* fields with timing values to match the current frequency of the
* ipg_clk. OTP writes will work at maximum bus frequencies as long
* as the HW_OCOTP_TIMING parameters are set correctly.
+ *
+ * Note: there are minimum timings required to ensure an OTP fuse burns
+ * correctly that are independent of the ipg_clk. Those values are not
+ * formally documented anywhere however, working from the minimum
+ * timings given in u-boot we can say:
+ *
+ * - Minimum STROBE_PROG time is 10 microseconds. Intuitively 10
+ * microseconds feels about right as representative of a minimum time
+ * to physically burn out a fuse.
+ *
+ * - Minimum STROBE_READ i.e. the time to wait post OTP fuse burn before
+ * performing another read is 37 nanoseconds
+ *
+ * - Minimum RELAX timing is 17 nanoseconds. This final RELAX minimum
+ * timing is not entirely clear the documentation says "This
+ * count value specifies the time to add to all default timing
+ * parameters other than the Tpgm and Trd. It is given in number
+ * of ipg_clk periods." where Tpgm and Trd refer to STROBE_PROG
+ * and STROBE_READ respectively. What the other timing parameters
+ * are though, is not specified. Experience shows a zero RELAX
+ * value will mess up a re-load of the shadow registers post OTP
+ * burn.

    - * Some ideapads don't have a hardware rfkill switch, reading VPCCMD_R_RF
    - * always results in 0 on these models, causing ideapad_laptop to wrongly
    - * report all radios as hardware-blocked.
    + * Some ideapads have a hardware rfkill switch, but most do not have one.
    + * Reading VPCCMD_R_RF always results in 0 on models without a hardware rfkill,
    + * switch causing ideapad_laptop to wrongly report all radios as hw-blocked.
    + * There used to be a long list of DMI ids for models without a hw rfkill
    + * switch here, but that resulted in playing whack a mole.
    + * More importantly wrongly reporting the wifi radio as hw-blocked, results in
    + * non working wifi. Whereas not reporting it hw-blocked, when it actually is
    + * hw-blocked results in an empty SSID list, which is a much more benign
    + * failure mode.
    + * So the default now is the much safer option of assuming there is no
    + * hardware rfkill switch. This default also actually matches most hardware,
    + * since having a hw rfkill switch is quite rare on modern hardware, so this
    + * also leads to a much shorter list.

  * The HP Pavilion x2 10 series comes in a number of variants:
  * + Bay Trail SoC    + AXP288 PMIC, Micro-USB, DMI_BOARD_NAME: "8021"
  * + Bay Trail SoC    + AXP288 PMIC, Type-C,   DMI_BOARD_NAME: "815D"
  * + Cherry Trail SoC + AXP288 PMIC, Type-C,   DMI_BOARD_NAME: "813E"
  * + Cherry Trail SoC+ TI PMIC,  Type-C,   DMI_BOARD_NAME: "827C" or "82F4"
  * +
  * + The variants with the AXP288 + Type-C connector are all kinds of special:
  * +
  * + 1. They use a Type-C connector which the AXP288 does not support, so when
  * + using a Type-C charger it is not recognized. Unlike most AXP288 devices,
this model actually has mostly working ACPI AC/Battery code, the ACPI code
"solves" this by simply setting the input_current_limit to 3A.
There are still some issues with the ACPI code, so we use this native driver,
and to solve the charging not working (500mA is not enough) issue we hardcode
the 3A input_current_limit like the ACPI code does.

2. If no charger is connected the machine boots with the vbus-path disabled.
Normally this is done when a 5V boost converter is active to avoid the PMIC
trying to charge from the 5V boost converter's output. This is done when
an OTG host cable is inserted and the ID pin on the micro-B receptacle is
pulled low and the ID pin has an ACPI event handler associated with it
which re-enables the vbus-path when the ID pin is pulled high when the
OTG host cable is removed. The Type-C connector has no ID pin, there is
no ID pin handler and there appears to be no 5V boost converter, so we
end up not charging because the vbus-path is disabled, until we unplug
the charger which automatically clears the vbus-path disable bit and then
on the second plug-in of the adapter we start charging. To solve the not
charging on first charger plugin we unconditionally enable the vbus-path at
probe on this model, which is safe since there is no 5V boost converter.

+/*
+ * Version History.
+ * 2016-10-26 0.6.0 fixed time fields in rtc_read_alarm function
+ *
+ * 2016-10-03 0.5.0 notify that UIE is not supported by our hw
+ * add mutex lock/unlock to read/set time functions
+ *
+ * 2016-07-12 0.4-0 Add clock_adj parameter for XT clock calibration
+ *
+ * 2016-04-20 0.3.0 Add board turn on feature
+ * Feature is enabled as parameter and can be changed
+ * via sysfs
+ * Trickle charger as module parameter
+ *
+ * 2016-04-010.2.0 Add alarm, watchdog functionality
+ * watchdog create a 60ms pulse on sRST pin 3.3V -> 0 -> 3.3V
+ * alarm create a 250ms pulse on nIRQ pin 3.3V -> 0 -> 3.3V
+ *
+ * 2016-01-220.1.0 First Release
+ * date time get/set commands
+ * 256 byte get/set via sysfs.
+ * ram_address allows to get/set ram_byte
+ * watchdog

 * - On entry ch_len holds the count of CCWs to be translated.
 * - On exit ch_len is adjusted to the count of successfully translated CCWs.
 * This allows cp_free to find in ch_len the count of CCWs to free in a chain.
 * The S/390 CCW Translation APIS (prefixed by 'cp_') are introduced
 * as helpers to do ccw chain translation inside the kernel. Basically

/* Determine whether the device requires a specific layer discipline */  
static enum qeth_discipline_id qeth_enforce_discipline(struct qeth_card *card) {
```

The code snippet provided is from a network driver, likely for a QEMU-based network emulator. It demonstrates the handling of a query to retrieve a user ID from the device, followed by a diagnostic call to a function `diag26c()` with a request and response structure. Error checks are performed on the returned code to ensure correctness. The snippet also includes logic to determine the layer discipline required by the device based on the response protocol. Finally, it includes a function declaration `qeth_enforce_discipline()`, which is presumably responsible for enforcing the correct discipline layer for the device based on the query response.
