/*
   * Compat (i.e. 32 bit) mode:
   * - PC has been set in the pt_regs struct in kernel_entry,
   * - Handle SP and LR here,
   * - Our handling of compat tasks (PERF_SAMPLE_REGS_ABI_32) is weird, but
we're stuck with it for ABI compatibility reasons.

For a 32-bit consumer inspecting a 32-bit task, then it will look at the first 16 registers (see arch/arm/include/uapi/asm/perf_regs.h).

These correspond directly to a prefix of the registers saved in our 'struct pt_regs', with the exception of the PC, so we copy that down (x15 corresponds to SP_hyp in the architecture).

So far, so good.

The oddity arises when a 64-bit consumer looks at a 32-bit task and asks for registers beyond PERF_REG_ARM_MAX. In this case, we return SP_usr, LR_usr and PC in the positions where the AArch64 SP, LR and PC registers would normally live. The initial idea was to allow a 64-bit unwinder to unwind a 32-bit task and, although it's not clear how well that works in practice, somebody might be relying on it.

At the time we make a sample, we don't know whether the consumer is 32-bit or 64-bit, so we have to cater for both possibilities.

```
if (compat_user_mode(regs)) {
    if ((u32)idx == PERF_REG_ARM64_SP)
        return regs->compat_sp;
    if ((u32)idx == PERF_REG_ARM64_LR)
        return regs->compat_lr;
    if (idx == 15)
        return regs->pc;
}
```

#ifndef _ASM_COMPILER_H
#define _ASM_COMPILER_H
+
+ /* With GCC 4.5 onwards we can use __builtin_unreachable to indicate to the
+ * compiler that a particular code path will never be hit. This allows it to be
+ * optimised out of the generated binary.
+ *
+ * Unfortunately at least GCC 4.6.3 through 7.3.0 inclusive suffer from a bug
+ * that can lead to instructions from beyond an unreachable statement being
+ * incorrectly reordered into earlier delay slots if the unreachable statement
+ * is the only content of a case in a switch statement. This can lead to
+ * seemingly random behaviour, such as invalid memory accesses from incorrectly
+ * reordered loads or stores. See this potential GCC fix for details:
+ *
+ *
+ * It is unclear whether GCC 8 onwards suffer from the same issue - nothing
+ * relevant is mentioned in GCC 8 release notes and nothing obviously relevant
+ * stands out in GCC commit logs, but these newer GCC versions generate very
+ * different code for the testcase which doesn't exhibit the bug.
+ *
+ * GCC also handles stack allocation suboptimally when calling noreturn
+ * functions or calling __builtin_unreachable():
+ *
+ *   https://gcc.gnu.org/bugzilla/show_bug.cgi?id=82365
+ *
+ * We work around both of these issues by placing a volatile asm statement,
+ * which GCC is prevented from reordering past, prior to __builtin_unreachable
+ * calls.
+ *
+ * The .insn statement is required to ensure that any branches to the
+ * statement, which sadly must be kept due to the asm statement, are known to
+ * be branches to code and satisfy linker requirements for microMIPS kernels.

--- linux-4.15.0.orig/arch/powerpc/include/asm/io.h
their hooks, a bitfield is reserved for use by the platform near the
top of MMIO addresses (not PIO, those have to cope the hard way).

- * This bit field is 12 bits and is at the top of the IO virtual
- * addresses PCI_IO_INDIRECT_TOKEN_MASK.
+ * The highest address in the kernel virtual space are:

- * The kernel virtual space is thus:
+ * d0003fffffffffff# with Hash MMU
+ * c00fffffffffff# with Radix MMU

- * 0xD000000000000000: vmalloc
- * 0xD000080000000000: PCI PHB IO space
- * 0xD000080000000000: ioremap
- * 0xD0000fffffffff: end of ioremap region

- * Since the top 4 bits are reserved as the region ID, we use thus
- * the next 12 bits and keep 4 bits available for the future if the
- * virtual address space is ever to be extended.
+ * The top 4 bits are reserved as the region ID on hash, leaving us 8 bits
+ * that can be used for the field.

- * The direct IO mapping operations will then mask off those bits
- * before doing the actual access, though that only happen when

- static inline void kvmppc_set_host_ipi(int cpu, u8 host_ipi)
+ /*
+ * To avoid the need to unnecessarily exit fully to the host kernel, an IPI to
+ * a CPU thread that's running/napping inside of a guest is by default regarded
+ * as a request to wake the CPU (if needed) and continue execution within the
+ * guest, potentially to process new state like externally-generated
+ * interrupts or IPIs sent from within the guest itself (e.g. H_PROD/H_IPI).
+ *
+ * To force an exit to the host kernel, kvmppc_set_host_ipi() must be called
+ * prior to issuing the IPI to set the corresponding 'host_ipi' flag in the
+ * target CPU's PACA. To avoid unnecessary exits to the host, this flag should
+ * be immediately cleared via kvmppc_clear_host_ipi() by the IPI handler on
+ * the receiving side prior to processing the IPI work.
+ *
+ * NOTE:
+ *
+ * We currently issue an smp_mb() at the beginning of kvmppc_set_host_ipi().
+ * This is to guard against sequences such as the following:
+ *
+ * CPU
+ * X: smp_mucked_ipt_set_message():
+ * X: smp_mb()
X: message[RESCHEDULE] = 1
X: doorbell_global_ipi(42):
X: kvmppc_set_host_ipi(42)
X: ppc_msgsnd_sync()/smp_mb()
X: ppc_msgsnd() -> 42
42: doorbell_exception(): // from CPU X
42: ppc_msgsync()
105: smp_muxed_ipi_set_message():
105: smb_mb()

// STORE DEFERRED DUE TO RE-ORDERING
--105: message[CALL_FUNCTION] = 1
| 105: doorbell_global_ipi(42):
| 105: kvmppc_set_host_ipi(42)
| 42: kvmppc_clear_host_ipi(42)
| 42: smp_ipi_demux_relaxed()
| 42: // returns to executing guest
| // RE-ORDERED STORE COMPLETES
| ->105: message[CALL_FUNCTION] = 1
| 105: ppc_msgsnd_sync()/smp_mb()
| 105: ppc_msgsnd() -> 42
| 42: local_paca->kvm_hstate.host_ipi == 0 // IPI ignored
| 105: // hangs waiting on 42 to process messages/call_single_queue

We also issue an smp_mb() at the end of kvmppc_clear_host_ipi(). This is
to guard against sequences such as the following (as well as to create
a read-side pairing with the barrier in kvmppc_set_host_ipi()):

CPU
X: smp_muxed_ipi_set_message():
X: smb_mb()
X: message[RESCHEDULE] = 1
X: doorbell_global_ipi(42):
X: kvmppc_set_host_ipi(42)

Various features indicating support for Spectre/Meltdown mitigations:

- The L1-D cache can be flushed with ori r30,r30,0
- The L1-D cache can be flushed with mtspr 882,r0 (aka SPRN_TRIG2)
- ori r31,r31,0 acts as a speculation barrier
- Entries in L1-D are private to a SMT thread
- Indirect branch prediction cache disabled
- bcct 2,0,0 triggers a hardware assisted count cache flush
- Features indicating need for Spectre/Meltdown mitigations
- The L1-D cache should be flushed on MSR[HV] 1->0 transition (hypervisor to guest)
- The L1-D cache should be flushed on MSR[PR] 0->1 transition (kernel to userspace)
- A speculation barrier should be used for bounds checks (Spectre variant 1)
- Firmware configuration indicates user favours security over performance
- Software required to flush count cache on context switch
- Software required to flush link stack on context switch
- The L1-D cache should be flushed when entering the kernel
- The L1-D cache should be flushed after user accesses from the kernel

-static DEFINE_IDA(vas_thread_ida);
-
-/*
- * We need to assign a unique thread id to each thread in a process.
-*/
-/**
+ * Assign a TIDR (thread ID) for task @t and set it in the thread
+ * structure. For now, we only support setting TIDR for 'current' task.
+ *
- * This thread id, referred to as TIDR, and separate from the Linux's tgid,
- * is intended to be used to direct an ASB_Notify from the hardware to the
- * thread, when a suitable event occurs in the system.
+ * Since the TID value is a truncated form of it PID, it is possible
+ * (but unlikely) for 2 threads to have the same TID. In the unlikely event
+ * that 2 threads share the same TID and are waiting, one of the following
+ * cases will happen:
*  
- * One such event is a "paste" instruction in the context of Fast Thread
- * Wakeup (aka Core-to-core wake up in the Virtual Accelerator Switchboard
- * (VAS) in POWER9.
+ * 1. The correct thread is running, the wrong thread is not
+ * In this situation, the correct thread is woken and proceeds to pass its
+ * condition check.
*  
- * To get a unique TIDR per process we could simply reuse task_pid_nr() but
- * the problem is that task_pid_nr() is not yet available copy_thread() is
- * called. Fixing that would require changing more intrusive arch-neutral
- * code in code path in copy_process()?
+ * 2. Neither threads are running
+ * In this situation, neither thread will be woken. When scheduled, the waiting
+ * threads will execute either a wait, which will return immediately, followed
+ * by a condition check, which will pass for the correct thread and fail
+ * for the wrong thread, or they will execute the condition check immediately.
*  
- * Further, to assign unique TIDRs within each process, we need an atomic
- * field (or an IDR) in task_struct, which again intrudes into the arch-
- * neutral code. So try to assign globally unique TIDRs for now.
+ * 3. The wrong thread is running, the correct thread is not
+ * The wrong thread will be woken, but will fail its condition check and
+ * re-execute wait. The correct thread, when scheduled, will execute either
+ * its condition check (which will pass), or wait, which returns immediately
+ * when called the first time after the thread is scheduled, followed by its
+ * condition check (which will pass).
*  
- * NOTE: TIDR 0 indicates that the thread does not need a TIDR value.
- * For now, only threads that expect to be notified by the VAS
- * hardware need a TIDR value and we assign values > 0 for those.
- * /

config TAU_INT
-bool "Interrupt driven TAU driver (DANGEROUS)"
+bool "Interrupt driven TAU driver (EXPERIMENTAL)"
depends on TAU
---help---
The TAU supports an interrupt driven mode which causes an interrupt
to get notified the temp has exceeded a range. With this option off,
a timer is used to re-check the temperature periodically.

- However, on some cpus it appears that the TAU interrupt hardware
- is buggy and can cause a situation which would lead unexplained hard
- lockups.
-
- Unless you are extending the TAU driver, or enjoy kernel/hardware
- debugging, leave this option off.
+ If in doubt, say N here.

+ * opencapi actags handling:
+ *
+ * When sending commands, the opencapi device references the memory
+ * context it's targeting with an 'actag', which is really an alias
+ * for a (BDF, pasid) combination. When it receives a command, the NPU
+ * must do a lookup of the actag to identify the memory context. The
+ * hardware supports a finite number of actags per link (64 for
+ * POWER9).
+ *
+ * The device can carry multiple functions, and each function can have
+ * multiple AFUs. Each AFU advertises in its config space the number
+ * of desired actags. The host must configure in the config space of
+ * the AFU how many actags the AFU is really allowed to use (which can
+ * be less than what the AFU desires).
+ *
+ * When a PCI function is probed by the driver, it has no visibility
+ * about the other PCI functions and how many actags they'd like,
+ * which makes it impossible to distribute actags fairly among AFUs.
+ *
+ * Unfortunately, the only way to know how many actags a function
+ * desires is by looking at the data for each AFU in the config space
+ * and add them up. Similarly, the only way to know how many actags
+ * all the functions of the physical device desire is by adding the
+ * previously computed function counts. Then we can match that against
+ * what the hardware supports.
+ *
+ * To get a comprehensive view, we use a 'pci fixup': at the end of
+ * PCI enumeration, each function counts how many actags its AFUs
+ * desire and we save it in a 'npu_link' structure, shared between all
+ * the PCI functions of a same device. Therefore, when the first
+ * function is probed by the driver, we can get an idea of the total
+ * count of desired actags for the device, and assign the actags to
+ * the AFUs, by pro-rating if needed.

The AQ/RL pair provides a RCpc critical section, but there's not really any way we can take advantage of that here because the ordering is only enforced on that one lock. Thus, we're just doing a full fence.

Since we allow writeX to be called from preemptive regions we need at least an "o" in the predecessor set to ensure device writes are visible before the task is marked as available for scheduling on a new hart. While I don't see any concrete reason we need a full IO fence, it seems safer to just upgrade this in order to avoid any IO crossing a scheduling boundary. In both instances the scheduler pairs this with an mb(), so nothing is necessary on the new hart.

/*
 * s390 arch random implementation.
 *
- * Copyright IBM Corp. 2017
- * Author(s): Harald Freudenberger <freude@de.ibm.com>
+ * Copyright IBM Corp. 2017, 2018
+ * Author(s): Harald Freudenberger
+ *
+ * The s390_arch_random_generate() function may be called from random.c

in interrupt context. So this implementation does the best to be very
fast. There is a buffer of random data which is asynchronously checked
and filled by a workqueue thread.
* If there are enough bytes in the buffer the s390_arch_random_generate()
* just delivers these bytes. Otherwise false is returned until the
* worker thread refills the buffer.
* The worker fills the rng buffer by pulling fresh entropy from the
* high quality (but slow) true hardware random generator. This entropy
* is then spread over the buffer with an pseudo random generator PRNG.
* As the arch_get_random_seed_long() fetches 8 bytes and the calling
* function add_interrupt_randomness() counts this as 1 bit entropy the
* distribution needs to make sure there is in fact 1 bit entropy contained
* in 8 bytes of the buffer. The current values pull 32 byte entropy
* and scatter this into a 2048 byte buffer. So 8 byte in the buffer
* will contain 1 bit of entropy.
* The worker thread is rescheduled based on the charge level of the
* buffer but at least with 500 ms delay to avoid too much CPU consumption.
* So the max. amount of rng data delivered via arch_get_random_seed is
* limited to 4k bytes per second.
*/

 *   ZSENDEP11CPRB
 *     Send an arbitrary EP11 CPRB to an EP11 coprocessor crypto card.
 *
-*   Z90STAT_STATUS_MASK
-*     Return an 64 element array of unsigned chars for the status of
-*     all devices.
+*   ZCRYPT_DEVICE_STATUS
+*     The given struct zcrypt_device_matrix_ext is updated with
+*     status information for each currently known apqn.
+*
+*   ZCRYPT_STATUS_MASK
+*     Return an MAX_ZDEV_CARDIDS_EXT element array of unsigned chars for the
+*     status of all devices.
 * 0x01: PCICA
 * 0x02: PCICC
 * 0x03: PCIXCC_MCL2
 * 0x04: PCIXCC_MCL3
 * 0x05: CEX2C
 * 0x06: CEX2A
-* 0x0d: device is disabled via the proc filesystem
-*
-*   Z90STAT_QDEPTH_MASK
-*     Return an 64 element array of unsigned chars for the queue
-*     depth of all devices.
-*
-*   Z90STAT_PERDEV_REQCNT
-*     Return an 64 element array of unsigned integers for the number
-*     of successfully completed requests per device since the device
-*     was detected and made available.
-*
-*   Z90STAT_REQUESTQ_COUNT
-*     Return an integer count of the number of entries waiting to be
-*     sent to a device.
-*
-*   Z90STAT_PENDINGQ_COUNT
-*     Return an integer count of the number of entries sent to all
-*     devices awaiting the reply.
-*
-*   Z90STAT_TOTALOPEN_COUNT
-*     Return an integer count of the number of open file handles.
-*
-*   Z90STAT_DOMAIN_INDEX
-*     Return the integer value of the Cryptographic Domain.
-*
```
The following ioctl's are deprecated and should be no longer used:

- Z90STAT_TOTALCOUNT
  - Return an integer count of all device types together.

- Z90STAT_PCICACOUNT
  - Return an integer count of all PCICAs.

- Z90STAT_PCICCCOUNT
  - Return an integer count of all PCICCs.

- Z90STAT_PCIXCMCL2COUNT
  - Return an integer count of all MCL2 PCIXCCs.

- Z90STAT_PCIXCMCL3COUNT
  - Return an integer count of all MCL3 PCIXCCs.

- Z90STAT_CEX2CCOUNT
  - Return an integer count of all CEX2Cs.
    + 0x07: CEX3C
    + 0x08: CEX3A
    + 0x0a: CEX4
    + 0x0b: CEX5
    + 0x0c: CEX6
    + 0x0d: device is disabled

- ZCRYPT_QDEPTH_MASK
  - Return an MAX_ZDEV_CARDIDS_EXT element array of unsigned chars for the queue depth of all devices.

- ZCRYPT_PERDEV_REQCNT
  - Return an MAX_ZDEV_CARDIDS_EXT element array of unsigned integers for the number of successfully completed requests per device since the device was detected and made available.

- Z90STAT_CEX2ACOUNT
  - Return an integer count of all CEX2As.

- ICAZ90STATUS
  - Return some device driver status in a ica_z90_status struct
    - This takes an ica_z90_status struct as its arg.

- Z90STAT_PCIXCCCOUNT
  - Return an integer count of all PCIXCCs (MCL2 + MCL3).
    - This is DEPRECATED now that MCL3 PCIXCCs are treated differently from MCL2 PCIXCCs.

 * The SMP TLB coherency scheme we use works as follows:
 * 1) mm->cpu_vm_mask is a bit mask of which cpus an address
 *    space has (potentially) executed on, this is the heuristic
 *    we use to avoid doing cross calls.
 * 2) TLB context numbers are shared globally across all processors
 *    in the system, this allows us to play several games to avoid
 *    cross calls.
 *    One invariant is that when a cpu switches to a process, and
 *    that processes tsk->active_mm->cpu_vm_mask does not have the
 *    current cpu's bit set, that tlb context is flushed locally.
 *    If the address space is non-shared (ie. mm->count == 1) we avoid
 *    cross calls when we want to flush the currently running process's
 *    tlb state. This is done by clearing all cpu bits except the current
 *    processor's in current->mm->cpu_vm_mask and performing the
 *    flush locally only. This will force any subsequent cpus which run
 *    this task to flush the context from the local tlb if the process
 *    migrates to another cpu (again).
 * 3) For shared address spaces (threads) and swapping we bite the
 *    bullet for most cases and perform the cross call (but only to
 *    the cpus listed in cpu_vm_mask).
 *    The performance gain from "optimizing" away the cross call for threads is
 *    questionable (in theory the big win for threads is the massive sharing of
address space state across processors).
+ * mm->cpu_vm_mask is a bit mask of which cpus an address
+ * space has (potentially) executed on, this is the heuristic
+ * we use to limit cross calls.

help
   Compile kernel with the retpoline compiler options to guard against
   kernel-to-user data leaks by avoiding speculative indirect
   branches. Requires a compiler with -mindirect-branch=thunk-extern
   support for full protection. The kernel may run slower.
   
   - Without compiler support, at least indirect branches in assembler
   - code are eliminated. Since this includes the syscall entry path,
   - it is not entirely pointless.

+prompt "TSX enable mode"
+depends on CPU_SUP_INTEL
+default X86_INTEL_TSX_MODE_OFF
+help
+ Intel's TSX (Transactional Synchronization Extensions) feature
+ allows to optimize locking protocols through lock elision which
+ can lead to a noticeable performance boost.
+
+ On the other hand it has been shown that TSX can be exploited
+ to form side channel attacks (e.g. TAA) and chances are there
+ will be more of those attacks discovered in the future.
+
+ Therefore TSX is not enabled by default (aka tsx=off). An admin
+ might override this decision by tsx=on the command line parameter.
+ Even with TSX enabled, the kernel will attempt to enable the best
+ possible TAA mitigation setting depending on the microcode available
+ for the particular machine.
+
+ This option allows to set the default tsx mode between tsx=on, =off
+ and =auto. See Documentation/admin-guide/kernel-parameters.txt for more
details.
+
+ Say off if not sure, auto if TSX is in use but it should be used on safe
+ platforms or on if TSX is in use and the security aspect of tsx is not
+ relevant.

+
+jmp .Lend_@
+
+.Lentry_from_kernel_@:
+
+/*
+ * This handles the case when we enter the kernel from
+ * kernel-mode and %esp points to the entry-stack. When this
+ * happens we need to switch to the task-stack to run C code,
+ * but switch back to the entry-stack again when we approach
+ * iret and return to the interrupted code-path. This usually
+ * happens when we hit an exception while restoring user-space
+ * segment registers on the way back to user-space or when the
+ * sysenter handler runs with eflags.tf set.
```
When we switch to the task-stack here, we can't trust the contents of the entry-stack anymore, as the exception handler might be scheduled out or moved to another CPU. Therefore we copy the complete entry-stack to the task-stack and set a marker in the iret-frame (bit 31 of the CS dword) to detect what we've done on the iret path.

On the iret path we copy everything back and switch to the entry-stack, so that the interrupted kernel code-path continues on the same stack it was interrupted with.

Be aware that an NMI can happen anytime in this code.

%esi: Entry-Stack pointer (same as %esp)
%edi: Top of the task stack
%eax: CR3 on kernel entry

Calculate number of bytes on the entry stack in %ecx

%esi, %ecx
%edi, %ecx
%eax

%esi to the top of entry-stack

Mark stackframe as coming from entry stack

Test the cr3 used to enter the kernel and add a marker

%esi and %edi are unchanged, %ecx contains the number of bytes to copy. The code at .Lcopy_pt_regs_@ will allocate the stack-frame on task-stack and copy everything over

jmp .Lcopy_pt_regs_@
.Lend_@:
/* Switch back from the kernel stack to the entry stack. */

/* The %esp register must point to pt_regs on the task stack. It will
first calculate the size of the stack-frame to copy, depending on
whether we return to VM86 mode or not. With that it uses 'rep movsl'
to copy the contents of the stack over to the entry stack.

We must be very careful here, as we can't trust the contents of the
task-stack once we switched to the entry-stack. When an NMI happens
while on the entry-stack, the NMI handler will switch back to the top
of the task stack, overwriting our stack-frame we are about to copy.
Therefore we switch the stack only after everything is copied over.

# since some emulators terminate on UD2, we cannot use it for WARN.

---

Open Source Used In 5GaaS Edge AC-4 11634
Since various instruction decoders disagree on the length of UD1, we cannot use it either. So use UD0 for WARN.

Despite that some emulators terminate on UD2, we use it for WARN().

(binutils knows about "ud1" but {en,de}codes it as 2 bytes, whereas our kernel decoder thinks it takes a ModRM byte, which seems consistent with various things like the Intel SDM instruction encoding rules)

Since various instruction decoders/specs disagree on the encoding of UD0/UD1.

```
#define ASM_UD0 		".byte 0x0f, 0xff"
#define ASM_UD1 		".byte 0x0f, 0xb9" /* + ModRM */
#define ASM_UD2 		".byte 0x0f, 0x0b"

#define INSN_UD00xff0f
#define INSN_UD20x0b0f

#define LEN_UD0 		2
#define LEN_UD2 		2
```

```
