/*
 * Read CIDER register first, however read it the "wrong" way around.
 * If the endian strap on the KS8851-16MLL in incorrect and the chip
 * is operating in different endianness than the CPU, then the meaning
 * of BE[3:0] byte-enable bits is also swapped such that:
 * BE[3,2,1,0] becomes BE[1,0,3,2]
 * Luckily for us, the byte-enable bits are the top four MSbits of
 * the address register and the CIDER register is at offset 0xc0.
 * Hence, by reading address 0xc0c0, which is not impacted by endian
 * swapping, we assert either BE[3:2] or BE[1:0] while reading the
 * CIDER register.
 * If the bus configuration is correct, reading 0xc0c0 asserts
 * BE[3:2] and this read returns 0x0000, because to read register
 * with bottom two LSbits of address set to 0, BE[1:0] must be
 * asserted.
 * If the bus configuration is NOT correct, reading 0xc0c0 asserts
 * BE[1:0] and this read returns non-zero 0x8872 value.

+*/ enum: GENERATION_END value, used together with GENERATION_START to verify
+* consistency of DMAAd data. For legacy firmware / drivers without extended
+* stats (more precisely, when DMA_LEN == MC_CMD_MAC_NSTATS *
+* sizeof(uint64_t)), this entry holds the GENERATION_END value. Otherwise,
+* this value is invalid/ reserved and GENERATION_END is written as the last
+* 64-bit word of the DMA buffer (at DMA_LEN - sizeof(uint64_t)). Note that
+* this is consistent with the legacy behaviour, in the sense that entry 96 is
+* the last 64-bit word in the buffer when DMA_LEN == MC_CMD_MAC_NSTATS *
+* sizeof(uint64_t). See SF-109306-TC, Section 9.2 for details.

-    "Use MMIO instead of PIO" if PCI || EISA
+    "Use MMIO instead of IOP" if PCI || EISA
 depends on DEFXX
-    default n if PCI || EISA
+    default n if EISA
+    default y
---help---
 This instructs the driver to use EISA or PCI memory-mapped I/O
-    (MMIO) as appropriate instead of programmed I/O ports (PIO).
+    (MMIO) as appropriate instead of programmed I/O ports (IOP).
   Enabling this gives an improvement in processing time in parts
   of the driver, but it may cause problems with EISA (DEFEA)
-    adapters. TURBOchannel does not have the concept of I/O ports,
-    so MMIO is always used for these (DEFTA) adapters.
+    of the driver, but it requires a memory window to be configured
+    for EISA (DEFEA) adapters that may not always be available.
+    Conversely some PCIe host bridges do not support IOP, so MMIO
+    may be required to access PCI (DEFPA) adapters on downstream PCI
+    buses with some systems. TURBOchannel does not have the concept
+ of I/O ports, so MMIO is always used for these (DEFTA) adapters.

If unsure, say N.

-if (WARN(fwrt->trans->state == IWL_TRANS_NO_FW,
- "Can't collect dbg data when FW isn't alive\n")
+/*
If the loading of the FW completed successfully, the next step is to get the SMEM config data. Thus, if fwrt->smem_cfg.num_lmacs is non-zero, the FW was already loaded successfully. If the state is "NO_FW" in such a case - exit, since FW may be dead. Otherwise, we can try to collect the data, since FW might just not be fully loaded (no "ALIVE" yet), and the debug data is accessible.

Corner case: got the FW alive but crashed before getting the SMEM config. In such a case, due to HW access problems, we might collect garbage.

```
if (fwrt->trans->state == IWL_TRANS_NO_FW && fwrt->smem_cfg.num_lmacs)
    return -EIO;
```

```
if (test_and_set_bit(IWL_FWRT_STATUS_DUMPING, &fwrt->status))
    return;
```

The following code is included, but not executed:

```
+ if (fwrt->ops->fw_running && !fwrt->ops->fw_running(fwrt->ops_ctx)) {
+     IWL_ERR(fwrt, "Firmware not running - cannot dump error\n");
+     iwl_fw_free_dump_desc(fwrt);
