This is the list of patches/features which have been temporarily reverted or disabled for BB:

+ AUFS
+ LSM stacking patches

+ UBUNTU: SAUCE: (no-up) nbd: Change default partitions per device to 15
+ UBUNTU: SAUCE: (no-up) firmware: Update bnx2x to current firmware version 7.2.51
+ UBUNTU: SAUCE: (no-up) Remove redundant cis firmware
+ UBUNTU: SAUCE: (no-up) Remove redundant ttusb-budget firmware
+ UBUNTU: SAUCE: (no-up) Remove redundant ositech/Xilinx7OD firmware
+ UBUNTU: SAUCE: (no-up) Remove redundant yamaha/ds1 firmware
+ UBUNTU: SAUCE: (no-up) Remove redundant keysuan_pda firmware
+ UBUNTU: SAUCE: (no-up) firmware: Remove ess files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) firmware: Remove kaweth files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) firmware: Remove edgeport files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) firmware: Remove ti_usb_3410_5052 duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) firmware: Remove adaptec files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) firmware: Remove advansys files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) firmware: Remove ambassador files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) firmware: Remove av7110 files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) firmware: Remove cpi2 files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) firmware: Remove obsolete Myricom firmware
+ UBUNTU: SAUCE: (no-up) firmware: Upgrade bnx2 to current versions
+ UBUNTU: SAUCE: (no-up) Remove yam files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) Remove tehuti files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) Remove matrox files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) Remove exgb3 files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) Remove r128 files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) Remove acenic files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) Remove keysuan files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) Remove sun files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) Remove radeon files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) Update bnx2x firmware to 7.8.2.0
+ UBUNTU: SAUCE: (no-up) Remove dsp56k files used only by m68k
+ UBUNTU: SAUCE: (no-up) Remove vicam files duplicated in linux-firmware
+ UBUNTU: SAUCE: (no-up) Update bnx2x firmware to 7.8.17.0
+ UBUNTU: SAUCE: (no-up) Update bnx2x firmware to 7.10.51.0
+ UBUNTU: SAUCE: (no-up) Update bnx2x firmware to 7.12.30.0
+ UBUNTU: SAUCE: drop obsolete bnx2x firmware
+ UBUNTU: firmware: Update bnx2x to 7.13.1.0
+ UBUNTU: SAUCE: (no-up) HID: Add quirk for Lenovo Yoga 910 with ITE Chips
+UBUNTU: SAUCE: igb: add support for using Broadcom 54616 as PHY
+UBUNTU: SAUCE: LIBIO: Introduce a generic PIO mapping method
+UBUNTU: SAUCE: OF: Add missing I/O range exception for indirect-I/O devices
+UBUNTU: SAUCE: LPC: Support the device-tree LPC host on Hip06/Hip07
+UBUNTU: SAUCE: LPC: Add the ACPI LPC support
+UBUNTU: SAUCE: PCI: Apply the new generic I/O management on PCI IO hosts
+UBUNTU: SAUCE: PCI: Restore codepath for !CONFIG_LIBIO
+UBUNTU: SAUCE: PCI: Support hibmc VGA cards behind a misbehaving HiSilicon bridge
+UBUNTU: SAUCE: Clear Linux: smpboot: reuse timer calibration
+UBUNTU: SAUCE: (no-up) disable -pie when gcc has it enabled by default

+config AUFS_FS
+tristate "Aufs (Advanced multi layered unification filesystem) support"
+help
+Aufs is a stackable unification filesystem such as Unionfs,
+which unifies several directories and provides a merged single
+directory.
+In the early days, aufs was entirely re-designed and
+re-implemented Unionfs Version 1.x series. Introducing many
+original ideas, approaches and improvements, it becomes totally
+different from Unionfs while keeping the basic features.
+
+if AUFS_FS
+choice
+prompt "Maximum number of branches"

+select FSNOTIFY
+endchoice
+
+config AUFS_EXPORT
+bool "NFS-exportable aufs"
+depends on EXPORTFS
+help
+If you want to export your mounted aufs via NFS, then enable this
There are several requirements for this configuration. See detail in aufs.5.

+ config AUFS_INO_T_64
  + bool
  + depends on AUFS_EXPORT
  + depends on 64BIT && !(ALPHA || S390)
  + default y
  + help
  + Automatic configuration for internal use.
  + */ typedef unsigned long/int __kernel_ino_t */
  + */ alpha and s390x are int */

+ config AUFS_XATTR
  + bool "support for XATTR/EA (including Security Labels)"
  + help
  + If your branch fs supports XATTR/EA and you want to make them available in aufs too, then enable this option and specify the branch attributes for EA.
  + See detail in aufs.5.

+ config AUFS_FHSM
  + bool "File-based Hierarchical Storage Management"
  + help
  + Hierarchical Storage Management (or HSM) is a well-known feature in the storage world. Aufs provides this feature as file-based.
  + with multiple branches.
  + These multiple branches are prioritized, ie. the topmost one should be the fastest drive and be used heavily.

+ config AUFS_RDU
  + bool "Readdir in userspace"
  + help
  + Aufs has two methods to provide a merged view for a directory, by a user-space library and by kernel-space natively. The latter is always enabled but sometimes large and slow.
  + If you enable this option, install the library in aufs2-util package, and set some environment variables for your readdir(3), then the work will be handled in user-space which generally shows better performance in most cases.
  + See detail in aufs.5.

+ config AUFS_DIRREN
  + bool "Workaround for rename(2)-ing a directory"
  + help
  + By default,aufs returns EXDEV error in renaming a dir who has his child on the lower branch, since it is a bad idea to issue rename(2) internally for every lower branch. But user may not
accept this behaviour. So here is a workaround to allow such
rename(2) and store some extra information on the writable
branch. Obviously this costs high (and I don't like it).
To use this feature, you need to enable this configuration AND
to specify the mount option 'dirren.'
See details in aufs.5 and the design documents.
+
+config AUFS_SHWH
+bool "Show whiteouts"
+help
+If you want to make the whiteouts in aufs visible, then enable
+this option and specify 'shwh' mount option. Although it may
+sounds like philosophy or something, but in technically it
+simply shows the name of whiteout with keeping its behaviour.
+
+config AUFS_BR_RAMFS
+bool "Ramfs (initramfs/rootfs) as an aufs branch"
+help
+If you want to use ramfs as an aufs branch fs, then enable this
+option. Generally tmpfs is recommended.
+Aufs prohibited them to be a branch fs by default, because
+initramfs becomes unusable after switch_root or something
+generally. If you sets initramfs as an aufs branch and boot your
+system by switch_root, you will meet a problem easily since the
+files in initramfs may be inaccessible.
+Unless you are going to use ramfs as an aufs branch fs without
+switch_root or something, leave it N.
+
+config AUFS_BR_FUSE
+bool "Fuse fs as an aufs branch"
+depends on FUSE_FS
+select AUFS_POLL
+help
+If you want to use fuse-based userspace filesystem as an aufs
+branch fs, then enable this option.
+It implements the internal poll(2) operation which is
+implemented by fuse only (currently).
+
+config AUFS_POLL
+bool
+help
+Automatic configuration for internal use.
+
+config AUFS_BR_HFSPLUS
+bool "Hfsplus as an aufs branch"
+depends on HFSPLUS_FS
+default y
+help
+ If you want to use hfsplus fs as an aufs branch fs, then enable
+ this option. This option introduces a small overhead at
+ copying-up a file on hfsplus.
+   + config AUFS_BDEVLOOP
+     bool
+     depends on BLK_DEV_LOOP
+     default y
+     help
+     Automatic configuration for internal use.
+     Convert =[ym] into =y.
+   + config AUFS_DEBUG
+     bool "Debug aufs"
+     help
+     Enable this to compile aufs internal debug code.
+     It will have a negative impact to the performance.
+   + config AUFS_MAGIC_SYSRQ
+     bool
+     depends on AUFS_DEBUG && MAGIC_SYSRQ
+     default y
+     help
+     Automatic configuration for internal use.

+/* The locking order around current->mmap_sem.
+ * - in most and regular cases
+ *   file I/O syscall -- aufs_read() or something
+ *   -- si_rwsem for read -- mmap_sem
+ *   (Note that [fdi]i_rwsem are released before mmap_sem).
+ * - in mmap case
+ *   mmap(2) -- mmap_sem -- aufs_mmap() -- si_rwsem for read -- [fdi]i_rwsem
+ *   This AB-BA order is definitely bad, but is not a problem since "si_rwsem for
+ *   read" allows multiple processes to acquire it and [fdi]i_rwsem are not held in
+ *   file I/O. Aufs needs to stop lockdep in aufs_mmap() though.
+ * It means that when aufs acquires si_rwsem for write, the process should never
+ * acquire mmap_sem.
+ *
+ * Actually aufs_iterate() holds [fdi]i_rwsem before mmap_sem, but this is not a
+ * problem since any directory is not able to be mmap-ed.

+/*
+ * Drop one or more refs of @node.
+ *
+ * 1. Locate the extent refs.
+ * It's either inline in EXTENT/METADATA_ITEM or in keyed SHARED_* item.
+ * Locate it, then reduce the refs number or remove the ref line completely.
+ *
+ * 2. Update the refs count in EXTENT/METADATA_ITEM
+ *
+ * Inline backref case:
+ *
+ * in extent tree we have:
+ *
* item 0 key (13631488 EXTENT_ITEM 1048576) itemoff 16201 itemsize 82
*refs 2 gen 6 flags DATA
This function gets called with:

node->bytenr = 13631488
node->num_bytes = 1048576
root_objectid = FS_TREE
owner_objectid = 257
owner_offset = 0
refs_to_drop = 1

Then we should get some like:

item 0 key (13631488 EXTENT_ITEM 1048576) itemoff 16201 itemsize 82
refs 1 gen 6 flags DATA
extent data backref root FS_TREE objectid 258 offset 0 count 1

Keyed backref case:

in extent tree we have:

item 0 key (13631488 EXTENT_ITEM 1048576) itemoff 3971 itemsize 24
refs 754 gen 6 flags DATA
[...]
item 2 key (13631488 EXTENT_DATA_REF <HASH>) itemoff 3915 itemsize 28
extent data backref root FS_TREE objectid 866 offset 0 count 1

This function get called with:

node->bytenr = 13631488
node->num_bytes = 1048576
root_objectid = FS_TREE
owner_objectid = 866
owner_offset = 0
refs_to_drop = 1

Then we should get some like:

item 0 key (13631488 EXTENT_ITEM 1048576) itemoff 3971 itemsize 24
refs 753 gen 6 flags DATA

And that (13631488 EXTENT_DATA_REF <HASH>) gets removed.

    {
        int refs;
-/* the ref bit is tricky. We have to make sure it is set
- * if we have the buffer dirty. Otherwise the
- * code to free a buffer can end up dropping a dirty
- * page
+/*
+ * The TREE_REF bit is first set when the extent_buffer is added
+ * to the radix tree. It is also reset, if unset, when a new reference
+ * is created by find_extent_buffer.
+ *
+ * Once the ref bit is set, it won't go away while the
+ * buffer is dirty or in writeback, and it also won't
+ * go away while we have the reference count on the
+ * eb bumped.
+ * It is only cleared in two cases: freeing the last non-tree
+ * reference to the extent_buffer when its STALE bit is set or
+ * calling releasepage when the tree reference is the only reference.
+ *
+ * We can't just set the ref bit without bumping the
+ * ref on the eb because free_extent_buffer might
+ * see the ref bit and try to clear it. If this happens
+ * free_extent_buffer might end up dropping our original
+ * ref by mistake and freeing the page before we are able
+ * to add one more ref.
+ * In both cases, care is taken to ensure that the extent_buffer's
+ * pages are not under io. However, releasepage can be concurrently
+ * called with creating new references, which is prone to race
+ * conditions between the calls to check_buffer_tree_ref in those
+ * codepaths and clearing TREE_REF in try_release_extent_buffer.
+ *
+ * So bump the ref count first, then set the bit. If someone
+ * beat us to it, drop the ref we added.
+ * The actual lifetime of the extent_buffer in the radix tree is
* adequately protected by the refcount, but the TREE_REF bit and
* its corresponding reference are not. To protect against this
* class of races, we call check_buffer_tree_ref from the codepaths
* which trigger io after they set eb->io_pages. Note that once io is
* initiated, TREE_REF can no longer be cleared, so that is the
* moment at which any such race is best fixed.

/*
 * Before we acquired the inode's lock, someone may have dirtied more
 * pages in the target range. We need to make sure that writeback for
 * any such pages does not start while we are logging the inode, because
 * if it does, any of the following might happen when we are not doing a
 * full inode sync:
We log an extent after its writeback finishes but before its checksums are added to the csum tree, leading to -EIO errors when attempting to read the extent after a log replay.

Therefore after the log replay we will have a file extent item pointing to an unwritten extent (and no data checksums as well).

So trigger writeback for any eventual new dirty pages and then we wait for all ordered extents to complete below.

```
ret = start_ordered_ops(inode, start, end);
if (ret) {
    up_write(&BTRFS_I(inode)->dio_sem);
    inode_unlock(inode);
    goto out;
}
```

We write the dirty pages in the range and wait until they complete out of the ->i_mutex. If so, we can flush the dirty pages by multi-task, and make the performance up. See @@ -2070,57 +2146,25 @@

    * Start any new ordered operations before starting to log the
    * inode. We will wait for them to finish in btrfs_sync_log().
    *
    * Right before acquiring the inode's mutex, we might have new
    * writes dirtying pages, which won't immediately start the
    * respective ordered operations - that is done through the
    * fill_delalloc callbacks invoked from the writepage and
    * writepages address space operations. So make sure we start
    * all ordered operations before starting to log our inode. Not
    * doing this means that while logging the inode, writeback
    * could start and invoke writepage/writepages, which would call
    * the fill_delalloc callbacks (cow_file_range,
    * submit_compressed_extents). These callbacks add first an
    * extent map to the modified list of extents and then create
    * the respective ordered operation, which means in
    * btrfs_log_inode() we might capture all existing
    * ordered operations (with btrfs_get_logged_extents()) before
    * the fill_delalloc callback adds its ordered operation, and by
    * the time we visit the modified list of extent maps (with
    * btrfs_log_changed_extents()), we see and process the extent
    * map they created. We then use the extent map to construct a
    * file extent item for logging without waiting for the
    * respective ordered operation to finish - this file extent
    * item points to a disk location that might not have yet been
    * written to, containing random data - so after a crash a log
    * replay will make our inode have file extent items that point
    * to disk locations containing invalid data, as we returned
    * success to userspace without waiting for the respective
    * ordered operation to finish, because it wasn't captured by
    * btrfs_get_logged_extents().

/*
 * Qgroup reserved space handler
 * Page here will be either
 * 1) Already written to disk
In this case, its reserved space is released from data rsv map and will be freed by delayed_ref handler finally. So even we call qgroup_free_data(), it won't decrease reserved space.

2) Not written to disk
This means the reserved space should be freed here. However, if a truncate invalidates the page (by clearing PageDirty) and the page is accounted for while allocating extent in btrfs_check_data_free_space() we let delayed_ref to free the entire extent.

1) Already written to disk or ordered extent already submitted
Then its QGROUP_RESERVED bit in io_tree is already cleaned.
Qgroup will be handled by its qgroup_record then.
btrfs_qgroup_free_data() call will do nothing here.

2) Not written to disk yet
Then btrfs_qgroup_free_data() call will clear the QGROUP_RESERVED bit of its io_tree, and free the qgroup reserved data space. Since the IO will never happen for this page.

@if (PageDirty(page))
btrfs_qgroup_free_data(inode, NULL, page_start, PAGE_SIZE);

 * + |----- f1 (ino 257)
 * + |
 * + |----- d2 (ino 258)
 * + *
 */

+ * When processing inode 257 we compute the name for inode 259 as "d1", and we
  + * cache it in the name cache. Later when we start processing inode 258, when
  + * collecting all its new references we set a full path of "d1/d2" for its new
+ * reference with name "d2". When we start processing the new references we
+ * start by processing the new reference with name "d1", and this results in
+ * orphanizing inode 259, since its old reference causes a conflict. Then we
+ * move on the next new reference, with name "d2", and we find out we must
+ * orphanize inode 260, as its old reference conflicts with ours - but for the
+ * orphanization we use a source path corresponding to the path we stored in the
+ * new reference, which is "d1/d2" and not "o259-6-0/d2" - this makes the
+ * receiver fail since the path component "d1/" no longer exists, it was renamed
+ * to "o259-6-0/" when processing the previous new reference. So in this case we
+ * must recompute the path in the new reference and use it for the new
+ * orphanization operation.

/*
 * If the no holes feature is enabled we need to make sure any hole between the
 * last extent and the i_size of our inode is explicitly marked in the log. This
 * is to make sure that doing something like:
 *  1) create file with 128Kb of data
 *  2) truncate file to 64Kb
 *  3) truncate file to 256Kb
 *  4) fsync file
 *  5) <crash/power failure>
 *  6) mount fs and trigger log replay
 * Will give us a file with a size of 256Kb, the first 64Kb of data match what
 * the file had in its first 64Kb of data at step 1 and the last 192Kb of the
 * file correspond to a hole. The presence of explicit holes in a log tree is
 * */
what guarantees that log replay will remove/adjust file extent items in the
fs/subvol tree.

Here we do not need to care about holes between extents, that is already done
by copy_items(). We also only need to do this in the full sync path, where we
lookup for extents from the fs/subvol tree only. In the fast path case, we
lookup the list of modified extent maps and if any represents a hole, we
insert a corresponding extent representing a hole in the log tree.

When using the NO_HOLES feature if we punched a hole that causes the
deletion of entire leaves or all the extent items of the first leaf (the one
that contains the inode item and references) we may end up not processing
any extents, because there are no leaves with a generation matching the
current transaction that have extent items for our inode. So we need to find
if any holes exist and then log them. We also need to log holes after any
truncate operation that changes the inode's size.

+ * This is really sick. What they wanted was a hybrid of
+ * link(2) and symlink(2) - they wanted the target resolved
+ * at syscall time (as link(2) would've done), be a directory
+ * (which link(2) would've refused to do) *AND* be a deep
+ * fucking magic, making the target busy from rmdir POV.
+ * symlink(2) is nothing of that sort, and the locking it
+ * gets matches the normal symlink(2) semantics. Without
+ * attempts to resolve the target (which might very well
+ * not even exist yet) done prior to locking the parent
+ * directory. This perversion, OTOH, needs to resolve
+ * the target, which would lead to obvious deadlocks if
+ * attempted with any directories locked.
+ */
Unfortunately, that garbage is userland ABI and we should've
said "no" back in 2005. Too late now, so we get to
play very ugly games with locking.

Try *ANYTHING* of that sort in new code, and you will
really regret it. Just ask yourself - what could a BOFH
do to me and do I want to find it out first-hand?

AV, a thoroughly annoyed bastard.

    +do {
      +*/
We have to redirty a page in these cases:
1) If buffer is dirty, it means the page was dirty because it contains a buffer that needs checkpointing. So the dirty bit needs to be preserved so that checkpointing writes the buffer properly.
2) If buffer is not part of the committing transaction (we may have just accidentally come across this buffer because inode range tracking is not exact) or if the currently running transaction already contains this buffer as well, dirty bit needs to be preserved so that the buffer gets writeprotected properly on running transaction's commit.

```c
+jh = bh2jh(bh);
