approach used in the other modes. With the secure reference model, the confidence of the compressor depends on acknowledgements from the decompressor for every context updating packet. Periodically the compressor sends context updating packets repeatedly until an acknowledgement is received from the decompressor.

unidirectional
Packets are sent in only one direction, from the compressor to the decompressor.

Usage
Use this command to specify the preferred feedback method to use between the compressor and the decompressor for the current RoHC profile.

Example
Use the following command to set the preferred feedback mode to bidirectional-reliable:

preferred-feedback-mode bidirectional-reliable
**rtp-sn-p**

The value of p in RTP SN (RTP Sequence Number) calculation. Least Significant Bits (LSB) encoding is used for header fields whose values are usually subject to small changes. With LSB encoding, the k least significant bits of the field value are transmitted instead of the original field value, where k is a positive integer. After receiving k bits, the decompressor derives the original value using a previously received value as reference (v_ref). The scheme is guaranteed to be correct if the compressor and the decompressor each use interpretation intervals as follows:

- In which the original value resides
- And in which the original value is the only value that has the exact same k least significant bits as those transmitted.

The interpretation interval can be described as a function:

\[ f(v_{\text{ref}}, k) = [v_{\text{ref}} - p, v_{\text{ref}} + (2^k - 1) - p] \]

Where p is an integer.

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**

```
**rtp-sn-p** value
```

```
**default** rtp-sn-p
```

```
default

Returns the command to its default value.
```

```
value

Default:
Specifies the number to use for the value of p in the RTP SN calculation. value must be an integer from 0 through 999.
```

**Usage**

Use this command to set the value to use for p when performing the RTP SN calculation.

**Example**

The following command sets the RTP Sequence Number integer “p” value to 100:

```
rtp-sn-p 100
```
rtp-sn-p-override

Allow an override of p in RTP SN calculation. This is disabled by default.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

[ default | no ] rtp-sn-p-override

  default
  Returns the command to its default value of disabled.

  no
  Disables overriding p in RTP SN calculation.

Usage
Use this command to allow an override of p in RTP SN calculations.

Example
The following command enables the override of p in the RTP SN calculation:

  rtp-sn-p-override
sliding-window-ts

Computes jitter as described in RFC 3095,[4.5.4]

Product
HSGW, PDSN

Privilege
Administrator

Syntax

sliding-window-ts size

default sliding-window-ts

default

Returns the command to its default value.

size

Default: 4
Set the size of the sliding window. size must be an integer from 1 through 1000.

Usage

Use this command to set the size of the sliding window used to compute jitter for the current RoHC profile.

Example

The following command sets the sliding window size to 500:

sliding-window-ts 500
use-clock-option

Controls usage of RoHC clock option. The clock option informs the compressor of the clock resolution of the decompressor. This is needed to allow the compressor to estimate the jitter introduced by the clock of the decompressor when doing timer-based compression of the RTP timestamp.

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**

```
[ default | no ] use-clock-option
```

- **default**
  Returns the command to its default value of enabled.

- **no**
  Disable use of the RoHC clock option.

**Usage**
Use this command to enable and disable the use of the RoHC clock option.

**Example**
The following command enables RoHC clock option usage:

```
use-clock-option
```

The following command disables RoHC clock option usage:

```
no use-clock-option
```
use-crc-option

Controls usage of the RoHC crc option. The CRC option contains an 8-bit CRC computed over the entire feedback payload, without the packet type and code octet, but including any CID fields.

Product
HSGW, PDSN

Syntax

[ default | no ] use-crc-option

| default |
---|
| Returns the command to its default value of enabled. |

| no |
---|
| Disable use of the CRC option. |

Usage
Use this command to enable and disable the use of the RoHC CRC option.

Example
The following command enables RoHC CRC option usage:

```
use-crc-option
```

The following command disables RoHC CRC option usage:

```
no use-crc-option
```
use-feedback

Controls use of the feedback channel. A feedback channel sends error recovery requests and (optionally) acknowledgments of significant context updates from the decompressor to the compressor.

Product
HSGW, PDSN

Privilege
Security Administrator, Administrator

Syntax

[ default | no ] use-feedback

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Returns the command to its default value of disabled.</td>
</tr>
<tr>
<td>no</td>
<td>Disable use of the feedback channel.</td>
</tr>
</tbody>
</table>

Usage
Use this command to enable and disable the use of the RoHC feedback channel.

Example
The following command enables RoHC feedback channel usage:

```
use-feedback
```

The following command disables RoHC feedback channel usage:

```
no use-feedback
```
use-jitter-option

Controls usage of RoHC jitter option. The jitter option allows the decompressor to report the maximum jitter it has observed.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

[ default | no ] use-jitter-option

default
Returns the command to its default value of enabled.

no
Disable use of the jitter option.

Usage
Use this command to enable and disable the use of the RoHC jitter option.

Example
The following command enables RoHC jitter option usage:

use-jitter-option

The following command disables RoHC jitter option usage:

no use-jitter-option
use-reject-option

Controls usage of RoHC reject option. The reject option informs the compressor that the decompressor does not have sufficient resources to handle the flow.

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**

```
[ default | no ] use-reject-option
```

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Returns the command to its default value of disabled.</td>
</tr>
<tr>
<td>no</td>
<td>Disable use of the reject option.</td>
</tr>
</tbody>
</table>

**Usage**
Use this command to enable and disable the use of the RoHC reject option.

**Example**
The following command enables RoHC reject option usage:

```
use-reject-option
```

The following command disables RoHC reject option usage:

```
no use-reject-option
```
use-sn-not-valid-option

Controls usage of the RoHC SN not valid option. The sn-not-valid option indicates that the SN of the feedback is not valid. A compressor must not use the SN of the feedback to find the corresponding sent header when this option is present.

Product
HSGW, PDSN

Privilege
Administrator

Syntax

[ default | no ] use-sn-not-valid-option

- default
  Returns the command to its default value of enabled.

- no
  Disable use of the sn-not-valid option.

Usage
Use this command to enable and disable the use of the RoHC sn not valid option.

Example
The following command enables RoHC sn not valid option usage:

```
use-sn-not-valid-option
```

The following command disables RoHC sn not valid option usage:

```
o use-sn-not-valid-option
```
use-sn-option

Controls usage of RoHC sn option. The sn option provides 8 additional bits of SN (Sequence Number. Usually RTP Sequence Number.)

Product
HSGW, PDSN

Privilege
Administrator

Syntax

[ default | no ] use-sn-option

    default
    Returns the command to its default value of enabled.

    no
    Disable use of the sn option.

Usage
Use this command to enable and disable the use of the RoHC sn option.

Example
The following command enables RoHC sn option usage:

    use-sn-option

The following command disables RoHC sn option usage:

    no use-sn-option
Chapter 172
Route-map Configuration Mode Commands

The Route-Map Configuration sub-mode is used for the OSPFv2 and BGP-4 routing protocols. This mode includes commands that configure matching rules and set actions to perform on matched routes.

![Diagram of Route-map Configuration Mode]

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the context configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Change the mode back to the Exec mode.
exit

Exits the context configuration mode and returns to the global configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
exit
```

Usage

Return to the global configuration mode.
**match as-path**

Match an AS path access list

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
match as-path AS_list
no match as-path AS_list
```

- **no**
  Disables matching the specified AS path access list.

- **AS_list**
  Specifies the name of an AS path access list for matching. `AS_list` must be from 1 to 79 alphanumeric characters in length.

**Usage**

This command is used for BGP-4 routing to specify an AS path access list to be matched. Refer to the `ip as-path access-list` command for more information.

**Example**

To match entries in an AS path access list named `ASlist1`, enter the following command:

```plaintext
match as-path ASlist1
```
match interface

Specifies the next-hop interface name of a route to be matched.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```markdown
match interface interface-name

no match interface interface-name
```

Usage

Use this command to specify the next hop interface name for routes to be matched.

Example

To match routes that have the next hop interface specified as Interface123, enter the following command:

```
match interface Interface123
```

To disable matching routes that have the next hop interface specified as Interface123, enter the following command:

```
no match interface Interface123
```
match ip address

This command matches routes with entries in a route-access-list or prefix-list.

Product
All

Privilege
Security Administrator, Administrator

Syntax

match ip address { prefix-list | route-access-list } list_name

no match ip address { prefix-list | route-access-list } list_name

no
Disable matching from the specified prefix list or route access list.

prefix-list
This command matches any routes with entries in a prefix-list.

route-access-list
This command matches any routes with entries in a route-access-list

list_name
The name of the IP prefix list or IP route access-list. This variable can be a string from 1 to 63 alphanumeric characters in length.

Usage
Use this command to match routes specified in a route-access-list or prefix-list.

Example
To match routes that are specified in a prefix list named Prefix100, enter the following command:

match ip address prefix-list Prefix100

To disable matching routes that are specified in a prefix list named Prefix100, enter the following command:

no match ip address prefix-list Prefix100
match ip next-hop

This command matches next-hop IP addresses with entries in specified standard prefix-list or route-access-list.

Product
All

Privilege
Security Administrator, Administrator

Syntax

match ip address next-hop { prefix-list | route-access-list } list_name
no match ip address next-hop { prefix-list | route-access-list } list_name

prefix-list
This command matches any routes that have a next-hop router address that has an entry in the specified prefix list.

route-access-list
This command matches any routes that have a next-hop router address that has an entry in the specified route-access-list.

list_name
The name of the IP prefix-list or IP route-access-list. This variable is a string from 1 through 63 alphanumeric characters in length.

Usage
Use this command to match next-hop IP addresses that have entries in the specified prefix-list or route-access-list.

Example
To match next-hop addresses with entries in a prefix-list named Prefix100, enter the following command:

    match ip address next-hop prefix-list Prefix100

To disable matching next-hop addresses with entries in a prefix-list named Prefix100, enter the following command:

    no match ip address next-hop prefix-list Prefix100
**match metric**

This command matches routes that have the specified route metric.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
match metric metric_value

no match metric metric_value
```

- **no**
  - Disables matching of the specified route metric.

- **metric_value**
  - This is the route metric to match. This must be an integer ranging from 0 through 4294967295.

**Usage**

Use this command to match routes that have the specified route metric.

**Example**

To match routes with the route metric of 1200, enter the following command:

```plaintext
match metric 1200
```

To disable matching routes with a route metric of 1200, enter the following command:

```plaintext
no match metric 1200
```
match origin

This command matches the origin code learned from BGP. This command is for route maps that are used with BGP routing only.

Product
HA

Privilege
Security Administrator, Administrator

Syntax

[ no ] match origin { egp | igp | incomplete }

- **no**
  Disables matching of the origin code.

- **egp**
  Match origins learned from the External Gateway Protocol (EGP)

- **igp**
  Match origins learned from the local Interior Gateway Protocol (IGP)

- **incomplete**
  Match origins with unknown heritage.

Usage
Use this command to match origin codes for BGP routing.

Example
To match origin codes learned from EGP, enter the following command:

```
match origin egp
```
**match route-type external**

Match external OSPF routes of the specified type.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] match route-type external { type-1 | type-2 }
```

- **type-1**
  Only match type-1 external routes.

- **type-2**
  Only match type-2 external routes.

**Usage**

Use this command to match external routes of a specific type.

**Example**

The following command matches all external routes that are type-2:

```
match route-type external type-2
```

The following command disables matching external routes that are type-2:

```
no match route-type external type-2
```
**match tag**

This command matches routes with the specified route tag value.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```diff
[ no ] match tag tag_value
```

- **no**
  Disable matching routes with the specified route tag value.

- **tag_value**
  The route tag value to match. This must be an integer from 0 through 4294967295.

**Usage**
Use this command to match routes that have the specified route tag value.

**Example**
Use the following command match routes that have a route tag value of 1234:

```
match tag 1234
```

Use the following command to disable matching routes that have a route tag value of 1234:

```
no match tag 1234
```
set as-path

Modify an AS path for a route by adding the specified AS numbers to the front of the path.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] set as-path prepend ASN

no
Disable prepending the AS path. Any previously set prepends are removed.

prepend
Prepends the autonomous system path.

ASN
AS number(s) to be prepended to the AS path. You can specify up to 16 different AS numbers to be prepended in the order specified. Each AS number must be separated by a space. `ASN` must be an integer from 1 through 65535.
```

**Usage**
Use this command to add up to 16 specified AS numbers to the front of the AS path.

**Example**
The following command prepends the AS numbers `100`, `200`, and `1000` to matching AS paths:

```
set as-path prepend 100 200 1000
```
**set ip next-hop**

Set the IP address that is applied as the next hop for routes.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```
[ no ] set ip next-hop ip_address
```

- **no**
  
  Disable the specified next hop address.

- **ip_address**
  
  This is the IP address of the next hop to which packets are output.

**Usage**

Use this command to set the IP address that is used as the next hop for routes.

**Example**

To set the next hop for routes to the IP address `192.168.2.100`, use the following command:

```
set ip next-hop 192.168.2.100
```

To disable setting the next hop for routes to the IP address `192.168.2.100`, use the following command:

```
no set ip next-hop 192.168.2.100
```
**set metric**

This command sets the route metric for matched routes to the specified value.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] set metric metric_value
```

- `metric_value`
  This is the metric value that is set for routes. This must be an integer from 1 through 4294967295.

**Usage**
Use this command to set the route metric for matched routes.

**Example**
To set the route metric to 12345, use the following command;

```
set metric 12345
```

To disable setting the route metric to 12345, enter the following command;

```
no set metric 12345
```
set metric-type

This command sets the route metric type to either Type-1 or Type-2 in the AS-external-LSA.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] set metric-type { type-1 | type-2 }
```

- **type-1**
  Set the route metric to external type-1.

- **type-2**
  Set the route metric to external type-2

**Usage**

Use this command to set the route metric to either external type-1 or external type-2.

**Example**

To set the route metric to type-1, enter the following command:

```
set metric type-1
```

To disable setting the metric to type, enter the following command:

```
no set metric type-1
```
set origin

This command sets the BGP origin code to the specified value. This command is for route maps that are used with BGP routing only.

Product
HA

Privilege
Security Administrator, Administrator

Syntax

```
[ no ] set origin {egp | igp | incomplete}
```

- **no**
  Disables setting the origin code.

- **egp**
  Set the origin code to specify that the path is from a remote External Gateway Protocol (EGP) system.

- **igp**
  Set the origin code to specify that the path is from a local Interior Gateway Protocol (IGP) system.

- **incomplete**
  Set the origin code to specify that the path is from an unknown system.

Usage

Use this command to set a specified origin code for BGP.

Example

To the origin code to EGP, enter the following command:

```
set origin egp
```
**set tag**

This command sets the route tag value for matched routes.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] set tag tag_value
```

- **no**
  Disable setting the route tag to the specified value.

- **tag_value**
  The route tag value to set. This must be an integer from 0 through 4294967295.

**Usage**

Use this command to set the route tag value that is applied to all matched routes.

**Example**

To set the route tag value to **12345**, enter the following command:

```
set tag 12345
```

To disable setting the route tag value to **12345**, enter the following command:

```
no set tag 12345
```
set weight

Set the weight in the routing table for matching routes to the specified value.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax
[ no ] set weight value

- no
  Disable setting the routing weight value.

- value
  The weight in the routing table to assign. must be an integer from 1 through 4294967295.

Usage
Use this command to set the routing table weight on matched routes.

Example
The following command sets the routing table weight for matched routes to 1000:

set weight 1000
Chapter 173
RS-232 Port Configuration Mode Commands

The RS-232 Port Configuration Mode is used to manage the RS-232 ports on the SPIO cards.

```
Exec Mode
    └── configure
       └── Global Configuration Mode
           └── port rs232 slot/port
               └── RS-232 Port Configuration Mode
```
default

Restores the port’s default speed and communication mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
default { preferred slot | terminal { all | databits | flowcontrol | parity | speed | stopbits } }
```

**preferred slot**
Sets the port for non-revertive operation for port redundancy auto-recovery; requiring an administrative user to manually issue a port switch to command to return service to the original port.

**terminal { all | databits | flowcontrol | parity | speed | stopbits }**
Sets the terminal settings for the rs-232 port to their default settings.
- **all**: Restore all settings to their default values.
- **databits**: Restore the databits setting to its default value of 8.
- **flowcontrol**: Restore the flowcontrol setting to its default value of none.
- **parity**: Restore the parity setting to its default value of none.
- **speed**: Restore the speed setting to its default value of 9600.
- **stopbits**: Restore the stopbits setting to its default value of 1.

**Usage**
Restores port-level parameters to their default values.

**Example**
The following command restores all terminal settings to their default values:

```
default terminal all
```
end

Exits the port configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Change the mode back to the Exec mode.
exit

Exits the port configuration mode and returns to the global configuration mode.

Product
- All

Privilege
- Security Administrator, Administrator

Syntax
```
exit
```

Usage
Return to the global configuration mode.
preferred slot

Assigns revertive or non-revertive control to port redundancy auto-recovery.

Default: non-revertive operation

Product
PDSN, FA, HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

preferred slot slot#

no preferred slot slot#

no
Disables revertive, or auto-recovery, operation for selected port.

slot#
Identifies the physical chassis slot where the SPIO card is installed.

Usage
This command enables or disables revertive port redundancy, wherein after a port failover, when the original port is restored to service (i.e. link up) the system will return service to that port automatically. Disabled, which is the default setting, causes non-revertive operation; requiring an administrative user to manually issue a port switch to command to return service to the original port.
This command must be issued on a per port basis, allowing you to configure specific ports to be used on individual LCs or SPIO cards. For example, ports 1 through 4 could be configured as “preferred” on the LC in slot 17 while ports 5 through 8 are “preferred” on the LC in slot 33. In this scenario, both LCs would be in an Active operational state while still providing LC and port redundancy for the other.

Important: This command is not supported on all platforms.

Example

preferred slot 24
**snmp trap link-status**

Enables/disables the generation of an SNMP trap for link status changes.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
  snmp trap link-status
  no snmp trap link-status
```

**Usage**
Enable link status change traps when a monitoring facility can use the information or if there are troubleshooting activities are in progress.

**Example**

```
  snmp trap link-status
  no snmp trap link-status
```

Disables the sending of traps for link status changes.
terminal

Configures the console port on the SPIO.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```plaintext
terminal { carrierdetect { off | on } | databits { 7 | 8 } | flowcontrol { hardware | none } | parity { even | none | odd } | speed { 115200 | 19200 | 38400 | 57600 | 9600 } | stopbits { 1 | 2 } }
```

- `carrierdetect { off | on }`
  Default: None
  Specifies whether or not the console port is to use carrier detect when connecting to a terminal.

- `databits { 7 | 8 }`
  Default: 8
  Specifies the number of data bits used to transmit and receive characters.

- `flowcontrol { hardware | none }`
  Default: None
  Specifies how the flow of data is controlled between the SPIO and a terminal.

- `parity { even | none | odd }`
  Default: None
  Specifies the type of error checking used on the port.
  - `even`: Enables error checking by setting the parity bit to 1 (if needed) making the number of 1s in the data bits even.
  - `none`: Disables error checking.
  - `odd`: Enables error checking by setting the parity bit to 1 (if needed) making the number of 1s in the data bits odd.

- `speed { 115200 | 19200 | 38400 | 57600 | 9600 }`
  Default: 9600
  Specifies the flow of data in bits per second between the console port and terminal.

- `stopbits { 1 | 2 }`
  Default: 1
  Specifies the number of stop bits between each transmitted character.

Usage

Sets the SPIO’s console port parameters for communication with the terminal device.
Example
The following command sets the SPIO’s console port. The terminal must support these values.

```
terminal carrierdetect off databits 7 flowcontrol hardware parity even speed 115200 stopbits 1
```
Chapter 174
SCCP Network Configuration Mode Commands

The SCCP Network Configuration Mode is used to configure properties for Signaling Connection Control Part (SCCP) services for SS7.

In this mode, the command prompt should be similar to:

```
[local]hostname(config-sccp-network-<sccp_id>)#
```

Signaling Connection Control Part (SCCP) is a routing protocol in the SS7 protocol suite in layer 4, which provides end-to-end routing for TCAP messages to their proper database.

---

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
associate

Associates an SS7 routing domain with the SCCP network.

**Product**
SGSN, HNB-GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
associate ss7-routing-domain rd_id

no associate
```

**no**
Removes the association with the SS7 routing domain from the system configuration.

**rd_id**
This number identifies an already defined SS7 routing domain.
`rd_id`: enter an integer from 1 through 12.

**Usage**
Use this command to associate SS7 routing domain configurations with SCCP network configurations.

**Example**
The following command associates the SCCP network with SS7 routing domain 2:

```plaintext
associate ss7-routing-domain 2
```
description

This command defines a string that describes the SCCP network. The description is used for operator reference.

**Product**
SGSN, HNB-GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
description string

no description
```

**string**
This is a string to describe the SCCP network.

*string* must be an alphanumeric string from 1 through 127 characters in length. If there are spaces in the string the string must be enclosed in double-quotes. For example; “This is a Description”.

**no**
Removes the description from the system configuration.

**Usage**
Use this command to configure a description of this SCCP service for operator reference.

**Example**
The following command sets the description to “This is the SCCP Service Number 1”:

```
description "This is the SCCP Service Number 1."
```
destination

This command configures the SCCP network destination information. Use this command multiple times to set all of the destination information required.

Product
SGSN, HNB-GW

Privilege
Security Administrator, Administrator

Syntax

destination dpc pt_code { name route_name | next-hop | ssn subsys_num | version sccp_ver }

no destination dpc p_code { name route_name | ssn ssn_num | version sccp_ver }

no
Deletes the specified destination information from the SCCP network configuration.

dpc pt_code
Specifies the SCCP destination point code.
pt_code: Must be in SS7 point code dotted-decimal ###.###.### format or decimal ####### format.

name route_name
The name of the SCCP destination route.
route_name: enter an alphanumeric string from 1 through 64 characters in length.

next-hop
Associates the next destination defined in the SS7 routing domain.

ssn subsys_num
The destination subsystem number.
ssubsys_num: enter an integer from 1 through 255.

version sccp_ver
sccp_ver: enter one of the following to select the SCCP variant:
- ANSI88
- ANSI92
- ANSI96
- BELL05
- GSM0806
- ITU88
- ITU92
Usage
Use this command to configure the destination information for the SCCP network.

Example
The following commands set the name of the destination route to default_route, the subsystem number to 1, and the variant version to ITU96, all with a destination point code of 1:

destination dpc 1 name default_route
destination dpc 1 ssn 1
destination dpc version ITU96
end

Exits the current configuration mode and returns to the Exec mode.

Product
SGSN, HNB-GW

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the global configuration mode.

Product
SGSN, HNB-GW

Privilege
Security Administrator, Administrator

Syntax

```
exit
```

Usage
Return to the global configuration mode.
global-title-translation

This command associates a GTT address-map with this SCCP network.

Product
SGSN, HNB-GW

Privilege
Security Administrator, Administrator

Syntax

```
global-title-translation address-map instance instance

no global-title-translation address-map instance instance
```

**no**
Deletes the GTT address-map instance associated with this SCCP network.

**instance**
This value uniquely identifies a specific previously defined instance of a GTT address-map.
instance: enter an integer from 1 to 4096.

Usage
Use this command to link a GTT address-map, configured with the GTT Address Map configuration mode, to a specific SCCP network configuration.

Example

```
global-title-translation address-map instance gtt-map1
```
### hop-count

This command specifies the hop count for this SCCP network.

**Product**
SGSN, HNB-GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
hop-count hop_cnt

default hop-count
```

**default**
Resets the hop-count value to the system default of 5.

**hop_cnt**
The hop count to assign to this SCCP network.

*hop_cnt*: enter an integer from 1 to 5.

**Usage**
Use this command to define the hop count for this SCCP network.

**Example**
The following command sets the hop count to 3:

```plaintext
hop-count 3
```
**self-point-code**

This command specifies the SS7 point code for this SCCP service.

**Product**
SGSN, HNB-GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
self-point-code point_code
no self-point-code
```

- **point_code**
  Defines the point code to assign to this SCCP network service. The value entered must adhere to the point code variant selected when the SCCP network instance was defined:
  - ITU Range 0.0.1 to 7.255.7
  - ANSI Range 0.0.1 to 255.255.255
  - TTC Range 0.0.1 to 15.31.255
  - A string of 1 to 11 combined digits ad period.

**Usage**
Use this command to assign the self point code to use for this SCCP service.

**Example**
The following command sets an ITU-based point code for this SCCP service:

```
self-pointcode 4.121.5
```

The following command removes the configured self-point code:

```
no self-pointcode
```
timeout

This command configures the timeout parameters for this SCCP network.

Product
SGSN, HNB-GW

Privilege
Security Administrator, Administrator

Syntax

```
timeout { attack-timer | congestion-timer | conn-est-timer | crd-timer | decay-timer | iar-timer | ias-timer | interval-timer | reassembly-timer | release-timer | repeat-release-timer | reset-timer | sst-timer } +
default timeout
no timeout timer
```

```
attack-timer time
Defines the time before the attack timer expires.
time: enter an integer between 1 and 10.

congestion-timer time
Defines the time before the congestion timer expires.
time: enter an integer between 1 and 10.

conn-est-timer time
Defines the time before the connection timer expires.
time: enter an integer between 6 and 12.

crd-timer time
Defines the time before the coordinated-state-change timer expires.
time: enter an integer between 60 and 120.

decay-timer time
Defines the time before the decay timer expires.
time: enter an integer between 1 and 10.

iar-timer time
Defines the time before the inactivity-receive timer expires.
time: enter an integer between 60 and 120.

ias-timer time
Defines the time before the inactivity-send timer expires.
time: enter an integer between 30 and 60.
```
**timeout**

Defines the time before the interval timer expires.
*time*: enter an integer between 6 and 12

**reassembly-timer** *time*

Defines the time before the reassembly-timer expires.
*time*: enter an integer between 10 and 20.

**release-timer** *time*

Defines the time before the release-assembly timer expires.
*time*: enter an integer between 1 and 2.

**repeat-release-timer** *time*

Defines the time before repeat-release timer expires.
*time*: enter an integer between 1 and 2.

**reset-timer** *time*

Defines the amount of time before the reset timer expires.
*time*: enter an integer between 1 and 2.

**sst-timer** *time*

Defines the amount of time before the subsystem status test timer expires.
*time*: enter an integer between 5 and 1200.

**default**

Resets the timeout parameter to the system default.

**no**

Deletes the specified timer configuration.

**Usage**

Use this command to assign timeout timers and timeout values for this SCCP service.

**Example**

```
timeout reset-timer 75
```
Chapter 175
Service Redundancy Protocol Configuration Mode Commands

The Service Redundancy Protocol Mode is used to configure properties for Interchassis Session Recovery services.

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
bind address

Binds the service to the IP address of the local chassis.

Product
HA, GGSN,

Privilege
Security Administrator, Administrator

Syntax

bind address {IPv4 _address | IPv6_address}

no bind address

no
Removes the IP bind address.

IPv4 _address | IPv6_address
The system IP address.

Usage
Defines the IP address of the local chassis defined as part of the Interchassis Session Recovery configuration.

Example

bind address 1.1.1.1
chassis-mode

Defines the chassis’s operational mode - primary or backup - for Interchassis Session Recovery.

Product
HA, GGSN,

Privilege
Security Administrator, Administrator

Syntax
chassis-mode \{ primary | backup \}
default chassis-mode

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resets the chassis mode to the default setting of backup.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>primary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configures the system as the primary chassis operating in active state.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>backup</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configures the system as the backup chassis operating in standby state.</td>
</tr>
</tbody>
</table>

Usage
Sets the chassis mode (primary or backup) for the system within the framework of Interchassis Session Recovery.

Example
chassis-mode primary
checkpoint session duration

Configures check pointing for Interchassis Session Recovery.

Product
HA, GGSN,

Privilege
Security Administrator, Administrator

Syntax
```plaintext
checkpoint session duration duration
default checkpoint session duration
```

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resets the checkpoint session duration to the default setting of 60 seconds.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>The amount of time (in seconds) that a call must be active before it is check pointed. duration must be an integer from 1 through 65535.</td>
</tr>
</tbody>
</table>

Usage
Sets the amount of time the chassis waits before check pointing an existing call session.

Example
```plaintext
checkpoint session duration 6500
```
configuration-interval

Defines the configuration validation interval.

Product
HA, GGSN

Privilege
Security Administrator, Administrator

Syntax
configuration-interval interval
default configuration-interval

- default
  Resets the configuration interval to the default setting of 3600 seconds.

- interval
  The amount of time (number of seconds) between one configuration validation and the next configuration validation. interval must be an integer from 1 through 65535.

Usage
This configures the interval between configuration validations of the primary and backup chassis.

Example
configuration-interval 34
dead-interval

The timeout interval before a peer is determined to be down.

Product
HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

dead-interval interval

default dead-interval

default
Resets the dead interval to the default setting of 30 seconds.

interval
The amount of time (in seconds) for the dead interval. interval must be an integer from 1 through 65535.

Usage
This command specifies the amount of time that one chassis waits to receive a communication from a peer before the listening chassis determines that the peer chassis is down.

Example

dead-interval 65
delay-interval

Configure the delay time, for starting the dead timer, after configuration files are loaded.

**Product**
HA, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[Syntax]
delay-interval interval

default delay-interval
```

**default**
Sets / Restores default value assigned for specified parameter.

**interval**
The amount of time (in seconds) for the delay interval. interval must be an integer from 1 through 65535.

**Usage**
This configures interval for starting the dead timer, after configuration files are loaded.

**Example**

delay interval 65
end

Exits the service recovery mode and returns to the Exec mode.

Product
HA, GGSN

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the Context Configuration mode.

Product
HA, GGSN

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Return to the context configuration mode.
**hello-interval**

 Defines the lapse time between sending the hello message.

**Product**

HA, GGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
hello-interval interval
```

```
default hello-interval
```

### default

*Resets the hello interval to the default setting of 10 seconds.*

```
default
```

### interval

*The lapse time (in seconds) between sending the hello message. interval must be an integer from 1 through 65535.*

**Usage**

This command configures the hello interval - the amount of time that lapses between the sending of each hello message. Each chassis sends the other chassis a hello message at the expiration of every hello interval.

**Example**

```
hello-interval 35
```
monitor authentication probe

Enables the monitoring of the connection between the primary chassis and a specified RADIUS server.

Product
HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

[ no ] monitor authentication probe context context_name { IPv4_address | IPv6_address } port port_number

- **no**
  Turns off the monitoring.

- **context context_name**
  Identifies the context being used.

- **IPv4 _address | IPv6_address**
  Defines the IP address of the RADIUS server to be monitored.

- **port port_number**
  Identifies a specific port for the authentication probe. port_number must be the port for the AAA server.

Usage
This command initiates monitoring of the connection between the primary chassis and the specified AAA server through the use of authentication probe packets. If the connection drops, the standby chassis becomes active.

Example

monitor authentication probe context test1 1.1.1.1 port 1025
monitor bgp

Enables monitoring of the connection between the specified BGP peer and the primary chassis.

**Product**
HA, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] monitor BGP context context_name IPv4_address vrf vrf_name
```

- **no**
  Disables monitoring.

- **context context_name**
  Identifies the context being used.

- **IPv4 _address / IPv6_address**
  Defines the IP address of the BGP peer to be monitored.

- **vrf vrf_name**
  Defines the VPN Routing/Forwarding instance.

**Usage**
This command initiates monitoring of the connection between the primary chassis and the specified BGP peer through the use of authentication probe packets. If the connection drops, the standby chassis becomes active.

**Example**

```
monitor bgp context test 125.2.1.56
```
peer-ip-address

Specifies the IP address for the peer chassis.

Product
HA, GGSN

Privilege
Security Administrator, Administrator

Syntax

```
peer-ip-address { IPv4_address | IPv6_address }
```

```
no peer-ip-address
```

no

Removes the peer IP address of the backup chassis.

```
IPv4_address | IPv6_address
```

The IP address of the backup chassis.

Usage

This command is used to identify the peer chassis in the Interchassis Session Recovery configuration. From the primary’s perspective, the peer is the backup and from the backup’s perspective, the peer is the primary.

Example

```
peer-ip-address 1.1.1.1
```
priority

Sets the initial Interchassis Session Recovery priority of each peer chassis.

***Important:*** `priority` takes affect only during simultaneous initializing of all chassis in an Interchassis Session Recovery configuration, and only if a misconfiguration has both chassis in the same mode (both Primary or both Backup).

**Product**
HA, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
priority priority_value

default priority
```

```
default

Resets the priority to the default setting of 125.

priority_value

The priority for the HA. `priority_value` must be an integer from 1 through 255.
```

**Usage**

This command determines which chassis transitions to the Active state when all chassis have the same mode configuration. `priority` acts as a tie breaker for the state determination only when all chassis initialize simultaneously. The chassis with the higher priority (higher number) becomes Active while the chassis with the lower priority (lower number) becomes Standby.

Once chassis become operational (after initialization), if there is an event requiring a chassis change of state, then each chassis returns to its previous state (Active or Standby) after both chassis recover.

**Example**

```
priority 5
```
route-modifier

Sets the route modifier for the peer chassis.

Product

HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

route-modifier threshold threshold_value

default route-modifier

default

Resets the route modifier to the default setting of 16.

threshold_value

The value that causes the route-modifier counter to be reset to the initial value. threshold_value must be an integer from 2 through 32.

Usage

This command is used to determine when the route modifier should be reset to its initial value to avoid rollover.

Example

route-modifier threshold 10
Chapter 176
SGSN APN Policy Configuration Mode Commands

The SGSN APN Policy configuration mode provides the commands to configure the access point name (APN) parameters specific to a particular SGSN operator policy.

The command prompt for this mode will be similar to:

```
[local]hostname(config-sgsn-op-policy-apn)#
```

**Important**: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
address-resolution-mode

Identify the address resolution mode for this SGSN APN policy.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

    address-resolution-mode { fallback-for-dns | local }

    default address-resolution-mode

    default
    Resets the configuration to the default value; i.e. fallback-for-dns.

    fallback-for-dns
    Default: Enabled
    This keyword instructs the system to first attempt DNS resolution. If this fails, then the system is to use locally configured addresses, if available.

    local
    Default: Disabled
    This keyword instructs the system not to use DNS query and to only use locally configured addresses.

Usage
Use this command to specify the DNS query or local address resolution for this SGSN APN policy.

Example
The following command sets the address resolution mode to attempt the DNS resolution first and if failed attempt to use available local address:

    address-resolution-mode fallback-for-dns
CC

This command provides the configurables to define the charging characteristics for this SGSN APN policy.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

cc { local-value-for-scdrs behavior bit_value profile index_bit | prefer { hlr-value-for-scdrs | local-value-for-scdrs } }

remove cc { local-value-for-scdrs | prefer }

remove

Removes the charging characteristics configuration for this APN policy.

local-value-for-scdrs behavior bit_value profile index_bit

Defaults: bit_value = 0x0; index_bit = 8

This keyword sets the SGSN APN policy to configure the value of the behavior bits and profile index for the charging characteristics for S-CDRs locally, when the HLR does not provide values for this.

If the HLR provides the charging characteristics with behavior bits and profile index and operator want to ignore it, then specify prefer local-value-for-scdrs keyword with this command.

bit_value: Must be a hexadecimal value between 0x0 and 0xFFF.

index_bit: Must be an integer value from 1 to 15.

Some of the index values are predefined according to 3GPP standard:

- 1 for hot billing
- 2 for flat billing
- 4 for prepaid billing
- 8 for normal billing

prefer { hlr-value-for-scdrs | local-value-for-scdrs }

Default: hlr-value-for-scdrs

Specifies preference for using charging characteristics settings received from HLR or set by SGSN locally.

• hlr-value-for-scdrs: Sets the operator policy to use charging characteristics settings received from HLR for S-CDRs. This is the default preference.

• local-value-for-scdrs: Sets the operator policy to use charging characteristics settings from SGSN only for S-CDRs.

Usage

Use this command to set the APN policy behavior in operator policy to use charging characteristic for S-CDRs either from HLR or locally from SGSN.

The charging characteristics parameters are configurable from SGSN Operator Policy Configuration mode too. For generation of M-CDRs the parameters configured in SGSN Operator Policy Configuration mode will
prevail but for generation of S-CDRs the parameters configured in this SGSN APN Policy Configuration mode will prevail.

Example
The following command configures the APN policy not to use charging characteristics setting received from HLR for S-CDR generation.

```
cc prefer hlr-value-for-scdrs
```
direct-tunnel

This command defines the permission for direct tunnel establishment by GGSNs resolved by this APN.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

direct-tunnel not-permitted-by-ggsn

remove direct-tunnel

remove
Removes the configured policy of not to permit direct tunnel by GGSNs resolved by this APN.

not-permitted-by-ggsn
Default: Disabled.
Specifies that a direct tunnel is not permitted by the GGSN resolved by this APN.

Usage
Use this command to enable/disable the permission for establishment of direct tunnels between RNC and GGSN.

Example
The following command configures the SGSN not to permit the direct tunnel with the GGSN which is resolved by this APN policy:

direct-tunnel not-permitted-by-ggsn
end

Exits the current configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the previous configuration mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Return to the previous configuration mode.
**gateway-address**

Configures the address of the gateway GPRS support node (GGSN) with priority to activate the GGSN. It also provides the load balancing through weight for specific GGSN address in this APN policy.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
gateway-address ip_address { priority priority | weight weight }
no gateway-address ip_address
```

- **no**
  Removes the preconfigured/defined GGSN address from this APN policy.

- **ip_address**
  Specifies the IP address for the GGSN in standard IPv4 or IPv6 notation.

- **priority priority**
  Specify the priority for the configured GGSN address for SGSN address selection. If one GGSN fails to respond, the next priority level GGSN is selected.
  *priority* is an integer from 1 to 100 to assign a priority to the GGSN IP address. Note that the lower the integer, the higher the priority so that 1 is the highest priority.

- **weight weight**
  Specifies the weight (importance) assigned to a GGSN for load balancing.
  *weight* is an integer from 1 to 100 to give a weight to the GGSN IP address.
  If a weight is assigned to an address for that APN, then load balancing (of primary CPC requests) depends on the weight value.
  For example:

  ```plaintext
  GGSN1 172.16.130.1 weight 30 and GGSN2 172.16.130.3 weight 70
  ```

  With this configuration, 30% of the activation requests for this APN will go to GGSN1 and 70% of the requests will go to GGSN2. Also note, the sum of the weights does not need to be 100. The calculation of weight percentiles is carried out proportionally; so the following configuration will also yeild the same 30% - 70% results:

  ```plaintext
  GGSN1 172.16.130.1 weight 6 and GGSN2 172.16.130.3 weight 14
  ```

**Usage**

Use this command to provide a priority and load balancing in GGSN selection through APN policy. Note that keyword priority and weight can not be used simultaneously in one APN policy. A maximum of 16 GGSN address can be configured with this command in an APN policy.
Example

gateway-address 123.123.123.1 priority 2
This command enables (by adding a configuration statement) or disables (by removing the configuration statement) the GTPC private extension. This command is available in releases 9.0 and higher.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ remove ] gtp private-extension loss-of-radio-coverage send-to-ggsn [ send-to-peer-sgsn ]
```

- **remove**
  Including this keyword, as part of the command, disables the inclusion of the GTPC private extension, thereby disabling the Overcharging Protection feature.

- **private-extension**
  This keyword is required as part of the gtp command to instruct the SGSN to set a proprietary GTPC private extension in the LORC Intimation IEs, in the event of loss of radio coverage (LORC). These private extension are only understood by a GGSN with an Overcharging Protection license.

- **loss-of-radio-coverage send-to-ggsn**
  This keyword set is required as part of the gtp command to instruct the SGSN to forward the private extension ‘flag’ to the GGSN in the event of loss of radio coverage (LORC).

- **send-to-peer-sgsn**
  This optional keyword instructs the SGSN to also forward the LORC private extension to the peer SGSN.

**Usage**

The `gtp private-extension` command is one of the two commands required to enable the Overcharging Protection feature. The second command sets the RANAP cause code in the Iu Release to enable the SGSN detect the LORC state of the MS/UE. This second command is configured in the IuPS service and is explained in the IuPS Service Configuration Mode chapter.

When there is a loss of coverage and the Overcharging Protection feature is enabled with the `gtp private-extension` command, then the SGSN includes the proprietary private extension in the GTP LORC Intimation IE messages. This LORC IE is also included in UPCQ, DPCQ, and SGSN Context Response GTP messages.

Refer to the SGSN Overview chapter of the SGSN Administration Guide for functional information regarding the Overcharging Protection feature.

**Example**

Use the following command to have the SGSN send the GGSN the GTPC private extension in the LORC Intimation IE:

```
gtp private-extension loss-of-radio-coverage send-to-ggsn
```
ip

Use this command to define the IP parameters for this APN policy.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

ip { qos-dscp { { downlink | uplink } { background | conversational | interactive | streaming } + } | source-violation { deactivate { all-pdp | exclude-from accounting | linked-pdp | tolerance-limit } | discard { exclude-from-accounting } | ignore }

default ip { qos-dscp { downlink | uplink } | source-violation }no qos-dscp { { downlink | uplink } { background | conversational | interactive | streaming } + }

Important: All parameters not specifically configured will be included in the configuration with default values.

default

Resets the configuration to the default values.

qos-dscp

Configures the different code point marking to be used for sending packets of a particular 3GPP QoS class. Defaults are

downlink with:
- conversational - ef;
- streaming - af11;
- interactive 1 - ef;
- interactive 2 - af21;
- interactive 3 - af21;
- background - be

downlink | uplink

Configures the packets for either downlink or uplink direction. downlink and uplink configuration must include one or more of the following:

- background - Configures the DSCP marking to be used for packets of sessions subscribed to 3GPP background class. Must be followed by a DSCP marking

- conversational - Configures the DSCP marking to be used for packets of sessions subscribed to 3GPP conversational class. Must be followed by a DSCP marking

- interactive - Configures the DSCP marking to be used for packets of sessions subscribed to different traffic priorities in the 3GPP interactive class. Must be followed by a traffic handling priority: 1, 2, or 3.
• **streaming** - Configures the DSCP marking to be used for packets of sessions subscribed to 3GPP streaming class. Must be followed by a DSCP marking

---

### DSCP marking options

Downlink and uplink configuration options must include a DSCP marking, supported options include:

- `af11` - Designates use of Assured Forwarding 11 PHB
- `af12` - Designates use of Assured Forwarding 12 PHB
- `af13` - Designates use of Assured Forwarding 13 PHB
- `af21` - Designates use of Assured Forwarding 21 PHB
- `af22` - Designates use of Assured Forwarding 22 PHB
- `af23` - Designates use of Assured Forwarding 23 PHB
- `af31` - Designates use of Assured Forwarding 31 PHB
- `af32` - Designates use of Assured Forwarding 32 PHB
- `af33` - Designates use of Assured Forwarding 33 PHB
- `af41` - Designates use of Assured Forwarding 41 PHB
- `af42` - Designates use of Assured Forwarding 42 PHB
- `af43` - Designates use of Assured Forwarding 43 PHB
- `be` - Designates use of Best Effort forwarding PHB
- `ef` - Designates use of Expedited Forwarding PHB

---

### source-violation

Configures settings related to IP source-violation detection with one of the following criteria:

- `deactivate` - deactivate the PDP context with one of the following conditions:

- `all-pdp` - deactivates all PDP context of the MS/UE. Default is to deactivate errant PDP contexts.

- `exclude-from-accounting` - excludes packets having an invalid source IP address from the statistics used in the accounting records.

- `linked-pdp` - deactivates all associated pdp contexts (primary and secondary). Default is to deactivate errant pdp context.

- `tolerance-limit` - Configures maximum number of allowed ip source violations before the session is deactivated.

- `discard` - discard errant packets, can include the following option:

- `exclude-from-accounting` - excludes packets having an invalid source IP address from the statistics used in the accounting records.

- `ignore` - ignore checking of packets for MS/UE IP source violation.

---

### Usage

This command is used to configure a range of IP functions to be associated with the APN policy; such as:

- SGSN action to detection of IP source violations,
- DSCP marking for downlink and uplink configuration per traffic class,
- QoS class diffserv code.
Example
Use the following command so the SGSN does not check incoming packets for IP source violation information.

```
ip source-violation ignore
```
pdp-data-inactivity

Configures APN policy regarding PDP data inactivity.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

pdp-data-inactivity { action { deactivate [ all-pdp | linked-pdp ] | detach-when { all-pdp-inactive | any-pdp-inactive } } | timeout minutes minutes }

default pdp-data-inactivity { action | timeout }

no pdp-data-inactivity

default
Resets the APN policy configuration to the default values for PDP data-inactivity.

no
Disables the PDP data-inactivity configuration defined for the APN policy.

action
Defines the action to be taken if PDP data-inactivity occurs:
• deactivate - defines which PDP context should be deactivated:
  • all-pdp - deactivates all PDP contexts.
  • linked-pdp - deactivates only linked PDP contexts.
• detach-when - defines the condition that warrants a detach:
  • all-pdp-inactive - detach when all PDP contexts are inactive.
  • any-pdp-inactive - detach when any PDP context is inactive.

timeout minutes minutes

minutes: Must be an integer from 1 to 1440. Note that even though the timeout is set for minutes, the configuration displays in seconds.

Usage
Use this command to define how the SGSN will handle a situation where the PDP is not fully active. Repeat the command, as needed, to configure more than one keyword-controlled function.

Example
Use the following command to have the SGSN deactivate all PDP contexts associated with the APN when it detects the PDP is inactive:
pdp-data-inactivity action deactivate all-pdp

Use the following command to have the SGSN wait 2 minutes after detecting PDP data inactivity:

    pdp-data-inactivity timeout 2
qos class

This command configures Quality of Service (QoS) parameters for traffic class configured for this APN policy.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

qos class { background | conversational | interactive | streaming } [qualif_option ]
default qos class { background | conversational | interactive | streaming } [qualif_option ]

default
Sets the APN policy to default QoS parameters for the specified traffic class.

class
Defines the class of service for this APN policy. Configuration must include one of the following class options:

- **background** - selects background class of service and can include one of the qualifying options.
- **conversational** - selects conversational class of service and can include one of the qualifying options.
- **interactive** - selects interactive class of service and can include a qualifying option.
- **streaming** - selects streaming class of service and can include a qualifying option.

qualif_option
Qualifying options include:

- **gbr-down** - guaranteed bit rate downlink; Enter an integer from the range 1 to 256000 kbps.
- **gbr-up** - guaranteed bit rate uplink in kbps. Enter an integer from 1 to 256000 kbps.
- **mbr-down** - maximum bit rate downlink. Enter an integer from the range 1 to 256000 kbps.
- **mbr-up** - maximum bit rate uplink in kbps. Enter an integer from 1 to 256000 kbps.
- **min-transfer-delay** - minimum transfer delay in milliseconds. Enter an integer from 80 to 4000.
- **residual-bit-error-rate** -
  - background residual-bit-error-rate range is from 4*10^-4 to 6*10^-8. Enter one of the following integers, where:
    - **4**: represents 4*10^-3
    - **7**: represents 10^-5
    - **9**: represents 6*10^-8
• **conversational residual-bit-error-rate** range is from $5 \times 10^{-2}$ to $10^{-6}$. Enter one of the following integers, where:
  - 1: represents $5 \times 10^{-2}$
  - 2: represents $10^{-2}$
  - 3: represents $5 \times 10^{-3}$
  - 5: represents $10^{-3}$
  - 6: represents $10^{-4}$
  - 7: represents $10^{-5}$
  - 8: represents $10^{-6}$

• **interactive residual-bit-error-rate** range is from $4 \times 10^{-4}$ to $6 \times 10^{-8}$. Enter one of the following integers, where:
  - 4: represents $4 \times 10^{-3}$
  - 7: represents $10^{-5}$
  - 9: represents $6 \times 10^{-8}$

• **streaming residual-bit-error-rate** range is from $5 \times 10^{-2}$ to $10^{-6}$. Enter one of the following integers, where:
  - 1: represents $5 \times 10^{-2}$
  - 2: represents $10^{-2}$
  - 3: represents $5 \times 10^{-3}$
  - 5: represents $10^{-3}$
  - 6: represents $10^{-4}$
  - 7: represents $10^{-5}$
  - 8: represents $10^{-6}$

• **sdu** - signalling data unit, must include one of the following options:
  • **delivery-order**: Enter one of the two following options:
    - no: without delivery order
    - yes: with delivery order
  • **erroneous**: Enter one of the two following options:
    - no: erroneous SDUs will not be delivered
    - no-detect: erroneous SDUs are not detected (‘-’)
    - yes: erroneous SDUs will be delivered
  • **error-ratio**: the SDU error-ratio range is from $10^{-3}$ to $10^{-6}$. Enter an integer from 1 to 6, where:
    - 3: represents $10^{-3}$
    - 4: represents $10^{-4}$
    - 6: represents $10^{-6}$
**max-size:** defines the maximum number of octets (size) of the SDU. Enter an integer from 10 to 1502.

**Usage**
Use this command to define the qualifying options for each QoS class parameter defined for this APN policy. Repeat the command as often as needed with different keywords to define all required QoS criteria.

**Example**
Use the following command to define a background QoS class qualified with mbr-down.

```
qos class background mbr-down 5600
```
qos prefer-as-cap

This command specifies operational preferences for QoS parameters, specifically QoS bit rates.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```bash
qos prefer-as-cap { both-hlr-and-local | hlr-subscription | local }
remove qos prefer-as-cap
```

**Important:** Command and keyword names have changed. `prefer` has become `prefer-as-cap` and `hlr` has become `hlr-subscription`. These changes will not impact configuration generated with earlier releases as the keywords are aliases for the previous names.

**remove**
Removes previous configuration changes and resets the default.

**both-hlr-and-local**
This keyword instructs the SGSN to use, as the capping value during session establishment, the lower of either the locally configured QoS bit rate or the HLR subscription.

**hlr-subscription**
Default.
Instructs the SGSN to take QoS bit rates from the HLR configuration and use HLR rate as the capping value for session establishment.

**local**
Instructs the SGSN to take QoS bit rate from the local configuration and use it for session establishment.

**Usage**
Use this command to instruct the SGSN to take QoS configuration as the bit rate for session establishment.

**Example**
Following command specifies use of the bit rate in subscription at the HLR:

```
qos prefer-as-cap hlr-subscription hlr
```

Instruct the SGSN to cap the bit rate with the lower rate of the two configurations, HLR or local:
qos prefer-as-cap both-hlr-and-local
qos rate-limit direction

Configure the parameters and actions governing the subscriber traffic flow if it violates or exceeds configured peak or committed data rates.

This command can be entered multiple times to specify different combinations of traffic direction and class. If this command is not configured at all, the GGSN does not perform traffic policing or QoS negotiation with the SGSN (i.e. it accepts all of the SGSN-provided values for the PDP context.

Additional information on the QoS traffic policing functionality is located in the System Enhanced Feature Configuration Guide.

**Important:** This command should be used in conjunction with the `max-contexts` command to limit the maximum possible bandwidth consumption by the APN.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
qos rate-limit direction { downlink | uplink } [ [ burst-size { auto-readjust [ duration seconds | bytes ] } ] [ class { background | conversational | interactive traffic_priority | streaming } ] ] [ exceed-action { drop | lower-ip-precedence | transmit } ] ] [ violate-action { drop | lower-ip-precedence | transmit } ] ]

remove qos rate-limit direction { downlink | uplink } [ class { background | conversational | interactive traffic_priority | streaming } ]
```

**remove**

Disables the QoS data rate limit configuration for the APN policy.

**Important:** If no Qos Profile is configured, the system’s default behavior is to use the information provided by the SGSN.

**downlink | uplink**

Apply the limits and actions configured with the other keywords to the selected link:

- **downlink** - This is the direction from GGSN to MS. (from Gn to Iu/Gb).
- **uplink** - This is the direction from MS to GGSN (from Iu/Gb to Gn).

**burst-size [ bytes | auto-readjust [ duration seconds ] ]**

Default: See the table of class default values in the Usage section below.

The peak burst size allowed. System measurements for this value exclude the GTP and outer packet headers.

Supported options include:

- **bytes**: Must be an integer from 1 through 6000000.
SGSN APN Policy Configuration Mode Commands

qos rate-limit direction

Important: It is recommended that the minimum value of this parameter be configured to the greater of the following two values: (1) 3 times greater than packet MTU for the subscriber connection, or (2) 3 seconds worth of token accumulation within the "bucket" for the configured peak-data-rate. In addition, if the committed-data-rate parameter is specified, the burst-size is applied to both the committed and peak rates.

•auto-readjust: This keyword enables dynamic burst-size calculation, for traffic policing, at the time PDP Activation/Modification is negotiated using QoS maximum bit-rates and guaranteed bit-rates.

•duration seconds: Must be an integer from 1 to 30. This keyword sets the number of seconds that the dynamic burst-size calculation will last. This allows the traffic to be throttled at the negotiated rates.

class { background | conversational | interactive traffic_priority | streaming }

Apply the specified limits and actions to PDP contexts of the specified UMTS traffic class. The following classes are supported:

•background: Specifies the QOS for traffic patterns in which the data transfer is not time-critical (for example email exchange). This traffic pattern should be the lowest QOS.

•conversational: Specifies the QOS for traffic patterns in which there is an constant flow of packets in each direction, upstream and downstream. This traffic pattern should be the highest QOS.

•interactive traffic_priority: Specifies the QOS for traffic patterns in which there is an intermittent flow of packets in each direction, upstream and downstream. This traffic pattern should be a higher QOS than the background pattern, but not as high as that for the streaming pattern. traffic_priority is the 3GPP traffic handling priority and can be an integer 1,2 or 3.

•streaming: Specifies the QOS for traffic patterns in which there is a constant flow of data in one direction, either upstream or downstream. This traffic pattern should be a higher QOS than the interactive pattern, but not as high as that for the conversational pattern.

Important: If this keyword is omitted, the same values are used for all classes.

exceed-action { drop | lower-ip-precedence | transmit }

Default: See the table of class default values in the Usage section below. The action to take on the packets that exceed the committed-data-rate but do not violate the peak-data-rate. The following actions are supported:

•drop: Drop the packet

•lower-ip-precedence: Transmit the packet after lowering the IP precedence

•transmit: Transmit the packet

violate-action { drop | lower-ip-precedence | transmit }

Default: See the table of class default values in the Usage section below. The action to take on the packets that exceed both the committed-data-rate and the peak-data-rate. The following actions are supported:

•drop: Drop the packet

•lower-ip-precedence: Transmit the packet after lowering the IP precedence
**transmit**: Transmit the packet

+ This symbol indicates that the keywords can be entered multiple times within a single command.

### Usage
This command configures the APN’s quality of service (QoS) data rate shaping through traffic policing. Configured actions prevent subscriber flow exceeding or violating configured peak or committed data rate limits.

**Important**: If either `exceed action` or `violate action` is set to “lower-ip-precedence”, this command may override the configuration of the `ip qos-dscp` command in the GGSN service configuration mode for packets from the GGSN to the SGSN. In addition, the GGSN service `ip qos-dscp` command configuration can override this APN setting for packets from the GGSN to the Internet.

</tbody>
</table>

**Important:** If a subscribed traffic class is received, the system changes the class to background and sets the following parameters: The uplink and downlink guaranteed data rates are set to 0. If the received uplink or downlink data rates are 0 and traffic policing is disabled, the default of 64 kbps is used. When enabled, the APN configured values are used. If the configured value for downlink max data rate is larger than can fit in an R4 QoS profile, the default of 64 kbps is used. If either the received uplink or downlink max data rates is non-zero, traffic policing is employed if enabled for the “Background” class. The received values are used for responses when traffic policing is disabled.

**Example**

The following command lowers the IP precedence when the committed-data-rate and the peak-data-rate are violated in uplink direction:

```
qos rate-limit direction uplink violate-action lower-ip-precedence
```

The following command buffers the excess user packets when the subscriber traffic violates the configured peak or committed data-rate bps in uplink direction. Once the peak/committed data rate for that subscriber goes below the configured limit it transmit them. It also transmits them if buffer memory is full:

```
qos rate-limit direction uplink violate-action shape transmit-when-buffer-full
```
ranap allocation-retention-priority-ie

This command configures the allocation/retention priority (ARP) IE for this APN policy.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
ranap allocation-retention-priority-ie subscription-priority priority class ( { background | conversational | interactive | streaming } { not-pre-emptable | priority | queuing-not-allowed | shall-not-trigger-pre-emptable } + )
```

**Important:** All parameters not specifically configured will be included in the configuration with default values.

```
[ default | remove | no ] ranap allocation-retention-priority-ie [ subscription-priority priority class { background | conversational | interactive | streaming } ]
```

**default**
Resets the configuration to the default values.

**no**
Disables the specified configuration

**remove**
Removes the specified configuration.

**subscription-priority priority**
This keyword sets the subscription priority. The lowest number means the highest priority. 
`priority` must be an integer from 1 to 3.

**class**
Configure allocation retention priority for specific QoS traffic classes. Include one or more of the following class options:

- `background` - background class of service
- `conversational` - conversational class of service
- `interactive` - interactive class of service
- `streaming` - streaming class of service

Default values will be included in the configuration for any class configuration not specified.

**qualifying options**
For each of the class options, the configuration must include one or more of the following qualifying options:
SGSN APN Policy Configuration Mode Commands

ranap allocation-retention-priority-ie

• **not-pre-emptable**
• **priority** - smallest number is the highest priority. Value must be an integer from 1 to 15
• **queuing-not-allowed**
• **shall-not-trigger-pre-emptable**

When entering more than one option, we recommend that you do it in the order in which they are listed.

+ This symbol indicates that the keywords can be entered multiple times within a single command.

Usage

Use this command to configure values for the allocation/retention priority (ARP) IE in the radio access bearer (RAB) assignment request message for RANAP that occurs during RAB setup.

This command can be used multiple times to define multiple priorities, with different combinations of **subscription-priority** and **class**.

If the HLR returns a matching value for the subscribed ARP for the desired traffic class, then the SGSN includes the configured qualifying options for the ARP IE in the RANAP message.

If there is no matching configuration, the SGSN includes the following default values for the traffic class (tc) within the ARP IE:

**Default values for tc=background:**
- priority-level = (subscribed-value * 3) + 3
- pre-emption-capability = may-trigger-pre-emption
- pre-emption-vulnerability = pre-emptable
- queuing-allowed = yes

**Default values for tc=interactive:**
- priority-level = (subscribed-value * 3) + 3
- pre-emption-capability = may-trigger-pre-emption
- pre-emption-vulnerability = pre-emptable
- queuing-allowed = yes

**Default values for tc=conversational:**
- priority-level = (subscribed-value * 3) + 2
- pre-emption-capability = may-trigger-pre-emption
- pre-emption-vulnerability = pre-emptable
- queuing-allowed = yes

**Default values for tc=streaming:**
- priority-level = (subscribed-value * 3) + 1
- pre-emption-capability = may-trigger-pre-emption
- pre-emption-vulnerability = pre-emptable
- queuing-allowed = yes
Example

The following series of commands define the highest priority for conversational traffic class with priority level 1-10 (Subscribed priority 0-3), PCI of shall-not-trigger-pre-emption, PVI of not-pre-emptable with queuing-not-allowed:

```plaintext
ranap allocation-retention-priority-ie subscription-priority 0 priority class conversational not-pre-emptable priority 1 shall-not-trigger-pre-emptable

ranap allocation-retention-priority-ie subscription-priority 1 priority class conversational not-pre-emptable priority 4 shall-not-trigger-pre-emptable

ranap allocation-retention-priority-ie subscription-priority 2 priority class conversational not-pre-emptable priority 7 shall-not-trigger-pre-emptable

ranap allocation-retention-priority-ie subscription-priority 3 priority class conversational not-pre-emptable priority 10 shall-not-trigger-pre-emptable
```
restrict access-type

This command configures the activation restrictions of PDP context on the basis of the access type and QoS class.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
restrict access-type { { gprs | umts } [ qos-class { background | conversational | interactive | streaming } ] } 
no restrict access-type { gprs | umts } [ qos-class ]
default restrict access-type { gprs | umts }
```

Usage

Use this command to configure the restriction rules in an APN policy for activation of PDP context on the basis of the access type. It also provides the facility to restrict type of traffic QoS class.
Example
The following command configures the APN policy to restrict all traffic from a GPRS network service having a QoS class of interactive:

```
restrict access-type grps qos-class interactive
```
Chapter 177
SGSN ASP Configuration Mode Commands

The ASP (application server process) configuration mode defines the M3UA end-point parameters for a specific SS7 routing domain instance. The ASP instance is generated and accessed via the SS7 routing domain configuration mode commands.

```
[local]hostname(config-ss7-rd-<ss7rd_id>-asp-inst-<asp_inst>)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current mode and returns to the Exec Mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Change the mode back to the Exec Mode.
end-point

This command defines or deletes the IP address and/or port number to be associated with the local SCTP end-point for this ASP. At least one address needs to be configured before the end-point can be activated.

When using the `bind` keyword, this command also activates the end-point once the address has been defined. Once bound, it cannot be reconfigured until it is unbound with the `no end-point bind` command.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end-point { address ip_address context context_id | bind | port port_number }
no end-point { address ip_address context context_id | bind }
```

---

**address ip_address context context_id:**
Specifies the IP address and the context associated with the address for this end-point.

`ip_address`: must be defined using the standard IPv4 dotted decimal notation or the colon notation of IPv6.

`context context_id`: a string of 1 to 79 alphanumeric characters to identify the specific context associated with the end-point address.

---

**bind**
Activates (binds) the end-point.

---

**Important:** Only use `bind` after you have configured other parameters.

---

**port port_number**
Identifies the M3UA’s SCTP port associated with this end-point.

`port_number`: must be an integer from 1 to 65535. Default is 2905.

---

**no**
Removes the end-point configuration or deactivates the end-point.

---

**Caution:** Entering this command will terminate all current subscriber sessions for associated peers.

**Usage**
Use this command to manage the ASP end-point. Once the ASP end-point is bound the end-point configuration can not be changed until it is unbound.

**Example**
Activate the end-point with the following command:
**end-point bind**

Deactivate or unbind the end-point with the following command:

```bash
no end-point bind
```

Set the end-point port to default for ASP 1 with the following command:

```bash
default asp instance 1 end-point port
```
**exit**

Exits the current mode and returns to the previous mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Returns to the previous mode.
Chapter 178
SGSN-Global Configuration Mode Commands

The commands in this mode configure SGSN-specific parameters that will independent of the GPRS or the IuPS services.
In this mode, your prompt will look similar to:

```
[local]hostname(config-sgsn-global)#
```

The SGSN-Global configuration mode is a sub-mode derived from the Global Configuration Mode.
bvc-unblock

This command enables (disabled by default) or disables the SGSN to unblock blocked BVCs based on the receipt of uplink packets from the BSC.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

bvc-unblock { data-or-flow-control | flow-control | ul-data }

[ default | no ] bvc-unblock

- **default**
  Include **default** with the command to disable the function.

- **no**
  Include **no** with the command to disable this function.

- **data-or-flow-control**
  Enables the BVC-Unblock function when the SGSN receives either a FLOW-CONTROL-BVC packet or a UL-UNITDATA packet.

- **flow-control**
  Enables the BVC-Unblock function when the SGSN receives a FLOW-CONTROL-BVC packet.

- **ul-data**
  Enables the BVC-Unblock function when the SGSN receives a UL-UNITDATA packet.

Usage
Configurations defined with this command are common to all NSE defined for the SGSN. This command is useful if there is a BVC status mismatch across different SGSN managers (such as the Session Manager and the Link Manager) when the BSC sends BVC-Block (SGSN should move to BLOCKED) followed by a BVC-Reset (SGSN should move to UNBLOCKED). Such mismatches can easily occur, particularly on Gb-IP network connection, when one link receives the BVC-Block and a different link receives the BVC-Reset with little delay between the two. If BVC-Unblock function is enabled, the SGSN ensures that BVCs which are in the BLOCKED state move to the UNBLOCKED state upon receipt of the configured packet type(s).

Example
Instruct the SGSN to perform BVC-Unblock when a mismatch occurs and the SGSN receives a FLOW-CONTROL-BVC packet:
bvc-unblock flow-control
end

Exits the current mode and returns to the Exec Mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Change the mode back to the Exec Mode.
exit

Exits the current mode and returns to the previous configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Change the mode to the Global Configuration Mode.
**tlli-cb-audit**

This command enable (default is disabled) or disables a periodic (hourly) audit of TLLI-CBs in the BSSGP layer.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
tlli-cb-audit
  [ default | no ] tlli-cb-audit
```

- **default**
  Include `default` with the command to disable the audit function.

- **no**
  Include `no` with the command to disable the audit function.

**Usage**

This command is used to clean-up hanging or unassociated TLLI in the BSSGP layer. This configuration defined with this command will be common to all NSE configured for this SGSN. Independent of this command configuration, the SGSN triggers and audit when the number of TLLI-CBs reaches 35,000.

**Example**

Use the following command to enable the hourly audit for unassociated TLLI-CBs:

```
tlli-cb-audit
```
Chapter 179
SGSN Multiple Address Group Configuration Mode
Commands

This configuration mode defines the IP addresses for the current SGSN Multiple Address Group.

```
Exec Mode
  configure
    Global Configuration Mode
      context name
        Context Configuration Mode
          ggsn-service name
            GGSN Service Configuration Mode
              sgsn define-multiple-address-group grp_name
                SGSN Multiple Address Group Configuration Mode
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
address

This command specifies and IP address to include in the current SGSN Multiple Address Group.

Product
GGSN

Privilege
Security Administrator, Administrator

Syntax

```
address  ip_address[/mask]
```

```
no
```

Delete the specified IP address or IP address and netmask from the current SGSN Multiple Address Group.

```
  ip_address[/mask ]
```

Specifies the IP address or IP address and netmask to include in the current SGSN Multiple Address Group. `ip_address` is an IPv4 address in dotted-decimal notation and `mask` is the number of subnet bits, representing a subnet mask in shorthand. These must be entered in the dotted-decimal notation/subnet bits format (1.1.1.1/24).

Usage

Use this command to specify an IP address or IP address and netmask to include in the current SGSN Multiple Address Group.

Example

The following command adds the IP address 10.1.2.250 to the current SGSN Multiple Address Group:

```
address 10.1.2.250
```
end

Exits the current configuration mode and returns to the Exec mode.

Product
GGSN

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the context configuration mode.

Product
GGSN

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Return to the GGSN Service configuration mode.
Chapter 180
SGSN Operator Policy Configuration Mode Commands

The SGSN Operator Policy configuration mode enables the operator to specify a single policy with rules governing the services, facilities, and privileges available to one, multiple, or all subscribers. These policies can override standard behaviors and provide mechanisms for an operator to get around the limitations of other infrastructure elements such as DNS servers and HLRs.

By configuring an operator policy, the operator fine-tunes any desired restrictions or limitations needed to control call handling per subscriber or for a group of callers within a defined IMSI range.

Important: To create and use an operator policy, you must first define the IMSI range using the mcc command. This does not apply to the default operator policy.

The system supports up to 1000 operator policies, including the single operator policy named default. This default operator policy must be configured by the user to define limitations to be applied to any IMSIs that are not covered by any other defined operator policy.

Upon accessing this mode, your prompt should look similar to the following:

```
(local) <hostname> (config-sgsn-op-policy<-pol_name>)#
```

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
accounting context

This command defines the name of the accounting context and optionally associates a GTPP group with this SGSN operator policy.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
accounting context ctxt_name [ gtpp group grp_name ]

remove accounting context

<table>
<thead>
<tr>
<th>remove</th>
</tr>
</thead>
</table>
| Remove the accounting configuration from this SGSN operator policy configuration.

<table>
<thead>
<tr>
<th>context ctxt_name</th>
</tr>
</thead>
</table>
| Use this keyword to identify the accounting context.
| ctxt_name: Enter a string of 1 to 79 alphanumeric characters.

<table>
<thead>
<tr>
<th>gtpp group grp_name</th>
</tr>
</thead>
</table>
| This keyword set identifies the GTPP group, where the GTPP related parameters have been configured in the GTPP Group configuration mode, to associate with this SGSN operator policy.
| grp_name: Enter a string of 1 to 63 alphanumeric characters to identify the GTPP group created with the gtp group command in the Context configuration mode.

Usage
This command can be used to associate a predefined GTPP server group - including all its associated configuration - with a specific operator policy. The GTPP group would have been defined with the gtpp group command in the Context Configuration Mode chapter of the CLI Reference Guide.
If the GTPP group is not specified, then a default GTPP group in the accounting context will be used.
If this command is not specified, use the name of the accounting context configured in the SGSN service configuration mode (for 3G) or the GPRS service configuration mode (for 2G), either will automatically use a “default” GTPP group generated in that accounting context.
If the accounting context is specified in the GPRS service or SGSN service and in an SGSN operator policy, then priority is given to the accounting context of the operator policy.

Example
For this SGSN operator policy, the following command identifies an accounting context called acctng1 and associates a GTPP server group named roamers with defined charging gateway accounting functionality.

accounting context acctng1 gtpp group roamers
**allocate-ptmsi-signature**

This command enables the allocation of a P-TMSI signature.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
allocate-ptmsi-signature
[ no | default ] allocate-ptmsi-signature
```

- **no**
  Disables the allocation of the P-TMSI signature.

- **default**
  Resets the configuration value to the default: allocates the P-TMSI signature.

**Usage**
Use this command to enable or disable the allocation of the P-TMSI signature.

**Example**

```
allocate-ptmsi-signature
```
apn

This command creates and associates an SGSN access point name (APN) configuration instance with the SGSN operator policy.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

[ no ] apn { network-identifier apn_net_id | operator-identifier apn_op_id }

default apn

no
Disables the specified APN policy.

default
Creates a default SGSN APN policy with default values for all parameters.

network-identifier apn_net_id

apn_net_id: Enter a string of 1 to 62 alphanumeric characters, including dots (.) and dashes (-), to define the GT-address network identifier. For releases 8.0 the maximum number of characters is 63; for releases 8.1 and higher, the maximum number of characters is 62.

operator-identifier apn_op_id

apn_op_id: Enter a string of 1 to 18 alphanumeric characters including dots (.). The entry must be in the following format, where # represents a digit: : MNC###.MCC###.GPRS.

Usage
Use this command, to create an SGSN APN policy configuration or to access the SGSN APN configuration mode to update/modify the policy. Either of the two keywords can be used to identify the specific APN policy configuration.

Example
For this SGSN operator policy, create an APN configuration for a network called cust1-net:

    apn network-identifier cust1-net
apn-restriction

Description: With this command, this SGSN operator policy instructs the system to apply APN restrictions at the SGSN-level.

Product: SGSN

Privilege: Security Administrator, Administrator

Syntax:

```
apn-restriction update-policy deactivate restriction
```

```
default apn-restriction
```

```
default
    Creates a default APN restriction configuration.
```

```
restriction
    Select one of the two restrictions:
        • least-restrictive: applies a lower APN restriction value.
        • most-restrictive: applies a higher APN restriction value.
```

Usage:

Configures the level of restrictions.

Example:

Apply the lowest level of APN restrictions.

```
apn-restriction update-policy deactivate least-restrictive
```
apn-selection-default

This command enables/disables and configures the Default APN feature for use when the normal APN selection process fails. This command is available in releases 8.1 and higher.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
```

```
o apn-selection-default
```

no
Delete the configuration statement and disable the Default APN feature.

```
network-identifier apn_net_id
```

The network identifier will be used as the default APN name.
`apn_net_id`: Enter a string of 1 to 62 alphanumeric characters, including dots (.) and dashes (-), to define the GT-address network identifier. For releases 8.0 the maximum number of characters is 63; for releases 8.1 and higher, the maximum number of characters is 62.

```
require-dns-fail-wildcard
```

This keyword is available in releases 9.0 and higher.
Enables the default APN to be used if the DNS query fails with the selected APN.

```
require-subscription-apn network-identifier apn_net_id
```

If defined, this APN name must also be included in the subscription data for the Default APN feature to function.
`apn_net_id`: Enter a string of 1 to 62 alphanumeric characters, including dots (.) and dashes (-), to define the GT-address network identifier. For releases 8.0 the maximum number of characters is 63; for releases 8.1 and higher, the maximum number of characters is 62.

Usage

The default APN feature will be used in error situations when the SGSN cannot select a valid APN via the normal APN selection process. Within an operator policy, a default APN can be configured for the SGSN to:

- override a requested APN when the HLR does not have the requested APN in the subscription profile.
- provide a viable APN if APN selection fails because there was no "requested APN" and wildcard subscription was not an option.

The default APN feature can also be used in the event of a DNS query failure with the selected APN, if:
- the `wildcard-apn` command is configured,
a wildcard subscription is present,
• the require-dns-fail-wildcard keyword is included with the apn-selection-default command
then the configured default APN will be used when the DNS query is retried.
In all of the instances outlined above, the SGSN can provide the default APN as an alternate behavior to ensure that PDP context activation is successful.

Example
Enable default APN feature for APN HomeNet1:

```
apn-selection-default network-identifier HomeNet1
```

Enable use of a default APN if the DNS query fails:

```
apn-selection-default network-identifier HomeNet1 require-dns-fail-wildcard
```
attach

This command defines attach-related configuration for this SGSN operator policy.

**Important:** Before using this command, ensure that the appropriate LAC information has been defined with the `location-area-list` command.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
attach access-type { gprs | umts } { all | location-area-list instance list_id } { failure-code code | user-device-release { before-r99 failure code code | r99-or-later failure code code }

default attach access-type { gprs | umts } { all | location-area-list instance list_id } { failure-code | user-device-release { before-r99 failure code | r99-or-later failure code }

[ no ] attach allow access-type { gprs | umts } { all | location-area-list instance list_id }

[ no ] attach restrict access-type { gprs | umts } { all | location-area-list instance list_id }
```

**no**
Deletes the specified attach configuration that was previously defined with this command for this operator policy.

**default**
Restores the default values for the operator policy for the specified parameter.

**access-type type**
Defines the type of access to be allowed or restricted.

* `*gprs`
* `*umts`

If this keyword is not included, then both access types are allowed by default.

**allow**
Allow re-enables attaches in the configuration after an `attach restrict` command has been used.
restrict
Restrict attaches (do not accept calls) of specified access-type and from specified location areas (defined using either the all or location-area-list keywords).

all
Instructs the SGSN to apply the command action to all location area lists. Location area lists should already have been created with the location-area-list command. The location area list consists of one or more LACs, location area codes, where the MS is when placing the call.

location-area-list instance list_id
Instructs the SGSN to apply the command action to a specific location area lists. Location area lists should already have been created with the location-area-list command. The location area list consists of one or more LACs, location area codes, where the MS is when placing the call. Using this keyword with either the allow or restrict keywords enables you to configure with more granularity.
list_id must be an integer between 1 and 5.

failure-code code
Specify a GMM failure cause code to identify the reason an attach did not occur. This GMM cause code will be sent in the reject message to the MS.
fail-code must be an integer from 2 to 111. Default is 14. Refer to the GMM failure cause codes listed below (information has been taken from section 10.5.5.14 of the 3GPP TS 124.008 v7.2.0 R7):
- 2 - IMSI unknown in HLR
- 3 - Illegal MS
- 6 - Illegal ME
- 7 - GPRS services not allowed
- 8 - GPRS services and non-GPRS services not allowed
- 9 - MSID cannot be derived by the network
- 10 - Implicitly detached
- 11 - PLMN not allowed
- 12 - Location Area not allowed
- 13 - Roaming not allowed in this location area
- 14 - GPRS services not allowed in this PLMN
- 15 - No Suitable Cells In Location Area
- 16 - MSC temporarily not reachable
- 17 - Network failure
- 20 - MAC failure
- 21 - Synch failure
- 22 - Congestion
- 23 - GSM authentication unacceptable
- 40 - No PDP context activated
- 48 to 63 - retry upon entry into a new cell
- 95 - Semantically incorrect message
- 96 - Invalid mandatory information
- 97 - Message type non-existent or not implemented
- 98 - Message type not compatible with state
- 99 - Information element non-existent or not implemented
- 100 - Conditional IE error
- 101 - Message not compatible with the protocol state
- 111 - Protocol error, unspecified

user-device-release { before-r99 | r99-or-later } failure-code code

Default: Disabled
Enables the SGSN to reject an Attach procedure based on the detected 3GPP release version of the MS equipment and selectively send a failure cause code in the reject message. The SGSN uses the following procedure to implement this configuration:
1. When Attach Request is received, the SGSN checks the subscriber’s IMSI and current location information.
2. Based on the IMSI, an operator policy is found that relates to this Attach Request.
3. Policy is checked for access limitations.
4. Attach Request is checked to see if the revision indicator bit is set
   - if not, then the configured common failure code for reject is sent;
   - if set, then the 3GPP release level is verified and action is taken based on the configuration of this parameter

One of the following options must be selected and completed:
- **before-r99**: Indicates the MS would be a 3GPP release prior to R99 and an appropriate failure code should be defined.
  
  **failure-code code**: Enter an integer from 2 to 111.
- **r99-or-later**: Indicates the MS would be a 3GPP Release 99 or later and an appropriate failure code should be defined.
  
  **failure-code code**: Enter an integer from 2 to 111.

**Usage**

Once the IMSI of an incoming call is known and matched with a specific operator policy, according to the filter definition of the `mcc` command, then that specific operator policy is selected to determine how the incoming call is handled.

By default, all attaches are allowed. If no access limitations are needed, then do not use the `attach` command.

**Important:** Before using this command, ensure that the appropriate LAC information has been defined with the `location-area-list` command.

Use this command to define this operator policy’s attach rules.
Use this command to fine-tune the attach configuration specifying which calls/subscribers can attach and which calls are restricted from attaching and what failure code is included in the Reject message.
Attachment restrictions can be based on any one or combination of the options, such as location area code or access type. It is even possible to restrict all attaches. The command can be repeated using different keyword values to further fine-tune the attachment configuration.

**Example**
For calls under this operator policy, the following command restricts the attaches of all subscribers using the GPRS access type.

```
attach restrict access-type gprs all
```

Use the next command to reverse the previous attach restrict command:

```
attach allow access-type gprs all
```

Or, change the attach restriction to only restrict attaches of GPRS subscribers from specified LACs included in location area list #2 and include failure-code 45 as the reject cause. This configuration requires two CLI commands:

```
attach restrict access-type gprs location-area-list instance 2
attach access-type gprs location-area-list instance 2 failure-code 45
```

In the case of a dual-access SGSN, it is possible to also add a second definition to restrict attaches of UMTS subscribers within the LACs included in location area list #3.

```
attach restrict access-type UMTS location-area-list instance 3
```

Change the configuration to allow attaches for GPRS access for all previously restricted LACs - note that GPRS attaches would still be limited.

```
no attach restrict access-type gprs all
```

Restrict (deny) all GPRS attach requests (coming from any location area) and assign a single failure code for the reject messages. This is a two command process:

```
attach restrict access-type gprs all
attach access-type gprs all failure-code 22
```

Remove the restrictions defined above - so that the access type is reset to the default (both types) and the failure code returns to the default value (14).

```
default attach access-type gprs all failure-code
```
authenticate

Product
This command enables/disables authentication for procedures like attach and service request.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

authenticate { activate | all-events | attach [ access-type | attach-type | frequency | inter-rat ] | detach | rau | service-request }

no authenticate { activate | attach | detach | rau | service-request }

default authenticate { activate | attach | detach | rau | service-request }

no
Disables and removes the defined authentication configuration for this SGSN operator policy.

default
Resets all parameters to default values for the authentication process configured for this SGSN operator policy.

activate
This keyword enables/disables authentication for activate requests and allows one or more of the following options to the configuration:

•access-type type : Select one of the two options:
  * gprs
  * umts

•first - Enables/disables authentication for first activate .

•frequency frequency - Defines 1-in-N selective authentication of subscriber events - where an event is an Attach Request, RAU, Service Request, Activate-Primary-PDP-Context Request, or Detach Request. If the frequency is set for 12, then the SGSN skips authentication for the first 11 events and authenticates on the 12th event.

frequency must be an integer from 1 to 16.

•primary - Enables/disables authentication for every primary activate request.

all-events
Specifies that procedures - attaches, service requests, RAUs, detaches, and activations - will be authenticated. This can be fine-tuned by adding either or both of the following parameters:

•access-type type must be one of the two:
  * gprs
**authenticate**

- **ums:**
- **frequency frequency**: Defines 1-in-N selective authentication of subscriber events - where an event is an Attach Request, RAU, Service Request, Activate-Primary-PDP-Context Request, or Detach Request. If the frequency is set for 12, then the SGSN skips authentication for the first 11 events and authenticates on the 12th event.

  **frequency** must be an integer from 1 to 16.

---

**attach**

This keyword configures the Attach authentication parameters. It enables/disables authentication for an Attach with a local P-TMSI or Attaches with an IMSI will be authenticated to acquire the CK (cipher key) and the IK (integrity key).

- **access-type type**: Must be one of the following options:
  - *gprs*
  - *umts*
- **attach-type type**: Must be one of the following options:
  - *combined*: Authenticates combined GPRS/IMSI Attaches.
  - *gprs-only*: Authenticates GRPS Attaches only.
- **frequency frequency**: Defines 1-in-N selective authentication of subscriber events - where an event is an Attach Request, RAU, Service Request, Activate-Primary-PDP-Context Request, or Detach Request. If the frequency is set for 12, then the SGSN skips authentication for the first 11 events and authenticates on the 12th event.

  **frequency** must be an integer from 1 to 16.

- **inter-rat**: Enables authentication for Inter-RAT Attaches.

---

**detach**

This keyword enables/disables and configures the access-type authentication for detach.

**access-type type**: must be one of the two:

- *gprs*
- *umts*

---

**rau**

This keyword enables/disables and configures authentication for routing area updates (RAUs).

- **access-type type**: Must be one of the two options:
  - *gprs*
  - *umts*
- **frequency frequency**: Defines 1-in-N selective authentication of subscriber events - where an event is an Attach Request, RAU, Service Request, Activate-Primary-PDP-Context Request, or Detach Request. If the frequency is set for 12, then the SGSN skips authentication for the first 11 events and authenticates on the 12th event.

  **frequency** must be an integer from 1 to 16.

- **periodicity duration**: Defines the length of time (number of minutes) that authentication can be skipped.

  **duration**: Must be an integer from 1 to 10800.
**authenticate**

**update-type**: Defines the type of RAU Request. Select one of the following:

- **combined-update** { access-type|with inter-rat-local-ptmsi }
- **imsi-combined-update** { access-type|with inter-rat-local-ptmsi }
- **periodic** { access-type|frequency|periodicity }
- **ra-update** { access-type|with inter-rat-local-ptmsi }

**service-request**

This keyword enables/disables authentication for service request.

- **frequency** frequency - Defines 1-in-N selective authentication of subscriber events - where an event is an attach request, RAU, service request, activate-primary-PDP-context request, or detach request. If the frequency is set for 12, then the SGN skips authentication for the first 11 events and authenticates on the 12th event. frequency must be an integer from 1 to 16.

- **periodicity** duration : Defines the length of time (number of minutes) that authentication can be skipped.

  duration : Must be an integer from 1 to 10800.

- **service-type**: Defines the service request type. Options include:

  - **data**
  - **signalling**
  - **paging response**

**Usage**

Use this command with the **frequency** keyword to determine the support for selective execution of the re-authentication and/or P-TMSI reallocation procedure in case of a 3G service request.

**Example**

Configure authentication to occur after every 10th event for GPRS access.

```
authenticate all-events frequency 9 access-type gprs
```

Disable authentication for Inter-RAT Attaches, use **default authenticate attach inter-rat**

Enable authentication for Inter-RAT RAU of the combined IMSI type:

```
authenticate rau update-type imsi-combined-update with inter-rat-local-ptmsi
```
CC

Description: This command defines the charging characteristics to be applied for CDR generation through SGSN operator policy.

Product: SGSN

Privilege: Security Administrator, Administrator

Syntax:

```plaintext
cc { behavior-bit no-records bit_value | local-value behavior bit_value profile index_bit | prefer { hlr-value | local-value } }

no cc behavior-bit no-records

remove cc { behavior-bit no-records | local-value | prefer }
```

**no**

Disables the charging characteristics configuration of behavior bit from this SGSN operator policy.

**remove**

Removes the configured charging characteristics from this operator policy.

**behavior-bit no-records bit_value**

Default: Disabled

Specify that which behavior bit in charging characteristic is used to no accounting records will be generated. no-records to indicate which behavior bit in charging characteristics, means that no accounting records should be generated.

If we use a charging characteristics with the no-records bit set, then we won’t generate any accounting records, regardless of what may be configured elsewhere. Use “no” to indicate that there is no such bit.

**local-value behavior bit_value profile index_bit**

Default: bit_value = 0x0
index_bit = 8

This keyword sets the SGSN operator policy to configure the value of the behavior bits and profile index for the charging characteristics when the HLR does not provide value for this.

If the HLR provides the charging characteristics with behavior bits and profile index and operator want to ignore it, then specify prefer local-value keyword with this command.

**bit_value** must be a hexadecimal value between 0x0 and 0xFFF.

**index_bit** must be an integer value from 1 through 15.

Some of the index values are predefined according to 3GPP standard:

- **1** for hot billing
- **2** for flat billing
- **4** for prepaid billing
SGSN Operator Policy Configuration Mode Commands

8 for normal billing

prefer
Default: `hlr-value`
Specifies preference for using charging characteristics settings received from HLR or set by SGSN locally.

• `hlr-value`: Sets the operator policy to use charging characteristics settings received from HLR. This is the default preference.

• `local-value`: Sets the operator policy to use charging characteristics settings from SGSN only. If no charging characteristics received from HLR then local value will be applicable.

Usage
Use this command to set the SGSN operator policy behavior to use charging characteristic either from HLR or locally from SGSN.
These charging characteristics parameters are configurable from SGSN APN Policy Configuration mode too.
For generation of M-CDRs the parameters configured in this mode of SGSN Operator Policy Configuration mode will prevail but for generation of S-CDRs the parameters configured in SGSN APN Policy Configuration mode will prevail.
The first four bits of charging characteristics (use keyword profile) is for the charging trigger profile index and is used to select different charging trigger profiles.
The 12 behavior bits (with keyword local-value behavior) can to enable or disable the CDR generation.

Example
The following command configures the SGSN operator policy not to use records for charging characteristics and to set behavior bit to 2:

`cc behavior-bit no-records 2`
charging context

**Description** This command has been deprecated in favor of the `accounting-context` command for configuration of charging per SGSN operator policy.
description

Set to a relevant descriptive string.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

description description

no description

description
Enter an alphanumeric string of 1 to 100 alphanumeric characters. The string may include spaces, punctuation, and case-sensitive letters if the string is enclosed in double quotes (" ").

no
Removes the description configuration from this SGSN operator policy.

Usage
Define information that identifies this particularly SGSN operator policy.

Example

description "sgsn1 operator policy carrier1"
direct-tunnel

This command allows direct tunneling if the direct tunneling is supported by destination node.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

direct-tunnel attempt-when-permitted

remove direct-tunnel

remove
Removes the configured setting to permit direct tunneling in this operator policy.

attempt-when-permitted
Default: Disabled.
Enables direct tunneling if the destination node allows it.

Usage
Use this command to enable the direct-tunnel feature at the operator policy level.
To ensure that direct tunnel is supported, check the settings of the direct-tunnel commands in the SGSN APN policy configuration mode and the Radio Network Controller (release 8.0) or RNC (releases 8.1 or higher) configuration mode. Direct tunneling must be enabled at these two points to allow direct tunneling for the MS/UE.

Example
The following command sets the SGSN operator policy to attempt to setup a direct tunnel if permitted at the destination node:

direct-tunnel attempt-when-permitted
**dns-ggsn**

Define the context to be used to do DNS lookup.

**Product**  
SGSN

**Privilege**  
Security Administrator, Administrator

**Syntax**

```
  dns-ggsn context  ctxt_name
  no dns-ggsn context  ctxt_name
```

- **no**  
  Removes the dns-ggsn configuration from this SGSN operator policy.

- **ctxt_name**  
  Enter an alphanumeric string of 1 to 64 alphanumeric characters.

**Usage**  
Use this command to define the context to be used to do DNS lookup to find the GGSN address.

**Example**

```
dns-ggsn context  sgsnl
```
**dns-sgsn**

Identify the context to be used to do DNS to find the SGSN Address

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
[ no ] dns-sgsn context ctxt_name
```

- **no**
  
  Removes the dns-sgsn configuration from this SGSN operator policy.

- **ctxt_name**
  
  Enter an alphanumeric string of 1 to 64 alphanumeric characters.

**Usage**

Use this command to configure the context ID for the SGSN address that will be used to do the DNS lookup.

**Example**

```plaintext
dns-sgsn context sgsnl
```
encryption-algorithm-umts

Defines the order of preference for the encryption algorithm. This feature is specific to a 3G configuration.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
encryption-algorithm-umts type
[ default | no ] encryption-algorithm-umts
```

- **default**
  Resets the encryption-algorithm definition with default values.

- **no**
  Disables the encryption-algorithm definition.

- **type**
  Enter your first choice, first. After entering the first choice, you are prompted to indicate another type as a second priority choice.
  - uea0 - No encryption algorithm
  - uea1 - uea1 Algorithm
  - uea2 - uea2 Algorithm

**Usage**
Use this command to determine which UMTS encryption algorithm is to be used first.

**Example**

```
encryption-algorithm-umts uea1 then-uea2
```
end

Exits the configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
end
equivalent-plmn

Configures the definition for an equivalent PLMNID and the preferred radio access technology (RAT). This command can be entered multiple times.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```bash
equivalent-plmn radio_access_technology { 2G | 3g | any } plmnid mcc_number mnc_number priority priority

no equivalent-plmn radio_access_technology { 2G | 3g | any } plmnid mcc_number mnc_number
```

**Usage**
Use the priority option to define the preferred equivalent PLMN to be used.

**Example**

```bash
equivalent-plmn radio_access_technology any plmnid mcc 121 mnc 767 priority 2
```
exit

Exits the configuration mode and returns to the previous configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

`exit`
gmm information-in-messages

This command provides the configuration to include the information in messages for the GPRS mobility management (GMM) parameters.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

gmm information-in-messages access-type { { gprs | umts } [ network-name { full-text name | short-text name } ] | [ send-after { attach | rau } ] } ]

[ default | no ] gmm { information-in-messages access-type { gprs | umts } }

no
Disables the GMM configuration from this SGSN operator policy.

default
Sets up a GMM configuration with system default values.

access-type
Must select one of the following options:
  *gprs* - General Packet Radio Service network
  *umts* - Universal Mobile Telecommunications System network
After selecting the access-type, an additional parameter can be configured:
  *network-name*: identifies the network name in either short text or full text.
  *send-after*: configures the information in message to send after attachment or Routing Area Update (RAU).

network-name { full-text name | short-text name }
This keyword provides the option to add the network name to the message. The network name will in full text or short text. Possible options are:
  *full-text name*: Indicate the network name in full text
  *short-text name*: Indicate the network name in short text

send-after { attach | rau }
This keyword configures the information in message to send after attachment or RAU message. Possible options are:
  *attach*: Information sent after attachment
  *rau*: Information sent after routing area update
gmm information-in-messages

Usage
Use this command to configure identifying information about the network that will be included in GMM messages.

Example

default gmm information-in-messages access-type gprs
gmm retrieve-equipment-identity

This command configures the International Mobile Equipment Identity (IMEI) or software version (SV) retrieval and validation procedure for SGSN operator policy.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
gmm retrieve-equipment-identity { imei | imeisv [ unciphered ] [ then-imei ] } [ verify-equipment-identity [ deny-greylisted ] ]

[ no | default ] gmm retrieve-equipment-identity
```

**no**
Disables the equipment identity retrieval procedure configured for this SGSN operator policy.

**default**
Sets the default action of equipment identity retrieval (EIR) procedure configuration from this SGSN operator policy:

- **retrieves-equipment-identity**: Default action is disabled - no retrieval of IMEI/IMEI-SV
- **verify-equipment-identity**: Default action is disabled - no verification with Equipment Identity Register (EIR)

**equipment-identity-type**
Default: disabled
Indicates the type of equipment identity to be configured for operator policy. The possible values are:

- **imei**: International Mobile Equipment Identity
- **imeisv**: International Mobile Equipment Identity - Software Version

**imei**
Indicates the equipment identity retrieval type to International Mobile equipment Identity (IMEI). IMEI is a unique 15 digit number consists of TAC (technical approval code), FAC (Final Assembly Code), SNR (Serial Number), and a check digit.

**imeisv [ unciphered ] [ then-imei ]**
Indicates the equipment identity retrieval type to IMEI with software version (SV). IMEI with SV becomes a unique 16 digit number consists of TAC (technical approval code), FAC (Final Assembly Code), SNR (Serial Number), and 2 digit software version number.

- **unciphered**: This optional keyword enables the unciphered retrieval of IMEI-SV. If this option is enabled the retrieval procedure will get IMEISV (if auth is still pending, get as part of Authentication and Ciphering Response otherwise, via explicit Identification Request after Security Mode Complete).
• **thenimei**: This optional keyword enables the retrieval of software version number before the IMEI. If this option is enabled the equipment identity retrieval procedure will get IMEISV on secured link (after Security mode procedure via explicit Gmm Identification Request), and if MS is not having IMEISV (responded with NO Identity), SGSN will try to get IMEI.

If no other keyword is provided, imeisv will get IMEISV on secured link (after Security mode procedure via explicit Gmm Identification Request).

---

**verify-equipment-identity [ deny-greylisted ]**

Default: disabled

This keyword enables the equipment identity validation and validates the equipment identity against EIR.

• **deny-greylisted**: This keyword finetunes the configuration and enables the restriction to the user having mobile equipment with an IMEI in the EIR’s grey list.

---

**Usage**

Use this command to enable and configure the procedures for mobile equipment identity retrieval and validation from the EIR identified in the MAP Service configuration mode.

---

**Example**

The following command enables the SGSN to send ‘check IMEI’ messages to the EIR:

```
  gmm retrieve-equipment-identity imei verify-equipment-identity
```
gs-service

This command associates the context of a Gs service interface with an SGSN operator policy.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
gs-service gs_svc_name context ctx_name
no gs-service svc_name
```

**no**
Removes/disassociates the named Gs service from an SGSN operator policy.

**gs_svc_name**
Specifies the name of a specific Gs service for which to display information. *gs_svc_name* is the name of a configured Gs service and can be from 1 to 63 alpha and/or numeric characters and is case sensitive.

**context ctx_name**
Specifies the specific context name where Gs service is configured. If this keyword is omitted, the named Gs service must exist in the same context as the GPRS/SGSN service. *ctx_name* is name of the configured context of Gs service. This can be from 1 to 63 alpha and/or numeric characters and is case sensitive.

**Usage**
Use this command to associate a specific Gs service interface with this GPRS service instance.

**Important:** A Gs service can be used with multiple SGSN and/or GPRS service.

**Example**
Following command associates a Gs service instance named *stargsl*, which is configured in context named *star_ctx*, with an SGSN operator policy:

```
gs-service stargsl context star_ctx
```
gtp send

This command configures which information elements (IE) this operator policy sends in GTP messages. These IEs are required by the GGSN.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
gtp send { imeisv | ms-timezone | rat | uli }
remove gtp send { imeisv | ms-timezone | rat | uli }
no gtp send
```

---

**remove**

Removes the specified GTP send definition from the system configuration.

**no**

Disables the specified GTP send configuration.

---

**imeisv**

Instructs the SGSN to include the IMEISV (international mobile equipment identity (and software version) of the mobile when sending GTP messages of the type “Create PDP Context Request”.

---

**ms-timezone**

Instructs the SGSN to include this IE in GTP messages of the type “Create PDP Request” and “Update PDP Context Request”. This IE specifies the offset between universal time and local time, where the MS currently resides, in steps of 15 minutes. This IE is sent by default.

---

**rat**

The RAT IE specifies which radio access technology (RAT) is being used by the MS (GERAN, UTRAN, or GAN). Including this keyword instructs the SGSN to include this IE when sending GTP messages of the type “Create PDP Request” and “Update PDP Context Request”. This IE is sent by default.

---

**uli**

The ULI IE specifies the CGI (MCC, MNC, etc.) and SAI of the MS where it is registered. Including this keyword instructs the SGSN to include the IE when sending GTP messages of the type “Create PDP Request” and “Update PDP Context Request”. This IE is not sent by default.
Usage
Use this command to define a preferred set of information to include when GTP messages are sent. Repeat this command multiple times to enable or disable multiple options. This instruction will be implemented when the specific operator policy is applied.

Example
Following command series instructs the SGSN to send ULI and RAT in the GTP messages.

   gtp send uligtp send rat
**gtpu fast-path**

This command enables/disables the network processing unit (NPU) Fast Path support for NPU processing of GTP-U packets of user sessions at the NPU.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ remove ] gtpu fast-path
```

*remove*

Removes the NPU fast path functionality from an operator policy.

**Usage**

Use this command to enable/disable the NPU processed fast-path feature for processing of GTP-U data packets received from GGSN/RNC. This feature enhances the GTP-U packet processing by adding the ability to fully process and forward the packets through the NPU itself.

**Important:** When enabled/disabled, fast-path processing will be applicable only to new subscriber who establishes a PDP context after issuing this command (enabling GTP-U fast path). No existing subscriber session will be affected by this command.

**Example**

Following command enables the NPU fast path processing for all new subscribers’ session established with this operator policy:

```
gtpu fast-path
```
integrity-algorithm-umts

This command configures the order of preference for the Integrity Algorithm used for 3G.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
integrity-algorithm-umts type then_ type
```

default integrity-algorithm-umts

```
default
Creates a configuration defining an order of preference based on system defaults.
```

```
type
Enter one or more of the following options in the order of preference:
• uia1 - uia1 Algorithm
• uia2 - uia2 Algorithm
```

Usage
Use this command to determine which integrity algorithm is preferred 3G. This command is configured in tandem with the algorithm type for encryption-algorithm-umts command.

Example

```
default integrity-algorithm-umts
```
location-area-list

Define the location area list to allow or restrict services in the specified location areas identified by location area code (LAC).

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
location-area-list instance instance area-code area_code [ area_code * ]

no location-area-list instance instance [ area-code area_code ]
```

**no**

If the `area-code` keyword is included in the command, then only the specified area code is removed from the identified list. If the `area-code` keyword is not included with the command then the entire list of LACs is removed from this operator policy.

**instance instance**

Specifies an identification for the specific location area list. `instance` must be an integer between 1 and 5.

**area-code area_code * **

This keyword defines the location area codes (LACs) to be used by this operator policy as a determining factor in the handling of incoming calls. Multiple LACs can be defined in a single location-area-list. `area_code` must be an integer between 1 and 65535.

* If desired, enter multiple LACs separated by a single blank space.

Usage

Use the command multiple times to configure multiple LAC lists or to modify the list.

Example

The following command creates a location area list for a single area code:

```
location-area-list instance 1 area-code 514
```

This command creates a second location area list for with multiple area codes - all separated by a single blank space:

```
location-area-list instance 2 area-code 514 62552 32 1513
```

The next command corrects an area code mistake (327 not 32) made in the previous configuration:

```
location-area-list instance 1 area-code 514 62552 327 1513
```
map

Use this command to configure the optional extensions to MAP messages.

Product  
SGSN

Privilege  
Security Administrator, Administrator

Syntax

[ remove ] map message update-gprs-location [ imeisv | private-extension access-type ]

remove
IMEI-SV is not included in the GLU request -- this is the default behavior.

update-gprs-location
Includes an GLU message. This keyword-set is required.

imeisv
Default: disabled
Specifies the International Mobile equipment Identity-Software Version (IMEI-SV) information to include in GPRS Location Update (GLU) request message. SGSN will include IMEI-SV if available in message.

private-extension access-type
Include specific access-type private extension in the message.

Usage
This command configures optional extensions to MAP messages. The HLR should ignore these extensions if not supported by the HLR.

Example

map message update-gprs-location private-extension access-type
map-service

This command identifies a MAP service to associate with the operator policy and the context in which the service is configured.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
map-service context ctxt_name service map_srvc_name

no map-service context

no
Disables use of MAP service with this operator policy.

ctxt_name
Enter an alphanumeric string of 1 to 64 alphanumeric characters.

map_srvc_name
Enter an alphanumeric string of 1 to 64 alphanumeric characters.
```

**Usage**

Use this command to enable or disable MAP service with this operator policy.

**Example**

```
no map-service context
```
max-attached-subscribers

Defines the maximum number of subscribers allowed to attach at one time.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

max-attached-subscribers number

default max-attached-subscribers
default
Creates a configuration based on a system default.

number
Enter an integer from 1 to 4294967295.

Usage
Use this command to limit the number of simultaneous subscriber sessions.

Example

max-attached-subscribers 1231231234
**mcc**

This command defines a range of IMSI (the international mobile subscriber identity) numbers upon which an operator policy is based. Specifically, this command identifies: the mobile country code (MCC), and the mobile network code (MNC).

Optionally, the command can define, either or both, the mobile subscriber international number (MSIN - the last portion of the IMSI) and the public land mobile network ID (PLMNID).

**Important:** This command is mandatory if an operator policy is to be used. However, you do not need to complete this command if you are using the default operator policy.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
mcc mcc_num mnc mnc_num [ msin first start_num last stop_num | plmnid id ] +
```

- **mcc mcc_num**
  - `mcc` defines the mobile country code (MCC) of an IMSI.
  - `mcc_num`: Enter a 3-digit number from 100 to 999. 000 to 099 are reserved.

- **mnc mnc_num**
  - `mnc` defines the mobile network code (MNC) of an IMSI.
  - `mnc_num`: Enter a 2 or 3-digit number from 00 to 999.

- **msin**
  - MSIN (mobile subscriber international number) portion of the IMSI.
  - `first start_num`: Defines first MSIN prefix number in a range.
  - `last stop_num`: Defines the last or final MSIN prefix number in a range.

- **plmnid**
  - PLMN-ID consists of the MCC (mobile country code) plus the MNC (mobile network code) to identify the public land mobile network (PLMN) for a specific operator. This keyword associates a specific PLMN with this specific SGSN operator policy.

+ This symbol indicates that command can be repeated to create repeated definitions.

**Usage**

An IMSI = maximum of 15 digits. An IMSI consists of the MCC (3 digits) + the MNC (2 or 3 digits) + the MSIN (the remaining 10 or 9 digits depending on the length of the MNC).
MCC and MNC are the minimum amount of information required to identify a unique operator policy with IMSI filtering. The MCC and MNC combine uniquely to identify the country and the network operator, for example: Cingular Wireless in the United States = `mcc 311 mnc 180`.

To improve the granularity of call handling, an operator policy with additional IMSI filtering parameters can be defined, to include filtering based on the MSIN, by defining a MSIN range - first (or start-of-range) MSIN and last (or end-of-range) MSIN. The range numbers do not include the maximum allowed for the MSIN but should include a sufficient number to enable the operator policy to filter effectively.

For the most efficient IMSI filter, the operator policy should include all of the above parameters and the PLMN ID which defines the current location of the MS – this parameter is particularly useful for highlighting which calls are roaming.

And if none of the operator policies contain useful filtering information, then the default operator policy will be applied as the information in this command is never defined for the default operator policy.

The following table will illustrate how these filtering parameters determine which operator policy will govern a call:

<table>
<thead>
<tr>
<th>Operator Policy ID</th>
<th>MCC</th>
<th>MNC</th>
<th>MSINfirst</th>
<th>MSINlast</th>
<th>PLMN ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>OpPol-1</td>
<td>123</td>
<td>45</td>
<td>67890</td>
<td>67898</td>
<td></td>
</tr>
<tr>
<td>OpPol-2</td>
<td>123</td>
<td>45</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>OpPol-3</td>
<td>123</td>
<td>45</td>
<td>67890</td>
<td>67898</td>
<td>23232</td>
</tr>
<tr>
<td>OpPol-4</td>
<td>123</td>
<td>45</td>
<td></td>
<td></td>
<td>23232</td>
</tr>
<tr>
<td>OpPol-5</td>
<td>123</td>
<td>45</td>
<td>6789012</td>
<td>6789019</td>
<td></td>
</tr>
<tr>
<td>OpPol-6</td>
<td>123</td>
<td>45</td>
<td>6789012</td>
<td>6789019</td>
<td>23232</td>
</tr>
<tr>
<td>default</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The filtering selects which operator policy will be used to determine how a call is handled - the operator policy that best matches the IMSI. So, a call with IMSI 123456789012345 PLMNID 23232 is best matched with OpPol-6.

In most cases, the operator policy with the most information defined will be used as a combination of PLMNID and IMSI provides the best match. But OpPol-6 won’t always be the best match. Using the table above:

OpPol-1 is the best match for IMSI 123456789011111.
OpPol-2 is the best match for IMSI 123456789099999
OpPol-5 is the best match for IMSI 123456789012345 if the PLMNID is 12344

**Example**

The following defines an operator policy with country code 310, mobile network code of 33, and PLMN ID of 42244.

```
mcc 310 mnc 33 plmnid 42244
```
network-initiated-pdp-activation

This command configures the Operator Policy to support activation of network-initiated PDP contexts and defines any desired activation restrictions.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

network-initiated-pdp-activation { allow | primary | restrict | secondary } +

allow
Allows either or both primary and secondary network-initiated PDP context activation.

primary
Specifies that only network-initiated primary PDP context activation is to be allowed.

restrict
Restricts network-initiated PDP context activation to either primary or secondary PDP contexts.

secondary
Specifies that only network-initiated secondary PDP context activation is to be allowed.

Usage
Use this command to define activation restrictions for network-initiated PDP contexts.

Example

network-initiated-pdp-activation allow
**nri**

This command specifies the network resource identifier (NRI) stored in bit 17 to bit 23 of Packet-temporary mobile subscriber identity (P-TMSI) to be retrieved by SGSN operator policy.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
nri length length [ value value ]
no nri [ value ]
```

- **no**
  
  Removes the configured NRI value and location in P-TMSI for retrieval by this SGSN operator policy.

- **length length**
  
  Specifies the length of bits to be used in the P-TMSI to retrieve NRI information. This starts from bit 23 of the P-TMSI.
  
  *length* must be an integer from 1 to 6.

- **value value**
  
  Specifies the value of the NRI to be retrieved from the P-TMSI. This value should not exceed the maximum possible value for the specified length.
  
  *value* must be an integer from 0 to 63.

**Usage**

Use this command to retrieve the NRI stored in bit 17 to bit 23 of the packet-temporary mobile subscriber identity (P-TMSI).

**Example**

The following command specifies the length of NRI information to 5 bit and length of the NRI information to 23:

```
nri length 5value 23
```
override-arp-with-ggsn-arp

This command enables the SGSN to configure whether or “not” to negotiate or to override an ARP value received from a GGSN.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

[ remove ] override-arp-with-ggsn-arp

remove
Adding the remove keyword to the command disables the override feature.

Usage
This command configures the SGSN to negotiate or change or "not" to negotiate or change the value of the ARP received from the GGSN. This configuration of the SGSN will allow the ARP sent by the GGSN, in CPCR / UPCR / UPCQ, to be applicable as an overriding value.

Example
Use this command to configure the SGSN to negotiate the ARP to be used as an overriding value:

override-arp-with-ggsn-arp
pdp-activate access-type

This command configures the PDP context activation option based on operator’s policy for type of access technology.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
pdp-activate access-type { grps | umts } { all | location-area-list instance instance } failure-code failure_code
```

```
default pdp-activate access-type { grps | umts } { all | location-area-list instance instance } failure-code code
```

**default**

Resets the configuration to system default values for PDP context activation request.

```
access-type { grps | umts }
```

Specifies the access technology type for PDP context activation.

- **grps**: Enables access type as GPRS.
- **umts**: Enables access type as UMTS.

```
all
```

Default: allow

Configures the system to allow to create all PDP context activation request from MS.

```
location-area-list instance instance
```

Specifies the location area instance to create PDP context.

**instance** must be an integer from 1 through 5. The value must be an already defined instance of a LAC list created with the **location-area-list** command.

```
failure-code code
```

Default: 8

Specifies the failure code for PDP context activation.

**code** must be an integer from 8 through 112.

**Usage**

Use this command to configure this policy to allow GPRS/UMTS access through PDP context activation request from MS.

**Example**
Following command configures the system to create the PDP context for request from MS for GPRS access type with location area list instance 2 and failure-code 45.

```
pdp-activate access-type gprs location-area-list 2 failure-code 45
```
pdp-activate allow

This command configures the system to allow the PDP context activation based on operator’s policy for type of access technology.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

[ no ] pdp-activate allow access-type { gprs | umts } location-area-list instance instance

no
Removes the configured permission to create PDP context on request of PDP context activation from MS for an access type.

access-type { gprs | umts }
Specifies the access technology type for PDP context activation.
• gprs: Enables access type as GPRS.
• umts: Enables access type as UMTS.

location-area-list instance instance
Specifies the location area instance to create PDP context.
instance must be an integer from 1 through 5. The value must be an already defined instance of a LAC list created with the location-area-list command.

Usage
Use this command to configure this policy to allow GPRS/UMTS access through PDP context activation request from MS.

Example
Following command configures the system to allow the PDP context activation for GPRS access type with location area list instance 2.

pdp-activate allow access-type gprs location-area-list instance 2
pdp-activate restrict

This command configures the system to restrict the PDP context activation based on operator’s policy for type of access technology.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
[ no ] pdp-activate restrict { access-type { gprs | umts } { all | location-area-list instance instance } | secondary-activation }
```

no

Removes the configured restriction on PDP context activation through this command.

access-type { gprs | umts }

Specifies the access technology type to restrict PDP context activation.

- gprs: Enables access type as GPRS.
- umts: Enables access type as UMTS.

all

Default: allow

Configures the system to restrict all PDP context activation request from MS.

location-area-list instance instance

Specifies the location area instance to restrict PDP context activation. list_id must be an integer from 1 through 5. The value must be an already defined instance of a LAC list created with the location-area-list command.

secondary-activation

Specifies the type of PDP context to restrict for secondary activation. This keyword restricts the system to create the secondary PDP context on receiving the PDP Context Activation Request from the MS.

Usage

Use this command to configure this policy to restrict GPRS/UMTS access through PDP context activation request from MS.

Example

Following command configures the system to restrict the PDP context activation for request from MS to access GPRS service with location area list instance 2.

```
pdp-activate restrict access-type gprs location-area-list instance 2
```
pdp-activate restrict
ptmsi-reallocate

Define P-TMSI reallocation for attach or RAU or service requests.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

ptmsi-reallocate { attach | frequency frequency | interval minutes | routing-area-update | service-request } access-type { gprs | umts }

[ no | default ] ptmsi-reallocate { attach | frequency | interval | routing-area-update | service-request } access-type { gprs | umts }

access-type
One of the following options must be used to identify the access-type extension.

• gprs - General Packet Radio Service
• umts - Universal Mobile Telecommunications System

no
Disables the definition in the configuration.

default
Resets the configuration with system defaults.

attach
Enables/disables P-TMSI reallocation for attach with local P-TMSI. IMSI or inter-SGSN attach will always be reallocated.

frequency frequency
Enter an integer from 1 to 50 to define how many times a particular message can be skipped.

interval minutes
Enter an integer between 60 and 1440 to define the time interval (in minutes) for skipping the service/RAU/attach request message procedure.

routing-area-update
Enables/disables P-TMSI reallocation for RAU (routing area update) with local P-TMSI. Inter-SGSN RAU will always be reallocated.

service-request
Enables/disables P-TMSI reallocation for service request.
Usage
Use this command to enable the various parameters that will determine the operation of P-TMSI reallocation.

Example

no ptmsi-reallocate attach access-type gprs
rau-inter

Define acceptable procedure for inter-SGSN routing area updates.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

rau-inter access-type { all | location-area-list instance instance } { failure-code fail_code | user-device-release { before-r99 } { failure-code fail_code | r99-or-later } { failure-code fail_code } }

default rau-inter access-type { all | location-area-list instance instance } user-device-release { before-r99 failure-code | r99-or-later failure-code }

no rau-inter { allow access-type | restrict access-type } { [ all ] failure-code fail_code | location-area-list instance instance }

default rau-inter { allow access-type | restrict access-type } { [ all ] failure-code fail_code | location-area-list instance instance }

---

no

Including ‘no’ as part of the command structure disables the values already configured for parameters specified in the command.

---

default

 Resets the configuration of specified parameters to system default values.

---

allow access-type

Including this keyword-set with one of the following options, configures the SGSN to allow MS/UE with the identified access-type extension to be part of the intra-RAU procedure.

•gprs - General Packet Radio Service
•umts - Universal Mobile Telecommunications System

---

restrict access-type

Including this keyword-set with one of the following options, configures the SGSN to restrict MS/UE with the identified access-type extension from the inter-RAU procedure.

•gprs - General Packet Radio Service
•umts - Universal Mobile Telecommunications System

all

all – adding this option to the keyword determines that the failure cause code will be applicable to all location areas.
location-area-list instance instance

list_id must be an integer between 1 and 5. The value must be an already defined instance of a LAC list created with the location-area-list command.

failure-code fail-code

Specify a GMM failure cause code to identify the reason an inter SGSN RAU does not occur. This GMM cause code will be sent in the reject message to the MS.

fail-code must be an integer from 2 to 111. Refer to the GMM failure cause codes listed below (information has been taken from section 10.5.5.14 of the 3GPP TS 124.008 v7.2.0 R7):

- 2 - IMSI unknown in HLR
- 3 - Illegal MS
- 6 - Illegal ME
- 7 - GPRS services not allowed
- 8 - GPRS services and non-GPRS services not allowed
- 9 - MSID cannot be derived by the network
- 10 - Implicitly detached
- 11 - PLMN not allowed
- 12 - Location Area not allowed
- 13 - Roaming not allowed in this location area
- 14 - GPRS services not allowed in this PLMN
- 15 - No Suitable Cells In Location Area
- 16 - MSC temporarily not reachable
- 17 - Network failure
- 20 - MAC failure
- 21 - Synch failure
- 22 - Congestion
- 23 - GSM authentication unacceptable
- 40 - No PDP context activated
- 48 to 63 - retry upon entry into a new cell
- 95 - Semantically incorrect message
- 96 - Invalid mandatory information
- 97 - Message type non-existent or not implemented
- 98 - Message type not compatible with state
- 99 - Information element non-existent or not implemented
- 100 - Conditional IE error
- 101 - Message not compatible with the protocol state
- 111 - Protocol error, unspecified
user-device-release { before-r99 | r99-or-later } failure-code code

Default: Disabled
Enables the SGSN to reject an Inter-RAU procedure based on the detected 3GPP release version of the MS equipment and selectively send a failure cause code in the reject message. The SGSN uses the following procedure to implement this configuration:

1. When Attach Request is received, the SGSN checks the subscriber’s IMSI and current location information.
2. Based on the IMSI, an operator policy is found that relates to this Attach Request.
3. Policy is checked for access limitations.
4. Attach Request is checked to see if the revision indicator bit is set
   • if not, then the configured common failure code for reject is sent;
   • if set, then the 3GPP release level is verified and action is taken based on the configuration of this parameter

One of the following options must be selected and completed:
- **before-r99**: Indicates the MS would be a 3GPP release prior to R99 and an appropriate failure code should be defined.
  
  failure-code code: Enter an integer from 2 to 111.

- **r99-or-later**: Indicates the MS would be a 3GPP Release 99 or later and an appropriate failure code should be defined.
  
  failure-code code: Enter an integer from 2 to 111.

---

**Usage**

Use this command to configure the restrictions and function of the inter-RAU procedure.

**Example**

```
default rau-inter allow access-type gprs location-area-list instance 1
```
rau-intra

Define acceptable procedure for intra-SGSN Routing Area Updates

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

rau-intra access-type { all | location-area-list instance instance } { failure-code fail_code | user-device-release { before-r99 } { failure-code fail_code | r99-or-later } { failure-code fail_code } }

default rau-intra access-type { all | location-area-list instance instance }
user-device-release { before-r99 failure-code | r99-or-later failure-code }

rau-intra { allow access-type | restrict access-type } { [ all ] failure-code fail_code | location-area-list instance instance } }

no rau-intra { allow access-type | restrict access-type } { [ all ] failure-code fail_code | location-area-list instance instance } }

default rau-intra { allow access-type | restrict access-type } { [ all ] failure-code fail_code | location-area-list instance instance } }

no
Including ‘no’ as part of the command structure disables the values already configured for parameters specified in the command.

default
Resets the configuration of specified parameters to system default values.

allow access-type
Including this keyword-set with one of the following options, configures the SGSN to allow MS/UE with the identified access-type extension to be part of the intra-RAU procedure.
  •gprs - General Packet Radio Service
  •umts - Universal Mobile Telecommunications System

restrict access-type
Including this keyword-set with one of the following options, configures the SGSN to restrict MS/UE with the identified access-type extension from the intra-RAU procedure.
  •gprs - General Packet Radio Service
  •umts - Universal Mobile Telecommunications System

all
all - adding this option to the keyword determines that the failure cause code will be applicable to all location areas.
**location-area-list instance instance**

`list_id` must be an integer between 1 and 5. The value must be an already defined instance of a LAC list created with the `location-area-list` command.

**failure-code fail-code**

Specify a GMM failure cause code to identify the reason an inter SGSN RAU does not occur. This GMM cause code will be sent in the reject message to the MS.

`fail-code` must be an integer from 2 to 111. Refer to the GMM failure cause codes listed below (information has been taken from section 10.5.5.14 of the 3GPP TS 124.008 v7.2.0 R7):

- 2 - IMSI unknown in HLR
- 3 - Illegal MS
- 6 - Illegal ME
- 7 - GPRS services not allowed
- 8 - GPRS services and non-GPRS services not allowed
- 9 - MSID cannot be derived by the network
- 10 - Implicitly detached
- 11 - PLMN not allowed
- 12 - Location Area not allowed
- 13 - Roaming not allowed in this location area
- 14 - GPRS services not allowed in this PLMN
- 15 - No Suitable Cells In Location Area
- 16 - MSC temporarily not reachable
- 17 - Network failure
- 20 - MAC failure
- 21 - Synch failure
- 22 - Congestion
- 23 - GSM authentication unacceptable
- 40 - No PDP context activated
- 48 to 63 - retry upon entry into a new cell
- 95 - Semantically incorrect message
- 96 - Invalid mandatory information
- 97 - Message type non-existent or not implemented
- 98 - Message type not compatible with state
- 99 - Information element non-existent or not implemented
- 100 - Conditional IE error
- 101 - Message not compatible with the protocol state
- 111 - Protocol error, unspecified
user-device-release { before-r99 | r99-or-later } failure-code code

Default: Disabled

Enables the SGSN to reject an Intra-RAU procedure based on the detected 3GPP release version of the MS equipment and selectively send a failure cause code in the reject message. The SGSN uses the following procedure to implement this configuration:
1. When Attach Request is received, the SGSN checks the subscriber’s IMSI and current location information.
2. Based on the IMSI, an operator policy is found that relates to this Attach Request.
3. Policy is checked for access limitations.
4. Attach Request is checked to see if the revision indicator bit is set
   • if not, then the configured common failure code for reject is sent;
   • if set, then the 3GPP release level is verified and action is taken based on the configuration of this parameter

One of the following options must be selected and completed:
• **before-r99**: Indicates the MS would be a 3GPP release prior to R99 and an appropriate failure code should be defined.
  failure-code code: Enter an integer from 2 to 111.

• **r99-or-later**: Indicates the MS would be a 3GPP Release 99 or later and an appropriate failure code should be defined.
  failure-code code: Enter an integer from 2 to 111.

Usage

Use this command to configure the restrictions and function of the intra-RAU procedure.

Example

default rau-intra allow access-type gprs location-area-list instance 1
re-authenticate

Enable or disable the re-authentication feature. This command is available in releases 8.1 and higher.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
re-authenticate [ access-type { gprs | umts } ]
```

```remove re-authenticate```

**Usage**

Use this command to enable or disable the re-authentication feature, which instructs the SGSN to retry authentication with another RAND in situations where failure of the first authentication has occurred. To address the introduction of new SIM cards, for security reasons a systematic "last chance" authentication retry with a fresh Authentication Vector is needed, particularly in cases where there is an SRES mismatch at authentication.

**Example**

```
re-authenticate
```
reuse-authentication-triplets

Creates an Operator Policy configuration entry to enable or disable the reuse of authentication triplets in the event of a failure.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

[ no | remove ] reuse-authentication-triplets no-limit

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
<tbody>
<tr>
<td>This keyword disables the SGSN Operator Policy from reusing triplets.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>remove</th>
</tr>
</thead>
<tbody>
<tr>
<td>This keyword causes the reuse configuration to be deleted from the Operator Policy configuration. This is the default behavior. Triplets are reused.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>no-limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>This keyword enables the SGSN Operator Policy to reuse triplets as needed.</td>
</tr>
</tbody>
</table>

Usage
Use this command to enable reuse of authentication triplets.

Example

reuse-authentication-triplets no limit
sgsn-address

Use this command to define the SGSN addresses for the static SGSN address table for peer SGSNs.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

sgsn-address rac rac-id lac lac_id [ nri nri ] prefer { fallback-for-dns address { ipv4 ip_address | ipv6 ip_address } | local address { ipv4 ip_address | ipv6 ip_address } }

no sgsn-address { ipv4 ip_address | ipv6 ip_address } rac rac_id lac lac_id

no
Disables the SGSN address configuration for the designated IP address.

rac rac_id
rac_id identifies foreign RAC of the peer SGSN address to be configured in the static peer SGSN address table.
rac_id must be an integer from 1 to 255.

lac lac_id
lac_id identifies foreign LAC of the peer SGSN address to be configured in the static peer SGSN address table.
lac_id must be an integer from 1 to 65535.

nri nri
nri identifies the network resource identifier stored in PTMSI (bit 17 to bit 23).
nri must be an integer from 0 to 63.

prefer
Indicate the preferred source of the address to be used.
fallback-for-dns - instructs the SGSN to do a DNS query to get the address.
local - instructs the system to use the local address present in the configuration.

address ip_address
  *ipv4 - enter a valid address in IPv4 standard notation.
  *ipv6 - enter a valid address in IPv6 standard notation.
sgsn-number

Define the SGSN’s E.164 number to be used for interactions via the MAP protocol.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
sgsn-number E164_number
no sgsn-number
```

- **no**
  Disables the use of this configuration definition.

- **E164_number**
  Enter a string of 1 to 16 digits to identify the SGSN’s E.164 identification.
sgtp-service

Identifies the SGTP service configuration to be used for this operator policy.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
sgtp-service context ctxt_name service sgp_service_name
no sgtp-service context
```

**Usage**
Use this command to enable or disable SGTP service with this operator policy.

**Example**

```plaintext
sgtp-service context ctxt_name service sgp_service_name
```
**sms-mo**

This command configures the operator policy dictating how mobile-originated SMS messages are handled.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

\[
\begin{align*}
\text{[ remove ] sms-mo} & \{ \{ \text{access-type} \ (gprs \mid \text{umts}) \ \{ \text{all-location-areas} \mid \\
\text{location-area-list} \} \} \mid \text{allow access-type} \ \{ \text{gprs} \mid \text{umts} \} \mid \text{restrict access-type} \\
\{ \text{gprs} \mid \text{umts} \} \}
\end{align*}
\]

- **remove**
  Deletes the specified configuration.

- **access-type type**
  Access by SMS will be limited to SMS coming from this network type:
  - *gprs
  - *umts

- **allow**
  Allow either GPRS or UMTS type access for SMS.

- **restrict**
  Restrict either GPRS or UMTS type access for SMS.

- **location-area-list instance instance**
  *instance* must be an integer between 1 and 5. The value must identify an already defined LAC list created with the *location-area-list* command.

- **failure-code code**
  *code*: Must be an integer from 2 to 111.

**Usage**
Configure filtering for SMS-MO messaging.

**Example**

```
sms-mo access-type gprs all-location-areas failure-code code
```
**sms-mt**

This command configures the operator policy dictating how mobile-terminated SMS messages are handled.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ remove ]sms-mt { { access-type { gprs | umts } { all-location-areas | location-area-list } | allow access-type { gprs | umts } | restrict access-type { gprs | umts } }
```

- **remove**
  Deletes the specified configuration.

  - **access-type type**
    Access by SMS will be limited to SMS coming from this network type:
    - *gprs
    - *umts

  - **allow**
    Allow either GPRS or UMTS type access for SMS.

  - **restrict**
    Restrict either GPRS or UMTS type access for SMS.

  - **location-area-list instance instance**
    *instance* must be an integer between 1 and 5. The value must identify an already defined LAC list created with the **location-area-list** command.

  - **failure-code code**
    *code*: Must be an integer from 2 to 111.

**Usage**
Configure filtering for SMS-MT messaging.

**Example**

```
sms-mt access-type gprs all-location-areas failure-code code
```
srns-inter

Inter-SRNS (Serving Radio Network Subsystem) relocation.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

srns-inter ( all failure-code | allow location-area-list instance instance | location-area-list instance instance failure-code code | restrict location-area-list instance instance )

no srns-inter ( allow location-area-list instance instance | restrict location-area-list instance instance )

default srns-inter { all | location-area-list-instance instance }

no
Deletes the inter-SRNS relocation configuration.

default
Resets the configuration to default values.

all failure-code code
Define the failure code that will apply to all inter-SRNS relocations.

code: Must be an integer from 2 to 111.

allow location-area-list instance instance
Identify the location area list Id (LAC Id) that will allow services in the defined location area.

location-area-list instance instance

instance: Must be an integer between 1 and 5 that identifies the previously defined location area list created with the location-area-list command.

restrict location-area-list instance instance
Identify the location area list Id (LAC Id) that indicates the location areas where services will be restricted.

Usage
This command defines the operational parameters for inter-SRNS relocation.

Example
Use the following command to allow services in areas listed in LAC list #3:
srns-inter allow location-area-list instance 3
srns-intra

Intra-SRNS (Serving Radio Network Subsystem) relocation.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
srns-intra { all failure-code | allow location-area-list instance instance | location-area-list instance instance failure-code code | restrict location-area-list instance instance }
```

```
no srns-intra { allow location-area-list instance instance | restrictlocation-area-list instance instance }
```

```
default srns-intra { all | location-area-list-instance instance }
```

no

Deletes the intra-SRNS relocation configuration.

default

Resets the configuration to default values.

```
all failure-code code
```

Define the failure code that will apply to all intra-SRNS relocations.

`code`: Must be an integer from 2 to 111.

```
allow location-area-list instance instance
```

Identify the location area list Id (LAC Id) that will allow services in the defined location area.

```
location-area-list instance instance
```

`instance`: Must be an integer between 1 and 5 that identifies the previously defined location area list created with the `location-area-list` command.

```
restrict location-area-list instance instance
```

Identify the location area list Id (LAC Id) of the target RNC to determine the location areas where services will be restricted.

Usage

This command defines the operational parameters for intra-SRNS relocation.

Example

Use the following command to restrict service in areas listed in the LAC list 1:

```
srns-intra restrict location-area-list instance 1
```
subscriber-control-inactivity

This command defines the time for the subscriber-control inactivity timer. The system seeks to detect inactivity where no PDP context is activated and then starts the timer.

Product  
SGSN

Privilege  
Security Administrator, Administrator

Syntax

```
subscriber-control-inactivity timeout minutes time detach { immediate | next-connection | reattach-time-period }

{ no | default } subscriber-control-inactivity
```

```
no
Deletes the timer configuration.

default
Resets the timer configuration to the default value of 7 days (10080 minutes).
```

```
time minutes time [ detach ]
Sets the number of minutes the SGSN monitors the connection after inactivity has been detected. When the timer expires, the subscriber will be detached.

time : Enter an integer from 1 to 20160 (two weeks).
```

```
detach [ immediate | next-connection | reattach-time-period ]
Instructs the SGSN to detach and can be configured to specify when the detach will occur after inactivity is detected. To fine-tune the detach instruction, include one of the following with the command:

• immediate - Instructs the SGSN to detach immediately after inactivity is detected. May combine with reattach-time-period.

• next-connection - instructs the SGSN to detach after the next Iu connection after inactivity is detected.
```

**Important:** Supported for 3G SGSNs only.

```
• reattach-time-period period[ action ] - Specify the number of seconds the SGSN will monitor a new re-attach after the previous detach was due to inactivity. Also, you can define the action to be taken regarding new attaches.

period : Enter an integer from 60 to 3600.

action - Select an action:

• deny

• permit-and-stop-monitoring
```
Usage
Use this command to configure the timeout timer. After this timer times out the subscriber is detached from
the SGSN.

Example
Instruct the SGSN to monitor the connection for up to 360 minutes after inactivity is detected or the SGSN should
detach the attached subscriber immediately after inactivity is detected:

```
subscriber-control-inactivity timeout minutes 360 detach immediate
```
super-charger

This command enables/disables the SGSN to work with a super-charged network.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
super-charger
remove super-charger
```

**Usage**
By enabling the super-charger functionality for 2G or 3G connections controlled by an operator policy, the SGSN changes the hand-off and location update procedures to reduce signalling traffic management.

**Example**
Enable the feature with the following command:

```
super-charger
```
wildcard-apn

Define the APN to be used in case a wildcard APN is included in the subscriber record.

Product  
SGSN

Privilege  
Security Administrator, Administrator

Syntax

wildcard-apn pdp-type pdp-type apn-network-identifier apn_net_id

no wildcard-apn pdp-type pdp-type

no
Removes the wildcard-apn definition from the configuration.

pdp-type pdp-type

pdp-type can be one of the following options:
  • ipv4 - for an ipv4 context
  • ipv6 - for an ipv6 context
  • ppp - for a PPP context

apn-network-identifier apn_net_id

apn_net_id: Must be one of the APN network IDs defined with the apn command in this SGSN operator policy configuration mode.
apn_net_id: Enter a string of 1 to 62 alphanumeric characters, including dots (.) and dashes (-), to define the network identifier. For releases 8.0 the maximum number of characters is 63; for releases 8.1 and higher, the maximum number of characters is 62.

Usage

This command is used to define a wildcard APN with the type of PDP context and the APN’s network ID. This wildcard APN would be used when an APN is not identified.

Example

Use this command to create an APN wildcard:

wildcard-apn pdp-type ipv4 apn-network-identifier homer1
zone-code

Create a zone code and define one or more LAC Ids to specify service.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

[ no ] zone-code zc_id lac lac_id

no
Removes either a specific LAC Id from the zone-code definition or if lac_id is not included in the command then the entire zone-code definition is removed from configuration.

zc_id
Must be an integer from 1 to 65535.

lac_id
This keyword identifies a location area-code list previously defined with the location-area-list command of this SGSN operator policy configuration mode.
lac_id must be an integer from 1 to 65535.

Usage
Repeat this command to include multiple LAC Ids in the service definition.

Example

zone-code 1 lac 413 zone-code 1 lac 1234 zone-code 1 lac 64321
Chapter 181
SGSN Pool Area Configuration Mode Commands

The Pool Area configuration mode configures the parameters used to setup the VLRs to use with a pool area in a Gs service.

With this mode, the command prompt will be similar to:

```
[ctx_name]hostname(config-gs-pool-area)#
```
**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the current configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the previous configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Return to the previous configuration mode.
hash-value

This command configures the load distribution for the VLRs that service this pool area.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
hash-value ( hash_value | range start_value to end_value | non-configured-values ) use-vlr vlr_name

no hash-value ( hash_value | range start_value to end_value | non-configured-values )
```

---

**no**

Removes the configured Gs procedures from this Gs service.

---

**hash_value**

Specifies the specific hash value for VLR(s).

*hash_value* must be an integer value from 0 through 999.

---

**range start_value to end_value**

Specifies the range of hash values for a VLR.

*start_value* specifies the start value for range of hash and is an integer value from 0 through 999.

*start_value* must be lower than *end_value*.

*end_value* specifies the end value for range of hash and is an integer value from 0 through 999.

*end_value* must be higher than *start_value*.

---

**non-configured-values**

This keyword assign all non-configured hash values to use the named VLR.

---

**use-vlr vlr_name**

Specifies the name of the VLR to be associated with this pool area.

*vlr_name* is the name of VLR and must be an alpha and/or numeric string of 1 to 63 characters.

---

**Usage**

Use this command to command configures the load distribution for the VLRs that service this pool area as defined in TS 23.236.

The algorithm for selection of VLR from a pool area is based on the hash value computed on the IMSI digits.

The SGSN derives a hash value (V) using procedure as defined in TS 23.236. Every hash value from the range 0 to 999 corresponds to a single MSC/VLR node. Typically many hash values may point to the same MSC/VLR node.

This command can be entered multiple times for different hash value.
Example
Following command configure the all non configured hash values to use VLR named `starvlr1` in this pool area:

```
hash-value non-configured-values use-vlr starvlr1
```
lac

This command defines a set of location area code (LAC) values for a pool area.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
lac lac_id +
no lac lac_id
```

**Usage**
Use this command to specify a set of LACs to use for a pool area. This command can be entered multiple times, subject to a limit of 32 LAC definitions (total for non-pool-area and pool-area configuration) per Gs service.

**Important:** LAC values across multiple pool areas and non-pool-areas must be unique within the Gs service.

**Example**
The following command configures LACs 101, 301, and 222 for the pool area.

```
lac 101 301 222
```
Chapter 182
SGSN PSP Configuration Mode Commands

The Peer-Server Process (PSP) configuration mode provides the commands to create, configure, bind, and manage a specific PSP instance included in an SS7 routing domain configuration.

In this mode, where information in italics is customer-defined, the command prompt should appear similar to:

```
[local]hostname(config-ss7-rd-1-ps-1-psp-1)#
```

---

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
associate

Defines an association between the PSP instance and an application server process (ASP) instance.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
associate asp instance asp_num
no associate

no
```

Removes the association between the PSP and the ASP from the routing domain configuration.

**Important:** Using this command will probably result in the termination of all current subscriber sessions active through the peer-server.

```
asp_num
```

Identifies a specific ASP configuration. Up to four ASP instances can be configured for a single SS7 routing domain.

*asp_num* must be an integer from 1 through 4.

Usage

Use this command to create an association between a specific peer-server process (PSP) and a specific application server process (ASP) instance.

Before using the `associate` command, the values for the `psp-mode` and `end-point` commands must be configured.

Before using the `associate` command, the M3UA end-point of the ASP must be configured. Use the commands defined in the `ASP Configuration Mode` chapter of the `Command Line Interface Reference`.

Example

Associate this PSP instance with an ASP configuration instance:

```
associate asp instance 2
```
end

Exits the configuration mode and returns to the Exec mode.

Product  SGSN

Privilege  Security Administrator, Administrator

Syntax

```
end
```

Usage

Change the mode back to the Exec mode.
end-point

This command defines or deletes the IP address to be associated with the local SCTP end-point for the application server process (ASP).

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
end-point { address ip_address | port port_number }

no end-point [ address ip_address ]
```

```
port port_number

Configures the M3UA’s SCTP port number for the end-point.
port_number: Must be an integer from 1 to 65535.
Default: 2905.
```

```
no

Removes the ASP end-point association configuration from the PSP configuration.
```

**Important:** This command can not be used as long as the PSP and the ASP are associated.

Usage

Use this command to manage the ASP end-point. At least one address needs to be configured for the ASP before the end-point can be associated with the PSP.

Example

Set the ASP end-point to IP address 192.168.1.1 with the following command:

```
end-point address 192.168.1.1
```
exchange-mode

Configures the exchange-mode for the PSP communication.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

exchange-mode [ double-ended | single-ended ]

Usage
Use this command to toggle the exchange modes for the PSP to match the exchange mode supported by the ASP. The exchange mode specifies what type of ASP messages exchange is used in an IPSP communication. The exchange-mode must be configured for ‘single-ended’ if the psp-mode has been configured for ‘client’.

Example
Change the exchange mode from the standard double-ended to single-ended:

```bash
exchange-mode single-ended
```
exit

Exits the current configuration mode and moves to the previous configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Return to the Peer-Service configuration mode.
**psp-mode**

Configures either client-mode or server-mode as the PSP’s operational mode.

**Product**  
SGSN

**Privilege**  
Security Administrator, Administrator

**Syntax**

```
psp-mode { client | server }
```

- **client**
  The PSP operates as a client.

- **server**
  The PSP operates as a server.

**Usage**

Instruct the peer-server process to operate in either client or server mode.

**Example**

Configure the PSP to operate in server mode:

```
psp-mode server
```
routing-context

Configures the behavior of the routing context in M3UA messages.

**Important:** This keyword function is only available in releases 8.1 and higher.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
routing-context { discard-inbound | process-inbound { insert-outbound | suppress-outbound }

default routing-context
```

**default**
Include this keyword with the command, to reset the configuration to the system default for routing-context which is a combination of process-inbound and insert-outbound.

**discard-inbound**
Sets the routing context received in M3UA messages to be discarded.

**process-inbound**
Sets the routing context received in M3UA messages to be processed.

**insert-outbound**
Sets the routing context so that it is added in the M3UA messages.

**suppress-outbound**
Sets the routing context so that it is suppressed in the M3UA messages.

**Usage**
In PSP (single-ended) configuration mode, the settings for both the local routing context (the SGSN's routing context) and the peer routing context (the RNC's routing context) should be the same. If the routing contexts created at the SGSN and on the peer are different then this can cause the M3UA link to fail.

Routing context is an optional parameter when an M3UA association has only one associated peer-server.

**Example**
If the peer does not support routing context, then disable the routing context feature:

```
routing-context discard-inbound suppress-outbound
```
sctp-alpha

This stream control transmission protocol (SCTP) retransmission time out (RTO) parameter defines the RTO-Alpha value.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

sctp-alpha value

default sctp-alpha

value

Defines a percentage (%) that represents the RTO portion of the round-trip time (RTT) calculation. This percentage value must be an integer between 0 and 65535.

default

Resets the sctp-alpha to the default value of 5%.

Usage

sctp-alpha is used in conjunction with other commands, such as the sctp-beta command, to determine the round-trip time (RTT) calculations. The Alpha parameter is used to manage load balancing within the SS7 environment for multi-homed peers.

Example

Set the SCTP RTO-Alpha value to 256% of the RTT calculation:

sctp-alpha 256
**sctp-beta**

This stream control transmission protocol (SCTP) retransmission time out (RTO) parameter defines the RTO-Beta value.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
sctp-beta value

default sctp-beta
```

- **value**
  Defines a percentage (%) that represents the RTO portion of the round-trip time (RTT) calculation. This percentage value must be an integer between 0 and 65535.

- **default**
  Resets the `sctp-beta` to the default value of 10%.

**Usage**
Use this command in conjunction with other commands, such as the `sctp-alpha` command, to determine the round-trip time (RTT) calculations. The Beta parameter is used to manage load balancing within the SS7 environment for multi-homed peers.

**Example**
Set the SCTP RTO-Alpha value to 512% of the RTT calculation:

```
sctp-beta 512
```
sctp-checksum-type

This command selects the type of checksum algorithm to be used.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

sctp-checksum-type { adler32 | crc32 }

default sctp-checksum-type

| ______ |
|________|
| adler32 |
| Selects the Adler-32 type of algorithm as a faster checksum function. |

| ______ |
|________|
| crc32 |
| Selects the CRC-32, a slower but more reliable 32-bit cyclic redundancy check. |

| ______ |
|________|
| default |
| Resets the sctp-checksum-type to the default of CRC-32. |

Usage
Use this command to set which type of checksum algorithm the SGSN is to use to validate SCTP packets.

Example

sctp-checksum-type crc32
sctp-cookie-life

This command sets the SCTP valid cookie life.

Product
  SGSN

Privilege
  Security Administrator, Administrator

Syntax

  sctp-cookie-life value

  default sctp-cookie-life

---

value
Sets the valid cookie life value in increments of 100 milliseconds. The range is 50 to 1200.

---

default
Resets the sctp-cookie-life value to the default, 600 (= .6 seconds).

---

Usage
Use this command to set the SCTP cookie life.

Example
Set the SCTP cookie life to 1 second (1000 milliseconds):

  sctp-cookie-life 1000
**sctp-max-assoc-retx**

This command sets the maximum number of datagram retransmissions to be associated with this peer server configuration.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
sctp-max-assoc-retx value

default sctp-max-assoc-retx
```

**value**
Defines the maximum number of datagram retransmissions for an association. The value must be an integer between 0 and 255.

**default**
Resets the default for `sctp-max-assoc-retx` to 10.

**Usage**
Use this command to configure the maximum number of datagram retransmissions for an association. The endpoint will be declared unreachable after `sctp-max-assoc-retx` number of consecutive retransmissions to an endpoint on any transport address.

**Example**

```
sctp-max-assoc-retx 3
```
sctp-max-init-retx

This command sets the maximum number of retries to send the INIT datagram.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
sctp-max-init-retx value
```

**default**

```
default sctp-max-init-retx
```

**value**
Sets the maximum number of retries. This value must be an integer between 0 and 255.

**default**
Resets the default for `sctp-max-init-retx` to 5.

**Usage**
Use this command to set the maximum number of retries the SCTP layer should make to send the INIT datagram to the peer to open an association.

**Example**

```
sctp-max-init-retx 3
```
**sctp-max-mtu size**

This command sets the number of bytes that comprise the maximum MTU size.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
sctp-max-mtu-size value
```

```
default sctp-max-mtu-size
```

- **value**
  Sets the maximum number of bytes for the SCTP MTU size. This value must be an integer between 508 and 65535.

- **default**
  Resets the default for `sctp-max-mtu-size` to 1500 bytes.

**Usage**
Use this command to configure the size of the MTU.

**Example**
Set the maximum size of the MTU to 3000 bytes:

```
sctp-max-mtu-size 3000
```
sctp-max-out-strms

This command sets the maximum number of outgoing streams through the PSP going towards the peer server.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
sctp-max-out-strms max#_out_streams
```

```
default sctp-max-out-strms
```

```
default
Resets the SGSN’s `sctp-max-out-strms` value to the default of 16.
```

```
max#_out_streams
The value must be an integer between 1 and 65535. The value should match the peer node’s (STP/SG/RNC/HLR) number of in-bound streams.
```

**Usage**

Use this command to balance the stream throughput from the PSP to the peer server. The value for this command is used to validate the incoming packets in the SCTP layer.

**Example**

```
sctp-max-out-strms 3500
```
**sctp-max-path-retx**

This command sets the maximum number of datagram retransmissions for this path.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
sctp-max-path-retx value
```

```
default sctp-max-path-retx
```

`value`
Sets the maximum number of datagram retransmission to a destination transport address. This value must be an integer from 0 to 255.

`default`
 Resets the `sctp-max-path-retx` default to 5.

**Usage**

Use this command to set the maximum number of datagram retransmissions to a destination transport address. The destination transport address will be declared unreachable after the SGSN exhausts the `sctp-max-path-retx` number of consecutive retransmissions to a destination transport address. Depending upon network conditions, lower values typically means faster detection of SCTP-Path failure.

**Example**

```
sctp-max-path-retx 10
```
**sctp-rto-initial**

This command sets the initial retransmission timeout for the SCTP.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
sctp-rto-initial value
```

```
default sctp-rto-initial
```

- **value**
  Sets the timeout in increments of 100 milliseconds. The value must be an integer between 1 and 1200.

- **default**
  Resets the system to the `sctp-rto-initial` default of 30 (3 seconds).

**Usage**

Use this command to define the initial retransmission timer.

- The value set for `sctp-rto-initial` should be greater than or equal to the minimum value set with `sctp-rto-min`.
- The value set for `sctp-rto-initial` should be less than or equal to the maximum value set with `sctp-rto-max`.

**Example**

```
sctp-rto-initial 240
```
sctp-rto-max

This command sets the maximum retransmission timeout value for the SCTP.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
sctp-rto-max value
```

default sctp-rto-max

default

Resets the system to the `sctp-rto-max` default of 600 (60 seconds).

value

Set the maximum retransmission timeout value in increments of 100 milliseconds (0.1 seconds) and the value must be an integer between 5 and 1200.

Usage

Use this command to configure the maximum time for retransmissions.
The value set for `sctp-rto-max` should be greater than or equal to the value set for `sctp-rto-initial`.

Example

The following sets the timeout for 45 seconds:

```
sctp-rto-max 450
```
sctp-rto-min

This command sets the minimum retransmission timeout (RTO) value for the SCTP.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

sctp-rto-min value

default sctp-rto-min

default
Resets the sctp-rto-min to the default of 10 (1 second).

value
Sets the minimum retransmission timeout in increments of 100 milliseconds. The value must be an integer from 1 to 50.

Usage
Use this command to set the minimum time for retransmission before timeout. The value set for sctp-rto-min should be less than or equal to the value set for sctp-rto-initial (sctp-rto-min <= sctp-rto-initial)

Example
The following sets the timeout for 2 seconds:

sctp-rto-min 20
**sctp-sack-frequency**

This command sets the frequency of transmission of SCTP selective acknowledgements (SACK).

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
sctp-sack-frequency value
```

```
default sack-frequency
```

**value**
Sets the maximum number of datagrams to be received prior to sending a SACK to the peer. The value must be an integer between 1 and 5.

**default**
Resets the `sctp-sack-frequency` default value of 2.

**Usage**
Use this command to set the maximum number of datagrams to be received before a SACK must be sent to the peer. The `sctp-sack-frequency` is used in conjunction with the `sctp-sack-period` to control the generation of SACK, depending on which one occurs first.

**Example**

```
sctp-sack-frequency 3
```
sctp-sack-period

This command sets the delay before sending an SCTP selective acknowledgement (SACK).

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

sctp-sack-period value

default sack-period

value

Sets the maximum time, in increments of 100 milliseconds, before the system must send a SACK to the peer. The value must be an integer from 0 to 5.

default

Resets the system to the sctp-sack-period default value, 2 (=200 milliseconds).

Usage
Use this command to set the time the SCTP waits to send a SACK.

Example

sctp-sack-period 3
**sctp-suppress-alarm**

This command enables/disables the suppression of alarms for SCTP path failure between two peer endpoints.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] sctp-suppress-alarm path-failure self-end-point-address
    orig_ipv4_address peer-end-point-address peer_ipv4_address
```

- **no**
  Disables the pre-configured alarm suppression for SCTP path failure.

- **path-failure**
  This keyword specifies that the alarm suppression is for SCTP path failure between two peer nodes.

- **self-end-point-address** `orig_ipv4_address`
  This keyword specifies the IP address of the originating endpoint.
  `orig_ipv4_address` is the IP address of originating endpoint in IPv4 dotted decimal notation.

- **peer-end-point-address** `peer_ipv4_address`
  This keyword specifies the IP address of the peer endpoint.
  `peer_ipv4_address` is the IP address of peer endpoint in IPv4 dotted decimal notation.

**Usage**

Use this command to configure the path failure alarm suppression. This command ignores the alarms generated on SCTP path failure.

**Example**

The following command suppresses the path failure alarms occurred in SCTP path between originating peer address `1.2.3.4` and peer endpoint `6.7.8.9`:

```
sctp-suppress-alarm path-failure self-end-point-address 1.2.3.4 peer-end-point-address 6.7.8.9
```
timeout

This command sets the times for various timeout timers.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
timeout { m3ua-periodic-dest-audit dest_timeout | sctp-bundle bundle_time | sctp-heart-beat hrt_bt_timeout }

default timeout sctp-heart-beat
```

default

Resets the system to the default value for the SCTP heartbeat interval.

```
m3ua-periodic-dest-audit dest_timeout
```

Sets the period (in increments of seconds) between the DAUD messages while auditing a destination state.

**dest_timeout:** Must be an integer from 1 to 65535. Default is 2.

```
sctp-bundle bundle_time
```

Enables SCTP bundling and sets the SCTP bundle timeout value in increments of 100 milliseconds. SCTP bundling provides better bandwidth utilization and less traffic, however, there is a 100 millisecond packet transmission delay.

**Important:** Peer end should also be configured to support SCTP bundling.

Default: SCTP bundling is disabled.

**bundle_time:** Enter an integer from 1 to 65535.

```
sctp-heart-beat hrt_bt_timeout
```

Sets the number of seconds in the SCTP heart-beat timer

**hrt_bt_timeout:** This value is an integer between 1 and 300. Default is 30.

Usage

Use this command to configure timers. Repeat the command with each of the keywords to set values for each.

Example

```
timeout m3ua-periodic-dest-audit 120
```
Chapter 183
SGSN Service Configuration Mode Commands

The SGSN Service configuration mode is used within the global configuration mode to specify the 3G operations of the SGSN and the available SGSN services for a specific context.

SGSN Service works with MAP Service, SGTP Service, GTPP Group, and IuPS Service. All five of these services must be configured to enable a 3G SGSN to communicate with other elements within a UMTS network.

In this mode, the command prompt should appear like:

```
[<ctx_name>]hostname(config-sgsn-service)#
```

![Diagram of command structure]

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
accounting

This command defines the accounting context name and enables/disables specific types of CDR generation for the accounting in the SGSN service.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

accounting ( cdr-types { mcdr | scdr | sms { mo-cdr | mt-cdr } } + | context cntx_name )

default accounting cdr-types

no accounting ( cdr-types | context )

---

default

Returns the system to default settings for the selected type of CDR.

---

no

Removes the pre-configured type of CDR generation for accounting from the SGSN service.

---

cdr-types { mcdr | scdr | sms { mo-cdr | mt-cdr } } +

Default: enabled
Defines the types of CDRs to be generated within the specified SGSN service for accounting:
- **mccd**: Enables generation of M-CDRs.
- **scdr**: Enables generation of S-CDRs.
- **sms**: Enables generation of SMS-type CDRs based on one of the following:
  - **mo-cdr**: SMS CDRs originates from the mobile.
  - **mt-cdr**: SMS CDRs terminates at the mobile.

---

+  
Specifies that the specified keywords with in the group can be entered multiple times with a single command.

---

context cntx_name

Specifies an accounting context to be associated with the SGSN service.

*cntx_name*: Define a string of 1 to 79 alphanumeric characters.

---

Usage

Use this command to define the type of CDRs to generate for SGSN service. By default all type of CDRs are generated. Note that change of this configuration will be applied to new call and/or to new PDP contexts only.
By default, generation of the S-CDR, M-CDR, SMS-MT-CDR, and SMS MO-CDR types is enabled.

**Example**
The following command configures the system to generate CDRs of M-CDR type for accounting in the current SGSN service:

```
accounting cdr-types mcdr
```
admin-disconnect-behavior

This command defines some of the actions the SGSN will take during an Admin-Disconnect procedure.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

    admin-disconnect-behavior { clear-subscription | detach-type { reattach-not-required | reattach-required } }

    [ default | no ] admin-disconnect-behavior { clear-subscription | detach-type }

---

clear-subscription

Including this keyword in the configuration instructs the SGSN to clear subscriber contexts and the subscription data database whenever the clear subscribers all command is issued (from the Exec mode) for attached subscribers. As well, the SGSN will issue an appropriate Map-Purge-MS-Req to the HLR if needed.  
Default: disabled

---

detach-type

Including this keyword defines which type of detach instruction to include in the Detach-Request message during an Admin-Disconnect procedure. One of the following options must be included when this command is entered:

* reattach-not-required
* reattach-required

Default: reattach-required

---

default | no

Including either default or no keyword in the command, instructs the SGSN to use the default value for the specified parameter.

---

Usage

Include the clear-subscription keyword with this command configuration to ensure that more than attached MM-context and active PDP-contexts are cleared when the clear subscribers all command is issued for attached subscribers.

To clear subscription data for detached subscribers, refer to the sgsn clear-detached-subscriptions command described in the Exec mode chapter.

Including the detach-type keyword with this command instructs the SGSN to include either a ‘reattach-required’ or a ‘reattach-no-required’ instruction in the Detach-Request message.

---

Example
Configure the SGSN to clear data such as PTMSI allocated, auth-vectors received, and NGAF flag values stored in the subscriber database for attached subscribers:

```
admin-disconnect-behavior clear-subscription
```
**cc profile**

Configures the charging characteristic (CC) profile with the triggers for generating various types of CDR as defined with the `accounting` command.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
cc profile profile_bits [ buckets number | interval time | tariff time1 mins hours [ time2 mins hours ] [ time3 mins hours ] [ time4 mins hours ] | volume { downlink down_vol uplink up_vol | total total_vol } ] +
[ no | default ] cc profile profile_bits [ buckets | interval | tariff | volume ]
```

- **no**
  Removes a previously configured CC profile.

- **default**
  Returns the specified CC profile to the original default system settings.

- **profile_bits**
  Defines the value of the profile bits for the SGSN service.
  `index` can be configured to any integer value from 0 to 15. Some of the values have been predefined according to 3GPP standard:
  - 1 for hot billing
  - 2 for flat billing
  - 4 for prepaid billing
  - 8 for normal billing

- **buckets number**
  Specifies the number of statistics container changes in the CDR due to QoS changes or tariff times that can occur before an accounting record (CDR) is closed
  Default: 4
  `number`: Must be integer from 1 to 4.

- **interval time**
  Specifies the normal time duration (in seconds) that must elapse before closing an accounting record (CDR) provided that any or all of the following conditions occur:
  `time`: Enter any integer from 60 to 40000000.
**tariff time1 mins hours [ time2 mins hours time3 mins hours time4 mins hours ]**

Specifies the time-of-day (based on a 24-hour clock) to close the current statistics container in the CDR, but not necessarily the CDR itself. One tariff time must be defined and up to four tariff times can be specified.

**Important:** The system assumes that the billing system uses the day/date to determine if the statistics container represents an actual tariff period.

- **mins:** The minutes of the hour. Enter an integer from 0 to 59.
- **hours:** The hour of the day. Enter an integer from 0 to 23.

**volume { downlink down_vol uplink up_vol | total total_vol }**

Specifies the downlink, uplink, and total volumes octet counts that must be met for the closure of the CDR.
- **down_vol:** Enter any integer from 100000 to 1345294336.
- **up_vol:** Enter any integer from 100000 to 400000000.
- **total_vol:** Enter any integer from 100000 to 400000000.

**Usage**

Charging characteristics consist of a profile index and behavior settings. This command configures the profile index for the SGSN’s charging characteristics. The SGSN supports up to 16 profile indexes.

**Example**

The following command configures a profile index of 10 with tariff times of 7:00 AM and 7:30 PM:

```
cc profile 10 tariff time1 0 7 time2 30 19 time3 0 7 time4 30 19
```
check-imei-timeout-action

This command configures the action to be taken if a Check-IMEI fails due to a timeout. This command is available in releases 8.1 and higher.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
check-imei-timeout-action [ continue | reject ]
default check-imei-timeout-action
```

- **default**
  Rejects the Attach or ISRAU procedure if a Check-IMEI timeout occurs.

- **continue**
  Instructs the SGSN to continue the Attach or ISRAU procedure if a Check-IMEI timeout occurs because the EIR is not reachable. This functionality matches standard call flow.

- **reject**
  Instructs the SGSN to reject the Attach or ISRAU procedure if a Check-IMEI timeout occurs.

**Usage**

Use this command only if the Gf interface (EIR) is available in the network. This command controls the SGSN reaction if the Check-IMEI procedure fails due to a timeout.

The `continue` option allows the SGSN to go forward with the MS Attach or RAU, if the first Check-IMEI fails to reach the EIR due to a timeout. Any subsequent activity (such as a RAU or Service Request) would force another Check-IMEI towards the EIR. If this subsequent MAP Check-IMEI should fail, then the same policy of continuing the procedure would apply.

**Example**

```
check-imei-timeout-action continue
```
core-network

This command specifies the numeric ID for a core network to identify which CN is to be used by the SGSN service.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
core-network id cn_id
no core-network id
```

Usage
Use this command to set a global ID to identify this SGSN in the core network.

Example
The following command sets the core network ID for the current SGSN service to 127:

```
core-network id 127
```
disable/enable super-charger

This command has been deprecated and replaced by the super-charger command. For the commands to configure the SuperCharger feature, refer to the SGSN Operator Policy Configuration Mode chapter.
**dns israu-mcc-mnc-encoding**

Configures either decimal or hexadecimal format for the MCC and MNC values in the DNS query which is sent during the ISRAU.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
dns israu-mcc-mnc-encoding { decimal | hexadecimal }
```

```
default dns israu-mcc-mnc-encoding
```

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Resets the SGSN to send the MCC and MNC values in decimal format for DNS queries.</td>
</tr>
<tr>
<td>decimal</td>
<td>Instructs the SGSN to send the MCC and MNC in decimal format in the DNS query.</td>
</tr>
<tr>
<td>hexadecimal</td>
<td>Instructs the SGSN to send the MCC and MNC in hexadecimal format in the DNS query.</td>
</tr>
</tbody>
</table>

**Usage**

Use this command to determine the type of encoding for the MCC and MNC to be included in the DNS query sent during the inter-SGSN RAU (ISRAU). The choice must match the format of the DNS server. For example:

In decimal, the MNC/MCC in a DNS query would appear like:

```
rac0017.lac42e3.mnc310.mcc722.gprs
```

In hexadecimal, the MNC/MCC in a DNS query would appear like:

```
rac0017.lac42e3.mnc0136.mcc02d2.gprs
```

**Example**

Use hexadecimal values for the MCC/MNC in the DNS query.

```
dns israu-mcc-mnc-encoding hexadecimal
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the context configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the context configuration mode.
This command defines the GPRS mobility management parameters for the SGSN service.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

gmm { T3302-timeout t3302_dur | T3312-timeout t3312_dur | T3313-timeout initial t3313_init [ decrease t3313_decrement | increase t3313_increment ] | T3322-timeout t3322_dur | T3350-timeout t3350_dur | T3360-timeout t3360_dur | T3370-timeout t3370_dur | implicit-detach-timeout impi_detach_dur | max-auth-retransmission auth_retrans | max-identity-retransmission id_retrans | max-page-retransmission page_retrans | max-ptmsi-reloc-retransmission ptmsi_reloc_retrans | mobile-reachable-timeout ms_reach_dur | perform-identity-on-auth-failure | purge-timeout purge_dur | trau-timeout trau_dur }

no gmm { implicit-detach-timeout | max-auth-retransmission | max-identity-retransmission | perform-identity-on-auth-failure }

default
Sets the default value for the specified parameter.

| **T3302-timeout** t3302_dur |
| Default: 10 |
| Specifies the retransmission timer value to guard the GPRS attach or RAU procedure on MS side. t3302_dur is the waiting duration in minutes before retransmitting the specific message and must be an integer from 1 through 186. |

| **T3312-timeout** t3312_dur |
| Default: 54 |
| Specifies the retransmission timer value to guard the RAU procedure initiation on network side. t3312_dur is the waiting duration in minutes before retransmitting the specific message and must be an integer from 1 through 186. |

| **T3313-timeout initial** t3313_init [ decrease t3313_decrement | increase t3313_increment ] |
| Default: 5 |
| Specifies the retransmission timer value to guard the for paging request procedure initiation on network side. |
**initial t3313_init** - Specifies the initial waiting duration in seconds before retransmitting the specific message. `t3313_init` must be an integer from 1 through 60.

**decrease t3313_decrement** - Specifies the decrement of the initial timer value in seconds. `t3313_decrement` must be an integer from 1 through 5.

**increase t3313_increment** - Specifies the increment of the initial timer value in seconds. `t3313_decrement` must be an integer from 1 through 5.

---

**T3322-timeout t3322_dur**

Default: 6

Specifies the retransmission timer value to guard the GPRS detach request procedure on network side. `t3322_dur` is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 20.

---

**T3350-timeout t3350_dur**

Default: 6

Specifies the retransmission timer value to guard the GPRS attach accept/RAU accept/realloc request procedure sent with P-TMSI and/or TMSI on network side. `t3350_dur` is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 20.

---

**T3360-timeout t3360_dur**

Default: 6

Specifies the retransmission timer value to guard the authentication and cipher request procedure on network side. `t3360_dur` is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 20.

---

**T3370-timeout t3370_dur**

Default: 6

Specifies the retransmission timer value to guard the identity request procedure on network side. `t3370_dur` is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 20.

---

**implicit-detach-timeout impli_detach_dur**

Default: 3600

Specifies the retransmission timer value to guard the implicit detach procedure on network side. `impli_detach_dur` is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 3600.

---

**max-auth-retransmission auth_retrans**

Default: 4

Specifies the maximum retransmission of authentication requests allowed. `auth_retrans` is the number of retries before declaring the authentication failure and must be an integer from 1 through 10.

---

**max-identity-retransmission id_retrans**

Default: 4

Specifies the maximum retransmission of identity requests allowed.
id_retrans is the number of retries before declaring the identity failure and must be an integer from 1 through 10.

**max-page-retransmission page_retrans**
Default: 5
Specifies the maximum retransmission of page requests allowed.

**max-ptmsi-reloc-retransmission ptmsi_reloc_retrans**
Default: 5
Specifies the maximum retransmission for P-TMSI relocation procedure allowed.

**mobile-reachable-timeout ms_reach_dur**
Default: 58
Specifies the retransmission timer value to guard the mobile reachability procedure on network side.

**perform-identity-on-auth-failure**
Default: Enabled
Configures the SGSN service to perform an identity check to ascertain the IMSI after an authentication failure on a PTMSI-based message.

**purge-timeout purge_dur**
Default: 10080 (7 days)
Specifies the timer value to guard the detach of MM context procedure on network side.

**trau-timeout trau_dur**
This timer is available in releases 9.0 and higher.
Default: 30
Specifies the number of seconds the “old” 3G SGSN waits to purge the MS’s data. This timer is started by the “old” SGSN after completion of the inter-SGSN RAU.

**Usage**
Repeat this command as needed to configure multiple parameters for GPRS mobility management in a UMTS network. This command provides the configuration of timers for mobility procedures and retries for different messages. GMM layer is defined in the 3GPP TS 24.008 (Release 7).

**Example**

Following command configures the timer to wait for 5 mins before retransmitting the message for GPRS attach or RAU procedure on MS side with maximum number of retries as 6 for authentication:

```gmm T3302-timeout 5 max-auth-retransmission 6```
gs-service

This command associates a previously defined Gs service interface to MSC/VLR along with its associated context with an SGSN service.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
gs-service gs_svc_name context ctx_name
no gs-service gs_svc_name
```

no
Removes/disassociates the named Gs service from this SGSN service.

```
gs_svc_name
```
Specifies the name of a specific Gs service for which to display information. 
```
svc_name
```
is the name of a configured Gs service and can be from 1 to 63 alpha and/or numeric characters and is case sensitive.

```
context ctx_name
```
Specifies the specific context name where Gs service is configured. If this keyword is omitted, the named Gs service must be exist in the same context as the SGSN service. 
```
ctx_name
```
is name of the configured context of Gs service. This can be from 1 to 63 alpha and/or numeric characters and is case sensitive.

Usage

Use this command to associate a specific Gs service interface with this SGSN service instance.

**Important:** A single Gs service can be used with multiple SGSN and/or GPRS service.

Example

Following command associates a Gs service instance named `stargsl`, which is configured in context named `star_ctx`, with an SGSN service:

```
gs-service stargsl context star_ctx
```
**lac**

This command defines the location area code (LAC in hexadecimal format.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
lac  hex

no lac
```

- **no**
  Erases the **lac** configuration statement.

- **hex**
  Enter a hexadecimal number between 0x0 and 0xFFFF
max-pdp-contexts

Configures the maximum number of PDP contexts for a MS (mobile station) that will be supported on this SGSN service.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
max-pdp-contexts per-ms number
```

```
default max-pdp-contexts per-ms
```

**Usage**

The following example defines 5 as the maximum number of primary and secondary PDP contexts that this SGSN will support for any connected MS.

**Example**

```
max-pdp-contexts per-ms 5
```
mobile-application-part

This command identifies an already defined MAP service (Mobile Application Part service) to associate with the SGSN service. Although the MAP service does not need to be defined in the same context as the SGSN service, there is a one-to-one relationship between a MAP service and an SGSN service.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

mobile-application-part service map_srvc [ context ctx_name ]

no mobile-application-part service

no
Remove the MAP service association from the SGSN service configuration.

service map_srvc
Specifies the name of the MAP service to be associated with this SGSN service. map_srvc must be the name of a MAP service previously configured on the system.

context ctx_name
Specifies the name of the context where the MAP service is configured. If the MAP service is not configured in the current context, then the context where it is configured must be specified to enable the SGSN to reach the MAP service.
If this keyword is not specified, the current context is used.
ctx_name: Must be the name of the context where the specified MAP service is configured.

Usage
Use this command to identify the MAP service configuration to be used by the SGSN service configuration. Also use this command to specify the context in which the MAP service configuration was created.
If the MAP service is not identified or if the correct context is not identified, then the SGSN service will not START.

Example
The following command specifies a MAP service named map1 that is configured in the same context as the current SGSN service:

mobile-application-part service map1
network-sharing cs-ps-coordination

Enables/disables the SGSN service to perform a CS-PS coordination check.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

network-sharing cs-ps-coordination

default network-sharing cs-ps-coordination

no network-sharing cs-ps-coordination

Usage

Use this command to facilitate the network sharing functionality. With this command, the SGSN can be instructed to perform a check to determine if CS-PS coordination is needed.

3GPP TS 25.231 section 4.2.5 describes the functionality of the SGSN to handle CS-PS (circuit-switching/packet-switching) coordination for attached networks not having a Gs-interface. In compliance with the standard, the SGSN rejects an Attach in a MOCN configuration with cause 'CS-PS coordination required', after learning the IMSI, to facilitate the RNC choosing the same operator for both CS and PS domains.

Example

Use the following syntax to disable the CS-PS coordination check:

no network-sharing cs-ps-coordination
nri length

This command defines the Network Resource Identifier (NRI) of the SGSN that is stored in the P-TMSI (bits 23 to 18).

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

nri length nri_length { nri-value nri_value | null-nri-value null_nri_value
non-broadcast mcc mcc mnc mnc lac lac_id rac rac_id [ nri-value value ]
no nri

no
Removes the configured NRI value and location in P-TMSI for retrieval by this SGSN operator policy.

nri length nri_length
Specifies the number of bits to be used in the P-TMSI, bits 23 to 18, to define the network resource identifier (NRI). The NRI length configuration also sets the maximum size of the pool. If not configured, the NRI length will be of zero length.
nri_length: Must be an integer from 1 to 6 to identify the number of bits.

null-nri-value null_nri_value
This keyword is only available in releases 8.1 and higher.
Configures the null NRI value which must be unique across the pool areas. This keyword is used for the offloading procedure for SGSN pooling (enabled with the sgsn offloading command, see the Exec Mode chapter).
null_nri_value: 0 (zero) indicates the keyword is not to be used and 1 to 63 are used to identify the SGSN to be used for the offloading procedure for SGSN pooling. There is no default value for this parameter.

non-broadcast mcc mcc mnc mnc lac lac_id rac rac_id
This keyword set is only available in releases 8.1 and higher.
Defines the non-broadcast LAC/RAC to be used in combination with the null-NRI for the offloading procedure. Including the MCC and MNC to specify the PLMN because the Iu-Flex feature supports multiple IuPS Services.
mcc identifies the mobile country code, the first part of the PLMN ID. Must be an integer between 100 and 999.
mnc identifies the mobile network code portion of the PLMN ID. Must be a 2- or 3-digit integer between 01 and 999.
lac_id defines a location area code associated with an RNC. Must be an integer between 1 and 65535.
rac_id defines the remote area code to be associated with an RNC. Must be an integer between 1 and 255.
nri-value nri_value

Specifies the MS-assigned value of the NRI to retrieve from the P-TMSI. This value must not exceed the maximum possible value specified by the NRI length. The NRI value must be unique across the pool or across all overlapping pools.

$nri\_value$ must be an integer from 1 to 63 to identify a specific SGSN in a pool. Use of 0 (zero) value is not recommended.

Multiple NRI values can be identified by providing multiple nri-values separated by a blank space for example: `nri length 6 nri-value 29 43 61`

Usage

Use this command to identify the SGSN identified with the NRI in the MS generated P-TMSI. This command adds or removes the Iu Flex configuration for this SGSN service. When using Iu Flex, all keywords must be defined. The command can be repeated to specify different values for any of the keyword parameters. If more than one NRI is configured, the SGSN service will round-robin between the available NRIs when new subscribers (re)connect.

Use this command to retrieve the NRI (identity of an SGSN) stored in bits 23 to 18 of the packet-temporary mobile subscriber identity (P-TMSI). If more than one NRI value is configured, the SGSN service will round-robin between the available NRIs when new subscribers (re)connect.

When using MOCN mode for network sharing without SGSN pooling, the NRI length and the NRI value should both be used.

Example

The following command specifies the the NRI length as 5 bits, identifies SGSN 23 with LAC 222 and RAC 12 for offloading procedure with NRIs 6 and 41:

```bash
nri length 5 null-nri-value 34 non-broadcast lac 222 rac 12 nri-value 6 41
```
override-lac-li

This command defines the override location area code (LAC) needed for the function of the lawful intercept feature.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

override-lac-li hex

no override-lac-li

no
Erases the override location area for this GGSN service from the configuration.

hex
Enter a hexadecimal number between 0x0 and 0xFFFF
override-rac-li

This command defines the override routing area code needed for the lawful intercept function.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
override-rac-li \textit{hex}

\texttt{no override-rac-li}

\texttt{no}
Erases the override routing area code for this GGSN service from the configuration.

\texttt{hex}
Enter a hexadecimal number between 0x0 and 0xFFFF
**rac**

This command defines the override routing area code needed for the lawful intercept function.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
rac  hex
no rac
```

- **no**
  Erases the routing area code configuration statement.

- **hex**
  Enter a hexadecimal number between 0x0 and 0xFFFF
ran-protocol

This command specifies the IuPS service for the SGSN service to use for communication with the RAN.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```plaintext
ran-protocol iups-service iups_srvc [ context ctx_name ]
no ran-protocol iups-service
```

**no**
Removes the IuPS service information from the SGSN service configuration.

**iups-service iups_srvc**
Specifies the name of an IuPS service already configured on the system.
```
iups_srvc: Enter an alphanumeric string of 1 to 63 characters.
```

**ctx_name**
```
ctx_name: Enter the name of the IuPS context, an alphanumeric string of 1 to 63 characters.
```

Usage
Use this command to configure the IuPS service context that the current SGSN service will use to communicate with the RAN. Up to 8 definitions can be defined for a single SGSN service to allow for multiple PLMNs support.

Example
The following command configures the SGSN service to use an IuPS service named `iups1` that has been configured in the same context as the SGSN service:

```plaintext
ran-protocol iups-service iups1
```
sgsn-number

This command defines the E.164 number that identifies this particular SGSN service context.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
sgsn-number  E.164_number
```

```
no sgsn-number
```

**no**
Removes the SGSN number configuration from the SGSN service configuration.

```
E.164_number
```
Enter a maximum of 15 digits to define the ‘phone’ number associated with this SGSN service in the specified context.

**Usage**
The SGSN supports multiple SGSN numbers – different numbers in the 2G GPRS service configuration and the 3G SGSN service configuration. If an HLR-initiated dialog is received, the SGSN will perform a lookup based on the IMSI and find the correct SGSN number with which the MS is associated. Subsequent messaging will use this address.

**Example**
To delete the sgsn-number associated with this SGSN service context, enter:

```
no sgsn-number
```
sgtp-service

This command creates an instance of an SGTP service.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
sgtp-service sgtp_svc_name
no sgtp-service
```

```
sgtp_svc_name
Enter the name of an SGTP service that will be used by this SGSN service
sgtp_svc_name: Enter a string of 1 to 63 alphanumeric characters.
```

Usage
Use this command to access the SGTP Service configuration mode to configure SGTP parameters.

Example
```
sgtp-service sgtp1
```
**sm**

This command configures session management parameters for this SGSN service. This command can be repeated multiple times to configure each parameter individually.

**Product**

SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
sm ( T3385-timeout time | T3386-timeout time | T3395-timeout time | max-actv-retransmission number | max-deactv-retransmission number | max-modf-retransmission number )

default sm timer
```

---

**default**

Resets the selected timer to the system default value.

---

**T3385-timeout**

Retransmission timer for network-initiated Activate Request. Default is 8 sec

---

**T3386-timeout**

Retransmission timer for network-initiated Modify Request. Default is 8 sec

---

**T3395-timeout**

Retransmission timer for network-initiated Deactivate Request. Default is 8 sec

---

**max-actv-retransmission**

Configures maximum retries for activate PDP ctxt request. Default is 4

---

**max-deactv-retransmission**

Configures maximum retries for deactivate PDP ctxt request. Default is 4

---

**max-modf-retransmission**

Configures maximum retries for modify PDP ctxt request. Default is 4

---

**Usage**

Repeat the command to configure multiple session management parameters for the SGSN service.

---

**Example**
sm T3385-timeout 5
Chapter 184
SGTP Service Configuration Mode Commands

The SGSN GPRS Tunneling Protocol (SGTP) Service configuration mode provides the configuration of GTP-C and GTP-U related parameters for the SGSN.

```
[<ctx_name>] hostname(config-sgtp-service)#
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
end

Exits the configuration mode and returns to the Exec mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Change the mode back to the Exec mode.
**exit**

Exits the configuration mode and returns to the Global configuration mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
exit
```

**Usage**
Return to the previous mode.
gtpc

Configure the GPRS Tunneling Protocol Control (GTP-C) settings for the SGTP service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtpc { bind address ip_address | dns-sgsn context ctxt_name | echo-interval seconds | guard-interval seconds | ignore response-port-validation | max-retransmissions num | retransmission-timeout seconds | send { common flags | rab-context } }
```

```
no gtpc { bind address ip_address | dns-sgsn context ctxt_name | echo-interval seconds | send { common flags | rab-context } }
```

```
default gtpc { echo-interval | guard-interval | ignore response-port-validation | max-retransmissions | retransmission-timeout | send { common flags | rab-context } }
```

```
no
```

Disables the configured GTPC setting.

```
default
```

Resets the specified parameter to its default value.

```
bind address ip_address
```

Binds SGTP service to the IP address of the interface. Enter a standard dotted-quad IPv4 address. The bind address for the gtpc and gtpu commands should be the same.

```
dns-sgsn context ctxt_name
```

Enter a string of 1 to 79 alphanumeric characters to identify the context name.

```
echo-interval seconds
```

Default: 60

```
seconds
```

must be an integer from 0 through 3600. Configures the duration between echos.

```
guard-interval seconds
```

Default: 100

Configures the interval (in seconds) for which the SGTP maintains responses sent to SGSN. This optimizes the handling of retransmitted messages. This value should be configured to be greater than the SGSN's configuration for max-retries multiple by retry-interval.

```
seconds
```

: Must be an integer from 10 to 3600.
**ignore response-port-validation**

This keyword is available in releases 8.1 and higher.
Default: disabled. To reset the default for this parameter, you must enter the following command: `no gtpc ignore response-port-validation`

This keyword instructs the SGSN to ignore the response port validation.
For the SGSN to process incoming GTP responses to an incorrect port,
- this keyword must be entered, and
- the same `bind address` must be configured for GTPC and GTPU in the SGTP service.

**max-retransmissions num**

Default: 4
Configures the maximum number of retries for packets.
`num`: Must be an integer from 0 to 15.

**retransmission-timeout seconds**

Default: 5
Configures the control packet retransmission timeout in GTP, in seconds.
`seconds` must be an integer value from 1 through 20.

**send { common-flags | rab-context }**

`common-flags`: This option configures the SGTP service to include or exclude the common flags IE during an Inter-SGSN RAU. When selected, the default is to send the common flags IE.
`rab-context`: This option configures the SGTP service to include/exclude the radio access bearer (RAB) context IE in SGSN ‘context response’ message during Inter-SGSN Routing Area Update procedure. Default is to send the RAB context IE.

**Usage**

Use this command to configure GTP-C settings for the current SGTP service.

**Example**

Following command excludes the radio access bearer (RAB) context IE in the SGSN Context Response message during the inter-SGSN RAU procedure:

```
no gtpc send rab-context
```
This command configures the GPRS Tunneling Protocol user data plane parameters (GTP-U) for this SGTP service.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

gtpu { bind address ip_address | echo-interval | max-retransmissions | retransmission-timeout } +

no gtpu { bind | echo-interval }

default gtpu { echo-interval | max-retransmissions | retransmission-timeout }

Usage
Use this command to configure the GTP-U settings for the SGTP service.

Example
gtpu echo-interval 5
path-failure

This command specifies the method for determining if path failure has occurred.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

path-failure detection-policy gtp type

no path-failure detection-policy

no
Deletes the path-failure definition from the configuration.

detection-policy gtp type
Default: echo (for both GTPC and GTPU)
Specifies the policy to be used, value options include:
  • echo - When set to 'echo', path failure is detected when the retries of echo messages time out.
  • non-echo - When set to 'non-echo', path failure is detected when the retries of non-echo messages time out.

Usage
Use this command to define the policy to detect gtp path failure.

Example

path-failure detection-policy gtp echo
This command enables the default SGSN functionality for (flex) pooling and enables inclusion of the configured pool hop-counter count in new SGSN context/identify request messages.

Product  
SGSN

Privilege  
Security Administrator, Administrator

Syntax

```
pool { default-sgsn | hop-counter count }

default pool hop-counter

no pool { default-sgsn | hop-counter }
```

- **default**
  Removes the SGSN pool hop-counter IE from the GTP Identity/context requests.

- **no**
  Disables the default SGSN pooling functionality or removes the SGSN pool hop-counter IE from the GTP Identity/context requests.

- **default-sgsn**
  Enables default SGSN pooling functionality for this SGSN.

- **hop-counter count**
  Default: 4
  Enables and configures the SGSN pool hop-counter to set the number of hops and to include the configured count in the new SGSN Context Requests or the new SGSN Identify Requests.
  If **default-sgsn** is enabled, then any messages relayed will have the default value of 4 for the counter if the message does not include this hop-counter ID.
  
  **count**: Must be an integer from 1 to 255.

Usage

Use this command to enable the default flex functionality without exposing the pool (flex) structure. This functionality provides a means for SGSNs outside of the pool to reach a pooled SGSN on the basis of its NRI. Once the pooling has been enabled. Repeat the command using the **hop-counter** keyword to enable inclusion of the hop-counter IE in SGSN context/identify request messages and to configure the count for the pooling hop-counter. If the SGSN is behaving as the ‘default SGSN’, this SGSN will forward (relay) requests with the hop-count included to the target SGSN.

Example

Enable the default pooling functionality which allows an outside SGSN to reach a pooled SGSN:
**pool default-sgsn**

Set the hop-count to be included in messages to 25:

```bash
pool hop-count 25
```
The S-GW (Serving Gateway) Service Configuration Mode is used to create and manage the relationship between an eGTP service used for either ingress or egress control plane and user data plane network traffic.
accounting context

Configures the GTPP accounting context and group selection for S-GW service.

Product
S-GW

Privilege
Administrator

Syntax

accounting context name [ gtpp group name ]

no accounting context

no
Removes the configured accounting context from this service.

context name
Specifies the context where GTPP accounting is performed. name must be an existing context configured on the system and be from 1 to 79 alpha and/or numeric characters.
If an accounting context name is not configured in the S-GW service, the context where the S-GW service resides is considered the accounting context and the default GTPP group is used.

gtpp group name
Specifies a GTPP group used to perform GTPP accounting. name must be an existing GTPP group configured on the system and be from 1 to 79 alpha and/or numeric characters.
If a GTPP group is not configured, the system will use the default GTPP group in the specified accounting context. If the accounting context is not specified, the system will use default GTPP group in the context where the S-GW service resides.

Usage
Use this command to specify the accounting context and/or GTPP accounting group the S-GW service will use to perform GTPP accounting.

Example
The following command specifies a GTPP accounting context named acct-2 and a GTPP accounting group named gtpp-grp-3 as the context and group the S-GW service will use:

accounting context acct-2 gtpp group gtpp-grp-3
**associate**

Associates the S-GW service with QoS and policy control and charging configurations.

**Product**

S-GW

**Privilege**

Administrator

**Syntax**

```
associate { accounting-policy name | egress-proto { gtp | gtp-pmip | pmip } | egress-context name [ egtp-service name ] [ mag-service name ] | ims-auth-service name | ingress egtp-service name | qci-qos-mapping name }

no associate { accounting-policy name | egress-proto [ egress-context [ egtp-service ] [ mag-service ] ] | ims-auth-service name | ingress egtp-service | qci-qos-mapping name | }
```

**no**

Removes the specified association from the S-GW service.

---

**accounting-policy name**

Associates the S-GW service with an accounting policy configured in the same context. *name* must be an existing accounting policy and be from 1 to 63 alpha and/or numeric characters. Accounting policies are configured through the policy accounting command in the Context Configuration Mode.

---

**egress-proto { gtp | gtp-pmip | pmip } | egress-context name [ egtp-service name ] [ mag-service name ]**

Associates and configures the egress protocol for this S-GW service.

- **gtp**: Specifies that GTP is to be used for the S-GW service egress.
- **gtp-pmip**: Specifies that either GTP or PMIP is to be used for the S-GW service egress.
- **pmip**: Specifies that PMIP is to be used for the S-GW service egress.

**egress-context name**: Specifies that the context in this keyword is to be used for the S-GW service egress. *name* must be an existing context on this system and be from 1 to 63 alpha and/or numeric characters.

**egtp-service name**: Specifies that the service in this keyword is to be used for the S-GW service egress. *name* must be an existing eGTP service on this system and be from 1 to 63 alpha and/or numeric characters.

**mag-service name**: Specifies that the service in this keyword is to be used for the S-GW service egress. *name* must be an existing MAG service on this system and be from 1 to 63 alpha and/or numeric characters.

---

**ims-auth-service name**

Associates the S-GW service with an IMS authorization service configured in the same context. *name* must be an existing IMS auth service and be from 1 to 63 alpha and/or numeric characters. IMS authorization services are configured through the ims-auth-service command in the Context Configuration Mode.
**S-GW Service Configuration Mode Commands**

**associate**

```
ingress egtp-service name
```

Associates and configures the eGTP service ingress for this S-GW service. `name` must be an existing eGTP service on this system and be from 1 to 63 alpha and/or numeric characters.

```
qci-qos-mapping name
```

Associates the S-GW service with QCI to QoS mapping parameters. `name` must be an existing QCI-QoS mapping configuration and be from 1 to 63 alpha and/or numeric characters. QCI-QoS mapping is configured through the `qci-qos-mapping` command in the Global Configuration Mode.

**Usage**

Use this command to select a pre-configured QoS mapping and/or policy control and charging configuration to be used by the S-GW service.

**Example**

The following command associates the S-GW service with an IMS authorization service named `ims-23`:

```
associate ims-auth-service ims-23
```
egtp-service

Configures an eGTP service to use as either an ingress (S1-U) or egress (S5/S8) service for the S-GW.

**Product**

S-GW

**Privilege**

Administrator

**Syntax**

```
egtp-service { egress { context name | service name } | ingress service name }
```

```
no egtp-service { egress { context | service } | ingress service }
```

```
no
```

Removes the selected EGTP service from this service.

```
egress { context name | service name }
```

Specifies the egtp-service to be used as the egress eGTP service on a GTP based S5/S8 interface.

- **context**: Specifies the name of the context where the eGTP service resides. `name` must be from 1 to 63 alpha and/or numeric characters and be an existing context name where an eGTP service resides.

- **Caution:** `context name` is not supported in this release.

```
service name: Specifies the name of the egress eGTP service. `name` must be from 1 to 63 alpha and/or numeric characters and be an existing eGTP service name.
```

```
ingress service name
```

Specifies the egtp-service to be used as the ingress eGTP service on the S11 interface. `name` must be from 1 to 63 alpha and/or numeric characters and be an existing eGTP service name.

**Usage**

Use this command to configure the eGTP service to use with this S-GW service. The eGTP service must be existing and be configured with the appropriate parameters supporting the intended service type.

**Example**

The following command configures the S-GW service to use an eGTP service named `slu-egtp` as its ingress service:

```
egtp-service ingress service slu-egtp
```
end

Exits the current mode and returns to the Exec Mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
end

**Usage**
Change the mode back to the Exec mode.
exit

Exits the current mode and returns to the previous mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
exit

**Usage**
Return to the previous mode.
**gtpu-error-ind**

Configures the actions to be taken upon receiving a GTP-U error indication from an eNodeB or P-GW.

**Product**
S-GW

**Privilege**
Administrator

**Syntax**

```plaintext
gtpu-error-ind { s1u { local-purge | page-ue [ custom1-behavior ] } | s5u { local-purge | signal-peer } }  
default gtpu-error-ind { s1u | s5u }
```

**default**
Rests the command to the default action for the specified interface. For S1-U, `page-ue` is the default action. For S5-U, `local-purge` is the default action.

```plaintext
gtpu-error-ind { s1u { local-purge | page-ue [ custom1-behavior ] } }
```

Specifies the action to take when a GTP-U error indication is received from an eNodeB over the S1-U interface.

- **local-purge**: The S-GW clears the affected bearer (or PDN if error-ind is received on default bearer) locally without informing peer.
- **page-ue [ custom1-behavior ]**: The S-GW moves the complete UE state to S1-Idle and starts paging for this UE. If the custom1-behavior option is specified, the S-GW will guard the paging attempt with a timer of 60 seconds. Within this time the bearer must have the eNodeB TEID refreshed by an MME. Otherwise, the S-GW will clear the affected bearer with signaling. This is the default action for GTP-U error indication messages received on the S1-U interface.

```plaintext
gtpu-error-ind { s5u { local-purge | signal-peer } }
```

Specifies the action to take when a GTP-U error indication is received from a P-GW over the S5-U interface.

- **local-purge**: The S-GW clears the affected bearer (or PDN if error-ind is received on a default bearer) locally without informing the peer. This is the default action for GTP-U error indication messages received on the S5-U interface.
- **signal-peer**: The S-GW initiates control signalling towards the peer MME and P-GW. When signalling:
  - For a bearer deletion, the S-GW sends a Delete-Bearer-Command message to the P-GW and a Delete-Bearer-Request (with EBI) message to the MME.
  - For PDN deletion, the S-GW sends a Delete-Session-Request message to the P-GW and a Delete-Bearer-Request (with LBI) message to the MME.
  - The S-GW will not wait for Delete replies from the peer. The request will be sent only once and local resources will be reset.

**Usage**

Use this command to specify the action to taken upon receiving a GTP-U error indication from either an eNodeB across an S1-U interface or from a P-GW across an S5-U interface.
Example
The following command sets the action to take upon receipt of a GTP-U error indication from the eNodeB to clear affected bearer:

```
gtpu-error-ind slu local-purge
```
mag-service

Identifies the Mobile Access Gateway (MAG) egress service through which calls are to be routed for this S-GW service.

**Product**

S-GW

**Privilege**

Administrator

**Syntax**

```
mag-service egress service name
```

```
o mag-service egress service
```

- **no**
  
  Removes the configured MAG egress service from this service.

- **egress service name**
  
  Specifies the MAG service name to be used as the egress MAG service on a PMIP based S5/S8 interface. `name` must be an existing MAG service and be from 1 to 63 alpha and/or numeric characters.

**Usage**

Use this command to specify the name of the MAG service where calls are to be routed.

**Example**

The following command specifies that an existing MAG service named `mag3` is to be used to route call through for this S-GW service:

```
mag-service egress service mag3
```
path-failure

Configures the action to take upon the occurrence of a path failure between the S-GW and the MME, P-GW, or eNodeB.

**Product**
S-GW

**Privilege**
Administrator

**Syntax**

```
path-failure { s11 | s1u | s5 | s5u } { local-purge | signal-peer }
default path-failure { s11 | s1u | s5 | s5u }
```

**default**

Returns the command to the default setting of “local purge” for the selected interface.

```
{ s11 | s1u | s5 | s5u }
```

Specifies the interface to which the action will be applied.

**s11** Indicates that the path failure action is to be applied to the S11 interface between the S-GW and the MME.

**s1u** Indicates that the path failure action is to be applied to the S1-U interface between the S-GW and the eNodeB.

**s5** Indicates that the path failure action is to be applied to the S5 interface between the S-GW and the P-GW.

**s5u** Indicates that the path failure action is to be applied to the S5-U interface between the S-GW and the P-GW.

```
( local-purge | signal-peer )
```

Specifies the action to apply to the selected interface.

**local-purge** The S-GW clears the affected bearer (or PDN if path failure is received on a default bearer) locally without informing the peer. This is the default action for all interface.

**signal-peer** The S-GW initiates control signalling towards the peer MME and P-GW. When signalling:

- For a bearer deletion, the S-GW sends a Delete-Bearer-Command message to the P-GW and a Delete-Bearer-Request (with EBI) message to the MME.
- For PDN deletion, the S-GW sends a Delete-Session-Request message to the P-GW and a Delete-Bearer-Request (with LBI) message to the MME.
- The S-GW will not wait for Delete replies from the peer. The request will be sent only once and local resources will be reset.

**Usage**

Use this command to specify the type of action to take when a path failure occurs on one of the supported interfaces.

**Example**

Use this command to specify the type of action to take when a path failure occurs on one of the supported interfaces.
The following command sets the path failure action for the S5 interface to “signal peer”:

```
policy-map brokerage
```

```
path-failure s5 signal-peer
```

```
Chapter 186
SMS Service Configuration Mode Commands

The SMS (short message service) Service configuration mode is used to create and manage properties of the SMS Service configuration.

The SGSN uses the SMS Service component to communicate via the Gd interface with a gateway message service controller (GMSC) to send short text messages (up to 140 octets in length) to a mobile (SMS-MT) and/or receive messages from a mobile (SMS-MO).

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
**cp-data**

Enables the SGSN to send and/or receive cp-data (text messages).

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
cp-data max-retransmission retries_num
```

```
default cp-data max-retransmissions
```

```
default
This keyword resets the SGSN’s max-retransmission to the default number of retries.
```

```
max-retransmission retries_num
retries_num: enter an integer from 1 to 3.
```

**Usage**
Use this command to configure the number of times the SGSN will attempt to retransmit a message.

**Example**

```
cp-data max-retransmission 2
```
end

Exits the current configuration mode and returns to the Exec mode.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**
```
end
```

**Usage**
Return to the Exec mode.
exit

Exits the current configuration mode and returns to the SMS configuration mode.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Move to the previous configuration mode.
mo-message-forwarding-destination

This command defines the SGSN’s handling policy for MO (mobile originating) message.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

[ default ] mo-message-forwarding-destination { gmsc-selected-from-imsi | smsc-supplied-by-subscriber }

default
Resets the SMS service configuration to the default message forwarding technique.

gmsc-selected-from-imsi
Entering this keyword enables SMS-MO messages to be forwarded on the basis of their IMSI prefix.

smsc-supplied-by-subscriber
Entering this keyword enables SMS-MO messages to be forwarded on the basis of the SMSC (SMS controller) address provided by the subscriber.

Usage
Use this command to define how the mobile originated SMS are to be routed.

Example

mo-message-forwarding-destination gmsc-selected-from-imsi
smsc-address-selection-prioritization

Define the routing selection priority for the SMSC (short message service center) address to be used for all MO-SMS.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
smsc-address-selection-prioritization from-ms priority imsi-prefix priority
msisdn-prefix priority
```

**default smsc-address-selection-prioritization**

- **from-ms priority**
  Configures a priority for the SMSC address send from the MS.
  *priority* : Value must be a single digit, range 1-3.

- **imsi-prefix priority**
  Configures a priority for the SMSC address that is based on the IMSI-prefix.
  *priority* : Value must be a single digit, range 1-3.

- **msisdn-prefix priority**
  Configures a priority for the SMSC address that is based on the MSISDN-prefix.
  *priority* : Value must be a single digit, range 1-3.

- **default**
  By including the **default** keyword with the command, the SGSN knows to use the encoded default priorities for SMSC address selection for SMSC routing:
  - *from-ms priority 1,*
  - *imsi-prefix priority 2,*
  - *msisdn-prefix priority 3.*

**Usage**

Use this command to define SMSC address routing priorities. Priorities must be defined for all parameters, all keywords, but they can be entered in any order. The addresses for the SMSCs are defined with the **smsc-routing** command.

An operator can use this configuration to prevent subscribers from using unauthorized SMSC addresses, for example, an unauthorized international SMSC.

**Example**

The keywords can be entered in any order but all keywords must be included in the command:
smsec-address-selection-prioritization msisdn-prefix 3 from-ms 1 imsi-prefix 2
**smsc-routing**

This command configures the routing to the SMSC (short message service center).

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] smsc-routing { { any | imsi-starts-with | msisdn-starts-with } { isdn
            isdn_number | mobile-global-title mgt_number | point-code pt_code } }
```

- **any**
  Configures routing according to any IMSI prefix.

- **imsi-starts-with ** *IMSI_prefix*
  Defines the IMSI prefix. Enter a string of up to 15 digits.

- **msisdn-starts-with ** *msisdn_prefix*
  Defines the MSISDN prefix. Enter a string of up to 15 digits.

- **isdn ** *isdn_number*
  Defines the ISDN E.164 number (up to 15 digits) of the SMSC.

- **mobile-global-title ** *mgt_number*
  Defines the mobile global title E.214 address to be used for IMSI conversion.

- **point-code ** *pt_code*
  Defines the point code for the SMSC. Enter a string of up to 11 digits in SS7 dotted decimal or decimal format

**Usage**

Use this command to define routing to the SMSC based on any point code.

**Example**

```
smsc-routing any point-code 1.222.1
```
timeout

This command defines the SMS service timers.

Product
SGSN

Privilege
Security Administrator, Administrator

Syntax

```
timeout { tc1n-timer time | tr1n-timer time | tr2n timer time }

default timeout { tc1n-timer | tr1n-timer | tr2n timer }
```

**default**

Resets the configuration to the default value for the specified timer.

**tc1n-timer time**

Configures the TC1N timer in seconds.

*time*: Must an integer from 1 to 255. The default is 5 seconds.

**tr1n-timer time**

Configures the TR1N timer in seconds.

*time*: Must an integer from 1 to 255. The default is 30 seconds.

**tr2n-timer time**

Configures the TR2N timer in seconds.

*time*: Must an integer from 1 to 255. The default is 30 seconds.

Usage

Use this command to set SMS service timers. The command can be repeated to set all of the timers, one-at-a-time.

Example

```
tr1n-timer 25
```
Chapter 187
SS7 Routing Domain Configuration Mode Commands

The SS7 Routing Domain configuration mode is used to configure Signaling System 7 (SS7) parameters. For convenience in configuration management, all SS7 parameters have been collected into a proprietary grouping called an SS7 routing domains.

```
[local]hostname(config-ss7-routing-domain-<ss7rd_id>)#
```

---

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
asp

This command creates or removes an M3UA Application Server Process (ASP) instance and enters the ASP configuration mode. See the SGSN ASP Configuration Mode chapter in the Command Line Interface Reference for command details.

**Product**
SGSN, HNB-GW

**Privilege**
Security Administrator, Administrator

**Syntax**

- `asp instance asp_inst`
- `no asp instance asp_inst`
- `default asp instance asp_inst end-point port`

  - `no`
    - Deletes the ASP instance for the SS7 routing domain configuration.

  - `default`
    - Sets the ASP instance parameters to the end-point port value of 2905.

  - `instance asp_inst`
    - Identifies a specific ASP configuration. Up to four ASP instances can be configured for a single SS7 routing domain.

    - `asp_inst`: Must be an integer from 1 through 4.

**Usage**
Use this command to create an ASP instance or enter the ASP configuration mode.

**Example**
The following command enters the ASP configuration mode for a specific ASP.

```
asp instance 1
```
description

This command defines an alphanumeric string that describes the current SS7 routing domain. This is used for operator reference only.

Product
SGSN, HNB-GW

Privilege
Security Administrator, Administrator

Syntax

description string

no description

no
Removes the description string from the current SS7 routing domain configuration.

string
Specifies the alphanumeric string that is stored. Strings with spaces must be enclosed in double-quotes (see the example below).

string: Must be from 1 to 255 alphanumeric characters.

Usage
Use this command to set a description for reference by operators.

Example
The following command sets the description to identify a routing domain for messages transmitted within a national boundary.

description "National Service Routing Domain"
**end**

Exits the current configuration mode and returns to the Exec mode.

**Product**  
SGSN, HNB-GW

**Privilege**  
Security Administrator, Administrator

**Syntax**  
`exit`

**Usage**  
Return to the Exec mode from any configuration mode.
exit

Exits the current configuration mode and returns to the context configuration mode.

**Product**
SGSN, HNB-GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
```

**Usage**

Return to the previous configuration mode.
**inbound-asp-identifier validate**

This command enables validation of ASP identifiers inbound to the SGSN via routes defined with this SS7 routing domain.

**Important:** This command is only available in releases 8.1 and higher.

**Product**
SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
inbound-asp-identifier validate
```

```
inbound-asp-identifier validate
    [ default | no ]

default
Validates the inbound ASP Id.

no
Disables validation of the inbound ASP Id.
```

**Usage**
The standard is to validate the ASP Id. However, in some circumstances it is necessary to skip such validation. For example, if the same ASP Id is assigned to more than one RNC (peer-server).

**Example**
Use the following command to skip validation of inbound ASP IDs:

```
no inbound-asp-identifier validate
```

Use either of the following commands to enable validation if it has been disabled:

```
default inbound-asp-identifier validate
inbound-asp-identifier validate
```
linkset

This command creates an instance of an MTP3 linkset and enters the linkset configuration mode. See the Linkset Configuration Mode chapter in Command Line Interface Reference for the commands to configure the linkset.

Product
SGSN, HNB-GW

Privilege
Security Administrator, Administrator

Syntax

[ no ] linkset id id

no
Removes the identified linkset definition from the system configuration.

id
This value uniquely identifies a linkset for the specific SS7 routing domain.
id: Must be an integer of 1 to 49.

Usage
This command creates instances of linkset configurations and provides access to the linkset configuration mode.

Example
Use the following command to create the 12th linkset:

linkset id 12
MTU-size

This command has been deprecated.
**peer-server**

This command creates a peer-server instance to setup a SIGTRAN peer for sending and receiving M3UA traffic. Completing the command automatically enters the peer-server configuration mode. To define 1 or more (up to 145) peer servers, use the commands documented in the *Peer-Server Configuration Mode* chapter in this reference.

**Product**
SGSN, HNB-GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
peer-server id srvr_id
no peer-server id srvr_id
```

**Usage**
Use the following command to create a definition for peer-server 2 and enter the configuration mode to configure the communication parameters for peer-server 12.

**Example**

```
peer-server id 12
```
route

This command configures SS7 routes for the current SS7 routing domain.

**Product**
SGSN, HNB-GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
route destination-point-code dp_code { linkset id id [ priority pri_value ] | peer-server-id srvr_id }
```

```
no route destination-point-code dp_code { linkset id id | peer-server-id srvr_id }
```

**no**
Removes the SS7 route from the current SS7 routing domain configuration.

**destination-point-code** *dp_code*
Specifies the SS7 destination point code for this route.
Reminder: the point-code structure must match the variant defined for the SS7 routing domain when the SS7RD was configured in the global configuration mode.

**linkset id id**
This keyword identifies a linkset instance, created and configured with the `linkset` command.
This keyword identifies a linkset instance, created and configured with the `linkset` command.
id: Must be an integer from 1 to 49.

**peer-server-id** *srvr_id*
This keyword identifies a peer-server configuration instance, created and configured with the `peer-server` command.
srvr_id must be an integer from 1 to 49.

**Usage**
This command associates the previously configured linksets and peer servers and the destination point codes with a specified SS7 route.

**Example**
Define a route setting an ITU-type destination point-code address for the linkset Id 12:

```
route destination-point-code 6.211.6 linkset id 12
```
**routing-context**

Identifies the routing context for this SS7 routing domain.

**Product**
SGSN, HNB-GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
routing-context value
```

```
default routing-context
```

**default**
Resets the local routing context value to the index (instance ID) for this SS7 routing domain.

**value**
An integer that uniquely identifies the routing context for this SS7 routing domain. **value**: Must be integers from 1 to 65535 (for release 8.0) or 1 to 4294967295 (for releases 8.1 and higher).

**Usage**
Use this command to set the routing context IDs for a specific SS7 routing domain configuration.

**Example**

```
routing-context 2355
```
This command sets the network indicator in the subservice field for SS7 message signal units (MSUs).

**Product**
SGSN, HNB-GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
ssf { international | national | reserved | spare }
```

- **international**
The network indicator identifies the message as international with a point code structure that does not match the national point code structure.

- **national**
The network indicator identifies the messages as having a national point code structure.

- **reserved**
Provides an alternate network indicator for national messages.

- **spare**
Provides an alternate network indicator for international messages.

**Usage**

In SS7 signaling, the Message Transfer Part (MTP) Level 2 message signal units (MSUs) contain a service information octet (SIO). The SIO field in an MSU contains a 4-bit subservice field (SSF) followed by a 4-bit service indicator. The indicator carried in the message’s routing information typically identifies the structure of the point code as a message from within a nation or as a message coming from outside the nation - international. As well, the 4-bit SSF determines the point code structure of the messages transmitted from the SGSN.

**Example**

For messages being transmitted within a country, set the indicator to national with the following command.

```
ssf national
```
Chapter 188
SSH Configuration Mode Commands

The Secure Shell Configuration Mode is used to manage the SSH server options for the current context.

```
Exec Mode
  configure
  Global Configuration Mode
    context name
    Context Configuration Mode
      server sshd
      SSH Configuration Mode
```
end

Exits the SSH server configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Administrator, Config-administrator

**Syntax**
end

**Usage**
Change the mode back to the Exec mode.
exit

Exits the secure shell server configuration mode and returns to the context configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
exit
```

Usage
Return to the context configuration mode.
listen

This command configures the SSH server in the current context to only listen for connections from the interface with the specified IP address. The default behavior is to listen on all interfaces.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
listen ip_address
no listen
```

Usage
Use this command to configure the SSH server for the current context to only listen for connections from the interface with the specified IP address. Only one IP address may be set for listening.

Example
The following command specifies that the Server should only listen for connections in the interface with the IP address of 192.168.0.10:

```
listen 192.168.0.10
```
max servers

Configures the maximum number of SSH servers that can be started within any 60 second interval. If this limit is reached, the system waits two minutes before trying to start any more servers.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
max servers number
```

- **number**
  Default: 40
  Specifies the maximum number of servers that can be spawned in any 60 second interval. number must be a value in the range from 1 to 100.

**Usage**
Set the number of servers to tune the system response as a heavily loaded system may need more servers to support the incoming requests.
The converse would be true as well in that a system can benefit by reducing the number of servers such that telnet services do not cause excessive system impact to other services.

**Example**

```
max servers 50
```
subsystem

Configures the system to perform file transfers using secure ftp (sftp) over ssh v2. Administrator users must be configured with the ftp attribute privilege to issue this command.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
subsystem { cli | sftp }
```

```
no subsystem { cli | sftp }
```

---

**no**

Disables either the sftp ssh file transfer method or disables access to the CLI over ssh.

---

**cli**

Default: Enabled
Configure the SSH system for the current context to allow access to the CLI.

---

**sftp**

Default: Disabled
Enables the SSH system for the current context to perform file transfers using secure ftp (sftp) over ssh v2.

---

**Usage**

Use this command to enable or disable file transfers using secure ftp over an ssh v2 tunnel. Also use this command to enable or disable access to the CLI over an SSH connection.

---

**Example**

The following command enables SFTP for the current context:

```
subsystem sftp
```

The following command disables access to the CLI through an SSH session for the current context:

```
no subsystem cli
```
Chapter 189
Subscriber Configuration Mode Commands

The Subscriber Configuration Mode is used to create local subscribers as well as to set default subscriber options for the current context.

```
Exec Mode
  configure
    Global Configuration Mode
      context name
        Context Configuration Mode
          subscriber
            { default |
              name name }
              Subscriber Configuration Mode
```
aaa group

Configures a AAA server group for AAA functionality at the subscriber level.

Product
All

Privilege
Security Administrator, Administrator

Syntax

[ no ] aaa group group_name

default aaa group

group_name
The AAA group to configure for authentication and/or accounting for the specific subscriber.
group_name must be an alpha and/or numeric string of 1 through to 63 characters in length.

no
Disables the specified AAA group for the specific subscriber.

default
Sets/restores default AAA group specified at the context level or default subscriber profile.

Usage
Instead of having a single list of servers per context, this feature configures multiple server groups within a context and applies individual server group for subscribers in that context. Each server group consists of a list of AAA servers for each AAA function (accounting, authentication, charging, etc.).

Example
The following command applies the AAA server group star1 to a subscriber within the specific context:

    aaa group star1

The following command disables the AAA group for the specific subscriber:

    no aaa group group_name
access-link ip-fragmentation

Configures IP fragmentation processing over the Access-link (\, GTP etc).

Product
All

Privilege
Security Administrator, Administrator

Syntax

access-link ip-fragmentation { normal | df-ignore | df-fragment-and-icmp-notify }

---

**df-ignore**

Default: Enabled
Ignore the DF bit setting. Fragment and forward the packet over the access link.

---

**df-fragment-and-icmp-notify**

Default: Disabled
Partially ignore the DF bit. Fragment and forward the packet, but also return an ICMP error message to the source of the packet. The number of ICMP errors sent like this is rate-limited to 1 ICMP error packet per second per session.

---

**normal**

Default: Disabled
Normal processing. Drop the packet and send an ICMP unreachable message to the source of packet. This is the default behavior.

---

Usage

If the IP packet to be forwarded is larger than the access-link MTU and if the DF (Don't Fragment) bit is set for the packet, then the fragmentation behavior configured by this command is applied. Use this command to fragment packets even if they are larger than the access-link MTU.

---

Example

Set fragmentation so that the DF bit is ignored and the packet is forwarded anyway by entering the following command:

access-link ip-fragmentation df-ignore
accounting-mode

This command sets the accounting mode for the current local subscriber configuration.

Product
PDSN, HA, ASN GW, S-GW

Privilege
Administrator

Syntax

accounting-mode { flow-based | gtp [ radius-diameter ] | none | radius-diameter [ gtp ] | rf-style }

default accounting-mode

default
Sets the type of accounting to be performed for the current local subscriber to the default setting.
Default: radius-diameter

flow-based
Diameter flow-based accounting is enabled for the current local subscriber.

GTP [ radius-diameter ]
GTPP CDR RADIUS accounting is enabled for the current local subscriber. The radius-diameter keyword is available if both GTPP RADIUS and RADIUS-Diameter accounting are to be used.

none
Accounting is disabled for the current local subscriber and no charging records will be generated.

radius-diameter [ gtp ]
RADIUS-Diameter accounting is enabled for the current local subscriber. The gtp keyword is available if both GTPP RADIUS and RADIUS-Diameter accounting are to be used.

rf-style
Diameter Rf interface accounting is enabled for the current local subscriber.

Usage
This command specifies which protocol, if any, will be used to provide accounting for PDP contexts accessing the APN profile.
Use this command to enable or disable RADIUS/Diameter accounting for any subscribers that use the current local subscriber configuration.
If the gtp option is used, then GTPP RADIUS is used as configured in the Context Configuration mode or the AAA Server Group Configuration mode and GTPP charging records will be enabled.
If the radius-diameter option is used, either the RADIUS or the Diameter protocol is used as configured in the Context Configuration mode or the AAA Server Group Configuration mode.
RADIUS accounting can also be enabled and disabled at the context level with the `aaa accounting` command in the Context Configuration Mode. If RADIUS accounting is enabled at the context level, the `accounting-mode` command can be used to disable RADIUS accounting for individual local subscriber configurations.

If the accounting mode is set to `rf-style`, then BM will generate accounting records corresponding to AIMS RF.

**Example**

To disable accounting for the current subscriber, enter the following command:

```
accounting-mode none
```
active-charging bandwidth-policy

This command configures the bandwidth policy to be used for the subscriber.

**Product**

ACS

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
active-charging bandwidth-policy bandwidth_policy_name

default | no active-charging bandwidth-policy
```

- **default**
  Specifies that the default bandwidth policy configured in the rulebase be used for this subscriber.

- **no**
  Disables bandwidth control for this subscriber.

- **bandwidth_policy_name**
  Specifies name of the bandwidth policy.
  - `bandwidth_policy_name` must be an alpha and/or numeric string of 1 through 63 characters in length.

**Usage**

Use this command to configure bandwidth policy to be used for subscribers.

**Example**

The following command configures a bandwidth policy named `standard` for the subscriber:

```plaintext
active-charging bandwidth-policy standard
```
active-charging rulebase

This command specifies the name of the rulebase to be used for this subscriber.

Product
ACS

Privilege
Security Administrator, Administrator

Syntax

```
active-charging rulebase rulebase_name
no active-charging rulebase
```

- **no**
  - Removes the previously configured rulebase for the subscriber.

- **rulebase_name**
  - Specifies name of the ACS rulebase.
  - `rulebase_name` must be the name of an ACS rulebase, and must be an alpha and/or numeric string of 1 through 63 characters in length.

Usage

This command specifies the name of the rulebase for specific subscriber (reals).
If the specified rulebase does not exist in the Active Charging service, the call will be rejected.

Example

The following command configures the ACS rulebase named `rule1` for the subscriber:

```
active-charging rulebase rule1
```
always-on

Once the idle timeout limit is reached, keep the current subscriber session connected as long as the subscriber is reachable.

⚠️ Caution: When always-on is enabled, the subscriber must have an idle time-out period configured (default is 0, no time-out). Failure to configure an idle time-out results in a subscriber session that is indefinite in length.

Two timers and a counter are associated with this feature. Refer to the timeout command in this chapter and the `ppp echo-retransmit-timeout msec` and `ppp echo-max-retransmissions num_retries` commands. Default: Disabled.

**Product**
PDSN, ASN GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
always-on

no always-on
```

```
no
```

Disables always-on. The user is disconnected after the idle time expires.

**Usage**
If this parameter is enabled for a subscriber, when the idle time-out limit is reached the subscribers IP/PPP session remains connected as long as the subscriber is reachable. This is true even if the airlink between the mobile device and the RN (Radio Node) is moved from active to dormant (inactive) status. When the idle timeout limit is reached, the PDSN determines availability using LCP keepalive messages. A response to these messages indicates that the “always-on” status should be maintained. Failure to respond to a predetermined number of LCP keepalive messages causes the PDSN to tear-down (disconnect) the subscriber session.

**Example**
Enable always on for the current subscriber by entering the following command:

```
always-on
```
asn nspid

This command specifies the network service provider (NSP) associated with a WIMAX subscriber in an ASN-GW service. When configured, the NSP ID is sent in the Access-Request and Accounting messages.

Product
ASN-GW

Privilege
Security Administrator, Administrator

Syntax

[ no ] asn nspid nsp_id

no
Removes/disables the configured identifiers for this network service provider in ASN-GW service.

asn nspid nsp_id
Specifies the network service provider for this subscriber. This enables the MS to discover all accessible NSPs, and to indicate the NSP selection during connectivity to the ASN.

Usage
Use this command to specify the NSP associated with a subscriber in an ASN-GW service. nsp_id is three bytes in HEX format. For example: FF-EE-01

Example
The following command specifies the NSP for a subscriber in an ASN service: **asn nspid 0F-01-FE**
asn-pdfid

This command configures the identifiers for packet data flow, service data flow, and service profile in an ASN-GW service.

Product
ASN-GW

Privilege
Security Administrator, Administrator

Syntax

[ no ] asn-pdfid pdf_id asn-service-profile-id svc_profile_id asn-sdfid sdf_id

no
Removes/disables the configured identifiers for this subscriber in ASN-GW service.

asn-pdfid pdf_id
Specifies the an unique ASN Packet Data Flow identifier for this subscriber.
pdf_id must be an integer between 1 and 65535.

asn-service-profile-id svc_profile_id
Specifies an unique ASN Service Profile Identifier for this subscriber.
svc_profile_id is a preconfigured Service Profile Identifier configured in the Context Configuration Mode.

asn-sdfid sdf_id
Specifies the an unique ASN Service Data Flow identifier for this subscriber.
sdf_id must be an integer between 1 and 65535.

Usage
Use this command to configure subscriber profile for QoS parameters in an ASN-GW service.
A maximum of 4 QoS profiles can be configured for a subscriber.

Example
The following command configures the QoS profile for a subscriber as PDF id 1, Service Profile id 3, and Service Data Flow id 2: asn-pdfid 1 asn-service-profile-id 3 asn-sdfid 2
asn-policy

This command configures the identifiers for packet data flow, service data flow, and service profile in an ASN GW service.

Product
ASN GW

Privilege
Security Administrator, Administrator

Syntax

asn-policy { classifiers downlink { strict | loose} } idle-mode { allow | disallow } auth-only {allow | disallow }

[ no | default ] asn-policy idle-mode

[ default ] asn-policy classifiers downlink

---

no

Removes/disables the configured policy for this subscriber in ASN GW service.

default

Sets the ASN policy to default for this subscriber. For downlink traffic classifier default policy is “loos” and for idle mode policy the default action is to allow idle mode operation in an ASN GW service.

idle-mode

Sets the idle mode policy for this subscriber in an ASN GW service.

allow

Default: enabled
Enables the policy for this subscriber to allow idle mode operation in an ASN GW service.

disallow

Default: disabled
Enable the policy for this subscriber to disallow idle mode operation in an ASN GW service.

classifiers downlink

Sets the classifier policy for all service flows coming from HA to FA for this subscriber’s matching classifier.

strict

Default: disabled
This option discards all the service flows coming from HA to FA and any other packets not matching to any of the classifiers set for this subscriber.
subscriber configuration mode commands

```
ASN - policy

loose
Default: enabled
This option allows all the service flows coming from HA to FA and any other packet does not matching to
any of the classifiers set for this subscriber and sent to the BS/MS over downlink flow.

auth-only
Specifies whether the call is Auth only or not.

allow
Enables the policy for this subscriber to allow auth-only in an ASN GW service.

disallow
Default
Disables the policy for this subscriber to allow auth-only in an ASN GW service.

Usage
Use this command to configure subscriber policy to allow/disallow the idle mode operation or the downlink
traffic flow for a subscriber in an ASN GW service.
For authentication configuration, the ASNGW supports the Initial Network Entry (INE) for Ethernet CS calls.
The base station supports Ethernet CS traffic to the network. The INE procedure includes the Authentication
of the service flows and IP-Address allocation through DHCP. Authentication is based on the Extensible
Authentication Protocol (EAP).
This command allows MS to transition to idle mode with an ASN GW.

Example
The following command configures the policy to allow the idle mode for an MS with an ASN GW:

default asn-policy idle-mode
```
**authorized-flow-profile-id**

When a profile ID is requested by the Mobile Node (MN), this command sets the value that is authorized by the AGW.

**Product**
PDSN, ASN GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
authorized-flow-profile-id profile_id direction { bidirectional | forward | reverse }
```

```plaintext
no authorized-flow-profile-id profile_id
```

- **no**
  Remove the existing profile ID setting specified by `profile_id`. `profile_id` must be an integer from 0 through 65535.

- **profile_id**
  The profile ID number that is authorized for the current subscriber. `profile_id` must be an integer from 0 through 65535.

- **direction { bidirectional | forward | reverse }**
  This specifies in which data direction the profile ID should be applied.
  - bidirectional: This profile ID pertains to both the forward and reverse directions.
  - forward: This profile ID pertains to data going to the MN.
  - reverse: This profile ID pertains to data coming from the MN.

**Usage**

Use this command to set the profile ID that the AGW will authorize for a subscriber.

**Example**

Set the profile ID for both directions to 3 for the current subscriber by entering the following command:

```plaintext
authorized-flow-profile-id 3 direction bidirectional
```
content-filtering category

This command enables/disables the specified preconfigured Category Policy Identifier for policy based Content Filtering support to the subscriber.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
content-filtering category policy-id cf_policy_id
no content-filtering category policy-id

no
Disables the configured category policy ID for content filtering support to the subscriber. This is the default setting.

category policy-id cf_policy_id
This command applies the content filtering category policy ID, configured in ACS Configuration Mode, to this subscriber.

cf_policy_id must be a category policy ID, and must be an integer from 1 through 4,294,967,295.
If the specified category policy ID is not configured in the ACS Configuration Mode, all packets will be passed regardless of the categories determined for such packets.
```

**Important:** Category Policy ID configured through this mode overrides the Category Policy ID configured using the `content-filtering category policy-id` command in the ACS Rulebase Configuration Mode.

Usage
Use this command to enter the Content Filtering Policy Configuration Mode and to enable or disable the Content Filtering Category Policy ID for a subscriber.

**Important:** If Content Filtering Category Policy ID is not specified here the similar command in the ACS Rulebase Configuration Mode determines the policy.

Up to 64 different policy identifier can be defined in a Content Filtering support service.

Example
The following command enters the Content filtering Policy Configuration Mode and enables the Category Policy ID 101 for Content Filtering support:

```
content-filtering category policy-id 101
```
cscf core-service

CSCF/A-BG core service that maps to the current domain.

Product
SCM (CSCF, A-BG)

Privilege
Security Administrator, Administrator

Syntax

```
cscf core-service name name
no cscf core-service
```

```
cscf core-service name name
Specifies the name of the CSCF/A-BG core service.
name must be from 1 to 63 alpha and/or numeric characters.
```

```
no cscf core-service
Removes the CSCF/A-BG core service from the domain.
```

Usage
Use this command to map a CSCF/A-BG core service to the current domain.

Example
The following command creates a CSCF core service named cs1:

```
cscf core-service name cs1
```

The following command removes the CSCF core service from this domain:

```
no cscf core-service
```
cscf county-name

Assigns a Last Routing Option (LRO) profile county name to the subscriber for finding the correct Public Safety Answering Point (PSAP) during emergency calls.

Product
SCM (S-CSCF)

Privilege
Security Administrator, Administrator

Syntax

[ no ] cscf county-name name

  cscf county-name name
  Specifies the LRO profile county name of the subscriber.
  name must be an existing LRO profile county name and be from 1 to 127 alpha and/or numeric characters.

  no
  Removes the LRO profile county name from the subscriber.

Usage
Use this command to assign an LRO profile county name to the subscriber.

Example
The following command assigns county name norfolk to the subscriber:

  cscf county-name norfolk

The following command removes county name norfolk from the subscriber:

  no cscf county-name norfolk
cscf nat-applicable

Indicates if NAT (Network Address Translation) processing is required for this domain.

Product
SCM (CSCF/A-SBC)

Privilege
Security Administrator, Administrator

Syntax

[ no ] cscf nat-applicable

no
Disables NAT processing for this domain.

Usage
Use this command to indicate whether NAT processing is required for this domain.

Example
The following command indicates NAT processing is required for this domain:

    cscf nat-applicable

The following command disables NAT processing for this domain:

    no cscf nat-applicable
cscf private-user-id

Assigns a private user identity to the subscriber.

Product
SCM (P-CSCF, S-CSCF, SIP Proxy)

Privilege
Security Administrator, Administrator

Syntax

[ no ] cscf private-user-id user_id

no
Removed the private user identity of the subscriber.

cscf private-user-id user_id
Specifies the private user identity of the subscriber.
user_id must be from 1 to 127 alpha and/or numeric characters.

Usage
Use this command to assign a private user identity to the subscriber.

Example
The following command assigns a private user identity named user007 to the subscriber:

cscf private-user-id user007

The following command removes private user identity named user007 from the subscriber:

no cscf private-user-id user007
cscf session-template

Assigns a CSCF session template to the subscriber profile.

**Product**
SCM (P-CSCF, S-CSCF, SIP Proxy)

**Privilege**
Security Administrator, Administrator

**Syntax**

```
cscf session-template name name
```

```
no cscf session-template
```

---

**cscf session-template name name**

Specifies the name of the CSCF session template.

*name* must be an existing CSCF session template name and be from 1 to 79 alpha and/or numeric characters.

---

**no cscf session-template**

Removes the assignment of a session template to the subscriber profile.

---

**Usage**
Use this command to bind a CSCF session template to a subscriber profile.

---

**Example**
The following command assigns a CSCF session template named *template4* to the subscriber profile:

```
cscf session-template name template4
```

The following command removes the assignment of a session template to the subscriber profile:

```
no cscf session-template
```
data-tunneling ignore df-bit

This command controls the handling of the DF (Don't Fragment) bit present in the user IPv4/IPv6 packet for GRE, IP-in-IP tunneling used for the MIP data path. If this feature is enabled, and fragmentation is required for the tunneled user IPv4/IPv6 packet, then the DF bit is ignored and the packet is fragmented. Also the DF bit is not copied to the outer header. Default is enabled.

Product
PDSN, HA, FA, ASN GW

Privilege
Security Administrator, Administrator

Syntax

```
data-tunneling ignore df-bit
no data-tunneling ignore df-bit
```

```
no

Disable this option. The DF bit in the tunneled IP packet header is not ignored during tunneling.
```

Usage

Use this command to configure a user so that during Mobile IP tunneling the DF bit is not ignored and packets are not fragmented.

Example

To disable fragmentation of a subscribers packets over a MIP tunnel even when the DF bit is present, enter the following command:

```
no data-tunneling ignore df-bit
```
dcca origin host

This command is obsolete. Refer to the dcca origin endpoint command.
dcca origin endpoint

This command is obsolete. To configure the Diameter Credit Control Origin Endpoint, in the Credit Control Configuration Mode, use the **diameter origin endpoint** command.
dcca peer-select

Specifies the Diameter credit control primary and secondary peer for credit control.

**Product**
ACS

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
dcca peer-select peer host_name [ realm realm_name ] [ secondary-peer host_name [ realm realm_name ] ]
```

**no dcca peer-select**

- **no**
  Removes the previously configured Diameter credit control peer selection.

- **peer host_name**
  A unique name that you specify for the peer. `peer_name` must be an alpha and/or numeric string of from 1 through 127 characters. `peer_name` allows punctuation marks.

- **secondary-peer host_name**
  Specifies a back-up host that is used for fail-over processing. When the route-table does not find an AVAILABLE route the secondary host performs a fail-over processing.

- **realm realm_name**
  The `realm_name` must be an alpha and/or numeric string of 1 through 127 characters in length. The realm may typically be a company or service name. `realm_name` allows punctuation characters.

**Usage**
Use this command to select a Diameter credit control peer and realm.

**WARNING:** This configuration completely overrides all instances of `diameter peer-select` that have been configured with in the Credit Control Configuration Mode for an Active Charging service.

**Example**
The following command selects a Diameter credit control peer named `test` and a realm of `companyx`

```plaintext
dcca peer-select peer test realm companyx
```
default

Restores the default value for the option specified for the current subscriber.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
default { access-link ip-fragmentation | accounting-mode | data-tunneling ignore df-bit | idle-timeout-activity dormant-downlink-data | inter-pdsn-handoff | ip { alloc-method | allowed-dscp | header-compression | hide-service-address | multicast discard | qos-dscp | source-validation | loadbalancetunnel-peers | long-duration-action | mobile-ip { home-agent | mn-aaa-removal-indication | mn-ha-hash-algorithm | reverse-tunnel | security-level | send { dns-address | terminal-verification } } | permission | ppp { always-on-vse-packet | data-compression { mode | protocols } | keepalive | min-compression-size | mtu } | radius accounting interim interval-timeout | timeout { absolute | idle } } }
```

**access-link ip-fragmentation**
Sets the method for fragmenting packets over the MN access link to its default of normal. Drop the packet and send ICMP unreachable to the source of packet.

**accounting-mode**
Enables Radius accounting for the current local subscriber configuration.

**data-tunneling ignore df-bit**
Sets this option to the default behavior, which is to send an ICMP unreachable - need to frag message back to the sender and drop the packet, in the case that fragmentation is required but the DF bit is set.

**idle-timeout-activity dormant-downlink-data**
Sets this option to the default behavior. When downlink data packets are transmitted to the Mobile node and the session is in dormant mode the session idle timer is reset.

**inter-pdsn-handoff**
During a handoff from one PDSN to another, if the Mobile requests an IP address of 0.0.0.0 or a mismatched IP address the PDSN will not disconnect the session immediately. The PDSN tries to assign the proposed address of the session in the IPCP configuration NAK.

**ip { | allowed-dscp | header-compression | hide-service-address | multicast discard | qos-dscp | source-validation | user-datagram-tos copy }**

**allowed-dscp**: resets the allowed DSCP parameters to the system defaults: class none, max-class be.
**hide-service-address**: specifies the default setting for hide the ip-address of the service from the subscriber. Default is Disabled

**multicast discard**: configures the default multicast settings which is to discard PDUs

**qos-dscp**: sets the quality of service setting to the system default.

**source-validation**: Specifies the default IP source validation. Default is Enabled.

**user-datagram-tos copy**: Disable copying of the IP TOS octet value to all tunnel encapsulation IP headers.

---

**loadbalance-tunnel-peers**

Sets the tunnel load balancing algorithm to the system default.

---

**long-duration-action**

Sets the action that is taken when the long duration timer expires to the default: detection.

---

**mobile-ip**

| home-agent | mn-aaa-removal-indication | mn-ha-hash-algorithm | reverse-tunnel | security-level | send { dns-address | terminal-verification } |

**allow-aaa-address-assignment**: Disables the FA from accepting a home address assigned by an AAA server.

**home-agent**: Sets home agent IP address to its default of 0.0.0.0.

**match-aaa-assigned-address**: Disables the FA validating the home address in the RRQ against the one assigned by AAA server.

**mn-aaa-removal-indication**: Sets this parameter to its default of disabled.

**mn-ha-hash-algorithm**: Sets the encryption algorithm to the default of hmac-md5.

**reverse-tunnel**: Sets this parameter to its default of enabled.

**security-level**: Sets this parameter to its default of none.

**send dns-address**: Disables the HA from sending the DNS address NVSE in the RRP.

**send terminal-verification**: Disables the FA from sending the terminal verification NVSE in the RRQ.

---

**permission**

Restores the subscriber’s service usage defaults.

---

**ppp**

| always-on-vse-packet | data-compression { mode | protocols } | ip-header-compression negotiation | keepalive | min-compression-size | mtu |

Sets the point-to-point protocol option defaults.

**always-on-vse-packet**: Re-enables the PDSN to send special 3GPP2 VSE PPP packets to the Mobile Node with a max inactivity timer value for always on sessions. This configuration is applicable only for PDSN sessions.

**data-compression { mode | protocols }**: restores the default value for either the data compression mode or compression protocols as follows:

- mode stateless
- all protocols enabled

**ip-header-compression negotiation**: sets the IP header compressions negotiation to the system default: force.

**keepalive**: sets the subscriber’s PPP keep alive option to the system default: 30 seconds.

**min-compression-size**: restores the PPP minimum packet size for compression: 128 octets.

**mtu**: sets the maximum message transfer unit packet size to the system default: 1500 octets.
radius accounting interim interval-timeout
Disables the RADIUS accounting interim interval for the current subscriber.

timeout [ absolute | idle | long-duration ]
When a keyword is entered, this command resets the specified timeout to the system default: 0. When no keyword is specified, all timeouts are reset to the system defaults: 0.

Usage
Reset subscriber data to the system defaults. This is useful in setting the subscriber back to the basic values to possibly aid in trouble shooting or tuning a subscriber’s access and options.

Example

default ip qos-dscp
default permission
default data-compression mode
dns

Configures the domain name servers for the current subscriber.

Product
All

Privilege
Security Administrator, Administrator

Syntax

[ no ] dns { primary | secondary } ip_address

- no
  Indicates the IP address is to be removed as either a primary or secondary domain name server.

- primary | secondary
  primary: Indicates the primary domain name server for the subscriber is to be updated.
  secondary: Indicates the secondary domain name server for the subscriber is to be updated.

- ip_address
  Specifies the IP address of the domain name server.

Usage
Set the subscriber DNS server lists as not all users will have the same set of servers.

Example

dns primary 1.2.3.4
no dns primary 1.2.3.4
dns secondary 1.2.5.6
no dns secondary 1.2.5.6
eap

This command specifies the lifetime for a master session key (MSK) for extensible authentication protocol (EAP) authentication.

Product
ASN GW

Privilege
Security Administrator, Administrator

Syntax

[ default ] eap msk-lifetime dur

**default**
Sets the lifetime duration to default value of 3600 seconds for master session key.

**msk-lifetime dur**
Specifies the lifetime duration on Master session key (MSK) in seconds for a WiMAX subscriber EAP authentication.

dur is the lifetime value in seconds and must be an integer from 60 through 65535.

Usage
This command is used to set the lifetime for MSK in EAP authentication for WiMAX subscriber.

Example
The following command sets the lifetime for MSK key to 4800 seconds for a WiMAX subscriber through EAP authentication:

```
eap msk-lifetime 4800
```
**encrypted password**

Designates use of password encryption.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
encrypted password password
```

- `password` is the encrypted password and must be an alpha and/or numeric string of from 1 to 63 characters.

**Usage**

This command is normally used only inside configuration files.

**Example**

The following command sets an encrypted password of `qsd12d4`:

```plaintext
encrypted password qsd12d4
```
end

Exits the subscriber configuration mode and returns to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Change the mode back to the Exec mode.
**exit**

Exits the subscriber configuration mode and returns to the context configuration mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**
exit

**Usage**
Return to the context configuration mode.
external-inline-server

This is a restricted command.
**firewall policy**

ℹ️ **Important:** This command is only available in StarOS 8.0. In StarOS 8.1 and later, this configuration is available in the ACS Rulebase Configuration Mode.

This command enables/disables Stateful Firewall support for the subscriber.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
firewall policy firewall-required
{ default | no } firewall policy
```

- **no**
  
  Disables Stateful Firewall support for this subscriber.

- **default**
  
  Configures the default setting for Stateful Firewall support.
  Default: Disabled

- **firewall-required**
  
  Enables Stateful Firewall support for this subscriber.

**Usage**
Use this command to enable or disable Stateful Firewall support for this subscriber.

ℹ️ **Important:** Unless Stateful Firewall support for this subscriber is enabled using this command, firewall processing for this subscriber is disabled.

ℹ️ **Important:** If firewall is enabled, and the rulebase has no firewall configuration, Stateful Firewall will cause all packets to be discarded.

**Example**
The following command enables Stateful Firewall support for this subscriber:

```plaintext
firewall policy firewall-required
```

The following command disables Stateful Firewall support for this subscriber:
no firewall policy
fw-and-nat policy

Important: This command is customer-specific and is only available in StarOS 8.1. This command must be used to configure the Policy-based Firewall-and-NAT feature.

This command configures the Firewall-and-NAT policy for the subscriber.

Product
FW, NAT

Privilege
Security Administrator, Administrator

Syntax
fw-and-nat policy fw_nat_policy
{ default | no } fw-and-nat policy

default
Specifies that the default Firewall-and-NAT policy configured in the rulebase be used for the subscriber.

no
Disables Firewall and NAT processing for the subscriber.

fw_nat_policy
Specifies the Firewall-and-NAT policy for the subscriber.
fw_nat_policy must be an alpha and/or numeric string of 1 through 63 characters in length. Note that this policy will override the default Firewall-and-NAT policy configured in the ACS rulebase.

Usage
Use this command to configure the Firewall-and-NAT policy for subscribers. Note that the policy configured in the subscriber mode will override the default policy configured in the ACS rulebase. If a policy is not configured in the subscriber mode, the default policy configured in the ACS rulebase will be applied.

Example
The following command configures a Firewall-and-NAT policy named standard for the subscriber:

fw-and-nat policy standard
idle-timeout-activity

Defines whether downlink (towards Mobile Node) data packets transmitted when the session is dormant is treated as activity for the idle-timer (inactivity timer).

By default, downlink data transmitted over a dormant session restarts the idle-timer for that session (it is treated as activity for the session).

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

[ no ] idle-timeout-activity dormant-downlink-data

| no |
| Dormant mode downlink data is not treated as activity for the session idle-timer. The session idle timer is not reset.

Usage
Use this command to disable or re-enable restarting the session idle timer when downlink data packets are transmitted to the Mobile Node when the session is in dormant mode.

Example
Use the following command to disable restarting the session idle timer when downlink data packets are transmitted to the Mobile Node when the session is in dormant mode:

idle-timeout-activity dormant-downlink-data

Use the following command to re-enable restarting the session idle timer when downlink data packets are transmitted to the Mobile Node when the session is in dormant mode:

no idle-timeout-activity dormant-downlink-data
### ims application-manager

Specifies the application manager for the subscriber.

**Product**

PDSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
[ no ] ims application-manager { domain-name domain-name | ipv4-address ipv4-address }
```

- **no**
  
  Disables the IMS application manager for this subscriber.

- **domain-name domain-name**
  
  Specifies the domain name of the application manager. `domain-name` must be from 1 to 63 alpha and/or numeric characters.

- **ipv4-address ipv4-address**
  
  Specifies the IPv4/IPv6 address of the application manager.

**Usage**

The ims application manager address is returned by HA to MN in DHCP Ack when it receives the DHCP inform from an AIMS subscriber.

**Example**

```
ims application-manager domain-name domain23ims application-manager ipv4-address 192.168.23.1
```
ims-auth-service

It applies an IMS authorization service to a subscriber in a network access service (PDSN or GGSN service) for Gx/Ty interface support and functionality.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax
[ default | no ] ims-auth-service auth_svc_name

default
Sets / Restores default state of IMS authorization service, disabled or as specified at the context or network access service level or in subscriber template.

no
Disables the applied IMS authorization service for specific subscriber.

auth_svc_name
Specifies the name of IMS authorization service name that is used for Ty interface support for specific subscriber.
auth_svc_name must be from 1 to 63 alpha and/or numeric characters preconfigured within the same context of this subscriber.

Usage
This feature provides the IMS authorization service configuration for Gx/Ty interface in IMS service node.

Example
Following command applies a previously configured IMS authorization service named ims_interface1 to a subscriber within the specific context.

ims-auth-service ims_interface1
inter-pdsn-handoff

Configure the system to enforce the MN’s use of its assigned IP address during IPCP negotiations resulting from inter-PDSN handoffs.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

[ no ] inter-pdsn-handoff require ip-address

no
Disables the rejecting of sessions when the MN uses a non-allocated IP address during IPCP re-negotiations.

Usage
This command is used to configure the system to reject sessions that are re-negotiating IPCP after an inter-PDSN handoff if the IP address they propose does not match the one initially provided by the PDSN. The session would be rejected even if the proposed address was 0.0.0.0.
If this parameter is disabled, the PDSN will attempt to re-assign the IP address initially provided.

Example
To set the PDSN to not allow a mismatched IP address during a PDSN to PDSN handoff of a MIP call, use the following command:

inter-pdsn-handoff require ip-address

To set the PDSN so that it will not disconnect the session immediately, if the Mobile requests an IP address of 0.0.0.0 or a mismatched IP address after inter-pdsn handoff, use the following command:

no inter-pdsn-handoff require ip-address
ip access-group

Configures IP access group for the current subscriber.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] ip access-group group_name [ in | out ]
```

- **no**
  Indicates the access group specified is to be cleared from the subscriber's configuration.

- **group_name**
  Specifies the name of the IPv4/IPv6 access group. `acl_group_name` is a configured ACL group and must be an alpha and/or numeric string of 1 to 79 characters.

- **in | out**
  Default: both (in and out)
  Specifies the access-group as either inbound or outbound by the keywords `in` and `out`, respectively. If neither of these key words is specified, the command associates the `group_name` access group with the current subscriber for both inbound and outbound access.

**Usage**
Set the subscriber access group to manage the access control for subscribers as a logical group.

**Example**
The following command associates the `sampleGroup` access group with the current subscriber for both inbound and outbound access:

```
  ip access-group sampleGroup
```

The following removes the outbound access group flag for `sampleGroup`:

```
  no ip access-group sampleGroup out
```
ip address

Configures a static IP address for use by the subscriber.

Product
PDSN, GGSN, HA, ASN GW

Privilege
Security Administrator, Administrator

Syntax

[ no ] ip address ip_address netmask

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
<tbody>
<tr>
<td>Removes a previously configured IP address assignment.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ip_address</th>
</tr>
</thead>
<tbody>
<tr>
<td>The IP address assigned to the subscriber.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>netmask</th>
</tr>
</thead>
<tbody>
<tr>
<td>The subnet mask that corresponds to the assigned IP address.</td>
</tr>
</tbody>
</table>

Usage
Use this command to assign a static IP address to the subscriber. This address will be used each time the subscriber establishes data sessions.

Example
The following command configures a static IP address of 192.168.1.15 with a subnet mask of 255.255.255.0 to the subscriber:

```plaintext
ip address 192.168.1.15 255.255.255.0
```
ip address pool

Configures IP address pool properties for the subscriber.

Product
PDSN, GGSN, HA, ASN GW

Privilege
Security Administrator, Administrator

Syntax

```
[ no ] ip address pool name pool_name
```

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
<tbody>
<tr>
<td>Removes a previously configured static address.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>name pool_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the IP address pool or IP address pool group from which the subscribers IP address is assigned. \n</td>
</tr>
</tbody>
</table>

Usage

Use this command to specify the name of an IP address pool configured on the system from which IP addresses are to be dynamically assigned to sessions from this subscriber.

This command can be issued multiple times to specify multiple address pools for the subscriber. If multiple pools are specified, addresses are assigned for subscriber sessions from the pools based on the order in which the pools were configured.

If an address can not be provided from the first-specified pool for whatever reason, the system attempts to assign an address from the second-specified pool, and so on. This operation is independent of the priorities configured for the pools. For example, if pool1 was specified for the subscriber first, and pool2 second, the system always attempts to assign addresses from pool1. If an address can not be assigned from pool1 (i.e. all addresses are in use), the system then attempts to assign an address from pool2.

Example

The following command configures the subscriber to receive IP addresses from an IP address pool named public1:

```
ip address pool name public1
```
ip address secondary-pool

Configures secondary IP address pool properties for the subscriber to provide multiple IP host configuration behind one WiMAX CPE.

Product
ASN GW

Privilege
Security Administrator, Administrator

Syntax

[ no ] ip address secondary-pool name aux_pool_name

no
Removes a previously configured auxiliary pool named aux_pool_name for multiple host support in ASN GW service.

name aux_pool_name
Specifies the secondary/auxiliary IP address pool or IP address pool group from which the IP address is assigned to host behind a WiMAX CPE having primary IP address. pool_name must be the name of an existing IP pool or IP pool group and from 1 to 31 alpha and/or numeric characters.

Usage
Use this command to specify the name of an IP address pool configured on the system from which IP addresses are to be dynamically assigned to host behind a WiMAX CPE for multiple host session support. This command designates the IP address to secondary hosts from locally configured secondary IP address pool. To enable multiple host support behind a WiMAX CPE and configure maximum number of supported hosts use secondary-ip-host command in ASN Gateway Service Configuration mode.

Example
The following command configures the subscriber to receive IP addresses from a secondary IP address pool named auxiliary for secondary hosts behind the WiMAX CPE:

ip address secondary-pool name auxiliary
**ip allowed-dscp**

This command sets the Quality of Service (QoS) Differentiated Services (DiffServ) marking that a subscriber session is allowed. This is disabled by default.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```bash
ip allowed-dscp class class max-class maxclass [ rt-marking marking ]
```

```bash
no ip allowed-dscp class
```

---

**class class**

This parameter specifies the Differentiated Services Codepoint (DSCP) class that the subscriber session may mark its packets with. If the subscriber sessions packets request a code point class higher than the code point class specified, the PDSN service re-marks the packets with the QOS-DSCP value specified by the `ip qos-dscp` command.

Default: none

*class* must be one of the following:
- a: packets with AF DSCPs are allowed
- e: packets with EF DSCP are allowed
- o: packets for experimental or local use are allowed
- ae: packets with AF and EF DSCPs are allowed
- ao: packets with AF DSCPs or packets for experimental or local use are allowed
- eo: packets with EF DSCPs or packets for experimental or local use are allowed
- aeo: packets with AF or EF DSCPs or packets for experimental or local use are allowed
- none: only the be and sc1 through sc7 codepoints are allowed

**max-class maxclass**

This parameter specifies the maximum code point that a subscriber session may mark its packets with. The subscriber sessions packets must be marked with a code point equal to or less than the code point specified. If the subscriber sessions packets request a code point higher than the code point specified, the PDSN service re-marks the packets with the QOS-DSCP value specified by the lower of the max-class and the `ip qos-dscp` command.

The list below lists the code points from lowest to highest precedence. For example, if the *maxclass* is set to af22, that becomes the maximum code point that the subscriber session may mark it’s packets with and only be, af13, af12, af11, af23, and af22 are allowed. If a subscriber session marks its packets with anything after af22 in this list, the PDSN service re-marks the packets with the QOS-DSCP value specified by the lower of the maxclass and the `ip qos-dscp` command.

If *class* is set to none only the be and sc1 through sc7 codepoints are allowed. For example; if *class* is set to none and you set `max-class` to sc1, only the sc1 and be codepoints are allowed.
Default: **be**

`maxclass` must be one of the following:

- **be**: best effort forwarding
- **af13**: assured Forwarding 13
- **af12**: assured Forwarding 12
- **af11**: assured Forwarding 11
- **af23**: assured Forwarding 23
- **af22**: assured Forwarding 22
- **af21**: assured Forwarding 21
- **af31**: assured Forwarding 31
- **af32**: assured Forwarding 32
- **af33**: assured Forwarding 33
- **af41**: assured Forwarding 41
- **af42**: assured Forwarding 42
- **af43**: assured Forwarding 43
- **ef**: expedited forwarding
- **sc1**: selector class 1
- **sc2**: selector class 2
- **sc3**: selector class 3
- **sc4**: selector class 4
- **sc5**: selector class 5
- **sc6**: selector class 6
- **sc7**: selector class 7

---

**rt-marking marking**

This parameter is used for Mobile IP (MIP) reverse tunnels. When a MIP sessions packets do not have a DSCP marking, the Foreign Agent (FA) marks the packets with the value specified by `rt-marking marking`.

If the MIP sessions packets have a DSCP marking, the marking is subjected to the conformance rules for the values of class and max-class, then the final DSCP marking is copied from the inner IP header to the outer IP header.

Default: **be**

`marking` must be one of the following:

- **be**: best effort forwarding
- **af11**: assured Forwarding 11
- **af12**: assured Forwarding 12
- **af13**: assured Forwarding 13
- **af21**: assured Forwarding 21
- **af22**: assured Forwarding 22
- **af23**: assured Forwarding 23
- **af31**: assured Forwarding 31
- **af32**: assured Forwarding 32
- **af33**: assured Forwarding 33
- **af41**: assured Forwarding 41
- **af42**: assured Forwarding 42
- **af43**: assured Forwarding 43
- **ef**: expedited forwarding
- **sc1**: selector class 1
- **sc2**: selector class 2
- **sc3**: selector class 3
- **sc4**: selector class 4
ip allowed-dscp

Usage
Use this command to configure Quality of Service (QoS) for a subscriber session to allow a Differentiated Services (DiffServ) Code Point (DSCP) marker in the header of each IP packet that prompts network routers to apply differentiated grades of service to various packet streams. This command uses class and type of marker (rt-marking for reverse tunnels) for configuration with max-class maximum code point that a subscriber session may mark its packets with.

Example
The following command will allow o packets for experimental or local use with best effort forwarding be:

```
ip allowed-dscp class o max-class be
```
**ip context-name**

Configures context to assign the subscriber to upon authentication. The context assigned to is considered the destination context which provides the configuration options for the services the subscriber is allowed to access.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```
[ no ] ip context-name name
```

- **no**
  - Removes the current assigned context from the subscriber’s data.

- **name**
  - Specifies the name of the context to assign the subscriber to once authenticated. *name* must be from 1 to 79 alpha and/or numeric characters.

**Usage**

Set the subscriber IP context to a common context when all subscribers from one or more contexts will use the same egress context.

**Example**

```
ip context-name sampleName

no ip context-name sampleName
```
ip header-compression

Configures the IP packet header compression options for the current subscriber. Although this command configures IP header compression algorithms, the IPCP negotiations determine when the header compression algorithm is applied.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
ip header-compression { rohc [ any [ mode { optimistic | reliable | unidirectional } ] ] | cid-mode { ( large | small ) [ marked-flows-only | max-cid | max-hdr value | mrru value ] } } | marked flows-only | max-hdr value | mrru value | downlink | uplink ] | vj } +
[ default | no ] ip header-compression
```

- **default**: Restores this command’s default setting to the Van Jacobsen (VJ) header compression algorithm.
- **no**: Disables all IP header compression.

**rohc [ any [ mode { optimistic | reliable | unidirectional } ] ] | cid-mode { ( large | small ) [ marked-flows-only | max-cid | max-hdr value | mrru value ] } } | marked flows-only | max-hdr value | mrru value | downlink | uplink ]

Specifies that the Robust Header Compression (ROHC) algorithms is used for data.

**Important**: ROHC is only supported for use with the PDSN.

- **any**: Apply ROHC header compression in both the uplink and downlink directions.
- **mode**: **optimistic**, **reliable**, **unidirectional**:
  - **optimistic**: Sets the ROHC mode to Bidirectional Optimistic mode (O-mode). In this mode packets are sent in both directions. A feedback channel is used to send error recovery requests and (optionally) acknowledgments of significant context updates from decompressor to compressor. Periodic refreshes are not used in the Bidirectional Optimistic mode.
  - **reliable**: Sets the ROHC mode to Bidirectional Reliable mode (R-mode). This mode applies an intensive usage of a feedback channel and a strict logic at both the compressor and the decompressor that prevents loss of context synchronization between the compressor and the decompressor. Feedback is sent to acknowledge all context updates, including updates of the sequence number field.
  - **unidirectional**: Sets the ROHC mode to Unidirectional mode (U-mode). With this mode packets are sent in one direction only, from the compressor to the decompressor. This mode therefore makes...
ROHC usable over links where a return path from the decompressor to the compressor is unavailable or undesirable.

cid-mode { { large | small } [ marked-flows-only | dm | max-hdr value | mrru value ] } : Specifies the ROHC packet type to be used.

*large | small { marked-flows-only | max-cid | max-hdr value | mrru value } : Defines the ROHC packet type as large or small and optionally sets the following parameters for the packet type selected:

*marked-flows-only: Specifies that ROHC is to be applied only to marked flows.

*max-cid integer: Default: 0 The highest context ID number to be used by the compressor. integer must be an integer from 0 through 15 when small packet size is selected and must be an integer from 0 through 31 when large packet size is selected.

*max-hdr value: Specifies the maximum header size to use. Default: 168. value must be an Integer from 0 through 65535.

*mrru value: Specifies the maximum reconstructed reception unit to use. Default: 65535. value must be an Integer from 0 through 65535.

marked-flows-only: Specifies that ROHC is to be applied only to marked flows.

max-hdr value: Specifies the maximum header size to use. Default: 168. value must be an Integer from 0 through 65535.

mrru value: Specifies the maximum reconstructed reception unit to use. Default: 65535. value must be an Integer from 0 through 65535.

downlink: Apply the ROHC algorithm only in the downlink direction.

uplink: Apply the ROHC algorithm only in the uplink direction.

**Important:** When ROHC is enabled for downlink or uplink only the operational mode is Unidirectional.

\[ vj \]

Specifies that the VJ algorithm is used for header compression.

\[ + \]

Either one or both of the keywords may be entered in a single command. If both \[ vj \] and \[ rohc \] are specified, \[ vj \] must be specified first.

**Important:** If both VJ and ROHC header compression are specified, the optimum header compression algorithm for the type of data being transferred is used for data in the downlink direction.

**Usage**

Header compression can be used to provide a higher level of security in IP traffic enhance bandwidth usage and lower bit errors.

By default the header compression algorithm is set to \[ vj \].

**Example**

The following command disables all IP packet header compression:

\[ no ip header-compression \]
The following command sets IP header compression to default vj algorithm:

```
default ip header-compression
```

The following command also sets the IP header compression to the vj algorithm:

```
ip header-compression vj
```

The following command enables the Internet Protocol Control Protocol (IPCP) to determine which protocol is the optimum algorithm for data in the downlink direction and use either VJ or ROHC as needed:

```
ip header-compression vj rohc
```

The following command enables ROHC for the downlink direction only:

```
ip header-compression rohc downlink
```

The following command enables ROHC in any direction using Bidirectional Optimistic mode:

```
ip header-compression rohc any mode Optimistic
```
ip hide-service-address

Hide the IP address of the service from the subscriber.

Product
All

Privilege
Security Administrator, Administrator

Syntax

[ no ] ip hide-service-address

no
Disable this commands function. This is the default behavior.

Usage
Use this command to prevent subscribers from using traceroute to discover the network addresses that are in the public domain and configured on services. This prevent users from pinging such addresses.
ip local-address

Configures the local-side IP address of the subscriber's point-to-point connection.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
ip local-address ip_address
no ip local-address

no
Removes a previously configured IP local-address.

ip_address
Specifies an IP address configured in a destination context on the system through which a packet data
network can be accessed.
```

**Usage**

This parameter specifies the IP address on the system that the MS uses as the remote-end of the PPP
connection. If no local address is configured, the system uses an “unnumbered” scheme for local-side
addresses.

**Example**

The following command configures a local address of 192.168.1.23 for the MS:

```
local-address 192.168.1.23
```
ip multicast discard

Configures the IP multicast discard packet behavior.

Product
GGSN

Privilege
Security Administrator, Administrator

Syntax

[ no ] ip multicast discard

no

Removes a previously configured IP multicast discard.

Usage

This command specifies if IP multicast discard is enabled or disabled.
ip qos-dscp

Configures quality of service options for the current subscriber using the differentiated services code point method. This is disabled by default.

Product
All

Privilege
Security Administrator, Administrator

Syntax

ip qos-dscp option
no ip qos-dscp

no
Sets the quality of service option to its default value.

option
Default: be
Specifies the subscriber’s per hop quality of service setting as one of:
- af11 (assured Forwarding 11)
- af12 (assured Forwarding 12)
- af13 (assured Forwarding 13)
- af21 (assured Forwarding 21)
- af22 (assured Forwarding 22)
- af23 (assured Forwarding 23)
- af31 (assured Forwarding 31)
- af32 (assured Forwarding 32)
- af33 (assured Forwarding 33)
- af41 (assured Forwarding 41)
- af42 (assured Forwarding 42)
- af43 (assured Forwarding 43)
- be (best effort forwarding)
- ef (expedited forwarding)

Usage
Set the quality of service for a subscriber based upon the service level agreements.

Example
ip qos-dscp ef
no ip qos-dscp
**ip route**

Configures the static route to use to reach the subscriber’s network.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] ip route ip_address ip_mask [ gateway_address ]
```

- **no**
  Removes the configured route information from the subscriber data.

- **ip_address**
  Specifies the target IP address for which the route information applies.

- **ip_mask**
  Specifies the networking mask for the route.
  1 bits in the `ip_mask` indicate that bit position in the `ip_address` must also have a value of 1.
  0 bits in the `ip_mask` indicate that bit position in the `ip_address` does not need to match, i.e., the bit can be either a 0 or a 1.
  For example, if the IP address and mask were specified as 172.168.10.0 and 255.255.255.224, respectively, the network mask will be 172.168.0.0 (obtained by logically ANDing the IP address with the IP mask).

- **gateway_address**
  Default: assigned remote IP address will be used as the gateway address.
  Specifies the IP address of the next hop gateway for the route.

**Usage**
The static routes are also known as framed IP routes for subscribers. Static routes are typically applicable for subscribers connecting via other networks or when the mobile device acts as a gateway to a network on the far side of the device.
For example, if the mobile device is assigned IP address 1.2.3.4 and it acts as a gateway for the network 10.2.3.0 (with a network mask of 255.255.255.0) a static route would be configured with the `ip_address` being 10.2.3.0, `ip_mask` being 255.255.255.0, and `gateway_address` being 1.2.3.4.

**Example**

```
no ip route 1.2.3.4 1.2.0.0
no ip route 1.2.3.4 1.2.0.0 1.2.255.254
```
ip source-validation

Enables/disables packet source validation for the current subscriber. Source validation requires the source address of received packets to match the IP address assigned to the subscriber (either statically or dynamically) during the session.

If an incorrect source address is received from the mobile node, the system attempts to renegotiate the PPP session. The parameters for IP source validation can be set by the `ip source-violation` command.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] ip source-validation
```

```
no

Disables source validation.
```

**Usage**

Source validation is useful if packet spoofing is suspected or for verifying packet routing and labeling within the network.

**Example**
The following command enables IP source validation:

```
ip source-validation
```

The following command disables IP source validation:

```
no ip source-validation
```
ip user-datagram-tos copy

This CLI controls copying of IP TOS octet value from IPv4/IPv6 datagrams to the IP header in tunnel encapsulation. This is disabled by default.

Product
PDSN, HA

Privilege
Security Administrator, Administrator

Syntax

```
ip user-datagram-tos copy [ access-link-tunnel | both | data-tunnel ]
no ip user-datagram-tos copy
```

no
Disable copying of the IP TOS octet value to all tunnel encapsulation IP headers.

```
access-link-tunnel
Copy the IP TOS octet value to the tunnel encapsulation IP header on the access side (RP) tunnel.
```

```
both
Use both access-link-tunnel and data-tunnel.
```

```
data-tunnel
Copy the IP TOS octet value to the tunnel encapsulation IP header on the MIP data tunnel or L3 tunnel (IP-in-IP, GRE).
```

Usage
Use this command to enable the copying of the IP TOS octet value to the tunnel encapsulation IP header. This functionality will enable PCF to detect special TOS marking in the outer IP header of A11 packets and to identify certain packets as QChat control messages. The BSC/PCF must give higher priority to QChat control messages.

Example
Enable copying of the IP TOS octet value to the tunnel encapsulation IP header for the access side tunnel by entering the following command:

```
$ ip user-datagram-tos copy access-link-tunnel
```

Disable copying of the IP TOS octet value to all tunnel encapsulation IP headers by entering the following command:

```
$ no ip user-datagram-tos copy
```
ip vlan

Configures subscriber-to-Virtual LAN (VLAN) associations.

Product
PDSN, HA

Privilege
Security Administrator, Administrator

Syntax

ip vlan vlan-id

[ default | no ] ip vlan

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resets the vlan ID to the default setting.</td>
</tr>
</tbody>
</table>

| no |
| Disables the vlan ID for the subscriber. |

| vlan-id |
| Is the vlan ID that is associated with the IP address for that session. vlan-id is an integer between 1 and 4094. |

Usage
This command configures the subscriber vlan ID which is used with the assigned address for the subscriber session to receive packets. If the IP pool from which the address is assigned is configured with a vlan ID, then this subscriber configured vlan ID overrides it. Subscriber traffic can be routed to specific VLANs based on the configuration of their user profile. Using this functionality provides a mechanism for routing all traffic from a subscriber over the specified VLAN. All packets destined for the subscriber must also be sent using only IP addresses valid on the VLAN or they will be dropped.

Example
Set the vlan ID to the default setting by entering the following command:

default ip vlan
**ipv6 access-group**

Configures the IPv6 access group for a subscriber.

**Product**
PDSN, GGSN, ASN GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
ipv6 access-group name [ in | out ]
```

- **in**
  Defines the access group as inbound.

- **out**
  Defines the access group as outbound.

**Usage**
Used to create an access group for a subscriber.

**Example**
The following command provides an example of an IPv6 access group with the name `list_1`:

```
ipv6 access-group list_1
```
ipv6 address

Configures a static IP address for use by the subscriber.

**Product**
PDSN, GGSN, ASN GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] ipv6 address { prefix address | prefix-pool name }
```

- **no**
  Deletes a previously configured ipv6 address.

- **prefix**
  Specifies a static IPv6 address.

- **prefix-pool**
  Specifies an IPv6 prefix pool name.

**Usage**

Use this command to assign a static IPv6 address to the subscriber. This address will be used each time the subscriber establishes data sessions.

**Example**

The following command configures a static IP address of 1:1:1:1:1:1:1:1 with a length of 24 to the subscriber:

```
ipv6 address 1:1:1:1:1:1:1:1/24
```
ipv6 dns

Configures the IPv6 Domain Name Service (DNS) servers.

Product
PDSN, GGSN, ASN GW

Privilege
Security Administrator, Administrator

Syntax

[ no ] ipv6 dns { primary | secondary } { ipv6_dns_address }

- no
  Deletes a previously configured DNS server.

- primary
  Configures the primary DNS server for the subscriber.

- secondary
  Configures the secondary DNS server for the subscriber. Only one secondary DNS server can be configured.

- ipv6_dns_address
  Configures the IP address of the DNS server.

Usage
DNS servers are configured on a per subscriber basis. This allows each subscriber to use specific servers.

Example
The following command provides an example of setting the primary IPv6 DNS server:

```
ipv6 dns primary 1::1:1:1:1:1:1:1
```
ipv6 dns-proxy

Configures the domain name server proxy for the current subscriber.

Product
PDSN, GGSN, ASN GW

Privilege
Security Administrator, Administrator

Syntax

[ default | no ] ipv6 dns-proxy

  default
  Disables the IPv6 DNs proxy functionality for a subscriber.

  no
  Removes the pre-enabled functionality of IPv6 DNS proxy for subscriber.

  dns-proxy
  Enables IPv6 DNS proxy functionality for a subscriber. If the functionality enabled, PDSN will act as a proxy DNS server. Default: disabled.

Usage
Used to enable/disable IPv6 DNS proxy for the subscriber. When enabled, the PDSN acts as a proxy DNS server for DNS IPv6 queries coming from the mobile station to the PDSN’s local PPP link address.

Example
The following command provides an example of disabling an IPv6 DNS proxy for the subscriber:

  no ipv6 dns-proxy
**ipv6 egress-address-filtering**

Configures the egress address filtering for the subscriber.

**Product**
- PDSN, GGSN, ASN GW

**Privilege**
- Security Administrator, Administrator

**Syntax**

```
[ no ] ipv6 egress-address-filtering
```

- **no**
  - Disables IPv6 egress address filtering.

- **ipv6 egress-address-filtering**
  - Enables IPv6 egress address filtering.

**Usage**

Used to filter packets that arrive from the internet to a particular site.

**Example**

The following command provides an example disabling egress address filtering:

```
no ipv6 egress-address-filtering
```
**ipv6 initial-router-advt**

Creates an IPv6 initial router advertisement interval for the subscriber.

**Product**
PDSN, GGSN, ASN GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
ipv6 initial-router-advt { interval value | num-advts value }
default ipv6 initial-router-advt { interval | num-advts }
```

**default**

Resets interval or num-advts to their default setting.

**interval value**

Default: 3000ms
The time interval the initial IPv6 router advertisement is sent to the mobile node in milliseconds.
value is an integer between 100 and 16000 milliseconds.

**num-advts value**

Default: 3
The number of initial IPv6 router advertisements sent to the mobile node.
value is an integer between 1 to 16.

**Usage**

This command is used to set the advertisement interval and the number of advertisements. Using a smaller advertisement interval increases the likelihood of router being discovered more quickly when it first becomes available.

**Example**

The following command specifies the initial ipv6 router interval to be 2000ms:

```
ipv6 initial-router-advt interval 2000
```
**ipv6 interface-id**

Provides an IPv6 interface ID for the subscriber.

**Product**
- PDSN, GGSN, ASN GW

**Privilege**
- Security Administrator, Administrator

**Syntax**

```
ipv6 interface-id ifid

[ default | no ] ipv6 interface-id
```

**default**
No interface id set for IPv6CP negotiation to subscriber.

**no**
Deletes a previously configured ipv6 interface id.

**interface-id ifid**
It is a interface ID assigned to the Mobile during IPv6CP negotiation.
`ifid` is a 64 bit unsigned integer.

**Usage**
Used to provide a IPv6 ifid for the subscriber when using 6to4 routing.

**Example**
The following command provides an example of assigning an IPv6 interface ID of `00-00-00-05-47-00-37-44` to the subscriber:

```
ipv6 interface-id 00-00-00-05-47-00-37-44
```
**ipv6 minimum-link-mtu**

Configures the IPv6 minimum-link-MTU value.

**Product**
PDSN, GGSN, ASN GW

**Privilege**
.Security Administrator, Administrator

**Syntax**

```
ipv6 minimum-link-mtu value

default ipv6 minimum-link-mtu

default
Resets minimum link MTU to their default setting.
Default: 1280

value
Default: 1280
value is an integer between 100 and 2000 MTUs.
```

**Usage**
Used to override the IPv6 minimum link MTU values recommended by the standard.

**Example**
The following command provides an example of assigning an IPv6 minimum link MTU to 1580 to the subscriber:

```
ipv6 minimum-link-mtu 1580
```
**ipv6 secondary-address**

Configures additional IPv6 4-bit prefixes to the subscriber session.

**Product**

PDSN, GGSN, ASN GW

**Privilege**

Security Administrator, Administrator

**Syntax**

```
[ no ] ipv6 secondary-address { prefix ipv6_address_prefix | prefix-pool pool_name }
```

- **no**
  
  Deletes a previously configured ipv6 secondary address.

- **ipv6_address_prefix**
  
  The IPv6 secondary address and must be specified using colon notation.

- **pool_name**
  
  The name given to the secondary address prefix pool (a string size from 1 to 31 characters).

**Usage**

An IPv6 prefix pool name may be configured for a dynamic prefix, while the prefix is static. This command may be executed multiple times to configure multiple prefixes.

**Example**

The following command provides an example of assigning an IPv6 secondary address prefix-pool name of `eastcoast` to the subscriber:

```
ipv6 secondary-address prefix-pool eastcoast
```
l2tp send accounting-correlation-info

This command enables the L2TP LAC to send accounting correlation information (Correlation-Id, NAS-IP-Address and NAS-ID) in L2TP control message (ICRQ) during session setup to LNS.

Product
PDSN, LNS, LAC

Privilege
Security Administrator, Administrator

Syntax

[ no | default ] l2tp send accounting-correlation-info

no
Disables the command and sets the setting to default mode for this subscriber.

default
Sets the setting to default mode of disable.

Usage
Use this command to enable the L2TP LAC to send accounting correlation information (Correlation-Id, NAS-IP-Address and NAS-ID) in L2TP control message (ICRQ) during session setup to LNS for this subscriber. LNS can be configured to include this information in ACS billing records, so that billing servers can easily correlate accounting records from PDSN/LAC and LNS. By default, this mode is disabled.

Example
Following command disables the inclusion of accounting correlation information in control messages during session setup to LNS for a subscriber:

default l2tp send accounting-correlation-info
l3-to-l2-tunnel address-policy

Configure the subscriber address allocation/validation policy, when subscriber L3 (IPV4) sessions are tunneled using an L2 tunneling protocol (e.g. L2TP).

**Product**
HA, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
l3-to-l2-tunnel address-policy { alloc-only | alloc-validate | no.alloc-validate }
```

**Usage**
Use this command to configure the L3 to L2 tunnel address policy for MIP HA sessions tunneled from the system using L2TP tunnels or for GGSN IP Context sessions tunneled using L2TP to a remote LNS. Also refer to the `resource` keyword of the context configuration mode `ip pool` command.

**Example**
To set the L3 to L2 tunnel address policy so that the current subscriber must have IP addresses allocated and validated locally on the system, enter the following command:

```
l3-to-l2-tunnel address-policy alloc-validate
```
loadbalance-tunnel-peers

Configures the load balancing of traffic bound for L2TP tunnels configured on the system for the selected subscriber.

**Product**
L2TP

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
loadbalance-tunnel-peers { balanced | prioritized | random }
```

- **balanced**
  Enables the equal use of all configured tunnel peers (LNSs) for the selected subscriber.

- **prioritized**
  Enables the use of all configured tunnel peers (LNSs) for the selected subscriber based on the preference number assigned to the peer address.

- **random**
  Default: Enabled
  Enables the random use of all configured tunnel peers (LNSs) for the selected subscriber.

**Usage**
Use to manage traffic loads on LAC ports and their respective L2TP Network Servers.

**Example**
Use the following command to randomly use all configured tunnel peers (LNSs):

```plaintext
loadbalance-tunnel peers random
```
long-duration-action

This command specifies what action is taken when the long duration timer expires.

**Product**
All

**Privilege**
Administrator

**Syntax**

```
long-duration-action { detection | disconnection [ dormant-only ] [ suppress-notification ] }
```

**detection**
Default: Enabled
Detects long duration sessions and sends SNMP TRAP and CORBA notification. This is the default behavior. Use this command to detect a session exceeding the limit set by the long duration timer.

**disconnection [ dormant-only ] [ suppress-notification ]**
Default: Disabled
Detects a long duration session and disconnects the session after sending SNMP TRAP and CORBA notification.

- `suppress-notification`: Suppress the SNMP TRAP and CORBA notification after detecting and disconnecting a long duration session. Default: Disabled
- `dormant-only`: Disconnects the dormant sessions after long duration timer and inactivity time with idle time-out duration expires. If the long duration timeout is fired and the call is not dormant, the call is disconnected when the call later moves to dormancy.

**Important:** For HA calls, the inactivity-time is considered as gauge for dormancy.

It sends the SNMP TRAP and CORBA notification after disconnecting a long duration session. Default: Disabled

**Usage**
Use this command to determine what action is taken when a session exceeds the limit set by the long duration timer.

**Example**
Use the following command to enable disconnecting sessions that exceed the long duration timer:

```
long-duration-action disconnection
```

Use the following command to disconnect the session that exceed the long duration timer without sending SNMP TRAP and CORBA notification:
long-duration-action disconnection suppress-notification

Use the following command to disconnect the session that is in dormant and exceed the long duration timer and send SNMP TRAP and CORBA notification:

long-duration-action disconnection dormant-only

Note that in case of HA calls, the inactivity-time is considered as gauge for dormancy.
**mobile-ip**

Enables/disables the subscriber for mobile IP services and access.

**Product**
HA, FA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] mobile-ip { allow-aaa-address-assignment | dns-address source-priority { aaa | home-agent } | gratuitous-arp aggressive | home-agent ip_address [alternate] | match-aaa-assigned-address | mn-aaa-removal-indication | mn-ha-hash-algorithm { hmac-md5 | md5 | rfc2002-md5 } | mn-ha-shared-key key | mn-ha-spi spi_num | reverse-tunnel | security-level { ipsec | none } | send { accounting-correlation-info | dns-address | imsi | terminal-verification } }
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Disables the mobile IP option specified.</td>
</tr>
<tr>
<td>allow-aaa-address-assignment</td>
<td>Enables the FA to accept a home address assigned by an AAA server. This should only be configured on the FA side.</td>
</tr>
<tr>
<td>dns-address source-priority { aaa</td>
<td>home-agent }</td>
</tr>
<tr>
<td>gratuitous-arp aggressive</td>
<td>Default: Disabled. When enabled, this mode will cause the HA to send out gratuitous ARP messages for all Mobile IP (MIP) registration renewals and handoffs. To disable this mode, use the no form of this command.</td>
</tr>
</tbody>
</table>

**Important**: This mode will only work for IP addresses that have been assigned from a static IP address pool.
home-agent ip_address [alternate]
Specifies the IP address of the mobile IP user’s home agent. ip_address must be a IPv4/IPv6 address.
alternate - Specifies the secondary, or alternate, Home Agent to use when Proxy Mobile IP HA Failover is enabled.

match-aaa-assigned-address
Default: Disabled.
Enables the FA to validate the home address in the RRQ against the one assigned by AAA server. This should only be configured on the FA side.

mn-aaa-removal-indication
Default: Disabled.
When enabled, the MN-FA challenge and MN-AAA Authentication extensions are removed when relaying a Registration Request (RRQ) to the Home Agent (HA)

mn-ha-hash-algorithm { hmac-md5 | md5 | rfc2002-md5 }
Specifies the encryption algorithm to use.
Default: hmac-md5
hmac-md5: Use HMAC-MD5 hash algorithm, as defined in RFC-2002bis. This is the default algorithm.
md5: Use the MD-5 hash algorithm.
rfc2002-md5: Use the MD-5 hash algorithm variant as defined in RFC-2002.

mn-ha-shared-key key
This is the used to verify the MN-HA Authentication for a local subscriber in the current context. A string or a Hexadecimal number beginning with "0x" up to 127 bytes

mn-ha-spi spi_num
Specifies the SPI number. spi_nummust be an integer from 256 through 4294967295.

reverse-tunnel
Default: enabled.
Enables the mobile IP user’s for reverse IP tunnels. The no keyword is used to disable this option.

security-level { ipsec | none }
Default: none
The security-level option configures the security level needed for the subscriber's traffic.
ipsec: both MIP control and data traffic are secured with IPSEC
none: none of the traffic is secured

**Important:** This keyword corresponds to the 3GPP2-Security-Level RADIUS attribute. This attribute indicates the type of security that the home network mandates on the visited network.

**Important:** For this attribute, integer value: 3 : Enables IPSec for tunnels and registration messages 4 : Disables IPSec
Subscriber Configuration Mode Commands

---

**send { accounting-correlation-info | dns-address | imsi | terminal-verification }**

**accounting-correlation-info**: Configures whether the FA sends the correlation info to the NVSE in the RRQ. Default is disabled.

**dns-address**: Enables the HA to send the DNS address NVSE in the RRP. Default is disabled. This should only be enabled on the HA side.

**imsi**: Configures sending the IMSI NVSE in the RRQ. Default is sending IMSI in custom-1 format.

**terminal-verification**: Enables the FA to send the terminal verification NVSE in the RRQ. Default is disabled. This should only be enabled on the FA side.

---

**Important**: send dns-address is a proprietary feature developed for a specific purpose and requires the MN to be able to renegotiate IPCP for DNS addresses and reregister MIP if necessary. Since this feature needs the MN to support certain PPP/MIP behavior, and not all MNs may support that particular behavior, send dns-address should be enabled only after careful consideration.

---

**Usage**

Use as subscriber service contracts change.

---

**Example**

```
mobile-ip home-agent
1.2.3.4

no mobile-ip reverse-tunnel
```
mobile-ip ha

Accommodates two MIP HA options in subscriber mode.

Product
PDSN, HA, ASN GW

Privilege
Security Administrator, Administrator

Syntax

[ no ] mobile-ip ha { assignment-table name | ignore-unknown-ha-addr-error }

no
Disables the mobile IP HA option specified.

assignment-table name
The name of an existing MIP HA Assignment table.
name must be a string of alphanumeric characters from 1 through 63 characters in length.

ignore-unknown-ha-addr-error
Default is disabled.
Enables or disables the HA to accept or reject the RRQ from a particular subscriber.

Usage
Use this command to assign a MIP HA Assignment table to the current subscriber.
Use this command to disable or enable the HA to accept or reject the RRQ from a particular subscriber when
the HA address in the incoming MIP RRQ is not the same as the HA service address. The feature is off by
default which causes the RRQ to be rejected with the error code UNKNOWN_HOME_AGENT.

Example
The following command assigns the MIP HA Assignment table named Atable1 to the current subscriber:

    mobile-ip ha assignment-table Atable1

The following command sets ignore-unknown-ha-addr-error to its default disabled state:

    no mobile-ip ha ignore-unknown-ha-addr-error
mobile-ip reg-lifetime-override

This command overrides the mobile IP registration lifetime from HA with value configured for subscriber.

**Product**
PDSN, HA, ASN-GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
mobile-ip reg-lifetime-override [ dur | infinite ]
[ default | no ] mobile-ip reg-lifetime-override
```

* **dur**
  Default: 100 secs.
  This the configurable value in seconds.
  Dur must be an integer from 1 through 65534.

* **infinite**
  Sets the mobile IP registration lifetime override value to infinite for a particular subscriber.

* **default**
  Sets the value of mobile IP registration lifetime override option to 100 seconds.

* **no**
  Disables the mobile IP registration lifetime override option specified.

**Usage**

Use this command to configure MIP registration-lifetime per realm/domain. This value overrides the default lifetime configured under HA service.

**Example**
The following command overrides the mobile IP registration lifetime value from HA service and assigns the MIP registration lifetime to 100 seconds for the current subscriber:

```
default mobile-ip reg-lifetime-override
```
mobile-ip send accounting-correlation-info

Enables the sending call correlation information NVSE’s to the HA in MIP RRQ.

**Product**
PDSN, HA, ACS

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ default | no ] mobile-ip send accounting-correlation-info
```

**default**
Disables the support for sending call correlation information NCSE’s to the HA in MIP RRQ.
This is the default mode.

**no**
Removes the configured support for sending call correlation information.

**Usage**
Use this command to support PDSN-Correlation-ID VSE and send the call correlation information.

**Example**
The following command enables sending call correlation information NVSE’s to the HA in MIP RRQ

```
mobile-ip send accounting-correlation-info
```
mobile-ipv6

Configures Mobile IPv6 related parameters for a subscriber.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

[ default | no ] mobile-ipv6 { home-address ipv6_address | home-agent ipv6_address | home-link-prefix ipv6_address | tunnel mtu value }

default
Disables the support for sending call correlation information NCSE’s to the HA in MIP RRQ. This is the default mode.

no
Removes the configured support for sending call correlation information.

home-address ipv6_address
Specifies the home address for the subscriber. ipv6_address must be a an IPv6 address in colon notation.

home-agent ipv6_address
Specifies the IPv6 address of the mobile IP user’s home agent. ipv6_address must be a an IPv6 address in colon notation.

home-link-prefix ipv6_address
Specifies the IPv6 address of the mobile IP user’s home link. ipv6_address must be a an IPv6 address in colon notation.

tunnel mtu value
Configures the tunnel MTU for the IPv6 tunnel between the HA and the mobile node. value must be an integer between 1024 and 2000. The default is 1500.

Usage
This command sets the mobile-ipv6 parameters for a subscriber. Use this command to set the home-address, home-agent, and home-link prefix.

Example
Use the following command to set the tunnel value to 1800:

    mobile-ipv6 tunnel mtu 1800
nai-construction-domain

After authentication, the domain name set by this command replaces the NAI constructed domain for subscriber.

Product
All

Privilege
Security Administrator, Administrator

Syntax

nai-construction-domain  domain_name

no nai-construction-domain

  domain_name
  Defines the domain name to use to replace the NAI constructed domain name. This must be a string of 1 to 79 characters.

  no
  Deletes the defined domain name.

Usage
Define or delete a domain name to use to replace the NAI constructed domain name after authentication.

Example
To set the domain name to private1 use the following command:

  nai-construction-domain  private1

To delete the previously configured domain name, use the following command:

  no nai-construction-domain
nbns

Configures and Enables use of NetBios Name Service for the subscriber.

**Product**
GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
 nbns { primary IPv4-address | secondary IPv4-address }
 no nbns { primary [ IPv4-address ] | secondary [ IPv4-address ] }
```

- **primary**
  Designates primary NBNS server. Must be followed with IPv4 address in dotted-decimal notation.

- **secondary**
  Designates secondary/failover NBNS server. Must be followed with IPv4 address in dotted-decimal notation.

- **IPv4-address**
  Specifies the IPv4 address used for this service.

- **no**
  Removes/disables use of a previously configured NetBios Name Service.

**Usage**

This command specifies NBNS parameters. The NBNS option is present for both pdp type IP and pdp type PPP for GGSN.

The system can be configured to use of NetBios Name Service for the APN.

**Example**

The following command configures the subscriber’s NetBios Name Service to primary IP 192.168.1.15:

```
 nbns primary 192.168.1.15
```
nexthop-forwarding-address

Configures the next hop forwarding address for the subscriber.

**Product**
PDSN, GGSN, ASN GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
no nexthop-forwarding-address

ip_address
```

- **ip_address**
  - Configures the IP address of the nexthop forwarding address.

- **no**
  - Disables this function. This is the default setting.

**Usage**
Use this command to configure the next hop forwarding address for the subscriber.

**Example**
The following command configures the next hop forwarding address to 1.1.1.1 using IPv4:

```
nexthop-forwarding-address 1.1.1.1
```
npu qos

Configures an NPU QoS priority queue for packets from the subscriber.

Product
PDSN, GGSN, ASN GW

Privilege
Security Administrator, Administrator

Syntax

npu qos traffic priority { best-effort | bronze | derive-from-packet-dscp | gold | silver }

- **best-effort**
  Assigns the best-effort queue priority. This is the lowest priority.

- **bronzel**
  Assigns the bronze queue priority. This is the third-highest priority.

- **derive-from-packet-dscp**
  Default: Enabled
  Specifies that the priority is to be determined from the DS field in the packet's TOS octet.

- **gold**
  Assigns the gold queue priority. This is the highest priority.

- **silver**
  Assigns the silver queue priority. This is the second-highest priority.

Usage
This command is used in conjunction with the Network Processing Unit (NPU) Quality of Service (QoS) functionality.
The system can be configured to determine the priority of a subscriber packet either based on the configuration of the subscriber, or from the differentiated service (DS) field in the packet's TOS octet (representing the differentiated service code point (DSCP) value).
Refer to the System Administration and Configuration Guide for additional information on NPU QoS functionality.

**Important:** This functionality is not supported for use with the PDSN at this time.

Example
The following command configures the subscriber’s priority queue to be gold:
npu qos traffic priority gold
nw-reachability-server

Bind the name of a configured network reachability server to the current subscriber and enable network reachability detection.

**Product**
HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
nw-reachability server server_name
```

```
no nw-reachability server
```

*server_name*

The name of a network reachability server that has been defined in the current context. This is a string of from 1 through 16 characters.

```
no nw-reachability server
```

Delete the name of the network reachability server from the current subscribers configuration and disable network reachability failure detection for the current subscriber.

**Usage**

Use this command to define the network reachability server for the current subscriber and enable network reachability failure detection for the current subscriber. If a network reachability server is defined in an IP pool, that setting takes precedence over this command.

**Important:** Refer to the HA configuration mode command `policy nw-reachability-fail` to configure the action that should be taken when network reachability fails.

**Important:** Refer to the context configuration mode command `nw-reachability server` to configure network reachability servers.

**Important:** Refer to the `nw-reachability server server_name` keyword of the `ip pool` command in the context configuration mode chapter to bind the network reachability server to an IP pool.

**Example**

To bind a network reachability server named `InternetDevice` to the current subscriber, enter the following command:

```
nw-reachability server InternetDevice
```
outbound

Configures the subscriber host password for use in authentication of PPP sessions.

Product
All

Privilege
Security Administrator, Administrator

Syntax

outbound [ encrypted ] password pwd

no outbound password

[outbound [ encrypted ] password pwd

Specifies the password to use for point-to-point protocol session host authentication. The encrypted keyword indicates the password specified uses encryption.

The password specified as pwd must be from 1 to 63 alpha and/or numeric characters without encryption and must be from 1 to 127 alpha and/or numeric characters when encryption has been indicated.

The encrypted keyword is intended only for use by the chassis while saving configuration scripts. The system displays the encrypted keyword in the configuration file as a flag that the variable following the password keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file.

no outbound password

Used to clear the outbound password configuration from the subscriber data.

Usage

Set the outbound (egress) password for increased security.

Example

outbound password secretPwd
outbound encrypted password scrambledPwd
no outbound password
overload-disconnect

Sets the threshold parameter for overload disconnect.

Product
ASN GW, HA, PDIF, PDSN, PHS GWPDG/TTG

Privilege
Security Administrator, Administrator

Syntax

overload-disconnect [ threshold { inactivity-time inactivity_time_threshold | connect-time connect_time_threshold } ]

[ default | no ] overload-disconnect [ threshold { inactivity-time | threshold connect-time } ]

<table>
<thead>
<tr>
<th>threshold inactivity-time inactivity_time_threshold</th>
</tr>
</thead>
</table>
| Sets the inactivity time threshold in seconds. This value must be from 0 to 4294967295. The default value of zero disables this feature. If inactivity-time for the subscriber’s session is greater than inactivity_time_threshold, the session becomes a candidate for disconnection.

<table>
<thead>
<tr>
<th>threshold connect-time connect_time_threshold</th>
</tr>
</thead>
</table>
| Sets the connection time threshold in seconds. This value must be from 0 to 4294967295. A value of zero disables this feature. If connect-time for the subscriber’s session is greater than connect_time_threshold, the session becomes a candidate for disconnection.

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
</table>
| This command enables the default condition for this subscriber.

<table>
<thead>
<tr>
<th>no</th>
</tr>
</thead>
</table>
| Disables the overload disconnect feature for this subscriber. This is the default condition for PDIF.

Usage

Set a subscriber’s overload disconnect threshold in seconds, based on either inactivity or connection time. When this threshold is exceeded during a session, the subscriber’s session becomes a candidate for disconnection. To set overload-disconnect policies for the entire chassis, see congestion-control overload-disconnect in Global Configuration Mode Commands.

Example

overload-disconnect threshold inactivity-time inactivity_time_threshold
default overload disconnect threshold connect-time
no overload-disconnect threshold connect-time
no overload disconnect
password

Configures the subscribers password for the current context.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
[ encrypted ] password pwd

no password
```

**encrypted**

Indicates the password provided is encrypted.

The `encrypted` keyword is intended only for use by the chassis while saving configuration scripts. The system displays the `encrypted` keyword in the configuration file as a flag that the variable following the `password` keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file.

**pwd**

Specifies the users password for authentication. `pwd` must be from 1 to 63 alpha and/or numeric characters or from 1 to 127 characters if the `encrypted` keyword was specified. A “null” password is allowed and is entered as consecutive quotes (""). See Example(s) for correct syntax.

**Important:** Subscribers configured with a null password will be authenticated using PAP and CHAP (MD5) only. Subscribers configured without a password (`no password`) will only be able to access services if the service is configured to allow no authentication.

**no**

Used to clear the subscriber password configuration from the subscriber data.

**Important:** Subscribers with no password will only be able to access services if the service is configured to allow no authentication.

**Usage**

Password management is critical to system security and all precautions should be taken to ensure passwords are not shared or to easily deciphered.

**Example**

```plaintext
password secretPwd
password ""
```
no password
pdif mobile-ip

Configures PDIF subscriber call setup parameters.

Product
PDIF

Privilege
Security Administrator, Administrator

Syntax
[ default | no ] pdif mobile-ip { release-tia | required | simple-ip-fallback }

Usage
Use this command to configure specific behavior for the PDIF subscriber during call setup.

Example
The following command enables the system to fall back to Simple IP when Mobile IP fails for this subscriber during call setup:

```
pdif mobile-ip simple-ip-fallback
```
permission

Enables/disables the ability to access wireless data services for the current subscriber.

Product
PDSN, HA

Privilege
Security Administrator, Administrator

Syntax

[ no ] permission { ha-mobile-ip | pdsn-mobile-ip | pdsn-simple-ip }

- *no*
  - Disables the usage of the specified service.

- *ha-mobile-ip | pdsn-mobile-ip | pdsn-simple-ip*
  - *ha-mobile-ip*: enable/disable the home agent support for mobile IP service.
  - *pdsn-mobile-ip*: enable/disable the packet data and foreign agent support for mobile IP service.
  - *pdsn-simple-ip*: enable/disable the packet data support for simple IP service.

Usage
This is necessary per the services the subscriber is allowed to access in the current context.

Example

permission pdsn-mobile-ip

no permission ha-mobile-ip
policy ipv6 tunnel

Tunnel MTU for IPv6 Tunnel between HA and Mobile Node.

Product
PDSN, HA

Privilege
Security Administrator, Administrator

Syntax

```
policy ipv6 tunnel mtu exceed { fragment | notify-sender }
```

```
mtu exceed { fragment | notify-sender }

fragment: Adjust Tunnel MTU and Fragment Packets
notfiy-sender: Send a ICMPv6 Packet Too Big the original sender
```

Usage
Use this command to configure Tunnel MTU for IPv6 Tunnel between HA and Mobile Node.

Example

```
policy ipv6 tunnel mtu exceed fragment
```
**policy-group**

This command assigns/removes a flow-based traffic policy group to a subscriber.

**Product**
PDSN, HA, ASN GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
[ no ] policy-group policy_group_name direction { in | out }
```

- **no**
  Removes assigned policy group from a subscriber configuration.

- **policy_group_name**
  Specifies the traffic policy group name for a subscriber session flow pre-configured within a destination context. The `policy_group_name` must consist of from 1 to 15 alpha and/or numeric characters in length and is case sensitive.

- **direction { in | out }**
  Specifies the direction of flow in which the traffic policies need to be applied.
  - **in**: specifies the incoming traffic
  - **out**: specifies the outgoing traffic

**Usage**

Use this command to assign traffic policy group to a subscriber for traffic policing.

**Example**

```
policy-group traffic_policy_group1 direction in
```
**ppp**

Configures the point-to-point protocol options for the current subscriber.

**Product**

PDSN, GGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
ppp { accept-peer-ipv6-ifid | always-on-vse-packet | data-compression { mode { normal | stateless } | protocols { protocols [ protocols ] } | ip-header-compression negotiation { detect | force | vj compress-slot-id { both | none | receive | transmit } } | ipv4 { disable | enable | passive } | ipv6 { disable | enable | passive } | keepalive seconds | min-compression-size min_octets | mtu max_octets | remote-renegotiation disconnect { always | nai-prefix-msid-mismatch } } }

default ppp { accept-peer-ipv6-ifid | always-on-vse-packet | data-compression { mode | protocols } | ip-header-compression negotiation { vj compress-slot-id } | ipv4 | ipv6 | keepalive | min-compression-size | mtu | remote-renegotiation disconnect }

no ppp { accept-peer-ipv6-ifid | always-on-vse-packet | data-compression protocols | ipv4 | ipv6 | keepalive | mtu | remote-renegotiation disconnect }
```

**default**

Restores the default value for the option specified.

**no**

Resets the option specified to its default.

**always-on-vse-packet**

Default: Enabled

If the always-on feature is enabled for a session, this keyword enables the PDSN to send special 3GPP2 VSE PPP packets to the Mobile Node with a max inactivity timer value. This configuration is applicable only for PDSN sessions.

**accept-ipv6-peer-ifid**

Default: None

This is used to configure a 6to4 tunnel. It controls the behavior of IPv6CP negotiation for Interface ID. If enabled, PDSN will accept a valid interface-id proposed by the peer.

**data-compression { mode { normal | stateless } | protocols { protocols [ protocols ] } }

Default: all protocols enabled.

Specifies the subscribers mode of data compression or the compression protocol to use.
mode: sets the mode of compression where modes must be one of:

- normal (packets are compressed using the packet history for automatic adjustment for best compression)
- stateless (each packet compressed individually)

protocols protocols: sets the compression protocol where protocols must be one of:

- deflate (DEFLATE algorithm)
- mppc (Microsoft PPP algorithm)
- stac (STAC algorithm)

ip-header-compression negotiation { detect | force | vj compress-slot-id { both | none | receive | transmit } }

Default: force
PPP IP compression Van Jacobson (VJ) negotiation scheme. This command is applicable only if IP header compression is enabled for the subscriber.

detect: The local side does not include the VJ Compression option in its IPCP configuration request unless the peer sends an IPCP NAK including a VJ compression option. If the peer requests the VJ compression option in its IPCP request the local side will ACK/NAK.

force: The IP header compression negotiation in IPCP happens normally. The local side requests the VJ compression option in its IPCP configure request. If the peer side requests VJ compression in its IPCP request, the local side will ACK/NAK the option.

vj compress-slot-id { both | none | receive | transmit }: This keyword configures the direction in which VJ slotid compression should be negotiated.

- both: If the client proposes VJ slotid compression, accept it and propose slotid compression for downlink and uplink.
- none: If the client proposes VJ slotid compression, NAK the offer, do not propose slotid compression for downlink.
- receive: (Default) If the client proposes VJ slotid compression in the uplink direction accept the configuration.
- transmit: Propose VJ slotid compression for uplink.

ipv4 { disable | enable | passive }

Default: enable
Controls IPCP negotiation during PPP negotiation.

disable: The PDSN does not negotiate IPCP with the mobile.
enable: The PDSN negotiates IPCP with the mobile.
passive: The PDSN initiates IPCP only when the mobile sends an IPCP request.

ipv6 { disable | enable | passive }

Default: enable
Controls IPv6CP negotiation during PPP negotiation.
disable: The PDSN does not negotiate IPCP with the mobile.
enable: The PDSN negotiates IPCP with the mobile.
passive: The PDSN initiates IPCP only when the mobile sends an IPCP request.

keepalive seconds

Default: 30
Specifies the frequency of sending the Link Control Protocol keep alive messages. seconds must be either 0 or in the range from 5 to 14400. The special value 0 disables the keep alive messages entirely.

```
min-compression-size min_octets
```
Default: 128
Specifies the smallest packet to which compression may be applied. min_octets must be a value in the range from 0 to 2000.

```
mtu max_octets
```
Default: 1500
Specifies the maximum size in octets the message transfer unit packets can reach. max_octets must be a value in the range from 100 to 2000.

```
remote-renegotiation disconnect { always | nai-prefix-msid-mismatch }
```
Default: Disabled
Terminates the already established PPP sessions if they are renegotiated by the remote side by sending LCP Conf-req/nak/ack. The following termination conditions are available:

- **always**: The session is automatically disconnected.
- **nai-prefix-msid-mismatch**: The session is disconnected only if the MSID of the session does not match NAI-Prefix (prefix before “@” for the NAI). The configuration of the renegotiated (new) NAI is used for the matching process.

**Usage**
Adjust packet sizes and compression to improve bandwidth utilization. Each network may have unique characteristics such that determining the best packet size and compression options may require system monitoring over an extended period of time.

**Example**
```
ppp data-compression protocols mode stateless
ppp mtu 500
no ppp data-compression protocols
no ppp keepalive
```
prepaid 3gpp2

Enables 3GPP2 compliant prepaid billing support for a subscriber to be configured by 3GPP2 attributes sent from a RADIUS server. If not enabled, prepaid attributes received from the RADIUS server are ignored.

Product
HA, PDSN

Privilege
Security Administrator, Administrator

Syntax

```bash
prepaid 3gpp2 { accounting [ no-final-access-request ] | duration-quota final-duration-algorithm { current-time | last-airlink-activity-time | last-user-layer3-activity-time } | preference { duration | volume } }

default prepaid 3gpp2 { duration-quota final-duration-algorithm | preference }

no prepaid 3gpp2 accounting
```

- **default prepaid 3gpp2 { duration-quota final-duration-algorithm | preference }
  - Sets the 3GPP2 Pre-paid settings to the default values.
  - **duration-quota final-duration-algorithm**: Reset the end of billing duration quota algorithm to the default of current-time.
  - **preference**: Reset the preference to duration, If both duration and volume attributes are present.

- **no prepaid 3gpp2 accounting**
  - Disables 3GPP2 prepaid accounting. All 3GPP2 Prepaid attributes received from a RADIUS server are ignored.

- **accounting [ no-final-access-request ]**
  - Default: Disabled
  - Enabled 3GPP2 prepaid accounting behavior.
  - Sets the low-watermark for remaining byte credits. `percentage` is a percentage of the subscriber sessions total credits. When the low-watermark is reached a new RADIUS access-request is sent to the RADIUS server to retrieve more credits. `percentage` must be an integer from 1 to 99.
  - **no-final-access-request**: Stops sending final online access-request on termination of 3GPP2 prepaid sessions. By default, this option is disabled.

- **duration-quota final-duration-algorithm { current-time | last-airlink-activity-time | last-user-layer3-activity-time }**
  - Define what behavior specifies the end of the billing duration for duration-based quota usage accounting. The default behavior is the duration quota algorithm set to current-time.
  - Default: current-time
  - **current-time**: Selects the duration quota as the difference between the session termination timestamp and the session setup timestamp.
  - **last-airlink-activity-time**: Selects the duration quota as the difference between the last-user-activity timestamp (G17) and the session setup timestamp.
last-user-layer3-activity-time: Selects the duration quota as the difference between the
timestamp of the last layer-3 packet sent to or received from the user and the session setup timestamp.

preference { duration | volume }
If both duration and volume RADIUS attributes are present this keyword specifies which attribute has
precedence.
Default: duration
duration: The duration attribute takes precedence.
volume: The volume attribute takes precedence

Usage
Use this command to enable prepaid support for a default user or for the default user of a domain alias.

Example
The following command enables 3GPP2 prepaid support for the default user:

    prepaid 3gpp2 accounting
prepaid custom

Enables custom prepaid billing support for a subscriber to be configured by attributes sent from a RADIUS server. If not enabled, prepaid attributes received from the RADIUS server are ignored. The keywords are to set prepaid values that are used if the corresponding RADIUS attribute is not present. If the RADIUS attribute is present it takes precedence over these values.

Product
HA, PDSN

Privilege
Security Administrator, Administrator

Syntax

```cpp
prepaid custom { accounting | byte-count compressed | low-watermark percent percentage | renewal interval seconds } | preference { duration | volume }

default prepaid custom { byte-count | low-watermark }

no prepaid custom { accounting | byte-count compressed | low-watermark | renewal }

default prepaid custom { byte-count | low-watermark }
```

- Reset custom prepaid settings to the default values.
- **byte-count**: Reset to the default of basing the prepaid byte credits on the flow of uncompressed traffic.
- **low-watermark**: Disable sending an access request to retrieve more credits when a low watermark is reached.

```cpp
no prepaid custom { accounting | byte-count compressed | low-watermark | renewal}
```

- **byte-count compressed**: The prepaid byte credits are based on the flow of uncompressed traffic. This is the default.
- **low-watermark**: Disables the low watermark feature. An access-request isn’t sent to the RADIUS server until the credits granted for the subscriber session are depleted.
- **renewal**: Disables time-based renewals for prepaid accounting.

```cpp
accounting
```

- Default: Disabled
- Enabled custom prepaid accounting behavior.

```cpp
byte-count compressed
```

- Default: uncompressed
- When compression is used, the prepaid byte credits are based on the flow of compressed traffic. The default is to base the prepaid byte credits on the flow of uncompressed traffic.

```cpp
low-watermark percent percentage
```

- Default: Disabled
Sets the low-watermark for remaining byte credits. `percentage` is a percentage of the subscriber sessions total credits. When the low-watermark is reached a new RADIUS access-request is sent to the RADIUS server to retrieve more credits. `percentage` must be an integer from 1 to 99.

**renewal interval** `seconds`

Default:
The time in seconds to wait before sending a new RADIUS access-request to the RADIUS server to retrieve more credits. `seconds` must be an integer from 60 through 65535.

**preference { duration | volume }**

If both duration and volume RADIUS attributes are present this keyword specifies which attribute has precedence.
Default: duration

- `duration`: The duration attribute takes precedence.
- `volume`: The volume attribute takes precedence

**Usage**

Use this command to enable prepaid support for a default user or for the default user of a domain alias.

**Example**

The following command enables custom prepaid support for the default user:

```
prepaid custom accounting
```
prepaid unclassify

This command provides customer specific functionality.
prepaid voice-push

This command provides customer specific functionality.
prepaid wimax

Enables WiMAX prepaid accounting for this subscriber. This feature is disabled by default.

**Product**
ASN GW

**Privilege**
Administrator

**Syntax**

```
[ no ] prepaid wimax accounting
```

```
no
Disables WiMAX prepaid accounting for this subscriber.
```

**Usage**

Use this command to enable WiMAX prepaid accounting for this subscriber.
proxy-dns intercept list-name

Identifies a proxy DNS intercept rules list for the selected subscriber.

Product
HA

Privilege
Security Administrator, Administrator

Syntax

[ no ] proxy-dns intercept list-name name

no
Remove the intercept list from the subscriber’s profile.

proxy-dns intercept list-name name
Specifies a name of a proxy DNS intercept list used for the selected subscriber. 
name is the name of the intercept list and must be a string from 1 to 63 characters in length.

Usage
Use this command to identify a proxy DNS rules list for the selected subscriber. For a more detailed explanation of the HA Proxy DNS Intercept feature, see the proxy-dns intercept-list command in the Context Configuration Mode Commands chapter.
**proxy-mip**

Configures support for Proxy Mobile IP for the subscriber.

**Product**

PDSN, GGSN, ASN GW, PDIF

**Privilege**

Security Administrator, Administrator

**Syntax**

```
[ no ] proxy-mip required
```

- **no**
  - Disables support for Proxy Mobile IP.

- **required**
  - Enables support for Proxy Mobile IP.

**Usage**

When enabled through the session license and feature use key, the system supports Proxy Mobile IP to provide a mobility solution for subscribers with mobile nodes (MNs) capable of supporting only Simple IP. For subscriber sessions using Proxy Mobile IP, R-P and PPP sessions get established as they would for a Simple IP session. However, the AGW/FA performs Mobile IP operations with an HA (identified by information stored in the subscriber’s profile) on behalf of the MN while the MN performs only Simple IP processes.

**Example**

The following command enables proxy mobile IP for the current subscriber:

```
proxy-mip required
```
qos rate-limit

Configure the action on subscriber traffic flow that violates or exceeds the peak/committed data rate under traffic policing functionality. When configured, the PDG/TTG performs traffic policing for the subscriber session. If the GGSN changes the QoS via an Update PDP Context Request, the PDG/TTG uses the new QoS values for traffic policing.

Product
PDG/TTG

Privilege
Security Administrator, Administrator

Syntax

qos rate-limit direction { downlink | uplink } [ class { background | conversational | interactive traffic_priority | streaming } ] [ exceed-action { drop | lower-ip-precedence | transmit } ] [ violate-action { drop | lower-ip-precedence | transmit } ]

noqosrate-limit direction( downlink | uplink ) [ class { background | conversational | interactive traffic_priority | streaming } ]

Disables the QoS data rate limit configuration for the APN.

downlink

Apply the specified limits and actions to the downlink (to the data coming from the GGSN over the Gn’ interface).

uplink

Apply the specified limits and actions to the uplink (to the data coming from the UE over the IPSec tunnel).

class { background | conversational | interactive traffic_priority | streaming }

Apply the specified limits and actions to the PDP contexts of the specified UMTS traffic class. The following classes are supported:

•background: Specifies the QoS for traffic patterns in which the data transfer is not time-critical (for example, e-mail exchanges). This traffic pattern should be the lowest QoS.

•conversational: Specifies the QoS for traffic patterns in which there is a constant flow of packets in each direction, upstream and downstream. This traffic pattern should be the highest QoS.

•interactive traffic_priority: Specifies the QoS for traffic patterns in which there is an intermittent flow of packets in each direction, upstream and downstream. This traffic pattern should be a higher QoS than the background pattern, but not as high as that for the streaming pattern. traffic_priority is the 3GPP traffic handling priority and can be the integers 1,2, or 3.

•streaming: Specifies the QoS for traffic patterns in which there is a constant flow of data in one direction, either upstream or downstream. This traffic pattern should be a higher QoS than the interactive pattern, but not as high as that for the conversational pattern.
### Important: If this keyword is omitted, the same values are used for all classes.

**exceed-action** { drop | lower-ip-precedence | transmit }

Default: See Usage section for this command
The action to take on the packets that exceed the committed-data-rate but do not violate the peak-data-rate. The following actions are supported:

- **drop**: Drop the packet.
- **lower-ip-precedence**: Transmit the packet after lowering the ip-precedence.
- **transmit**: Transmit the packet.

**violate-action** { drop | lower-ip-precedence | transmit }

Default: See Usage section for this command
The action to take on the packets that exceed both the committed-data-rate and the peak-data-rate. The following actions are supported:

- **drop**: Drop the packet.
- **lower-ip-precedence**: Transmit the packet after lowering the IP precedence.
- **transmit**: Transmit the packet.

### Usage

This command configures the APN’s quality of service (QoS) data rate shaping through traffic policing. This command enables the actions on subscriber flow exceeding or violating peak/committed data rate allowed. The shaping function also provides an enhanced function to buffer the exceeded user packets in a buffer memory and sends them to the subscriber when subscriber traffic goes below the committed or peak data rate limit.

### Important: The user packet buffer function in traffic shaping is not applicable for real-time traffic.

**Important**: If the exceed/violate action is set to “lower-ip-precedence”, this command may override the configuration of the `ip qos-dscp` command in the GGSN service configuration mode for packets from the GGSN to the PDG/TTG. In addition, the GGSN service `ip qos-dscp` command configuration can override the APN setting for packets from the GGSN to the Internet. Therefore, it is recommended that command not be used in conjunction with this action.

The command can be entered multiple times to specify different combinations of direction and class. If this command is not configured at all, the GGSN does not perform traffic policing or QoS negotiation with the PDG/TTG (i.e., it accepts all of the PDG/TTG-provided values for the PDP context.

### Important: This command should be used in conjunction with the max-contexts command to limit the maximum possible bandwidth consumption by the APN.

Additional information on the QoS traffic shaping and policing functionality is located in the *System Enhanced Feature Configuration Guide*.

### Default values:

The following table displays the default values for each of the traffic classes:
### Class: Conversational

<table>
<thead>
<tr>
<th>Downlink Traffic: Disabled</th>
<th>Uplink Traffic: Disabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>Peak Data Rate (bps): 16000000</td>
<td>Peak Data Rate (bps): 8640000</td>
</tr>

<tr>
<td>Exceed Action: n/a</td>
<td>Exceed Action: n/a</td>
</tr>
<tr>
<td>Violate Action: drop</td>
<td>Violate Action: drop</td>
</tr>
</tbody>
</table>

---

**Example**

The following command lowers the IP precedence when the committed-data-rate and the peak-data-rate are violated in uplink direction:

```
qos rate-limit direction uplink violate-action lower-ip-precedence
```
qos traffic-police

Enables and configures traffic policing through the bandwidth limits and action for the subscriber traffic if it exceeds/violates the peak or committed data rate. Uplink and downlink limits are configured separately.

**Product**
PDSN, HA, GGSN, ASN GW

**Privilege**
Security Administrator, Administrator

**Syntax**
```
qos traffic-police direction { downlink | uplink } [ burst-size bytes ] [ committed-data-rate bps ] [ exceed-action { drop | lower-ip-precedence | transmit } ] [ peak-data-rate bps ] [ violate-action { drop | lower-ip-precedence | transmit } ]
```

```
no qos traffic-police direction { downlink | uplink }
```

**downlink**
Apply the specified limits and actions to the downlink (data to the subscriber).

**uplink**
Apply the specified limits and actions to the uplink (data from the subscriber).

**burst-size bytes**
Default: 3000
The peak burst size allowed, in bytes. 
`bytes` must be an integer from 0 through 4294967295.

**Important**: It is recommended that this parameter be configured to at least the greater of the following two values: 1) 3 times greater than packet MTU for the subscriber connection, OR 2) 3 seconds worth of token accumulation within the “bucket” for the configured peak-data-rate.

**committed-data-rate bps**
Default: 144000
The committed data rate (guaranteed-data-rate) in bps (bits per second). 
`bps` must be an integer from 0 through 4294967295.

**exceed-action { drop | lower-ip-precedence | transmit }**
Default: lower-ip-precedence
The action to take on the packets that exceed the committed-data-rate but do not violate the peak-data-rate. 
The following actions are supported:
- **drop**: Drop the packet
- **lower-ip-precedence**: Transmit the packet after lowering the ip-precedence
- **transmit**: Transmit the packet
**peak-data-rate bps**

Default: 256000

Specifies the peak data-rate for the subscriber, in bps (bits per second). bps must be an integer from 0 through 4294967295.

**violate-action ( drop | lower-ip-precedence | transmit )**

Default: drop

The action to take on the packets that exceed both the committed-data-rate and the peak-data-rate. The following actions are supported:

- drop: Drop the packet
- lower-ip-precedence: Transmit the packet after lowering the IP precedence
- transmit: Transmit the packet

**no**

Disable traffic policing for the specified direction for the current subscriber.

**Usage**

Use this command to limit the bandwidth a subscriber uses in the uplink and downlink directions.

**Important:** If the exceed/violate action is set to “lower-ip-precedence”, the TOS value for the outer packet becomes “best effort” for packets that exceed/violate the traffic limits regardless of what the ip user-datatype-tos copy command is configured to. In addition, the “lower-ip-precedence” option may also override the configuration of the ip qos-dscp command. Therefore, it is recommended that command not be used when specifying this option.

Details on the QoS traffic policing functionality is located in the System Enhanced Feature Configuration Guide.

**Example**

The following command sets an uplink peak data rate of 128000 bps and lowers the IP precedence when the committed-data-rate and the peak-data-rate are exceeded:

```bash
qos traffic-police direction uplink peak-data-rate 128000 violate-action lower-ip-precedence
```

The following command sets a downlink peak data rate of 256000 bps and drops packets when the committed-data-rate and the peak-data-rate are exceeded:

```bash
qos traffic-police direction downlink peak-data-rate 256000 violate-action drop
```
qos traffic-shape

Enables and configures traffic shaping functionality to provide the traffic shaping by means of buffering the data packets during congestion or when subscriber exceeds the configured peak or committed data rate limit. It buffers the data packets instead of discarding instantaneous burst and deliver it to subscriber when traffic flow is below the peak or committed data rate. Uplink and downlink traffic shaping are configured separately.

**Important:** This feature is NOT supported for real-time traffic.

**Product**
PDSN, HA, GGSN, ASN GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
qos traffic-shape direction { downlink | uplink } [ burst-size bytes ] [ committed-data-rate bps ] [ exceed-action { drop | lower-ip-precedence | transmit } ] [ peak-data-rate bps ] [ violate-action { drop | lower-ip-precedence | buffer [ transmit-when-buffer-full ] | transmit } ] +
```

```
o qos traffic-shape direction { downlink | uplink }
```

**downlink**
Apply the specified limits and actions to the downlink (data to the subscriber).

**uplink**
Apply the specified limits and actions to the uplink (data from the subscriber).

**burst-size bytes**
Default: 3000
The peak burst size allowed, in bytes.

**Important:** It is recommended that this parameter be configured to at least the greater of the following two values: 1) 3 times greater than packet MTU for the subscriber connection, OR 2) 3 seconds worth of token accumulation within the “bucket” for the configured peak-data-rate.

**committed-data-rate bps**
Default: 144000
The committed data rate (guaranteed-data-rate) in bps (bits per second).

**Important:** This parameter must be an integer from 0 through 4294967295.
### Subscriber Configuration Mode Commands

**qos traffic-shape**

**subcommand:**

- **exceed-action** (`drop` | `lower-ip-precedence` | `transmit`)
  
  **Default:** lower-ip-precedence
  
  The action to take on the packets that exceed the committed-data-rate but do not violate the peak-data-rate. The following actions are supported:
  
  - **drop**: Drop the packet
  - **lower-ip-precedence**: Transmit the packet after lowering the ip-precedence
  - **transmit**: Transmit the packet

- **peak-data-rate** (`bps`)
  
  **Default:** 256000
  
  Specifies the peak data-rate for the subscriber, in bps (bits per second). `bps` must be an integer from 0 through 4294967295.

- **violate-action** (`drop` | `lower-ip-precedence` | `buffer [transmit-when-buffer-full]` | `transmit`)
  
  **Default:** See Usage section for this command
  
  The action to take on the packets that exceed both the committed-data-rate and the peak-data-rate. The following actions are supported:
  
  - **drop**: Drop the packet
  - **lower-ip-precedence**: Transmit the packet after lowering the IP precedence
  - **buffer [transmit-when-buffer-full]**: Enables the traffic shaping and provides the buffering of user packets when subscriber traffic violates the allowed peak/committed data rate. The `transmit-when-buffer-full` keyword allows the packet to be transmitted when buffer memory is full.
  - **transmit**: Transmit the packet

More than one of the above keywords can be entered within a single command.

- **no**
  
  Disable traffic policing for the specified direction for the current subscriber.

---

**Usage**

Use this command to provide the traffic shaping function to a subscriber in the uplink and downlink directions. This feature is providing a traffic flow control different to QoS traffic policing. When a subscriber violates or exceeds the peak data rate instead of dropping the packets, as in QoS traffic policing, this feature provides the buffering facility of subscriber data packets and it sends the buffered data when the traffic flow is low or not in congestion state.

**Important:** If the exceed/violate action is set to "lower-ip-precedence", the TOS value for the outer packet becomes "best effort" for packets that exceed/violate the traffic limits regardless of what the `ip user-datagram-tos copy` command is configured to. In addition, the "lower-ip-precedence" option may also override the configuration of the `ip qos-dscp` command. Therefore, it is recommended that command not be used when specifying this option.

Details on the QoS traffic policing functionality is located in the System Enhanced Feature Configuration Guide.
Example
The following command sets an uplink peak data rate of 128000 bps and lowers the IP precedence when the committed-data-rate and the peak-data-rate are exceeded:

```
qos traffic-shape direction uplink peak-data-rate 128000 violate-action lower-ip-precedence
```

The following command buffers the excess user packets when the subscriber traffic violates the configured peak-data-rate 256000 bps in downlink direction. Once the peak/committed data rate for that subscriber goes below the configured limit it transmit them. It also transmits them if buffer memory is full:

```
qos traffic-shape direction downlink peak-data-rate 256000 violate-action buffer transmit-when-buffer-full
```
radius accounting

Sets the RADIUS accounting parameters for the subscriber or domain. This command takes precedence over the similar context configuration command. This command is disabled by default.

Product
All

Privilege
Administrator

Syntax

radius accounting { interim { interval-timeout timeout | normal | suppress } | ip remote-address list-id list_id | mode { session-based | access-flow-based { none | auxillary-flows | all-flows | main-a10-only } } | start { normal | suppress } | stop { normal | suppress } }

no radius accounting { ip remote-address list-id list_id | interim { interval-timeout } }

<table>
<thead>
<tr>
<th>interim { interval-timeout timeout</th>
<th>normal</th>
<th>suppress }</th>
</tr>
</thead>
<tbody>
<tr>
<td>interval-timeout timeout: Indicates the time (in seconds) between updates to session counters (log file on RADIUS or AAA event log) during the session. timeout must be an integer from 50 to 40000000.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

⚠️ Caution: Interim interval settings received from the RADIUS server take precedence over this setting on the system. While the low limit of this setting on the system is a minimum of 50 seconds, the low limit setting on the RADIUS server can be as little as 1 second. To avoid increasing network traffic unnecessarily and potentially reducing network and system performance, do not set this parameter to a value less than 50 on the RADIUS server.

normal: If RADIUS accounting is enabled, send this Acct-Status-Type message when required by normal operation

suppress: If RADIUS accounting is enabled, suppress the sending of this Acct-Status-Type message.

ip remote-address list-id list_id

Specifies the identification number of the IP address list to use for the subscriber for remote address-based accounting.

list_id: Specifies the RADIUS accounting remote IP address list identifier for remote-address accounting for the subscriber. list_id must be an integer from 1 through 65535.

This command is used as part of the Remote Address-based accounting feature and associates the subscriber with a list of remote addresses. Remote address accounting data is collected each time the subscriber communicates with any of the addresses specified in the list.

Remote address lists are configured using the list keyword in the radius accounting ip remote-address command in the Context Configuration mode.

mode { session-based | access-flow-based { none | auxillary-flows | all-flows | main-a10-only } } 

Default: session-based

Specifies if the radius accounting mode is either session-based or access-flow-based.
**session-based**: configures session-based RADIUS accounting behavior for the subscriber - which means a single radius accounting message generated for the subscriber session not separate accounting messages for individual A10 connections or flows.

**access-flow-based**: configures access-flow-based RADIUS accounting behavior for the subscriber. This offers flexibility by generating separate accounting messages for flows and A10 sessions.

  - **all-flows**: Generates separate RADIUS accounting messages per access flow. Separate accounting messages are not generated for data path connections. (For example, separate messages are not sent for the main A10 or auxiliary connections.)

  - **auxiliary-flows**: Generates RADIUS accounting records for the main data path connection and for access-flows for all auxiliary data connections. (For example, separate RADIUS accounting messages are generated for the main A10 session and for access-flows within auxiliary A10 connections. The main A10 session accounting does not include octets or other accounting information from the auxiliary flows.)

  - **main-a10-only**: Configures access-flow-based single accounting messages (for example only single start/interim/stop) are generated for the main A-10 flows only.

  - **none**: Separate RADIUS accounting messages are generated for all data path connections (for example, PDSN main or auxiliary A10 connections) but not for individual access-flows. This is essentially A10 connection-based accounting.

```plaintext
start { normal | suppress }
```

- **normal**: If RADIUS accounting is enabled, send this Acct-Status-Type message when required by normal operation
- **suppress**: If RADIUS accounting is enabled, suppress the sending of this Acct-Status-Type message.

```plaintext
stop { normal | suppress }
```

- **normal**: If RADIUS accounting is enabled, send this Acct-Status-Type message when required by normal operation
- **suppress**: If RADIUS accounting is enabled, suppress the sending of this Acct-Status-Type message.

```plaintext
no
```

- **ip remote-address list-id list_id** Deletes the entry for the specified list_id.
- **interim [ interval-timeout ]**: Disables the interim interval setting.

**Usage**

Use this command to allow a per-domain setting for the RADIUS accounting.

**Example**

Set the accounting interim interval to one minute (60 seconds) for all sessions that use the current subscriber configuration:

```plaintext
radius accounting interim interval-timeout 60
```

Do not send RADIUS interim accounting messages:

```plaintext
radius accounting interim suppress
```

Sets the accounting message start normal for main A-10 flows only.
radius accounting mode main-a10-only start normal
radius group

It applies a RADIUS server group at the subscriber level for AAA functionality.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
radius group group_name
[ default | no ] radius group
```

- **group_name**
  Specifies the name of the server group that is used for authentication and/or accounting for the specific subscriber.
  - *group_name* must be an alpha and/or numeric string of 1 through 63 characters in length. It must be the same as configured earlier within the same context of subscriber.

- **default**
  Sets / Restores default RADIUS server group specified at the context level or default subscriber profile.

- **no**
  Disables the applied RADIUS group for specific subscriber.

Usage

This feature provides the RADIUS configurables under radius group node. Instead of having a single list of servers per context, this feature configures multiple server groups within a context and applies individual RADIUS server group for subscriber in that context. Each server group consists of a list of AAA servers. In case no RADIUS group is applied for the said subscriber or default subscriber profile, then the default server group available at context level is applicable for accounting and authentication of specific subscriber.

Example

Following command applies a previously configured RADIUS server group named *star1* to a subscriber within the specific context:

```
radius group star1
```

Following command disables the applied RADIUS server group for the specific subscriber.

```
no radius group
```
radius returned-framed-ip-address

Sets the policy whether or not to reject a call when the RADIUS server supplies 255.255.255.255 as the framed IP address and the MS does not supply an address.

Product
GGSN

Privilege
Security Administrator, Administrator

Syntax

radius returned-framed-ip-address 255.255.255.255-policy { accept-call-when-ms-ip-not-supplied | reject-call-when-ms-ip-not-supplied }

default radius returned-framed-ip-address 255.255.255.255-policy

---

accept-call-when-ms-ip-not-supplied
Accept calls when the RADIUS server does not supply a framed IP address and the MS does not supply an address.

---

reject-call-when-ms-ip-not-supplied
Reject calls when the RADIUS server does not supply a framed IP address and the MS does not supply an address.

---

default
Set the policy to its default of rejecting calls when the RADIUS server does not supply a framed IP address and the MS does not supply an address.

---

Usage
Use this command to set the behavior for the current subscriber when the RADIUS server supplies 255.255.255.255 as the framed IP address and the MS does not supply an address.

---

Example
Use the following command to set the subscriber profile to reject calls when the RADIUS server does not supply a framed IP address and the MS does not supply an address:

radius returned-framed-ip-address 255.255.255.255-policy reject-call-when-ms-ip-not-supplied
**rohc-profile-name**

Identifies the RoHC profile configuration to be applied to bearer sessions belonging to this subscriber.

**Product**
HSGW, PDSN

**Privilege**
Administrator

**Syntax**

```
rohc-profile-name name
```

`name`

Specifies the name of the RoHC profile this subscriber will use to apply header compression and decompression parameters to bearer session data. `name` must be an existing RoHC profile and be from 1 to 63 alpha and/or numeric characters.

**Usage**

Use this command to specify a RoHC configuration profile to be applied to bearer sessions belonging to this subscriber. RoHC profiles are configured through the Global Configuration Mode using the `rohc-profile` command.

**Example**

The following command specifies that the RoHC profile named `rohc-cfg1` is to be applied to all bearer sessions belonging to this subscriber:

```
rohc-profile-name rohc-cfg1
```
secondary ip pool

This command specifies a secondary IP pool to be used as backup pool for NAT.

**Important:** This command is license dependent, requiring the 600-00-7871 NAT Bypass license. Please contact your local sales representative for more information.

**Product**
NAT

**Privilege**
Security Administrator, Administrator

**Syntax**

```
secondary ip pool pool_name
no secondary ip pool
```

**no**
Removes the previous secondary IP pool configuration.

```
pool_name
```

Specifies the secondary IP pool name.

*pool_name* must be an alpha and/or numeric string of 1 through 31 characters in length.

**Usage**
Use this command to configure a secondary IP pool for NAT subscribers, which is not overwritten by the RADIUS supplied list. The secondary pool configured will be appended to the RADIUS supplied IP pool list / subscriber template provided IP pool list whichever is applicable during call setup.

**Example**
The following command configures a secondary IP pool named *test123*:

```
secondary ip pool test123
```
simultaneous

Enables/disables the simultaneous use of both Mobile and Simple IP services.

Product
PDSN, FA, HA, ASN-GW

Privilege
Security Administrator, Administrator

Syntax

[ no ] simultaneous simple-and-mobile-ip

no

Disables the simultaneous use.

Usage
Subscribers with mobile devices supporting mobile and simple IP services concurrently require this option to be set.

Example

no simultaneous simple-and-mobile-ip

simultaneous simple-and-mobile-ip
timeout

Configures the subscriber session timeouts.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
timeout { absolute | idle } seconds
no timeout [ absolute | idle ]
```

<table>
<thead>
<tr>
<th><strong>absolute</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0</td>
</tr>
<tr>
<td>The absolute maximum time a session may exist in any state (active or dormant).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>idle</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0</td>
</tr>
<tr>
<td>The maximum duration of the session, in seconds, before the system automatically terminates the session due to inactivity.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>seconds</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the maximum amount of time, in seconds, before the specified timeout action is activated.</td>
</tr>
<tr>
<td><code>seconds</code> must be a value in the range from 0 through 4294967295.</td>
</tr>
<tr>
<td>The special value 0 disables the timeout specified.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>no</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Indicates the timeout specified is to be returned to its default behavior. If no specific timeout is specified then all are set to their default behavior.</td>
</tr>
</tbody>
</table>

**Usage**
Reduce the idle timeout to free session resources faster for use by new requests.

**Example**

```
timeout absolute 1800
no timeout
```
**timeout long-duration**

Configures the long duration timeout and optionally the inactivity duration of HA subscriber session.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```
timeout long-duration ldt_timeout [ inactivity-time inact_timeout ]
[ no | default ]timeout long-duration
```

- **no**
  
  Indicates the timeout specified is to be returned to its default behavior. If no specific timeout is specified then all are set to their default behavior.

- **long-duration ldt_timeout**
  
  Default: 0
  
  Designates the maximum duration of the session, in seconds, before the system automatically reports/terminates the session.
  
  `ldt_timeout` must be a value in the range from 0 through 4294967295.
  
  The special value 0 disables the timer.

- **inactivity-time inact_timeout**
  
  Specifies the maximum amount of time, in seconds, before the specified session is marked as dormant.
  
  `inact_timeout` must be a value in the range from 0 through 4294967295.
  
  The special value 0 disables the inactivity time specified.

**Usage**

Use this command to set the long duration timeout period and inactivity timer for subscriber sessions. Reduce the idle timeout to free session resources faster for use by new requests.

Refer to the `long-duration-action detection` and `long-duration-action disconnection` section for more information.

**Example**

Following command sets the long duration timeout duration to 300 seconds and inactivity timer for subscriber session to 45 seconds:

```
timeout long-duration 300 inactivity-time 45
```
tunnel address-policy

This command specifies the policy for address allocation and validation for all tunneled calls (IP-IP, IP-GRE) except L2TP calls. This means that GGSN IP address validation could be disabled for specified incoming calls.

For GGSN systems, this command can also be specified in the APN Configuration mode (tunnel address-policy) which would mean the system defers to the old 13-to-12-tunnel address policy command for calls coming through L2TP tunnels.

**Product**
PDSN, GGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
tunnel address-policy { alloc-only | alloc-validate | no-alloc-validate }
default tunnel address-policy
```

<table>
<thead>
<tr>
<th>alloc-only</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP addresses are allocated locally and no validation is done.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>alloc-validate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default. The VPN Manager allocates and validates all incoming IP addresses from a static pool of IP addresses.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>no-alloc-validate</th>
</tr>
</thead>
<tbody>
<tr>
<td>No IP address assignment or validation is done for calls coming in via L3 tunnels. Incoming static IP addresses are passed. This allows for the greatest flexibility.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resets the tunnel address-policy to alloc-validate.</td>
</tr>
</tbody>
</table>

**Usage**

This command supports scalable solutions for Corporate APN deployment as many corporations handle their own IP address assignment. In some cases this is done to relieve the customer or the mobile operators from the necessity of reconfiguring the range of IP addresses for the IP pools at the GGSN.

**Example**

Use the following command to reset the IP address validation policy to validate against a static pool of address:

```plaintext
default tunnel address-policy
```

Use the following command to disable all IP address validation for calls coming through tunnels:

```plaintext	tunnel address-policy no-alloc-validate```
tunnel address-policy
tunnel gre

Configures Generic Routing Encapsulation (GRE) tunnel parameters for the current subscriber.

Product
PDSN, GGSN, ASN-GW

Privilege
Security Administrator, Administrator

Syntax

tunnel gre peer-address peer_address local-address local_addr

no tunnel gre peer-address peer_address

peer-address peer_address
Specifies the IP address of the external gateway terminating the GRE tunnel.

local-address local_addr
Specifies the IP address of the interface in the destination context originating the GRE tunnel.

no
Disables GRE tunneling for the current subscriber.

Usage
Subscriber IP payloads are encapsulated with IP/GRE headers and tunneled by the AGW to an external gateway.

Example
The following command configures the system to encapsulate subscriber traffic using GRE and tunnel it from a local address of 192.168.1.100 to a gateway with an IP address of 192.168.1.225:

tunnel gre peer-address 192.168.1.225 local-address 192.168.1.100
tunnel ipip

Configures IP-in-IP tunnelling parameters for the current subscriber.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax

```
tunnel ipip peer-address peer_address local-address local_addr ]
```

```
no tunnel ipip
```

```
  peer-address peer_address
  Specifies the IP address of the external gateway terminating the IP-in-IP tunnel.

  local-address local_addr
  Specifies the IP address of the interface in the destination context originating the IP-in-IP tunnel.

no
Disables IP-in-IP tunneling for the current subscriber.

Usage
Subscriber IP payloads are encapsulated with IP-in-IP headers and tunneled by the GGSN or PDSN to an external gateway.

Example
The following command configures the system to encapsulate subscriber traffic using IP-in-IP and tunnel it from a local address of 192.168.1.100 to a gateway with an IP address of 192.168.1.225:

```
tunnel ipip peer-address 192.168.1.225
local-address 192.168.1.100
```
tunnel ipsec

This command configures sessions for the current subscriber to use an IPSEC tunnel based on the IP pool corresponding to the subscribers assigned ip address.

Product
PDSN, GGSN

Privilege
Security Administrator, Administrator

Syntax

```
tunnel ipsec use-policy-matching-ip-pooler-address
no tunnel ipsec [ use-policy-matching-ip-pooler-address ]
```

**Usage**
Use this command to set the current subscribers sessions to use an IPSEC policy that is assigned to the IP pool that the subscribers assigned IP address relates to.

**Example**
The following command enables the use of the policy that matches the IP pool address:

```
tunnel ipsec use-policy-matching-ip-pooler-address
```
tunnel l2tp

Configures the L2TP tunnel for the subscriber.

Product
L2TP

Privilege
Security Administrator, Administrator

Syntax

```
tunnel l2tp [ peer-address ip_address [ [ encrypted ] [ secret secret] ] [ preference number] [ tunnel-context context ] [ local-address ip_address ] [ crypto-map map_name { [ encrypted ] isakmp-secret secret } ] ]

no tunnel l2tp [ peer-address ip_address ]
```

**peer-address ip_address**
A peer L2TP Network Server (LNS) associated with this LAC (L2TP Access Concentrator). ip_address must be an IP address in IPv4/IPv6 format.

**[ encrypted ] secret secret**
The shared key (secret) between the L2TP Network Server (LNS) associated with this LAC (L2TP Access Concentrator). secret must be between 1 and 63 alpha and/or numeric characters and is case sensitive.

**encrypted**: The encrypted shared key between the L2TP Network Server (LNS) associated with this LAC (L2TP Access Concentrator). secret must be between 1 and 128 alpha and/or numeric characters and is case sensitive.

The encrypted keyword is intended only for use by the system while saving configuration scripts. The system displays the encrypted keyword in the configuration file as a flag that the variable following the secret keyword is the encrypted version of the plain text secret. Only the encrypted secret is saved as part of the configuration file.

**preference number**
Default: 1
The order in which a group of tunnels configured for this subscriber will be tried. number must be an integer between 1 and 65535.

**tunnel-context context**
The name of the context containing ports through which this subscriber’s data traffic is to be communicated between this LAC and the LNS. context must be between 1 and 79 alpha and/or numeric characters.

**local-address ip_address**
A LAC service bind address which is given as a hint used to select a particular LAC service. ip_address must be an IP address in IPv4/IPv6 format.
crypto-map map_name { [encrypted] isakmp-secret secret }

map_name is the name of a crypto map that has been configured in the current context. map_name must be a string from 1 to 127 alphanumeric characters.

isakmp-secret secret: The pre-shared key for IKE. secret must be a string from 1 to 127 alphanumeric characters.

encrypted isakmp-secret secret: The pre-shared key for IKE. Encryption must be used when sending the key. secret must be a string from 1 to 127 alphanumeric characters.

no

Disables tunneling for the current subscriber. When peer-address is included, the tunneling for that specific L2TP Network Server (LNS) is disabled but tunneling to other configured LNSs is still enabled.

Usage

Use this command to configure specific L2TP tunneling parameters for the current subscriber.

Example

To specify L2tp tunneling to the LNS peer at the IP address 198.162.10.100 with a shared secret of bigco and preference of 1, enter the following command:

```
tunnel 12tp peer-address 198.162.10.100 secret bigco preference 1
```
Chapter 190
Telnet Configuration Mode Commands

The Telnet Configuration Mode is used to manage the Telnet server options for the current context.
end

Exits the telnet server configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
end
```

**Usage**
Change the mode back to the Exec mode.
exit

Exits the telnet server configuration mode and returns to the context configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Return to the context configuration mode.
max servers

Configures the maximum number of telnet servers that can be started within any 60 second interval. If this limit is reached, the system waits two minutes before trying to start any more servers.

Product
All

Privilege
Security Administrator, Administrator

Syntax

max servers count

count
Default: 40
Specifies the maximum number of servers that can be spawned in any 60 second interval. count must be a value in the range from 1 to 100.

Usage
Set the number of servers to tune the system response as a heavily loaded system may need more servers to support the incoming requests.
The converse would be true as well in that a system can benefit by reducing the number of servers such that telnet services do not cause excessive system impact to other services.

Example

max servers 50
Chapter 191
TFTP Configuration Mode Commands

The TFTP configuration mode is used to manage the TFTP servers for the current context.
end

Exits the TFTP server configuration mode and returns to the Exec mode.

```

**Usage**
Change the mode back to the Exec mode.
exit

Exits the context configuration mode and returns to the global configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Return to the global configuration mode.
policy

This command assigns the traffic policies, pre-configured in Policy-Map configuration mode, to a Policy Group for flow-based traffic policing to a subscriber session flow.

Product
PDSN, HA

Privilege
Security Administrator, Administrator

Syntax

[ no ] policy policy_map_name precedence value direction [ in | out ]

no
Disables/removes configured policy for traffic policing.

direction [ in | out ]
Specifies the direction in which the policies need to be applied.

policy_map_name
Specifies the policy string of size 1 to 15.

precedence value
Specifies the precedence of traffic policies to resolve.
value is an integer in the range from 1 through 16. If a session flow matches multiple policies this keyword resolves them.

Usage
Use this command to form a policy-group with a set of pre-configured Policy-Maps.

Example
The following commands assigns the traffic policy policymap1 with precedence 2.

policy policymap1 precedence 2
Chapter 193
Traffic Policy-Map Configuration  Mode Commands

Policy-Map is used to configure a flow-based traffic policy for Traffic Policy feature within a destination context. It designates the flow treatment based on the classification rules configured in Class-Map mode for a subscriber session flow.
3gpp2 data-over-signaling

This command configures 3GPP2 related flow treatment policy for the flow-based traffic policing to subscriber session.

Product
PDSN, HA

Privilege
Security Administrator, Administrator

Syntax

3gpp2 data-over-signaling marking [ class-map class_name ]

no 3gpp2 data-over-signaling marking

Usage
Use this command to mark traffic flows for 3GPP2 related policy.

Example
3gpp2 data-over-signaling marking
access-control

This command configures the access control action for traffic flow matching with Class-Map rules.

Product
PDSN, HA, ASN GW

Privilege
Security Administrator, Administrator

Syntax
access-control { allow | discard }

allow
This option allows the packets, if policy matches with the criteria defined in Class-Map assigned to the specific traffic policy.

discard
This option discards the packets, if policy matches with the criteria defined in Class-Map assigned to the specific traffic policy.

Usage
Configures the action or treatment for traffic flows matching with criteria specified in assigned Class-Map.

Example
The following command allows the packets or traffic flow on matching with criteria specified in assigned Class-Map for specific traffic policy.
access-control allow
accounting suppress

This command suppresses accounting action on traffic flow matching the policy map.

Product
PDSN, HA, ASN GW

Privilege
Security Administrator, Administrator

Syntax

Usage
Use this command to suppress accounting action on traffic flow matching this policy map. Policy maps configured for accounting suppression are used to implement the QChat Billing Suppression feature to selectively start and terminate accounting sessions based on the categorization of traffic as being interesting or non-interesting. See the accounting trigger command.

Example
The following command configures suppression of accounting on traffic flows matching this policy map:
accounting suppress
accounting trigger

This command configures an accounting trigger policy map to selectively start and terminate accounting sessions based on the categorization of traffic as being interesting or non-interesting to support the QChat Billing Suppression feature.

Product
PDSN

Privilege
Security Administrator, Administrator

Syntax

```
[ no | default ] accounting trigger { inactivity-timeout | interesting-traffic | intra-service-handoff }
```

- **default**
  Sets / Restores default value assigned for specified parameter.

- **no**
  Disables previously configured triggers.

- **inactivity-timeout**
  Generates an accounting stop message if there has been no data activity on the session for the interim accounting timeout interval.
  Default: disabled

- **interesting-traffic**
  Generates an accounting start message upon arrival of interesting traffic.
  Default: disabled

- **intra-service-handoff**
  Generates accounting start and stop messages during intra service handoffs within the same service.
  Default: enabled
  If this is disabled, the messages are suppressed during the handoffs. The current accounting session continues and no stop or start messages are generated during the intra service handoff.

Usage

Use this command to configure an accounting trigger policy map (ATPM) to selectively start and terminate accounting sessions based on the categorization of traffic as being interesting or non-interesting to support the QChat Billing Suppression feature.

Interesting traffic is identified as traffic that does not match any of the other Accounting Policy Maps (APMs) configured for accounting suppression. See the **accounting suppress** command.

An ATPM is similar to an APM, but without the class map rules. The ATPM is configured as of type accounting using the **type accounting** command.
In the ATPM, the trigger to start accounting for interesting traffic is configured using the `accounting trigger interesting-traffic` command. Accounting Start is triggered on arrival of interesting traffic, or change in airlink parameters conveyed through active-start airlink record. If an active-start record was included in the initial connection setup, Accounting Start is not triggered. But if the active-start comes separately and is the first one for the session, it is treated as airlink change and an Accounting Start is sent. Optionally, timeout can be triggered when there is no data traffic for the interim accounting timeout interval using the `accounting trigger inactivity-timeout stop` command. On timeout, the accounting session is terminated and an Accounting Stop message is sent. A new accounting session is created if interesting traffic resumes.

The ATPM should have the lowest precedence among the APMs. As the airlink events are generated on the ingress side, the ATPM must be included in a policy group that is applied to the ingress direction in the subscriber profile. The configuration is applicable only for standard trigger policy and session based accounting mode.

**Example**
The following command sets the trigger to generate accounting start message upon arrival of interesting traffic:

```
accounting trigger interesting-traffic
```
class-map

This command assigns a traffic classification rule (Class-Map) to the policy map.

**Product**
PDSN, HA, ASN GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
[no] class-map name
```

- **no**

  Enables/Disables `class-map`.

- **name**

  Specifies the name of the class map assigned for this policy map. The class map should be one that was configured in the Class Map Configuration Mode.

  `name` must be the name of a class map, and must be a string of 1 through 15 characters in length.

**Usage**

Use this command to assign a class map to the policy map for traffic policing. The class map is configured in the Class Map Configuration Mode.

**Example**

The following command assigns the class map `classification1` to the current policy map:

```plaintext
class classification1
```
**end**

This command exits the current mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**
Use this command to change to the Exec mode.
exit

This command exits the current mode and returns to the parent mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

exit

**Usage**

Use this command to return to the parent mode.
## flow-tp-trigger

This command specifies that the traffic volume will be calculated based on the traffic on the flow.

### Product

PDSN, HA, ASN GW

### Privilege

Security Administrator, Administrator

### Syntax

```
flow-tp-trigger volume traffic_volume_threshold

no flow-tp-trigger volume
```

- **traffic_volume_threshold**

  Specifies the volume threshold to trigger traffic policing.
  - `volume` is the value in bytes, and must be an integer from 1 through 4294967295.

### Usage

This command is available if you have purchased and installed the Intelligent Traffic Control License on your system. Use this command to calculate the traffic volume based on the traffic on the flow.

### Example

```
flow-tp-trigger volume 500
```
ip header-compression

Enables the system to mark IP flows for RObust Header Compression.

Product
PDSN, HA, ASN GW

Privilege
Security Administrator, Administrator

Syntax

[ no ] ip header-compression rohc flow-marking

- no
  Disables the setting.

- rohc flow-marking
  Marks the IP flow for SO67 and PPP ROHC.

Usage

Use this command to mark IP flows for SO67 and PPP ROHC.

Example

ip header-compression rohc flow-marking
qos encaps-header

Enables and configures Quality of Service (QoS) policy to use Differentiated Service Code Point (DSCP) marking in IP header field for the flow-based traffic policing to subscriber session flow.

**Product**
PDSN, HA, ASN GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
qos encaps-header dscp-marking { dscp_code|copy-from-user-datagram[ignore-pcf-signaled-dscp]}
no qos encaps-header dscp-marking { dscp_code|copy-from-user-datagram[ignore-pcf-signaled-dscp]}
```

**no**
Enables/Disables the *qos encaps-header*
The value must be expressed as a hexadecimal value from 0x00 through 0x3F.

**dscp_code**
Specifies the DSCP code value marked in IP header of packet/flow to determine the QoS for traffic policing.
The value must be expressed as a hexadecimal value from 0x00 through 0x3F.

**copy-from-user-datagram**
Specifies to use DSCP code value from user datagram (UDP header) to determine the QoS for traffic policing.

**ignore-pcf-signaled-dscp**
Specifies to override the highest priority DSCP value signaled by the PCF.

**user-datagram**
Specifies to use the DSCP value copied from the user datagram.

**Usage**

Use this command to apply the QoS policy based on DSCP code value encapsulated in IP packet header or User datagram packet to subscriber session flow for flow-based traffic policing.

**Important:** Details on the QoS traffic policing functionality is located in the System Administration and Configuration Guide.

**Example**
The following command sets QoS policy with DSCP code value to 0x0C for Class 1, silver (AF12):
```
qos encaps-header dscp-marking 0x0C
```
**qos traffic-police**

Enables and configures Quality of Service (QoS) policy for the flow-based traffic policing to subscriber session flow on per-flow basis.

**Product**

PDSN, HA, ASN GW

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
go traffic-policecommitted bpspeakbpsburst-size bytes exceed-action { drop | lower-ip-precedence | allow } violate-action { drop | lower-ip-precedence | allow }
no qos traffic-police
```

**Important:** It is recommended that this parameter be configured to at least the greater of the following two values: 1) 3 times greater than packet MTU for the subscriber connection, OR 2) 3 seconds worth of token accumulation within the “bucket” for the configured peak-data-rate.

**burst-size bytes**

Default: 3000

The peak burst size allowed, in bytes. `bytes` must be an integer from 0 through 4294967295.

**Important:** It is recommended that this parameter be configured to at least the greater of the following two values: 1) 3 times greater than packet MTU for the subscriber connection, OR 2) 3 seconds worth of token accumulation within the “bucket” for the configured peak-data-rate.

**committed bps**

Default: 144000

The committed data rate (guaranteed-data-rate) in bps (bits per second). `bps` must be an integer from 0 through 4294967295.

**exceed-action { drop | lower-ip-precedence | allow }**

Default: lower-ip-precedence

The action to take on the packets that exceed the committed-data-rate but do not violate the peak-data-rate. The following actions are supported:

- **drop:** Drop the packet
- **lower-ip-precedence:** Transmit the packet after lowering the ip-precedence
- **allow:** Transmit the packet
Traffic Policy-Map Configuration Mode Commands

qos traffic-police

<table>
<thead>
<tr>
<th>peak bps</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 256000</td>
</tr>
<tr>
<td>Specifies the peak data-rate for the subscriber, in bps (bits per second). bps must be an integer from 0 through 4294967295.</td>
</tr>
</tbody>
</table>

| violate-action { drop | lower-ip-precedence | allow } |
|-----------------------------------------------|
| Default: drop                                |
| The action to take on the packets that exceed both the committed-data-rate and the peak-data-rate. The following actions are supported: |
| drop: Drop the packet                        |
| lower-ip-precedence: Transmit the packet after lowering the IP precedence |
| allow: Transmit the packet                   |

Usage

Use this command to apply the QoS policy to subscriber session flow for flow-based traffic policing.

Important: Details on the QoS traffic policing functionality are located in the System Administration.

Example

The following command sets committed data rate of 102400 bps with peak data rate of 128000 bps and burst size 2048 bytes. This lowers the IP precedence when the committed-data-rate exceeded and drops the packets when peak-data-rate are violated:

gos traffic-police committed 102400 peak 128000 burst-size 2048 exceed-action lower-ip-precedence violate-action drop
qos user-datagram dscp-marking

Enables and configures Quality of Service (QoS) policy related to differentiated service code point (DSCP) marking in user datagram of subscriber session flow on per-flow basis.

Product
PDSN, HA, ASN GW

Privilege
Security Administrator, Administrator

Syntax

```
qos user-datagram dscp-marking dscp_code
no qos user-datagram dscp-marking
```

*dscp_code*
Specifies the DSCP code value marked in IP header of packet/flow to determine the QoS for traffic policing. The value must be expressed as a hexadecimal value from 0x00 through 0x3F.

Usage
Use this command to apply the QoS policy to subscriber session flow by DSCP marking in user datagram.

Example
The following command sets DSCP marking for user datagram as 0x01 for QoS to subscriber session flow:

```
qos user-datagram dscp-marking 0x01
```
**sess-tp-trigger**

This command configures the trigger traffic control based on traffic volume on a session.

**Product**
PDSN, HA, ASN GW

**Privilege**
Security Administrator, Administrator

**Syntax**

```
(sess-tp-trigger) volume volume direction { both | downlink | uplink }
```

```
(no sess-tp-trigger)
```

**Usage**
This command is available if you have purchased and installed the Intelligent Traffic Control License on your system. Use this command to configure the trigger traffic control based on traffic volume on a session.

**Example**

```
sess-tp-trigger 500
```
type

This command specifies the type of traffic policy within specific Policy-Map.

Product
PDSN, HA, ASN GW

Privilege
Administrator

Syntax

\[
\text{type \{ \text{accounting} | \text{dynamic}\{ \text{three-gpp2 rev-A profile-id} \{ \text{any} | \text{id profile-id} | \text{range low_value to high_value} \} \text{flow-id} \{ \text{any} | \text{id flow_id} | \text{range low_value to high_value} \} | \text{pre-provisioned wimax asn-service-profile-id} \{ \text{any} | \text{id service_id} \} \text{ asn-pdfid} \{ \text{any} | \text{id pdf_id} \} | \text{static} | \text{template} \} \}
\]

accounting

Specifies the type of traffic policing as accounting for this specific policy map. This configuration is used for enabling/disabling the accounting of different flows matching with conditions within this Policy-Map.

dynamic

Identifies the type of policy map as dynamic.

three-gpp2 rev-A

Configures dynamic policy map type for CDMA2000-3GPP2 RevA service.

profile-id \{ \text{any} | \text{id profile_id} | \text{range low_hex to high_hex} \}

Specifies the profile id matching in this policy map.
any allows any profile identifier matching with in this policy map.
id profile_id allows specific profile identifier matching with in this policy map. profile_id must be either a value in hexadecimal format from 0X0 to 0xFFFF.
r
ange low_value to high_value: identifies a range in which a profile identifier must fall within to be considered a match. low_value and high_value must be either a value in hexadecimal format from 0X0 to 0xFFFF or 0 to 65535 - a string of size 1 to 6.

flow-id \{ \text{any} | \text{id flow_id} | \text{range low_hex to high_hex} \}

Specifies the flow id matching in this policy map.
any allows any flow identifier matching with in this policy map.
id flow_id allows specific flow identifier matching with in this policy map. flow_id must be either a value in hexadecimal format from 0X0 to 0xFFFF or an integer from 0 to 65535.
r
ange low_value to high_value: identifies a range in which a flow identifier must fall within to be considered a match. low_value and high_value must be either a value in hexadecimal format from 0X0 to 0xFFFF or 0 to 65535 - a string of size 1 to 6.

pre-provisioned

Identifies the type of policy map as pre-provisioned.
Traffic Policy-Map Configuration Mode Commands

**wimax**
Configures WiMAX service policy map in an ASN-GW service.

**asn-service-profile { any | id service_id }**
Specifies the ASN Service profile identifier to match with in this policy map.
- **any**: Allows any ASN Service Profile Identifier matching within this policy map.
- **id service_id**: Allows specific Service Profile matching to a specified identifier. *service_id* must be an integer from 1 to 65535 and must match a service ID that was configured in the Subscriber Configuration Mode.

**asn-pdfid { any | id pdf_id }**
Specifies the ASN Packet Data Flow Identifier to match with in this policy map.
- **any**: Allows any ASN Packet Data Flow Identifier matching within this policy map.
- **id pdf_id**: Allows specific Packet Data Flow matching to a specified identifier. *pdf_id* must be an integer from 1 to 255 and must match a PDF ID that was configured in the Subscriber Configuration Mode.

**static**
Specifies the type of traffic policing as static for this specific Policy Map. In this type of policy, the traffic flow classification and flow treatment is pre-defined with classification rules through Class-Map configuration.
This is the detailed type of policy map.

**template**
Specifies the type of traffic policy to as a template to all subscribers associated with this policy map.

**Usage**
Specifies the type of traffic policy within the specific Policy-Map.

**Example**
The following commands configures the traffic policy for this Policy-Map as static:

```
 type static
```

The following commands configures the traffic policy for this Policy-Map as pre-provisioned for WiMAX service requiring a match of any service profile and PDF id of 3:

```
 type pre-provisioned wimax asn-service-profile any asn-pdfid id 3
```
Chapter 194
Tunnel Interface Configuration Mode Commands

The Tunnel Interface Configuration Mode is used to create and manage the IP interfaces for various type of tunnels and its parameters like addresses, address resolution options, etc.

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
description

Configures the description text for the current interface.

Product
All

Privilege
Security Administrator, Administrator

Syntax

description text

no description

no
Clears the description for the interface.

text
Specifies the descriptive text to use. text must be 0 to 79 alpha and/or numeric characters with no spaces or a quoted string of printable characters. The interface description is case sensitive.

Usage
Set the description to provide useful information on the interface’s primary function, services, end users, etc. Any information useful may be provided.

Example
Following command sets the description about this interface:

description sampleInterfaceDescriptiveText
**end**

Exits the interface configuration mode and returns to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
end
```

**Usage**

Change the mode back to the Exec mode.
exit

Exits the Interface Configuration Mode and returns to the Context Configuration Mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Return to the context configuration mode.
### ip address

This command configures the IPv4 address for the specific tunnel interface.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
ip address [ip_address/ip_mask | ip_address ip_mask]

no ip address ip_address
```

**no**
Removes the configured IPv4 address bound to a tunnel interface.

```plaintext
ip_address/ip_mask | ip_address ip_mask
```

Specifies a destination IP address or group of addresses that will use this route.

- **ip_address/ip_mask**: Specifies a combined IP address subnet mask bits to indicate what IP addresses to which the route applies. `ip_address/ip_mask` must be specified using the form 'IP Address/Mask Bits' where the IP address is specified using the standard IPv4 dotted decimal notation and the mask bits are a numeric value which is the number of bits in the subnet mask.
- **ip_address**: Specifies an IP address and the networking (subnet) mask pair which is used to identify the set of IP addresses to which the route applies. `ip_address` must be specified using the standard IPv4 dotted decimal notation.
- **ip_mask**: Must be specified using the standard IPv4 dotted decimal notation as network mask for subnets.

The mask as specified by `ip_mask` or resulting from `ip_address/ip_mask` is used to determine the network for packet routing.

0’s in the resulting mask indicate the corresponding bit in the IP address is not significant in determining the network.

1’s in the resulting mask indicate the corresponding bit in the IP address is significant in determining the network.

**Usage**

Use this command to bind the IPv4 address to a tunnel interface. This address does not affect the encapsulation of packets going out on the tunnel interface.

**Example**
The following command will assign the **1.2.3.4** as IPv4 address to this tunnel interface:

```plaintext
ip address 1.2.3.4
```
ipv6 address

This command configures the IPv6 address for the specific tunnel interface.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```
ipv6 address ipv6_address/ipv6_mask

no ipv6 address ipv6_address
```

**no**

Removes the configured IPv6 address bound to a tunnel interface.

```
ipv6_address/ipv6_mask
```

Specifies a destination IP address or group of addresses that will use this route.

```
ipv6_address/ipv6_mask
```

Specifies a combined IP address subnet mask bits to indicate what IP addresses to which the route applies. `ipv6_address/ipv6_mask` must be specified using the form ‘IP Address/Mask Bits’ where the IP address is specified using the standard IPv4 dotted decimal notation and the mask bits are a numeric value which is the number of bits in the subnet mask.

**Usage**

Use this command to bind the IPv6 address to a tunnel interface. This address does not affect the encapsulation of packets going out on the tunnel interface.

**Example**

The following command will assign the `1001::2:010:1234` as IPv4 address to this tunnel interface:

```
ipv6 address 1001::2:010:1234
```
tunnel-mode

This command configures the tunnel mode type for specific tunnel interface. It also creates the specific tunnel configuration mode if required.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

tunnel-mode {gre | ipv6ip}

default tunnel-mode

**default**
Sets the default tunnel mode for this interface. By default tunnel mode is set to IPv6-to-IPv4 type.

**gre**
Default: Disabled
This keyword sets the tunnel interface mode to GRE type and creates the GRE tunnel Configuration mode if required.

**ipv6ip**
Default: Enabled
This keyword sets the tunnel interface mode to IPv6-to-IPv4 type and creates the IPv6-to-IPv4 Tunnel Configuration mode, if required.

**Usage**
Use this command to set the tunnel mode type of GRE or IPv6-to-IPv4 for tunneling interface.

**Example**
The following command sets the tunnel mode to GRE for specific interface:

```bash
tunnel-mode gre
```
Chapter 195
UDR Format Configuration Mode Commands

The UDR Format Configuration Mode enables configuring User Detail Record (UDR) formats. UDR file formats are represented in Comma Separated Value (CSV).

```
Exec Mode
  active-charging
    service name
  ACS Configuration Mode
  udr-format name
  UDR Format Configuration Mode
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
attribute

This command specifies the order of fields in the UDR.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```plaintext

no attribute attribute [ priority priority ]
```

no
Removes the specified attribute configuration.

attribute
Specifies the attribute.

attribute must be one of the following:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>diameter-session-id</td>
<td>Unique Diameter session identifier.</td>
</tr>
<tr>
<td></td>

</table>
| sn-charging-type       | Charging type:  
  - offline  
  - online  

**Important:** This attribute is customer specific, and is only available in Release 8.3 and later. |
| sn-closure-reason      | Includes reason for the termination of the flow/UDR:  
  - 0: normal, i.e., subscriber session ended  
  - 1: handoff control processing specified  
  - 2: subscriber session terminated  
  - 3: flow timeout  |
| sn-content-id          | Unique identifier for the content-id.                                                                                                         |
| sn-content-label       | Identifier for text label for content-id.                                                                                                      |
| sn-content-vol         | Identifier for content volume.                                                                                                                  |
| sn-correlation-id      | RADIUS correlation identifier.                                                                                                                 |
| sn-duration            | Duration between the last and first packet for the record.                                                                                      |
| sn-end-time [ format format] | Timestamp for last packet of flow in UTC.                                                                                                                                                         |
| sn-fa-correlation-id   | RADIUS Correlation Identifier of the Foreign Agent (FA).                                                                                       |
| sn-filler-blank        | Keeps attributes place blank and generates an empty UDR field.                                                                                   |
| sn-filler-zero         | Fills ‘0’ for this attribute place in the EDR/UDR.                                                                                             |
| sn-format-name         | Indicates the name of the UDR/EDR format used.                                                                                                 |
| sn-group-id            | Indicates the sequence group identifier for the records.                                                                                       |
| sn-ha-ip-address       | Home Agent IP address.                                                                                                                         |

</table>
UDR Format Configuration Mode Commands

Specifies the timestamp format.

localtime
Specifies the local time. By default, timestamps are displayed in GMT.

{ bytes | pkts } { downlink | uplink }
Specifies bytes/packets sent/received from/by mobile.

priority priority
Specifies the position priority of the value within the UDR. Lower numbered priorities (across all attribute, event-label, and rule-variable) occur first.
priority must be an integer from 1 through 65535. Up to 50 position priorities (across all attribute, event-label, and rule-variable) can be configured.

Usage
Use this command to set the attributes and priority for UDR file format.
A particular field in UDR format can be entered multiple times at different priorities. While removing the UDR field using the no attribute command either you can remove all occurrences of a particular field by specifying the field name or a single occurrence by additionally specifying the optional priority keyword.

Example
The following is an example of this command:

attribute radius-user-name priority 12
**end**

This command returns the CLI prompt to the Exec mode.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
end
```

**Usage**
Use this command to change to the Exec mode.
event-label

This command configures an optional event ID to use in generated billing records.

**Product**

All

**Privilege**

Security Administrator, Administrator

**Syntax**

```plaintext
event-label label priority priority

no event-label
```

**no**

Removes the previously configured event label for UDR attribute.

**label**

Specifies event label for attribute to be used for UDR format.

*label* must be an alpha and/or numeric string of 1 through 63 characters in length.

**priority priority**

Specifies the CSV position of event ID in UDR.

*prioritymust be an integer from 1 through 65535.*

**Usage**

Use this command to set the event ID and its position in UDR file format.

**Example**

The following is an example of this command:

```plaintext
event-label radius_csv1 priority 23
```
exit

This command exits the UDR Format Configuration Mode and returns the CLI prompt to the ACS Configuration Mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
exit

Usage
Use this command to return to the ACS Configuration Mode.
rule-variable

This command specifies the order of fields in the UDR.

Product
All

Privilege
Security Administrator, Administrator

Syntax

rule-variable protocol rule priority priority

no rule-variable [ priority priority ] protocol rule

no
Removes the rule-variable protocol configuration.

protocol rule
Specifies the rule variable for UDR format.
protocol must be one of the following with specified rule:

• bearer 3gpp2: Bearer-related configuration:
  • always-on
  • bsid
  • carrier-id
  • esn
  • ip-qos
  • ip-technology
  • meid
  • release-indicator
  • service-option
  • session-begin
  • session-continue

Important: For more information on protocol-based rules see the ACS Ruledef Configuration Mode Commands chapter.

priority priority
Specifies the CSV position of the value in the UDR.
priority must be an integer from 1 through 65535.
Use this command to set the rule variables priority for UDR file format. A particular field in UDR format can be entered multiple times at different priorities. While removing the UDR field using the `no rule-variable` command either you can remove all occurrences of a particular field by specifying the field name or a single occurrence by additionally specifying the optional priority keyword.

**Example**
The following is an example of this command:

```
rule-variable bearer 3gpp2 bsid priority 36
```
Chapter 196
UDR Module Configuration Mode Commands

The UDR Module Configuration Mode is accessed from the Context Configuration Mode.

```
Exec Mode
  configure
    Global Configuration Mode
      context name
        Context Configuration Mode
          udr-module active-charging-service
            UDR Module Configuration Mode
```

**Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).
cdr

This command configures the EDR/UDR file parameters.

**Product**
All

**Privilege**
Security Administrator, Administrator

**Syntax**

```plaintext
cdr [ push-interval value ] [ push-trigger space-usage-percent trigger_percentage ] [ remove-file-after-transfer ] [ transfer-mode { pull | push primary { encrypted-url encrypted_url | url url } [ via local-context ] [ secondary { encrypted-secondary-url enc_sec_url | url sec_url } ] } ] + [ use-harddisk ]

no cdr [ remove-file-after-transfer | use-harddisk ] +

default cdr [ push-interval | push-trigger space-usage-percent | remove-file-after-transfer | transfer-mode { push via | use-harddisk } ] +

no

Disables the configured CDR storage and CDR file processing in this mode:

- **remove-file-after-transfer**: Retains a copy of the file even after it has been pushed or pulled to another server.
- **use-harddisk**: Disables data storage on the SMC hard disk.

**Important**: `use-harddisk` keyword is available only on the ASR 5000 chassis.

default

Configures the default setting for the specified keyword(s):

- **push-interval**: 300 seconds
- **push-trigger**: 80 percent
- **remove-file-after-transfer**: Disabled
- **transfer mode**: Pull
- **push via**: LC is used for push
- **use-harddisk**: Disabled

**Important**: `use-harddisk` keyword is only available on ASR 5000 chassis.

**push-interval value**

Specifies the transfer interval, in seconds, to push EDR and UDR files to an external file server. `value` must be an integer from 60 through 3600.
Default: 300

```
push-trigger space-usage-percent trigger_percentage
```
Specifies the EDR/UDR disk space utilization percentage, upon reaching which an automatic push is triggered and files are transferred to the configured external server.

_trigger_percentage_ specifies the EDR/UDR disk utilization percentage for triggering push, and must be an integer from 10 through 80.
Default: 80%

```
remove-file-after-transfer
```
Specifies that the system must delete EDR/UDR files after they are transferred to the external file server.
Default: Disabled

```
transfer-mode { pull | push primary { encrypted-url encrypted_url | url url } [ via local-context ] [ secondary { encrypted-secondary-url enc_sec_url | secondary-url sec_url} ] }
```
Specifies the EDR/UDR file transfer mode.

- **pull**: Specifies that the L-ESS is to pull the CDR files.
- **push**: Specifies that the system is to push CDR files to the configured L-ESS.

- **primary encrypted-url encrypted_url**: Specifies the primary URL location in encrypted format to which the system pushes the CDR files.

  _encrypted_url_ must be the location name in an encrypted format, and must be an alpha and/or numeric string of 1 through 1024 characters in length.

- **primary url url**: Specifies the primary URL location to which the system pushes the CDR files.

  _url_ must be an alpha and/or numeric string of 1 through 1024 characters in the //user:password@host:[port]/directory format.

- **via local-context**: Configuration to select LC/SPIO for transfer of CDRs. The system pushes the UDR files via SPIO in the local context.

- **encrypted-secondary-url enc_sec_url**: Specifies the secondary URL location in encrypted format to which the system pushes the CDR files when the primary location is unreachable or fails.

  _enc_sec_url_ must be the location name in an encrypted format, and must be an alpha and/or numeric string of 1 through 1024 characters in length.

- **secondary-url sec_url**: Specifies the secondary URL location to which the system pushes the CDR files when the primary location is unreachable or fails.

  _sec_url_ must be an alpha and/or numeric string of 1 through 1024 characters in //user:password@host:[port]/directory format.

```
use-harddisk
```
Specifies that on ASR 5000 chassis the hard disk on the SMC be used to store EDR/UDR files. On configuring to use the hard disk for EDR/UDR storage, EDR/UDR files are transferred from RAMFS on the PSC to the hard disk on the SMC.
Default: Disabled

**Important**: The _use-harddisk_ keyword is available only on the ASR 5000 chassis.
Indicates that more than one of the previous keywords can be entered within a single command.

Usage
Use this command to configure how charging data records (CDR) are moved and stored.
On the ST16 chassis, run this command only from the context where the EDR/UDR module is configured. Running in any other context will fail and deliver an error message.
On the ASR 5000 chassis, run this command only from the local context. Running in any other context would fail and deliver an error message.
The `use-harddisk` keyword is only available on the ASR 5000 chassis. This command can be run only in a context where CDRMOD is running. Configuring in any other context will result in failure with the message “Failure: Please Check if CDRMOD is running in this context or not.”
This configuration can be applied either in the EDR/UDR module, but will be applicable both to the EDR and UDR modules. Configuring in one of the modules prevents the configuration to be done in the other module.
If PUSH transfer mode is selected, the L-ESS server URL to which the CDR files need to be transferred to must be specified. The configuration allows a primary and a secondary server to be configured. Configuring the secondary server is optional. Whenever a file transfer to the primary server fails for four consecutive times, the files will be transferred to the secondary server. The transfer will switch back to the original primary server when:
- Four consecutive transfer failures to the secondary server occur
- After switching from the primary server, 30 minutes elapses
When changing `transfer-mode` from pull to push, disable the PULL from L-ESS and then change the transfer mode to push. Make sure that the push server URL configured is accessible from the local context. Also, make sure that the base directory that is mentioned contains udr directory created within it.
When changing `transfer-mode` from push to pull, after changing, enable PULL on the L-ESS. Any of the ongoing PUSH activity will continue till all the scheduled file transfers are completed. If there is no PUSH activity going on at the time of this configuration change, all the PUSH related configuration is nullified immediately.

Example
The following command configures the system to retain a copy of the data file after it has been transferred to the storage location:

```
no cdr remove-file-after-transfer
```
end

This command returns the CLI prompt to the Exec mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax
end

Usage
Use this command to change to the Exec mode.
exit

This command exits the current mode and returns to the parent configuration mode.

Product
All

Privilege
Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.
file

This command sets UDR file parameters.

Product
All

Privilege
Security Administrator, Administrator

Syntax

default file [ charging-service-name ] [ compression ] [ current-prefix ] [ delete-timeout ] [ directory ] [ field-separator ] [ file-sequence-number ] [ headers ] [ name ] [ reset-indicator ] [ rotation { num-records | time | volume } ] [ sequence-number ] [ storage-limit ] [ time-stamp ] [ trailing-text ] [ udr-seq-num ]

**default**

Configures the default setting for the specified keyword(s). Using the `default file` command will reset some but not all keyword parameters to their default values. To ensure that the default is reset for a specific parameter, include the keyword in the command.

**charging-service-name** { include | omit }

Configures the inclusion and exclusion of charging service name in the file name.

- **include**: Sets this command to include the Charging service name in UDR file name.
- **omit**: Sets this command to exclude or omit the Charging service name from UDR file name.

Default: **include**

**compression** { gzip | none }

Configures the compression of the UDR file.

- **gzip**: Enables GNU zip compression of the UDR file at approximately 10:1 ratio.
- **none**: Disables Gzip compression.

Default: **none**

**current-prefix** string

Specifies a string to add to the beginning of the UDR file that is currently being used to store UDR records. The `string` must be an alpha and/or numeric string of 1 through 31 characters in length.

Default: **curr**

**delete-timeout** seconds

Specifies a time period, in seconds, when completed UDR files are deleted. By default, files are never deleted.

The `seconds` must be an integer from 3600 through 31536000.

Default: Disabled
directory directory_name

Specifies a subdirectory in the default directory in which to store UDR files.

directory_name must be an alpha and/or numeric string of 1 through 191 characters in length.
Default: /records/udr

exclude-checksum-record

When entered, this keyword excludes the final record containing #CHECKSUM followed by the 32-bit
Cyclic redundancy check (CRC) of all preceding records from the UDR file.
Default: Disabled, inserts checksum record into the UDR file header.

field-separator { hyphen | omit | underscore }

Specifies the field separators between two fields of UDR file name.

- **hyphen**: Specifies the field separator as '-' (hyphen) symbol between two fields.
- **omit**: Removes or omits the field separator between two fields.
- **underscore**: Specifies the field separator as '_' (underscore) symbol between two fields.

Default: underscore

file-sequence-number rulebase-seq-num

Generates unique file sequence numbers for different rulebase-formatname combinations.

headers

Includes a file header summarizing the record layout.

name file_name

Default: udr

Specifies a string to use as the base file name for UDR files.

**file_name** must be an alpha and/or numeric string of 1 through 31 characters in length. The file name
format is as follows:

base_rulebase_format_sequence_num_timestamp

- **base**: Specifies type of record in file or contains the operator-specified string.
  Default: udr
- **rulebase**: Specifies the name of the ACS rulebase. UDRs from different rulebases go into different
  UDR files.
- **format**: Specifies the name of the UDR format if **single-udr-format** is specified, else the
  format field (and the trailing underscore) is omitted from the file name.
- **sequence_num**: This is a 5-digit sequence number to detect the missing file sequence. It is unique
  among all UDR files on the system.
- **timestamp**: Contains a timestamp based on file creation time in UTC time in
  MMDDYYYYHHMMSS format.

UDR files that have not been closed have a string added to the beginning of their file names.

File name for a UDR file in CSV format that contains information for rule base named **rulebase1** and a
UDR schema named **udr_schema1** appears as follows:

udr_rulebase1_udr_schema1_00005_01302006143409

If file name is not configured it creates files for EDRs/UDRs/FDRs (xDRs) having following name template
with limits to 256 characters:
UDR Module Configuration Mode Commands

file

basename_ChargSvcName_timestamp_SeqNumResetIndicator_FileSeqNumber

- **basename**: A global-based configurable text string that is unique per system that uniquely identifies the global location of the system running ACS.
- **ChargSvcName**: A system context-based configurable text string that uniquely identifies a specific context-based charging service.
- **timestamp**: Date and time at the instance of file creation. Date and time in the form of “MMDDYYHHmmSS” where HH is a 24-hour value from 00-23.
- **SeqNumResetIndicator**: A one-byte counter used to discern the potential for duplicated FileSeqNumber with a range of 0 through 255, which is incremented by a value of 1 for the following conditions:
  - Failure of an ACS software process on an individual PAC/PSC
  - Failure of the system such that a second system takes over (for example, a standby or backup chassis put in place according to Inter-chassis Session Recovery)
  - File Sequence Number (FileSeqNumber) rollover from 999999999 to 0
- **FileSeqNumber**: unique file sequence number for the file with 9 digit integer having range from 000000000 to 999999999. It is unique on each chassis system.

File name for a closed xDR file in CSV format that contains information for ACS system `xyz_city1` and charging service name `prepaid2` with timestamp `12311969190000`, and file sequence number counter reset indicator to `002` for file sequence number `034939002` appears as follows:

`xyz_city1 prepaid2_12311969190000_002_034939002`

File name for a running xDR file in CSV format that contains information for the same parameters for file sequence number `034939003` prefixed with `curr_` and appears as follows:

`curr_xz_city1 prepaid2_12311969190000_002_034939002`

**reset-indicator**

This option includes the reset indicator counter value from 0 to 255 in UDR file name and is incremented (by one) whenever any of the following conditions occur:

- An ACSMgr/SessMgr process fails
- A peer chassis has taken over in compliance with our Inter-chassis Session Recovery feature
- The sequence number in sequence-number keyword has rolled over to zero

**rotation { num-records records | time seconds | volume bytes }**

Specifies when to close a UDR file and create a new one.

- **num-records records**: Specifies the number of records that should be added to the file. When the number of records in the file reaches the specified value, the file is complete.

  `records` must be an integer from 100 through 10240.

  Default: 1024

- **time seconds**: Specifies the period of time to wait before closing the UDR file and creating a new one.

  `seconds` must be an integer from 30 through 86400.

  Default: 3600 seconds

- **volume bytes**: Specifies the maximum size of the UDR file before closing it and creating a new one.

  `bytes` must be an integer from 51200 through 62914560.
Note that higher sets may provide the best compression ratio when the \texttt{compression} keyword is set to \texttt{gzip}.

Default: 102400 bytes

\begin{verbatim}
sequence-number \{ length length | omit | padded | padded-six-length | unpadded \}
\end{verbatim}

Specifies including/excluding sequence number in the file name.

- \texttt{length length}: Includes the sequence number with the specified length.
  \texttt{length} must be the file sequence number length with preceding zeroes in the file name, and must be an integer from 1 through 9.

\begin{itemize}
  \item \texttt{omit}: Excludes the sequence number from the file name.
  \item \texttt{padded}: Includes the padded sequence number with preceding zeros in the file name. This is the default setting.
  \item \texttt{padded-six-length}: Includes the padded sequence number with six preceding zeros in the file name.
  \item \texttt{unpadded}: Includes the unpadded sequence number in the file name.
\end{itemize}

Default: \texttt{padded}

\begin{verbatim}
storage-limit limit
\end{verbatim}

Default: 33554432

Specifies deleting files when the specified amount of space, in bytes, is used up for UDR/EDR file storage on the PSC/PAC RAM.

On an ST16 chassis, \texttt{limit} must be an integer from 10485760 through 268435456.

On an ASR 5000 chassis, \texttt{limit} must be an integer from 10485760 through 536870912.

\begin{itemize}
  \item \texttt{Important}: On ST16 chassis, the total storage limit is 268435456 bytes (256 MB). This limit is for both UDR and EDR files combined.
  \item \texttt{Important}: On an ASR 5000 chassis, the total storage limit is 536870912 bytes (512 MB). This limit is for both UDR and EDR files combined.
\end{itemize}

\begin{verbatim}
time-stamp \{ expanded-format | rotated-format | unix-format \}
\end{verbatim}

Specifies the timestamp of when the file was created be included in the file name.

- \texttt{expanded-format}: Specifies the UTC MMDDYYYYHHHMMS format.
- \texttt{rotated-format}: Specifies the YYYYMMDDHHHMMS format.
- \texttt{unix-format}: Specifies the UNIX format of \texttt{x.y}, where \texttt{x} is the number of seconds since 1/1/1970 and \texttt{y} is the fractional portion of the current second that has elapsed.
trailing-text string
Specifies the inclusion of arbitrary text string in the file name.
string must be an alpha and/or numeric string of 1 through 30 characters in length.

trap-on-file-delete
This keyword instructs the system to send an SNMP notification (trap) when an EDR/UDR file is deleted due to lack of space.
Default: Disabled

udr-seq-num
Specifies that the file sequence numbers that are part of the UDR file names be independently generated. If disabled, a single set of sequence numbers are shared by both EDR files and UDRs.
Default: Disabled

xor-final-record
Specifies inserting an xor checksum (in place of the CRC checksum) into the UDR file header if the exclude-checksum-record keyword is left at its default setting.
Default: Disabled

+ More than one of the previous keywords can be entered within a single command.

Usage
Use this command to configure UDR file characteristics.

Example
The following command sets the prefix of the current active UDR file to current:

    file current-prefix current

The following command sets the base file name to UDRfile:

    file name UDRfile
Chapter 197
VLAN Configuration Mode Commands

The VLAN Configuration Mode is used to create and manage Virtual LANs and their bindings between contexts.

- Exec Mode
- configure
  - Global Configuration Mode
    - port ethernet slot/port
      - Port Configuration Mode
        - vlan vlan_tag_id
          - VLAN Configuration Mode
bind interface

Configures a virtual interface to context association for the current VLAN.

**Product**
PDSN, HA, SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
bind interface interface_name context_name
```

```
no bind interface interface_name context_name
```

**no**
Indicates the binding between the virtual interface specified and the context specified is to be unbound for the current VLAN.

**interface_name**
Specifies the name of the virtual interface to be bound to the context. *interface_name* must be from 1 to 79 alpha and/or numeric characters.

**context_name**
Specifies the name of the context to be bound to the virtual interface. *context_name* must refer to a previously configured context.

**Usage**
Bind a virtual interface and context to allow the VLAN to provide service.

**Example**

```
bind interface sampleVirtual sampleContext
```

```
no bind interface sampleVirtual sampleContext
```
end

Exits the port configuration mode and returns to the Exec mode.

**Product**

PDSN, HA

**Privilege**

Security Administrator, Administrator

**Syntax**

```
end
```

**Usage**

Change the mode back to the Exec mode.
exit

Exits the VLAN configuration mode and returns to the port configuration mode.

**Product**
PDSN, HA

**Privilege**
Security Administrator, Administrator

**Syntax**

```
exit
``` 

**Usage**

Return to the port configuration mode.
**ingress-mode**

This command toggles between enabling and disabling the port ingress mode.

**Product**
PDSN, HA, SGSN

**Privilege**
Security Administrator, Administrator

**Syntax**

```
ingress-mode
```

**Usage**
Use this command to enable or disable the ingress mode for the port.

**Example**
```
ingress-mode
```
**shutdown**

Disables/enables traffic over the current VLAN.

**Product**

PDSN, HA

**Privilege**

Security Administrator, Administrator

**Syntax**

```
shutdown
no shutdown
```

```
no
```

Enables the VLAN. When omitted the VLAN is shutdown.

**Usage**

Shut down a VLAN.

This command is necessary to bring a VLAN into service by enabling it via the `no` keyword.

**Example**

To disable a VLAN from sending or receiving network traffic use the following command:

```
shutdown
```

To enable a VLAN use the following command:

```
no shutdown
```
vlan-map

This command sets a single next-hop IP address so that multiple vlans can use a single next-hop gateway. `vlan-map` is associated with a specific interface.

**Product**

PDSN, HA, SGSN

**Privilege**

Security Administrator, Administrator

**Syntax**

```
vlan-map next-hop ip_address
```

**Usage**

Use vlan-map to combine multiple vlan links to go through a single IP address. This feature is used in conjunction with nexthop forwarding and overlapping IP pools.

After configuring the vlan-map, move to the Port Ethernet configuration mode to attach the vlan-map to a specific vlan.

**Example**

The following command sets an IPv4 for a next-hop gateway.

```
vlan-map next-hop 123.123.123.1
```
