+/** @def VBOX_LOGGROUP_NAMES
+ * VirtualBox Logging group names.
+ *
+ * Must correspond 100% to LOGGROUP!
+ * Don't forget commas!
+ *
+ * @remark It should be pretty obvious, but just to have
+ * mentioned it, the values are sorted alphabetically (using the
+ * english alphabet) except for _DEFAULT which is always first.
+ *
+ * If anyone might be wondering what the alphabet looks like:
+ * a b c d e f g h i j k l m n o p q r s t u v w x y z
+ */

### Description

This code snippet is a part of a function that performs the `cpuid` instruction with special handling for different architectures.

#### Function Signature

```c
DECLASM(void) ASMCpuId(uint32_t uOperator, void RT_FAR *pvEAX, void RT_FAR *pvEBX, void RT_FAR *pvECX, void RT_FAR *pvEDX);
```

#### Function Parameters

- **uOperator**: CPUID operation (eax).
- **pvEAX**: Where to store eax.
- **pvEBX**: Where to store ebx.
- **pvECX**: Where to store ecx.
- **pvEDX**: Where to store edx.

#### Remark

We're using void pointers to ease the use of special bitfield structures and such.

#### Notes

- The function uses different assembly calls based on the architecture (AMD64 or x86) to perform the `cpuid` instruction.
- For AMD64, it uses the `xchgl` instruction to swap registers.
- For x86, it uses the `cpuid` instruction directly.

---

```

The code snippet is a C function that performs the CPUID instruction and returns the value in EBX. It includes conditional compilation directives to handle different architectures and optimization levels. The function is defined inline for performance considerations and includes a documentation comment explaining the purpose of the function and its parameters.

### Function Documentation

`ASMInStrU16` reads a string of 16-bit unsigned integer items from an I/O port, ordered.

#### Function Signature

```c
# if RT_INLINE_ASM_EXTERNAL && !RT_INLINE_ASM_USES_INTRIN
DECLASM(void) ASMInStrU16(RTIOPORT Port, uint16_t RT_FAR *pau16, size_t c);
# else
DECLINLINE(void) ASMInStrU16(RTIOPORT Port, uint16_t RT_FAR *pau16, size_t c)
```

#### Parameters
- **Port**: I/O port to read from.
- **pau16**: Pointer to the string buffer (output).
- **c**: The number of items to read.

#### Function Implementation

```asm
    __asm {
        mov     dx, [Port]
        mov     ecx, [c]
        mov     eax, [pau16]
        xchg    esi, eax
        rep outsw
        xchg    esi, eax
    }
```

### ASM Mod S64 by S32, Returned as S32

This function performs a 64-bit signed division by a 32-bit signed divisor, returning the remainder as a 32-bit signed result.

#### Code

```assembly
#if RT_INLINE_ASM_EXTERNAL && defined(RT_ARCH_X86)
DECLASM(int32_t) ASMModS64ByS32RetS32(int64_t i64, int32_t i32);

            idiv    ecx
            mov     [i32], edx
        }
    # endif
    # endif

    return (uint32_t)(i64 % i32);
}
#endif
#endif
```

#### Description

- **Purpose:** Performs a 64-bit signed division by a 32-bit signed divisor, returning the remainder.
- **Returns:** The remainder as a 32-bit signed integer.
- **Remarks:** The result should not exceed `UINT32_MAX` to avoid overflow.

/** @defgroup grp_rt_asm    ASM - Assembly Routines
 * @ingroup grp_rt
 *
 * @remarks The difference between ordered and unordered atomic operations are that
 *          the former will complete outstanding reads and writes before continuing
 *          while the latter doesn't make any promises about the order. Ordered
 *          operations doesn't, it seems, make any 100% promise wrt to whether
 *          the operation will complete before any subsequent memory access.
 *          (please, correct if wrong.)
 *
 *          ASMAtonicSomething operations are all ordered, while ASMAtonicUoSomething
 *          are unordered (note the Uo).
 *
 * @remarks Some remarks about __volatile__: Without this keyword gcc is allowed to reorder
 *          or even optimize assembler instructions away. For instance, in the following code
```
the second rdmsr instruction is optimized away because gcc treats that instruction as deterministic:

```c
@code
static inline uint64_t rdmsr_low(int idx)
{
  uint32_t low;
  __asm__ ("rdmsr" : "=a"(low) : "c"(idx) : "edx");
}
...
uint32_t msr1 = rdmsr_low(1);
foo(msr1);
msr1 = rdmsr_low(1);
bar(msr1);
@endcode
```

The input parameter of rdmsr_low is the same for both calls and therefore gcc will use the result of the first call as input parameter for bar() as well. For rdmsr this is not acceptable as this instruction is _not_ deterministic. This applies to reading machine status information in general.

Atomically tests and toggles a bit in a bitmap, ordered.

@returns true if the bit was set.
@returns false if the bit was clear.

@param pvBitmap Pointer to the bitmap. Must be 32-bit aligned, otherwise the memory access isn't atomic!
@param iBit The bit to test and toggle.

@remarks x86: Requires a 386 or later.

#include <iprt/stdarg.h>
#include <iprt/assertcompile.h>

/** @defgroup gr0t_rt_assert     Assert - Assertions
 * @ingroup gr0t
 *
 * Assertions are generally used to check preconditions and other
 * assumptions. Sometimes it is also used to catch odd errors or errors
 * that one would like to inspect in the debugger. They should not be
 * used for errors that happen frequently.
 *
 * IPRT provides a host of assertion macros, so many that it can be a bit
 * overwhelming at first. Don't despair, there is a system (surprise).
 *
 * First there are four families of assertions:
 *      - Assert        - The normal strict build only assertions.
 *      - AssertLogRel  - Calls LogRel() in non-strict builds, otherwise like Assert.
 *      - AssertRelease - Triggers in all builds.
 *      - AssertFatal   - Triggers in all builds and cannot be continued.
 *
 * Then there are variations wrt to argument list and behavior on failure:
 *      - Msg           - Custom RTStrPrintf-like message with the assertion message.
 *      - Return        - Return the specific rc on failure.
 *      - ReturnType    - Return (void) on failure.
 *      - Break         - Break (out of switch/loop) on failure.
 *      - Stmt          - Execute the specified statement(s) on failure.
 *      - RC            - Assert RT_SUCCESS.
 *      - RCSuccess    - Assert VINF_SUCCESS.
 *
 * @remarks As you might have noticed, the macros don't follow the
 * coding guidelines wrt to macros supposedly being all uppercase
 * and underscored. For various reasons they don't, and nobody
 * has complained yet. Wonder why... :-(
 *
 * @remarks Each project has its own specific guidelines on how to use
 * assertions, so the above is just trying to give you the general idea
 * from the IPRT point of view.
 *

### Convenience Assertions Macros

#### AssertRC

Asserts a iprt status code successful.

```c
#define AssertRC(rc) AssertMsgRC(rc, ("%Rra\n", (rc)))
```

#### AssertRCStmt

Asserts a iprt status code successful, bitch (RT_STRICT mode only) and execute @a stmt if it isn't.

```c
#define AssertRCStmt(rc, stmt) AssertMsgRCStmt(rc, ("%Rra\n", (rc)), stmt)
```

#### AssertRCReturn

Asserts a iprt status code successful, bitch (RT_STRICT mode only) and return if it isn't.

```c
#define AssertRCReturn(rc, rcRet) AssertMsgRCReturn(rc, rcRet)
```
/** @def AssertMsgRC
 * Asserts a iprt status code successful.
 * It prints a custom message and hits a breakpoint on FAILURE.
 *
 * @param   rc      iprt status code.
 * @param   msg     printf argument list (in parenthesis).
 * @remark  rc is referenced multiple times. In release mode is NOREF()'ed.
 */
#define AssertMsgRC(rc, msg) \
    do { AssertMsg(RT_SUCCESS_NP(rc), msg); NOREF(rc); } while (0)

/** @def RT_LIKELY
 * Give the compiler a hint that an expression is very likely to hold true.
+ * Some compilers support explicit branch prediction so that the CPU backend
+ * can hint the processor and also so that code blocks can be reordered such
+ * that the predicted path sees a more linear flow, thus improving cache
+ * behaviour, etc.
+ */
+ IPRT provides the macros RT_LIKELY() and RT_UNLIKELY() as a way to utilize
+ this compiler feature when present.
+
+ A few notes about the usage:
+
+ - Generally, order your code use RT_LIKELY() instead of RT_UNLIKELY().
+ - Generally, use RT_UNLIKELY() with error condition checks (unless you
+   have some _strong_ reason to do otherwise, in which case document it),
+   and/or RT_LIKELY() with success condition checks, assuming you want
+   to optimize for the success path.
+ - Other than that, if you don't know the likelihood of a test succeeding
+   from empirical or other 'hard' evidence, don't make predictions unless
+   you happen to be a Dirk Gently character.
+ - These macros are meant to be used in places that get executed a lot. It
+   is wasteful to make predictions in code that is executed rarely (e.g.
+   at subsystem initialization time) as the basic block reordering that this
+   affects can often generate larger code.
+ - Note that RT_SUCCESS() and RT_FAILURE() already makes use of RT_LIKELY()
+   and RT_UNLIKELY(). Should you wish for prediction free status checks,
+   use the RT_SUCCESS_NP() and RT_FAILURE_NP() macros instead.
+
+ @returns the boolean result of the expression.
+ @param   expr        The expression that's very likely to be true.
+ @see     RT_UNLIKELY
+ */
+/** @def RT_UNLIKELY
+ * Give the compiler a hint that an expression is highly unlikely to hold true.
+ * See the usage instructions give in the RT_LIKELY() docs.
+ * @returns the boolean result of the expression.
+ * @param   expr        The expression that's very unlikely to be true.
+ * @see     RT_LIKELY
+ * @deprecated Please use RT_LIKELY() instead wherever possible! That gives us
+   a better chance of the windows compilers to generate favorable code
+   too. The belief is that the compiler will by default assume the
+   if-case is more likely than the else-case.

+ /** @def RT_ALIGN
+ * Align macro.
+ * @param  u      Value to align.
+ * @param  uAlignment  The alignment. Power of two!
+ *
+ * @remark  Be extremely careful when using this macro with type which sizeof != sizeof int.
+ * When possible use any of the other RT ALIGN_* macros. And when that's not
+ * possible, make 101% sure that uAlignment is specified with a right sized type.
+ */
```
Specifying an unsigned 32-bit alignment constant with a 64-bit value will give you a 32-bit return value!

In short: Don't use this macro. Use RT_ALIGN_T() instead.

```c
#define RT_ALIGN(u, uAlignment)                 ( ((u) + ((uAlignment) - 1)) & ~((uAlignment) - 1) )
```

/** @def RT_ALIGN_T
 * Align macro.
 * @param   u           Value to align.
 * @param   uAlignment  The alignment. Power of two!
 * @param   type        Integer type to use while aligning.
 * @remark  This macro is the preferred alignment macro, it doesn't have any of the pitfalls RT_ALIGN has.
 */
```c
#define RT_ALIGN_T(u, uAlignment, type)         ( ((type)(u) + ((uAlignment) - 1)) & ~(type)((uAlignment) - 1) )
```

/** @def RT_ALIGN_32
 * Align macro for a 32-bit value.
 * @param   u32         Value to align.
 * @param   uAlignment  The alignment. Power of two!
 */

/** Macro to work around error C2593 of the not-so-smart MSVC 7.x ambiguity
 * resolver. The following snippet clearly demonstrates the code causing this
 */
@media

class A
{
    public:
    operator bool() const { return false; }
    operator int*() const { return NULL; }
};

int main()
{
    A a;
    if (!a);
    if (a && 0);
    return 0;
The code itself seems pretty valid to me and GCC thinks the same.

This macro fixes the compiler error by explicitly overloading implicit global operators !, && and || that take the given class instance as one of their arguments.

The best is to use this macro right after the class declaration.

@note The macro expands to nothing for compilers other than MSVC.

@def WORKAROUND_MSVC7_ERROR_C2593_FOR_BOOL_OP_TPL
/* @param Tpl       Name of the template class to apply the workaround to
   @param ArgsDecl arguments of the template, as declared in |<>| after the

+ * Translates pszLatin1 from Latin-1 (ISO-8859-1) to UTF-16, allocating the
+ * result buffer if requested.
+ *
+ * @returns iprt status code.
+ * @param pszLatin1 The Latin-1 string to convert.
+ * @param cchLatin1 The maximum size in chars (the type) to convert. The
+ * conversion stops when it reaches cchLatin1 or the
+ * string terminator (\0). Use RTSTR_MAX to
+ * translate the entire string.
+ * @param ppwsz If cwc is non-zero, this must either be pointing
+ * to pointer to a buffer of the specified size, or
+ * pointer to a NULL pointer.
+ * If *ppwsz is NULL or cwc is zero a buffer of at
+ *
least cwc items will be allocated to hold the
translated string. If a buffer was requested it
must be freed using RTUtf16Free().
+ * @param cwc The buffer size in RTUTF16s. This includes the
terminator.
+ * @param pcwc Where to store the length of the translated string,
excluding the terminator. (Optional)
+ * This may be set under some error conditions,
however, only for VERR_BUFFER_OVERFLOW and
VERR_NO_STR_MEMORY will it contain a valid string
length that can be used to resize the buffer.
+ * @param pszTag Allocation tag used for statistics and such.
+ */

### RTMemPageAlloc

- Allocate page aligned memory with default tag.
- @returns Pointer to the allocated memory.
- @returns NULL if we're out of memory.
- @param cb Size of the memory block. Will be rounded up to page size.

```c
#define RTMemPageAlloc(cb)              RTMemPageAllocTag((cb), RTMEM_TAG)
```

### RTMemPageAllocTag

- Allocate page aligned memory with custom tag.
- @returns Pointer to the allocated memory.
- @returns NULL if we're out of memory.
- @param cb Size of the memory block. Will be rounded up to page size.
- @param pszTag Allocation tag used for statistics and such.

```c
RTDECL(void *) RTMemPageAllocTag(size_t cb, const char *pszTag) RT_NO_THROW_PROTO;
```

### RTMemPageAllocZ

- Allocate zero'd page aligned memory with default tag.
- @returns Pointer to the allocated memory.
- @returns NULL if we're out of memory.
- @param cb Size of the memory block. Will be rounded up to page size.

```c
#define RTMemPageAllocZ(cb)             RTMemPageAllocZTag((cb), RTMEM_TAG)
```

### RTMemPageAllocZTag

- Allocate zero'd page aligned memory with custom tag.
- @returns Pointer to the allocated memory.
- @returns NULL if we're out of memory.
- @param cb Size of the memory block. Will be rounded up to page size.
- @param pszTag Allocation tag used for statistics and such.

```c
RTDECL(void *) RTMemPageAllocZTag(size_t cb, const char *pszTag) RT_NO_THROW_PROTO;
```

### RTMemPageFree

- Free a memory block allocated with RTMemPageAlloc() or RTMemPageAllocZ().
- @param pv Pointer to the block as it was returned by the allocation function.
- @param cb The allocation size. Will be rounded up to page size.

```c
RTDECL(void) RTMemPageFree(void *pv, size_t cb) RT_NO_THROW_PROTO;
```

Notification callback.

The context this is called in differs a bit from platform to platform, so be careful while in here.

On Windows we're running with IRQL=PASSIVE_LEVEL (rescheduleable) according to the KeRegisterProcessorChangeCallback documentation - unrestricted API access. Probably not being called on the onlined/offlined CPU...

On Solaris we're holding the cpu_lock, IPL/SPL/PIL is not yet known, however we will most likely -not- be firing on the CPU going offline/online.

On Linux it looks like we're called with preemption enabled on any CPU and not necessarily on the CPU going offline/online.

There is no callbacks for darwin at the moment, due to lack of suitable KPI.

@todo We'll be adding a flag to this soon to indicate whether the callback should be called on all CPUs that are currently online while it's being registered. This is to help avoid some race conditions (we'll hopefully be able to implement this on linux, solaris/win is no issue).

@returns IPRT status code.

@retval VINF_SUCCESS on success.
@retval VERR_NO_MEMORY if a registration record cannot be allocated.
@retval VERR_ALREADY_EXISTS if the pfnCallback and pvUser already exist in the callback list.

@returns IPRT status code.

@param idCpu The CPU this applies to.
@param enmEvent The event.
@param pvUser The user argument.

typedef DECLCALLBACK(void) FNRTMPNOTIFICATION(RTMPEVENT enmEvent, RTCPUID idCpu, void *pvUser);

typedef FNRTMPNOTIFICATION *PFNRTMPNOTIFICATION;

/** Pointer to a FNRTMPNOTIFICATION(). */

+Registers a notification callback for cpu events.

+ On platforms which doesn't do cpu offline/online events this API will just be a no-op that pretends to work.

+ @todo We'll be adding a flag to this soon to indicate whether the callback should be called on all CPUs that are currently online while it's being registered. This is to help avoid some race conditions (we'll hopefully be able to implement this on linux, solaris/win is no issue).

@returns IPRT status code.

@param pfnCallback The callback.
@param pvUser The user argument to the callback function.

+RTDECL(int) RTMpNotificationRegister(PFNRTMPNOTIFICATION pfnCallback, void *pvUser);
This deregisters a notification callback registered via RTMpNotificationRegister().
+ The pfnCallback and pvUser arguments must be identical to the registration call
+ of we won’t find the right entry.
+ *
+ @returns IPRT status code.
+ @retval VINF_SUCCESS on success.
+ @retval VERR_NOT_FOUND if no matching entry was found.
+ *
+ @param pfnCallback The callback.
+ @param pvUser The user argument to the callback function.

+ *
+* @param   pszPath         The path to append pszAppend to. This serves as both
+*                          input and output. This can be empty, in which case
+*                          pszAppend is just copied over.
+ * @param   cbPathDst       The size of the buffer pszPath points to, terminator
+ *                          included. This should NOT be strlen(pszPath).
+ * @param   pszAppend       The partial path to append to pszPath. This can be
+ *                          NULL, in which case nothing is done.
+ *
+ * @remarks See the RTPathAppendEx remarks.
+ */
+RTDECL(int) RTPat
+
+* Appends one partial path to another.
+ *
+* The main purpose of this function is to deal correctly with the slashes when
+* concatenating the two partial paths.
+ *
+* @retval  VINF_SUCCESS on success.
+ * @retval  VERR_BUFFER_OVERFLOW if the result is too big to fit within
+ *          cbPathDst bytes. No changes has been made.
+ * @retval  VERR_INVALID_PARAMETER if the string pointed to by pszPath is longer
+ *          than cbPathDst-1 bytes (failed to find terminator). Asserted.
+ */
+ @retval VERR_INVALID_PARAMETER if the string pointed to by pszPath is longer
+ than cbPathDst-1 bytes (failed to find terminator). Asserted.
+ *
+ @param pszPath The path to append pszAppend to. This serves as both
+ input and output. This can be empty, in which case
+ pszAppend is just copied over.
+ @param cbPathDst The size of the buffer pszPath points to, terminator
+ included. This should NOT be strlen(pszPath).
+ @param pszAppend The partial path to append to pszPath. This can be
+ NULL, in which case nothing is done.
+ @param cchAppendMax The maximum number or characters to take from @a
+ pszAppend. RTSTR_MAX is fine.
+ *
+ @remarks On OS/2, Window and similar systems, concatenating a drive letter
+ specifier with a slash prefixed path will result in an absolute
+ path. Meaning, RTPathAppend(strcpy(szBuf, "C:"), sizeof(szBuf),
+ "/bar") will result in "C:/bar". (This follows directly from the
+ behavior when pszPath is empty.)
+ *
+ On the other hand, when joining a drive letter specifier with a
+ partial path that does not start with a slash, the result is not an
+ absolute path. Meaning, RTPathAppend(strcpy(szBuf, "C:"),
+ sizeof(szBuf), "bar") will result in "C:bar".

+ *
+ *
@returns Pointer to the allocated string. The first byte is always set
to the string terminator char, the contents of the remainder of the
memory is undefined. The string must be freed by calling RTStrFree.

NULL is returned if the allocation failed. Please translate this to
VVERR_NO_STR_MEMORY and not VERR_NO_MEMORY. Also consider
RTStrAllocEx if an IPRT status code is required.

@returns Pointer to the allocated string. The first byte is always set
to the string terminator char, the contents of the remainder of the
memory is undefined. The string must be freed by calling RTStrFree.

How many bytes to allocate. If this is zero, we
will allocate a terminator byte anyway.
Allocation tag used for statistics and such.

Allocates memory for string storage, with status code (default tag).
You should normally not use this function, except if there is some very
custom string handling you need doing that isn't covered by any of the other
APIs.

Where to return the allocated string. This will
be set to NULL on failure. On success, the
returned memory will always start with a
terminator char so that it is considered a valid
C string, the contents of rest of the memory is
undefined.

How many bytes to allocate. If this is zero, we
will allocate a terminator byte anyway.

Allocates memory for string storage, with status code (custom tag).
You should normally not use this function, except if there is some very
custom string handling you need doing that isn't covered by any of the other
APIs.

Where to return the allocated string. This will
be set to NULL on failure. On success, the
returned memory will always start with a
+ * terminator char so that it is considered a valid
+ * C string, the contents of rest of the memory is
+ * undefined.
+ * @param cb How many bytes to allocate. If this is zero, we
+ * will allocate a terminator byte anyway.
+ * @param pszTag Allocation tag used for statistics and such.
+ */

/** @page pg_rt_str_format  The IPRT Format Strings
 * IPRT implements most of the commonly used format types and flags with the
 * exception of floating point which is completely missing. In addition IPRT
 * provides a number of IPRT specific format types for the IPRT typedefs and
 * other useful things. Note that several of these extensions are similar to
 * \%p and doesn't care much if you try add formatting flags/width/precision.
 */

/* Group 0a, The commonly used format types:
   - \%s - Takes a pointer to a zero terminated string (UTF-8) and
       prints it with the optionally adjustment (width, -) and
       length restriction (precision).
   - \%Is - Same as \%s except that the input is UTF-16 (output UTF-8).
   - \%Ls - Same as \%s except that the input is UCS-32 (output UTF-8).
   - \%S - Same as \%s, used to convert to current codeset but this is
       now done by the streams code. Deprecated, use \%s.
   - \%IS - Ditto. Deprecated, use \%Is.
   - \%LS - Ditto. Deprecated, use \%Ls.
   - \%c - Takes a char and prints it.
   - \%d - Takes a signed integer and prints it as decimal. Thousand
       separator (,), zero padding (0), adjustment (+-), width,
       precision
   - \%i - Same as \%d.
   - \%u - Takes an unsigned integer and prints it as decimal. Thousand
       separator (,), zero padding (0), adjustment (+-), width,
       precision
   - \%x - Takes an unsigned integer and prints it as lowercased
       hexadecimal. The special hash (#) flag causes a '0x'
       prefixed to be printed. Zero padding (0), adjustment (+-),
       width, precision.
   - \%X - Same as \%x except that it is upercased.
   - \%o - Takes an unsigned (?) integer and prints it as octal. Zero
- Padding (0), adjustment (+), width, precision.
- Takes a pointer (void technically) and prints it. Zero
- Takes a pointer (void technically) and prints it. Zero.
- The %d, %i, %lu, %x, %X and %o format types support the following
- argument type specifiers:
  - %ll - long long (uint64_t).
  - %L - long long (uint64_t).
  - %l - long (uint32_t, uint64_t)
  - %h - short (int16_t).
  - %hh - char (int8_t).
  - %H - char (int8_t).
  - %z - size_t.
  - %j - intmax_t (int64_t).
  - %t - ptrdiff_t.
- The type in parentheses is typical sizes, however when printing those types
- you are better off using the special group 2 format types below (%RX32 and
- such).

* Group 0b, IPRT format tricks:
  - %M - Replaces the format string, takes a string pointer.
  - %N - Nested formatting, takes a pointer to a format string
    followed by the pointer to a va_list variable. The va_list
    variable will not be modified and the caller must do va_end()
    on it. Make sure the va_list variable is NOT in a parameter
    list or some gcc versions/targets may get it all wrong.

* Group 1, the basic runtime typedefs (excluding those which obviously are
  * pointer):
    - %RTbool - Takes a bool value and prints 'true', 'false', or '!%d!'.
    - %RTfile - Takes a #RTFILE value.
    - %RTfmode - Takes a #RTFMODE value.
    - %RTfoff - Takes a #RTFOFF value.
    - %RTfp16 - Takes a #RTFAR16 value.
    - %RTfp32 - Takes a #RTFAR32 value.
    - %RTfp64 - Takes a #RTFAR64 value.
    - %RTgid - Takes a #RTGID value.
    - %RTino - Takes a #RTINODE value.
    - %RTint - Takes a #RTINT value.
    - %RTiop - Takes a #RTIOPORT value.
    - %RTldrm - Takes a #RTLDRMOD value.
    - %RTmac - Takes a #PCRTMAC pointer.
    - %RTnaddr - Takes a #PCRTNETADDR value.
    - %RTnaipv4 - Takes a #RTNETADDRIPV4 value.
    - %RTnaipv6 - Takes a #PCRTNETADDRIPV6 value.
    - %RTnthrd - Takes a #RTNATIVETHREAD value.
+ * - %RTnhrd - Takes a #RTNATIVETHREAD value.
+ * - %RTproc - Takes a #RTPROCESS value.
+ * - %RTptr - Takes a #RTINTPTR or #RTUINTPTR value (but not void *).
+ * - %RTreg - Takes a #RTCCUINTREG value.
+ * - %RTsel - Takes a #RTSEL value.
+ * - %RTsem - Takes a #RTSEMEVENT, #RTSEMEVENTMULTI, #RTSEMMUTEX, #RTSEMFASTMUTEX, or #RTSEMRW value.
+ * - %RTsock - Takes a #RTSOCKET value.
+ * - %RTthrd - Takes a #RTTHREAD value.
+ * - %RTuid - Takes a #RTUID value.
+ * - %RTuint - Takes a #RTUINT value.
+ * - %RTunicp - Takes a #RTUNICP value.
+ * - %RTutf16 - Takes a #RTUTF16 value.
+ * - %RTuuid - Takes a #PCRTUUID and will print the UUID as a string.
+ * - %RTxuint - Takes a #RTUINT or #RTINT value, formatting it as hex.
+ * - %RGi - Takes a #RTGCINT value.
+ * - %RGp - Takes a #RTGCPHYS value.
+ * - %RGr - Takes a #RTGCUINTREG value.
+ * - %RGv - Takes a #RTGCPTR, #RTGCINTPTR or #RTGCUINTPTR value.
+ * - %RGx - Takes a #RTGCUINT or #RTGCINT value, formatting it as hex.
+ * - %RHi - Takes a #RTHCINT value.
+ * - %RHp - Takes a #RTHCPHYS value.
+ * - %RHr - Takes a #RTHCUINTREG value.
+ * - %RHu - Takes a #RTHCUINT value.
+ * - %RHv - Takes a #RTHCPTR, #RTHCINTPTR or #RTHCUINTPTR value.
+ * - %RHx - Takes a #RTHCUINT or #RTHCINT value, formatting it as hex.
+ * - %RRv - Takes a #RTRCINTPTR or #RTRCUINTPTR value.
+ * - %RCi - Takes a #RTINT value.
+ * - %RCp - Takes a #RTCCPHYS value.
+ * - %RCr - Takes a #RTCCUINTREG value.
+ * - %RCu - Takes a #RTUINT value.
+ * - %RCv - Takes a #uintptr_t, #intptr_t, void * value.
+ * - %RCx - Takes a #RTUINT or #RTINT value, formatting it as hex.

+ * Group 2, the generic integer types which are preferred over relying on what
+ * bit-count a 'long', 'short', or 'long long' has on a platform. This are
+ * highly preferred for the [u]intXX_t kind of types:
+ * - %RI[8|16|32|64] - Signed integer value of the specified bit count.
+ * - %RU[8|16|32|64] - Unsigned integer value of the specified bit count.
+ * - %RX[8|16|32|64] - Hexadecimal integer value of the specified bit count.
+ *
+ * Group 3, hex dumpers and other complex stuff which requires more than simple
+ * formatting:
+ * - %Rhxd - Takes a pointer to the memory which is to be dumped in typical
+ *   hex format. Use the precision to specify the length, and the width to
set the number of bytes per line. Default width and precision is 16.
- %RhxD - Same as %Rhxd, except that it skips duplicate lines.
- %Rhxs - Takes a pointer to the memory to be displayed as a hex string,
i.e. a series of space separated bytes formatted as two digit hex value.
Use the precision to specify the length. Default length is 16 bytes.
The width, if specified, is ignored.
- %Rrc - Takes an integer iprt status code as argument. Will insert the
status code define corresponding to the iprt status code.
- %Rrs - Takes an integer iprt status code as argument. Will insert the
short description of the specified status code.
- %Rrf - Takes an integer iprt status code as argument. Will insert the
full description of the specified status code.
- %Rra - Takes an integer iprt status code as argument. Will insert the
status code define + full description.
- %Rwc - Takes a long Windows error code as argument. Will insert the status
code define corresponding to the Windows error code.
- %Rwf - Takes a long Windows error code as argument. Will insert the
full description of the specified status code.
- %Rwa - Takes a long Windows error code as argument. Will insert the
error code define + full description.
- %Rhrc - Takes a COM/XPCOM status code as argument. Will insert the status
code define corresponding to the Windows error code.
- %Rhrc - Takes a COM/XPCOM status code as argument. Will insert the
full description of the specified status code.
- %Rhra - Takes a COM/XPCOM error code as argument. Will insert the
error code define + full description.
- %Rfn - Pretty printing of a function or method. It drops the
return code and parameter list.
- %Rbn - Prints the base name. For dropping the path in
order to save space when printing a path name.
- %Rbs - Same as %ls except inut is big endian UTF-16.
On other platforms, %Rw? simply prints the argument in a form of 0xXXXXXXXX.

Group 4, structure dumpers:
- %RDtimespec - Takes a PCRTTIMESPEC.

Group 5, XML / HTML escapers:
- %RMas - Takes a string pointer (const char *) and outputs
  it as an attribute value with the proper escaping.
  This typically ends up in double quotes.
- %RMes - Takes a string pointer (const char *) and outputs
it as an element with the necessary escaping.

Group 6, CPU Architecture Register dumpers:
- `%RaX86[reg]` - Takes a 64-bit register value if the register is 64-bit or smaller. Check the code wrt which registers are implemented.

/** @defgroup grp_rt_timer      RTTimer - Timer
 *
 * The IPRT timer API provides a simple abstraction of recurring and one-shot callback timers.
 * Because of the great variation in the native APIs and the quality of
 * the service delivered by those native APIs, the timers are operated
 * on at best effort basis.
 * All the ring-3 implementations are naturally at the mercy of the scheduler,
 * which means that the callback rate might vary quite a bit and we might skip
 * ticks. Many systems have a restriction that a process can only have one
 * timer. IPRT currently makes no efforts at multiplexing timers in those kind
 * of situations and will simply fail if you try to create more than one timer.
 * Things are generally better in ring-0. The implementations will use interrupt
 * time callbacks wherever available, and if not, resort to a high priority
 * kernel thread.
 */

}
```

### Parameters

- `pResult`: The result variable.
- `pValue1`: The first value.
- `uValue2`: The second value, 32-bit.

### Returns

The result of the multiplication, stored in `pResult`.

+RTDECL(int) RTUtf16ICmpUtf8(PCRTUTF16 pwsz1, const char *psz2);
+ */
Performs a case insensitive string compare between an UTF-16 string and a pure ASCII string.

Since this compare only takes cares about the first 128 codepoints in unicode, no tables are needed and there aren't any real complications.

@returns < 0 if the first string less than the second string.
@returns 0 if the first string identical to the second string.
@returns > 0 if the first string greater than the second string.

@param pwsz1 First UTF-16 string. Null is allowed.
@param psz2 Second string, pure ASCII. Null is allowed.

Performs a case insensitive string compare between two UTF-16 strings using the current locale of the process (if applicable).

This differs from RTUtf16ICmp() in that it will try, if a locale with the required data is available, to do a correct case-insensitive compare. It follows that it is more complex and thereby likely to be more expensive.

@returns < 0 if the first string less than the second string.
@returns 0 if the first string identical to the second string.
@returns > 0 if the first string greater than the second string.

@param pwsz1 First UTF-16 string. Null is allowed.
@param pwsz2 Second UTF-16 string. Null is allowed.

Performs a case insensitive string compare between two UTF-16 strings, stopping after N characters.

This is a simplified compare, as only the simplified lower/upper case folding specified by the unicode specs are used. It does not consider character pairs as they are used in some languages, just simple upper & lower case compares.

@returns < 0 if the first string less than the second string.
@returns 0 if the first string identical to the second string.
@returns > 0 if the first string greater than the second string.

@param pwsz1 First UTF-16 string. Null is allowed.
@param pwsz2 Second UTF-16 string. Null is allowed.
@param cwcMax Maximum number of characters to compare.

+ * will be used as the output buffer.
+ *
+ * VERR_BUFFER_OVERFLOW will be returned if this is
+ * insufficient.
+ *
+ * If cch is zero or *ppsz is NULL, then a buffer of
+ * sufficient size is allocated. cch can be used to
+ * specify a minimum size of this buffer. Use
+ *
+ * RTUtf16Free() to free the result.
+ *
+ * @param cch The buffer size in chars (the type). This includes
+ * the terminator.
+ * @param pcch Where to store the length of the translated string,
+ * excluding the terminator. (Optional)
+ *
+ * This may be set under some error conditions,
+ *
+ * however, only for VERR_BUFFER_OVERFLOW and
+ *
+ * VERR_NO_STR_MEMORY will it contain a valid string
+ * length that can be used to resize the buffer.
+ */
#define RTUtf16ToLatin1Ex(pwszString, cwcString, ppsz, cch, pcch)  
  RTUtf16ToLatin1ExTag((pwszString), (cwcString), (ppsz), (cch), (pcch), RTSTR_TAG) 
+  /* Translates UTF-16 to Latin-1 (ISO-8859-1) using buffer provided by the caller
+ * or a fittingly sized buffer allocated by the function (custom tag).
+ * @returns iprt status code.
+ * @param pwszString The UTF-16 string to convert.
+ * @param cwcString The number of RTUTF16 items to translate from
+ * pwszString. The translation will stop when reaching
+ * cwcString or the terminator ('\0'). Use RTSTR_MAX
+ * to translate the entire string.
+ * @param ppsz Pointer to the pointer to the Latin-1 string. The
+ * buffer can optionally be preallocated by the caller.
If cch is zero, *ppsz is undefined.

If cch is non-zero and *ppsz is not NULL, then this will be used as the output buffer. VERR_BUFFER_OVERFLOW will be returned if this is insufficient.

If cch is zero or *ppsz is NULL, then a buffer of sufficient size is allocated. cch can be used to specify a minimum size of this buffer. Use RTUtf16Free() to free the result.

The buffer size in chars (the type). This includes the terminator.

Where to store the length of the translated string, excluding the terminator. (Optional)

This may be set under some error conditions, however, only for VERR_BUFFER_OVERFLOW and VERR_NO_STR_MEMORY will it contain a valid string length that can be used to resize the buffer.

Allocation tag used for statistics and such.

Calculates the length of the UTF-16 string in Latin-1 (ISO-8859-1) chars. This function will validate the string, and incorrectly encoded UTF-16 strings will be rejected. The primary purpose of this function is to help allocate buffers for RTUtf16ToLatin1() of the correct size. For most other purposes RTUtf16ToLatin1Ex() should be used.

Returns Number of char (bytes).

Returns 0 if the string was incorrectly encoded.

The UTF-16 string.

Calculates the length of the UTF-16 string in Latin-1 (ISO-8859-1) chars. This function will validate the string, and incorrectly encoded UTF-16 strings will be rejected.
+ * @param   pwsz    The string.
+ * @param   cwc     The max string length. Use RTSTR_MAX to process the
+ *                entire string.
+ * @param   pcch    Where to store the string length (in bytes). Optional.
+ *                This is undefined on failure.
