 * We keep multiple buckets open for writes, and try to segregate different
 * write streams for better cache utilization: first we look for a bucket where
 * the last write to it was sequential with the current write, and failing that
 * we look for a bucket that was last used by the same task.
 * write streams for better cache utilization: first we try to segregate flash
 * only volume write streams from cached devices, secondly we look for a bucket
 * where the last write to it was sequential with the current write, and
 * failing that we look for a bucket that was last used by the same task.
 *
 * The ideas is if you've got multiple tasks pulling data into the cache at the
 * same time, you'll get better cache utilization if you try to segregate their
 * data and preserve locality.
 *
 * For example, say you've starting Firefox at the same time you're copying a
 * bunch of files. Firefox will likely end up being fairly hot and stay in the
 * cache awhile, but the data you copied might not be; if you wrote all that
 * data to the same buckets it'd get invalidated at the same time.

+/*
+ * This function is only called when CACHE_SET_IO_DISABLE is set, which means
+ * cache set is unregistering due to too many I/O errors. In this condition,
+ * the bcache device might be stopped, it depends on stop_when_cache_set_failed
+ * value and whether the broken cache has dirty data:
+ * dc->stop_when_cache_set_failed dc->has_dirty stop bcache device
+ * BCH_CACHED_STOP_AUTO 0 NO
+ * BCH_CACHED_STOP_AUTO 1 YES
+ * BCH_CACHED_DEV_STOP_ALWAYS 0 YES
+ * BCH_CACHED_DEV_STOP_ALWAYS 1 YES
*/
The expected behavior is, if stop_when_cache_set_failed is configured to "auto" via sysfs interface, the bcache device will not be stopped if the backing device is clean on the broken cache device.

```
static void conditional_stop_bcache_device(struct cache_set *c, struct bcache_device *d, struct cached_dev *dc)
{
    if (dc->stop_when_cache_set_failed == BCH_CACHED_DEV_STOP_ALWAYS) {
        pr_warn("stop_when_cache_set_failed of %s is "always", stop it for failed cache set %pU.\n", d->disk->disk_name, c->sb.set_uuid);
        bcache_device_stop(d);
    } else if (atomic_read(&dc->has_dirty)) {
        /*
         * dc->stop_when_cache_set_failed == BCH_CACHED_STOP_AUTO
         * and dc->has_dirty == 1
         */
        pr_warn("stop_when_cache_set_failed of %s is "auto" and cache is dirty, stop it to avoid potential data corruption.\n", d->disk->disk_name);
        /* make others know io_disable is true earlier */
        smp_mb();
        bcache_device_stop(d);
    } else {
        /*
         * dc->stop_when_cache_set_failed == BCH_CACHED_STOP_AUTO
         * and dc->has_dirty == 0
         */
        pr_warn("stop_when_cache_set_failed of %s is "auto" and cache is clean, keep it alive.\n", d->disk->disk_name);
    }
}
```

There might be a small time gap that cache set is released but bcache device is not. Inside this time gap, regular I/O requests will directly go into backing device as no cache set attached to. This behavior may also introduce potential inconsistency data in writeback mode while cache is dirty.

Therefore before calling bcache_device_stop() due to a broken cache device, dc->io_disable should be explicitly set to true.

```

+ * type->iterate_devices() should be called when the sanity check needs to
+ * iterate and check all underlying data devices. iterate_devices() will
+ * iterate all underlying data devices until it encounters a non-zero return
+ * code, returned by whether the input iterate_devices_callout_fn, or
+ * iterate_devices() itself internally.
+ *
+ * For some target type (e.g. dm-stripe), one call of iterate_devices() may
iterate multiple underlying devices internally, in which case a non-zero
return code returned by iterate_devices_callout_fn will stop the iteration
in advance.

* Cases requiring _any_ underlying device supporting some kind of attribute,
  should use the iteration structure like dm_table_any_dev_attr(), or call
  it directly. @func should handle semantics of positive examples, e.g.
  capable of something.

* Cases requiring _all_ underlying devices supporting some kind of attribute,
  should use the iteration structure like dm_table_supports_nowait() or
  dm_table_supports_discards(). Or introduce dm_table_all_devs_attr() that
  uses an @anti_func that handle semantics of counter examples, e.g. not
  capable of something. So: return !dm_table_any_dev_attr(t, anti_func, data);

+default m
+help
+ Select this option to enable the ocxl driver for Open
+ Coherent Accelerator Processor Interface (OpenCAPI) devices.
+
+ OpenCAPI allows FPGA and ASIC accelerators to be coherently
+ attached to a CPU over an OpenCAPI link.
+
+ The ocxl driver enables userspace programs to access these
+ accelerators through devices in /dev/ocxl/.
+
+ For more information, see http://opencapi.org.
+
+ This is not to be confused with the support for IBM CAPI
+ accelerators (CONFIG_CXL), which are PCI-based instead of a
+ dedicated OpenCAPI link, and don't follow the same protocol.
+
+ If unsure, say N.
