This selftest exercises the powerpc alignment fault handler.

We create two sets of source and destination buffers, one in regular memory, the other cache-inhibited (we use /dev/fb0 for this).

We initialise the source buffers, then use whichever set of load/store instructions is under test to copy bytes from the source buffers to the destination buffers. For the regular buffers, these instructions will execute normally. For the cache-inhibited buffers, these instructions will trap and cause an alignment fault, and the alignment fault handler will emulate the particular instruction under test. We then compare the destination buffers to ensure that the native and emulated cases give the same result.

TODO:
   - Any FIXMEs below
   - Test VSX regs < 32 and > 32
   - Test all loads and stores
   - Check update forms do update register
   - Test alignment faults over page boundary
   - Some old binutils may not support all the instructions.

return chunk_start;
+

The "word-offset" of a word-aligned address inside a chunk, is defined to be the number of words that precede the address in that chunk.

#define WORD_OFFSET_BITS(__builtin_ctz(WORDS_PER_CHUNK))
+ *
+ * A "sweep" is defined to be the sequential execution of the
+ * rim-sequence by a rim_thread on its chunk one word at a time.
+ * starting from the first word of its chunk and ending with the last
+ * word of its chunk.
+ * Each sweep of a rim_thread is uniquely identified by a sweep_id.
+ * SWEEP_ID_BITS denote the number of bits required to represent
+ * the sweep_ids of rim_threads.
+ * As to why SWEEP_ID_BITS are computed as a function of THREAD_ID_BITS,
+ * WORD_OFFSET_BITS, and WORD_BITS, see the "store-pattern" below.
+ */
+#define SWEEP_ID_BITS(WORD_BITS - (THREAD_ID_BITS + WORD_OFFSET_BITS))
+#define SWEEP_ID_MASK((1 << SWEEP_ID_BITS) - 1)
+*/
+ * A "store-pattern" is the word-pattern that is stored into a word
+ * location in the 4)STORE step of the rim-sequence.
+ * In the store-pattern, we shall encode:
+ * - The thread-id of the rim_thread performing the store
+ *   (The most significant THREAD_ID_BITS)
+ * - The word-offset of the address into which the store is being
+ *   performed (The next WORD_OFFSET_BITS)
+ * - The sweep_id of the current sweep in which the store is
+ *   being performed. (The lower SWEEP_ID_BITS)
+ * Store Pattern: 32 bits
+ |------------------|--------------------|---------------------------------|
+ |    Thread id     |  Word offset       |         sweep_id                |
+ |------------------|--------------------|---------------------------------|
+ |    THREAD_ID_BITS     WORD_OFFSET_BITS          SWEEP_ID_BITS
In the store pattern, the (Thread-id + Word-offset) uniquely identify the address to which the store is being performed i.e,

$$ \text{address} = \text{map1} + \text{(Thread-id \times RIM_CHUNK_SIZE)} + (\text{Word-offset \times WORD_SIZE})$$

And the sweep_id in the store pattern identifies the time when the store was performed by the rim_thread.

We shall use this property in the 3)COMPARE step of the rim-sequence.

```c
#define SWEEP_ID_SHIFT 0
#define WORD_OFFSET_SHIFT(SWEEP_ID_BITS)
#define THREAD_ID_SHIFT(WORD_OFFSET_BITS + SWEEP_ID_BITS)

+/*
+ * When a COMPARE step of a rim-sequence fails, the rim_thread informs
+ * everyone else via the shared_memory pointed to by
+ * corruption_found variable. On seeing this, every thread verifies the
+ * content of its chunk as follows.
+ *
+ * Suppose a thread identified with @tid was about to store (but not
+ * yet stored) to @next_store_addr in its current sweep identified
+ * @cur_sweep_id. Let @prev_sweep_id indicate the previous sweep_id.
+ *
+ * This implies that for all the addresses @addr < @next_store_addr,
+ * Thread @tid has already performed a store as part of its current
+ * sweep. Hence we expect the content of such @addr to be:
+ *
+ * |-------------------------------------------------|
+ * | tid   | word_offset(addr) |    cur_sweep_id     |
+ * |-------------------------------------------------|
+ *
+ * Since Thread @tid is yet to perform stores on address
+ * @next_store_addr and above, we expect the content of such an
+ * address @addr to be:
+ *
+ * |-------------------------------------------------|
+ * | tid   | word_offset(addr) |    prev_sweep_id    |
+ * |-------------------------------------------------|
+ *
+ * The verifier function @verify_chunk does this verification and logs
+ * any anomalies that it finds.

+* mov_ss_trap.c: Exercise the bizarre side effects of a watchpoint on MOV SS
+ *
+* This does MOV SS from a watchpointed address followed by various
+* types of kernel entries. A MOV SS that hits a watchpoint will queue
+* up a #DB trap but will not actually deliver that trap. The trap
+* will be delivered after the next instruction instead. The CPU's logic
+* seems to be:
+* 
+* - Any fault: drop the pending #DB trap.
+* - INT $N, INT3, INTO, SYSCALL, SYSENTER: enter the kernel and then
+*    deliver #DB.
ICEBP: enter the kernel but do not deliver the watchpoint trap
- breakpoint: only one #DB is delivered (phew!)
- There are plenty of ways for a kernel to handle this incorrectly. This
test tries to exercise all the cases.
- This should mostly cover CVE-2018-1087 and CVE-2018-8897.

Fix up the KBUILD_EXTMOD as we are not building externally.

```
for make in vbox/*/Makefile
    do
        sed -i -e '1iKBUILD_EXTMOD=${srctree}/ubuntu/vbox' $make
    done

Fix up KERN_DIR to point at the kernel source tree

```

```
for make in vbox/*/Makefile.include.header
    do
        sed -i -e 's/^KERN_DIR := .*$/KERN_DIR := $(srctree)/' $make
    done
```

We're now using the vboxvideo module in drivers/staging, so disable
the version that was imported.

```
sed -i -e 's vboxvideo/:: vbox/Makefile
```

Reduce the version of the in-kernel module just slightly so it
will not clash with the dkms package.

```
for version in vbox/*/version-generated.h
    do
        sed -i -e 's/_Ubuntu"/_ KernelUbuntu"/' $version
    done
```

Record the version number and nominal source.

```

+
+/** *
+ @page pg_rtlog    Runtime - Logging
+ *
+ VBox uses the IPRT logging system which supports group level flags and multiple
+ destinations. The GC logging is making it even more interesting since GC logging will
+ have to be buffered and written when back in host context.
+ *
+ [more later]
+ *
+ @section sec_logging_destination     The Destination Specifier.
+ *
+ The \{logger-env-base\}_DEST environment variable can be used to specify where
+ the log output goes. The following specifiers are recognized:
+ *
+ - file=\<filename\>
+   This sets the logger output filename to \<filename\>. Not formatting
+   or anything is supported. Each logger specifies a default name if
+   file logging should be enabled by default.
+ *
+ - nofile
+   This disables the file output.
+ *
+ - stdout
+   Enables logger output to stdout.
+ *
+ - nostdout
+   Disables logger output to stdout.
+ *
+ - stderr
+   Enables logger output to stderr.
+ *
+ - nostderr
+   Disables logger output to stderr.
+ *
+ - debugger
+   Enables logger output to native debugger. (Win32/64 only)
- nodebugger
  Disables logger output to native debugger. (Win32/64 only)

- user
  Enables logger output to special backdoor if in guest r0.

- nodebugger
  Disables logger output to special user stream.

@section sec_logging_group The Group Specifier.

The \{logger-env-base\} environment variable can be used to specify which
logger groups to enable and which to disable. By default all groups are
disabled. For your convenience this specifier is case in-sensitive (ASCII).

The specifier is evaluated from left to right.

[more later]

The groups settings can be reprogrammed during execution using the
RTLogGroupSettings() command and a group specifier.

@section sec_logging_default The Default Logger

The default logger uses VBOX_LOG_DEST as destination specifier. File output is
enabled by default and goes to a file "/VBox-\<pid\>.log".

The default logger have all groups turned off by default to force the developer
to be careful with what log information to collect - logging everything is
generally NOT a good idea.

The log groups of the default logger can be found in the LOGGROUP in enum. The
VBOX_LOG environment variable and the .log debugger command can be used to
configure the groups.

Each group have flags in addition to the enable/disable flag. These flags can
be appended to the group name using dot separators. The flags correspond to
RTLOGGRPFLAGS and have a short and a long version:

- e - Enabled: Whether the group is enabled at all.
- l - Level2: Level-2 logging.
- f - Flow: Execution flow logging (entry messages)
- s - Sander: Special Sander logging messages.
- b - Bird: Special Bird logging messages.
Example:

VBOX_LOG=+all+pgm.e.s.b.z.l-qemu

Space and ';' separators are allowed:

VBOX_LOG=+all +pgm.e.s.b.z.l ; - qemu

Example:

VBOX_LOG=+all+pgm.e.s.b.z.l-qemu

Space and ';' separators are allowed:

VBOX_LOG=+all +pgm.e.s.b.z.l ; - qemu

VBoxGuest is the device driver for VMMDev.

The device driver is shipped as part of the guest additions. It has roots in
the host VMM support driver (usually known as VBoxDrv), so fixes in platform
specific code may apply to both drivers.

The common code lives in VBoxGuest.cpp and is compiled both as C++ and C.
The VBoxGuest.cpp source file shall not contain platform specific code,
though it must occasionally do a few \#ifdef RT_OS_XXX tests to cater for
platform differences. Though, in those cases, it is common that more than
one platform needs special handling.

On most platforms the device driver should create two device nodes, one for
full (unrestricted) access to the feature set, and one which only provides a
restrict set of functions. These are generally referred to as 'vboxguest'
and 'vboxuser' respectively. Currently, this two device approach is only
implemented on Linux!

+***************************************************************
+* Header Files
+*
Main memory heap consists of double linked list
of chunks. Memory blocks are allocated inside these chunks
and are members of Allocated and Free double linked lists.

When allocating a block, we search in Free linked
list for a suitable free block. If there is no such block,
a new chunk is allocated and the new block is taken from
the new chunk as the only chunk-sized free block.
Allocated block is excluded from the Free list and goes to
Alloc list.

When freeing block, we check the pointer and then
exclude block from Alloc list and move it to free list.

For each chunk we maintain the allocated blocks counter.
If 2 (or more) entire chunks are free they are immediately
deallocated, so we always have at most 1 free chunk.

When freeing blocks, two subsequent free blocks are always
merged together. Current implementation merges blocks only
when there is a block after the just freed one.

+* Internal Functions *
+******************************************************************************
+static void rtThreadDestroy(PRTTHREADINT pThread);
**@page pg_rt_thread  IPRT Thread Internals**

+ * IPRT provides interface to whatever native threading that the host provides,
+ * preferably using a CRT level interface to better integrate with other libraries.

+ * Internally IPRT keeps track of threads by means of the RTTHREADINT structure.
+ * All the RTTHREADINT structures are kept in an AVL tree which is protected by a
+ * read/write lock for efficient access. A thread is inserted into the tree in
+ * three places in the code. The main thread is 'adopted' by IPRT on rtR3Init()
+ * by rtThreadAdopt(). When creating a new thread there the child and the parent
+ * race inserting the thread, this is rtThreadMain() and RTThreadCreate.

+ * RTTHREADINT objects are using reference counting as a mean of sticking around
+ * till no-one needs them any longer. Waitable threads is created with one extra
+ * reference so they won't go away until they are waited on. This introduces a
+ * major problem if we use the host thread identifier as key in the AVL tree - the
+ * host may reuse the thread identifier before the thread was waited on. So, on
+ * most platforms we are using the RTTHREADINT pointer as key and not the
+ * thread id. RTThreadSelf() then have to be implemented using a pointer stored
+ * in thread local storage (TLS).

+ * In Ring-0 we only try keep track of kernel threads created by RTThreadCreate
+ * at the moment. There we really only need the 'join' feature, but doing things
+ * the same way allow us to name threads and similar stuff.

# RTThreadSetType

**Synopsis**

Sets the type of the specified thread.

**Declaration**

```c
RTDECL(RTTHREADTYPE) RTThreadSetType(RTTHREAD Thread, RTTHREADTYPE enmType);
```

**Parameters**

- **Thread**
  - The thread in question.

- **enmType**
  - The thread type.

**Return Value**

- **RT_SUCCESS** if successful.
- **VERR_INVALID_HANDLE** if the thread handle is invalid.
- **VERR_INVALID_PARAMETER** if the thread handle is invalid.

**Description**

Sets the type of the specified thread. This function is exported for use in the RT implementation.

**Error Handling**

- If `enmType` is invalid, the function returns `VERR_INVALID_PARAMETER`.
- If the thread handle is invalid, the function returns `VERR_INVALID_HANDLE`.
- If the thread is not alive, the function returns `VERR_THREAD_IS_DEAD`.

**Examples**

```c
void example()
{
    RTTHREADTYPE enmType = RTTHREADTYPE_INVALID;
    RTTHREAD Thread = rtThreadCreate();
    RTThreadSetType(Thread, enmType);
}
```

 */

/* It is considered internal in ring-3, please use the VbgIR3 functions.

- I/O controls for user and/or kernel mode starts at 0.
*/
- IDC specific requests descends from 127.
- Bits 7 and 6 are currently reserved for future hacks.

@remarks When creating new IOCTL interfaces keep in mind that not all OSes supports reporting back the output size. (This got messed up a little bit in VBoxDrv.)

The request size is also a little bit tricky as it's passed as part of the request code on unix. The size field is 14 bits on Linux, 12 bits on *BSD, 13 bits Darwin, and 8-bits on Solaris. All the BSDs and Darwin kernels will make use of the size field, while Linux and Solaris will not. We're of course using the size to validate and/or map/lock the request, so it has to be valid.

For Solaris we will have to do something special though, 255 isn't sufficient for all we need. A 4KB restriction (BSD) is probably not too problematic (yet) as a general one.

More info can be found in SUPDRVIOC.h and related sources.

@remarks If adding interfaces that only has input or only has output, some new macros needs to be created so the most efficient IOCTL data buffering method can be used.

```
+ * IOCTL to for acquiring and releasing guest capabilities.
+ *
+ * This is used for multiple purposes:
+ * 1. By doing @a acquire r3 client application (e.g. VBoxTray) claims it will
+ *    use the given session for performing operations like @a seamless or
+ *    @a auto-resize, thus, if the application terminates, the driver will
+ *    automatically cleanup the caps reported to host, so that host knows guest
+ *    does not support them anymore
+ * 2. In a multy-user environment this will not allow r3 applications (like
+ *    VBoxTray) running in different user sessions simultaneously to interfere
+ *    with each other. An r3 client application (like VBoxTray) is responsible
+ *    for Acquiring/Releasing caps properly as needed.
+ *
+ * VERR_RESOURCE_BUSY is returned if any capabilities in the fOrMask are
+ * currently acquired by some other VBoxGuest session.

 * different.
 */
+ * @section sec_guest_lib_ring0   Ring-0
+ *
+ * In ring-0 there are two version:
+ *  - VBOX_LIB_VBGL_R0_BASE / VBoxGuestR0LibBase for the VBoxGuest main driver,
+ *    who is responsible for managing the VMMDev virtual hardware.
+ *  - VBOX_LIB_VBGL_R0 / VBoxGuestR0Lib for other (client) guest drivers.
+ *
+ * The library source code and the header have a define VBGL_VBOXGUEST, which is
+ * defined for VBoxGuest and undefined for other drivers. Drivers must choose
+ * right library in their makefiles and set VBGL_VBOXGUEST accordingly.
+ *
+ * The libraries consists of:
+ *  - common code to be used by both VBoxGuest and other drivers;
+ *  - VBoxGuest specific code;
+ *  - code for other drivers which communicate with VBoxGuest via an IOCTL.
+ *
+ *
+ * @section sec_guest_lib_ring3   Ring-3
+ *
+ * There are more variants of the library here:
+ *  - VBOX_LIB_VBGL_R3 / VBoxGuestR3Lib for programs.
+ *  - VBOX_LIB_VBGL_R3_XFREE86 / VBoxGuestR3LibXFree86 for old style XFree
+ *    drivers which uses special loader and or symbol resolving strategy.
+ *  - VBOX_LIB_VBGL_R3_SHARED / VBoxGuestR3LibShared for shared objects / DLLs /
+ *    Dylibs.
+ *

+ *
+ ****
+ * The data consists of 1 bpp AND mask followed by 32 bpp XOR (color) mask.
+ *
+ * For pointers without alpha channel the XOR mask pixels are 32 bit values: (lsb)BGR0(msb).
+ * For pointers with alpha channel the XOR mask consists of (lsb)BGRA(msb) 32 bit values.
+ *
+ * Guest driver must create the AND mask for pointers with alpha channel, so if host does not
+ * support alpha, the pointer could be displayed as a normal color pointer. The AND mask can
+ * be constructed from alpha values. For example alpha value >= 0xf0 means bit 0 in the AND mask.
+ *
+ * The AND mask is 1 bpp bitmap with byte aligned scanlines. Size of AND mask,
+ * therefore, is cbAnd = (width + 7) / 8 * height. The padding bits at the
+ * end of any scanline are undefined.
+ *
+ * The XOR mask follows the AND mask on the next 4 bytes aligned offset:
+ * uint8_t *pXor = pAnd + (cbAnd + 3) & ~3
+ * Bytes in the gap between the AND and the XOR mask are undefined.
+ * XOR mask scanlines have no gap between them and size of XOR mask is:
+ * cXor = width * 4 * height.
+ ****

+ * address. */
+** VERR_PGM_PHYS_PAGE_RESERVED: No page directory available for the hypervisor.

+** VERR_PGM_NO_HYPERVISOR_ADDRESS: The shadow page pool was flushed. This means that a global CR3 sync was flagged. Anyone receiving this kind of status will have to get down to a SyncCR3 ASAP. See also VINF_PGM_SYNC_CR3.

+** VERR_PGM_POOL_FLUSHED: The shadow page pool was cleared. This is a error code internal to the shadow page pool, it will be converted to VERR_PGM_POOL.Flushed before leaving the pool code.

+** VINF_PGM_CACHED_PAGE: The returned shadow page is cached.

+** VINF_PGM_GCPHYS_ALIASED: Returned by handler registration, modification and deregistration when the shadow PTs could be updated because the guest page aliased or/and mapped by multiple PTs.

+** VINF_PGM_CHANGE_MODE: PGMCChangeMode() uses this to force a switch to R3 so it can safely deal with a mode switch.

+** VINF_PGM_SYNCPAGE_MODIFIED_PDE: SyncPage modified the PDE. This is an internal status code used to communicate back to the #PF handler that the PDE was (probably) marked not-present and it should restart the instruction.

+** VINF_PGM_GCPHYS_RANGE_CROSSES_BOUNDARY: Conflict between the core memory and the intermediate paging context, try again.

+** VERR_PGM_INTERMEDIATE_PAGING_CONFLICT: The dynamic mapping cache for physical memory failed.

+** VERR_PGM_DYNMAP_FAILED: The auto usage cache for the dynamic mapping set is full.

+** VERR_PGM_DYNMAP_SETERROR: The initialization of the dynamic mapping cache failed.

+** VERR_PGM_DYNMAP_EXPAND_ERROR: The page is unassigned (akin to VERR_PGM_INVALID_GC_PHYSICAL_ADDRESS).

+** VERR_PGM_PHYS_TLB_CATCH_ALL: Catch any access and route it thru PGM.

+
+@def VBOX_LOGGROUP_NAMES
+ * VirtualBox Logging group names.
+ *
+ * Must correspond 100% to LOGGROUP!
+ * Don't forget commas!
+ *
+ * @remark It should be pretty obvious, but just to have
+ * mentioned it, the values are sorted alphabetically (using the
+ * english alphabet) except for _DEFAULT which is always first.
+ *
+ * If anyone might be wondering what the alphabet looks like:
+ *
