  */
  /* Need to duplicate file references for the sake of garbage
  /* collection. Otherwise a socket in the fps might become a
  /* candidate for GC while the skb is not yet queued.
  */
  +* Garbage collection of unix sockets starts by selecting a set of
  +* candidate sockets which have reference only from being in flight
  +* (total_refs == inflight_refs). This condition is checked once during
  +* the candidate collection phase, and candidates are marked as such, so
  +* that non-candidates can later be ignored. While inflight_refs is
  +* protected by unix_gc_lock, total_refs (file count) is not, hence this
  +* is an instantaneous decision.
  +*
  +* Once a candidate, however, the socket must not be reinstalled into a
  +* file descriptor while the garbage collection is in progress.
  +*
  +* If the above conditions are met, then the directed graph of
  +* candidates (*) does not change while unix_gc_lock is held.
  +*
  +* Any operations that changes the file count through file descriptors
  +* (dup, close, sendmsg) does not change the graph since candidates are
  +* not installed in fds.
  +*
  +* Dequeing a candidate via recvmsg would install it into an fd, but
  +* that takes unix_gc_lock to decrement the inflight count, so it's
  +* serialized with garbage collection.
  +*
  +* MSG_PEEK is special in that it does not change the inflight count,
  +* yet does install the socket into an fd. The following lock/unlock
  +* pair is to ensure serialization with garbage collection. It must be
  +* done between incrementing the file count and installing the file into
  +* an fd.
  +*
  +* If garbage collection starts after the barrier provided by the
  +* lock/unlock, then it will see the elevated refcount and not mark this
* as a candidate. If a garbage collection is already in progress
* before the file count was incremented, then the lock/unlock pair will
* ensure that garbage collection is finished before progressing to
* installing the fd.
* (*) A -> B where B is on the queue of A or B is on the queue of C
* + which is on the queue of listening socket A.

****************************************************************************
* The only valid Service GUIDs, from the perspectives of both the host and *
* Linux VM, that can be connected by the other end, must conform to this *
- * format: <port>-facb-11e6-bd58-64006a7986d3, and the "port" must be in *

Open Source Used In 5GaaS Edge AC-4 34874
When we write apps on the host to connect(), the GUID ServiceID is used.
When we write apps in Linux VM to connect(), we only need to specify the
port and the driver will form the GUID and use that to request the host.

- From the perspective of Linux VM:
  - 1. the local ephemeral port (i.e. the local auto-bound port when we call
  connect() without explicit bind()) is generated by __vsock_bind_stream(),
  - and the range is [1024, 0xFFFFFFFF).
  - 2. the remote ephemeral port (i.e. the auto-generated remote port for
  a connect request initiated by the host's connect()) is generated by
  hvs_remote_addr_init() and the range is [0x80000000, 0xFFFFFFFF).

+.TH LSVMBUS 8
+.SH NAME
+lsvmbus \- List Hyper-V VMBus devices
+.SH SYNOPSIS
+.ft B
+.B lsvmbus [-vv]
+.br
+.SH DESCRIPTION
+\fBlsvmbus\fP
+displays devices attached to the Hyper-V VMBus.
+.SH OPTIONS
+\"  With -v more information is printed including the VMBus Rel_ID, class ID,
+Rel_ID, and which channel is bound to which virtual processor. Use -vv
+for additional detail including the Device_ID and the sysfs path.
+\"

- Regular files with '.json' extension in the name are assumed to be
- JSON files, each of which describes a set of PMU events.
-
-- Regular files with basename starting with 'mapfile.csv' are assumed
- to be a CSV file that maps a specific CPU to its set of PMU events.
- (see below for mapfile format)
+- The CSV file that maps a specific CPU to its set of PMU events is to
+ be named 'mapfile.csv' (see below for mapfile format).
-
- Directories are traversed, but all other files are ignored.
+- To reduce JSON event duplication per architecture, platform JSONs may
+ use "ArchStdEvent" keyword to dereference an "Architecture standard
+ events", defined in architecture standard JSONs.
+ Architecture standard JSONs must be located in the architecture root
+ folder. Matching is based on the "EventName" field.
+
The PMU events supported by a CPU model are expected to grouped into topics such as Pipelining, Cache, Memory, Floating-point etc. All events for a topic should be placed in a separate JSON file - where the file name identifies

Cache.json Memory.json Virtual-Memory.json
Frontend.json Pipeline.json

+The JSONs folder for a CPU model/family may be placed in the root arch
+folder, or may be placed in a vendor sub-folder under the arch folder
+for instances where the arch and vendor are not the same.
+
Using the JSON files and the mapfile, 'jevents' generates the C source file, 'pmu-events.c', which encodes the two sets of tables:
