#include <linux/capability.h>

/* Copyright (c) 2020 Red Hat
 * Author: Lenny Szubowicz <lszubowi@redhat.com>
 *
 * This module contains the kernel support for the Linux EFI Machine
 * Owner Key (MOK) variable configuration table, which is identified by
 * the LINUX_EFI_MOK_VARIABLE_TABLE_GUID.
 *
 * This EFI configuration table provides a more robust alternative to
 * EFI volatile variables by which an EFI boot loader can pass the
 * contents of the Machine Owner Key (MOK) certificate stores to the
 * kernel during boot. If both the EFI MOK config table and corresponding
 * EFI MOK variables are present, the table should be considered as
 * more authoritative.
 *
 * This module includes code that validates and maps the EFI MOK table,
 * if its presence was detected very early in boot.
 *
 * Kernel interface routines are provided to walk through all the
 * entries in the MOK config table or to search for a specific named
 * entry.
 *
 * The contents of the individual named MOK config table entries are
 * made available to user space via read-only sysfs binary files under:
 *

 * efi_mokvar_table_init() - Early boot validation of EFI MOK config table
 */
If present, validate and compute the size of the EFI MOK variable configuration table. This table may be provided by an EFI boot loader as an alternative to ordinary EFI variables, due to platform-dependent limitations. The memory occupied by this table is marked as reserved.

This routine must be called before efi_free_boot_services() in order to guarantee that it can mark the table as reserved.

Implicit inputs:
- efi.mokvar_table: Physical address of EFI MOK variable config table or special value that indicates no such table.

Implicit outputs:
- efi_mokvar_table_size: Computed size of EFI MOK variable config table. The table is considered present and valid if this is non-zero.

```c
void __init efi_mokvar_table_init(void)
{
  efi_memory_desc_t md;

+ * For Gen9 we can still rely on the h/w to enforce cmd security, and only
+ * need to re-enforce the register access checks. We therefore only need to
+ * teach the cmdparser how to find the end of each command, and identify
+ * register accesses. The table doesn't need to reject any commands, and so
+ * the only commands listed here are:
+ * 1) Those that touch registers
+ * 2) Those that do not have the default 8-bit length
+ *
+ * Note that the default MI length mask chosen for this table is 0xFF, not
+ * the 0x3F used on older devices. This is because the vast majority of MI
+ * cmds on Gen9 use a standard 8-bit Length field.
+ * All the Gen9 blitter instructions are standard 0xFF length mask, and
+ * none allow access to non-general registers, so in fact no BLT cmds are
+ * included in the table at all.
+ *
+ */

+*/
+ * A list of devices for which there is a specialized driver on HID bus.
+ *
+ * Please note that for multitouch devices (driven by hid-multitouch driver),
+ * there is a proper autodetection and autoloading in place (based on presence
+ * of HID DG CONTACTID), so those devices don't need to be added to this list,
+ * as we are doing the right thing in hid_scan_usage().
+ *
+ * Autodetection for (USB) HID sensor hubs exists too. If a collection of type
+ * physical is found inside a usage page of type sensor, hid-sensor-hub will be
+ * used as a driver. See hid_scan_report().

+ * directly for sub-channels, because sc_creation_callback() ->
+ * vmbus_open() may never get the host's response to the
+ * OPEN_CHANNEL message (the host may rescind a channel at any time,
+ * e.g. in the case of hot removing a NIC), and vmbus_onoffer_rescind()
+ * may not wake up the vmbus_open() as it's blocked due to a non-zero
+ * vmbus_connection.offer_in_progress, and finally we have a deadlock.
+ * The above is also true for primary channels, if the related device
+ * drivers use sync probing mode by default.
+ * And, usually the handling of primary channels and sub-channels can
+ * depend on each other, so we should offload them to different
+ * workqueues to avoid possible deadlock, e.g. in sync-probing mode,
+ * NIC1's netvsc_subchan_work() can race with NIC2's netvsc_probe() ->
+ * rtnl_lock(), and causes deadlock: the former gets the rtnl_lock
and waits for all the sub-channels to appear, but the latter
can't get the rtnl_lock and this blocks the handling of
sub-channels.

+/*
+ * We are an i2c-adapter which itself is part of an i2c-client. This means that
+ * transfers done through us take adapter->bus_lock twice, once for our parent
+ * i2c-adapter and once to take our own bus_lock. Lockdep does not like this
+ * nested locking, to make lockdep happy in the case of busses with muxes, the
+ * i2c-core's i2c_adapter_lock_bus function calls:
+ * rt_mutex_lock_nested(&adapter->bus_lock, i2c_adapter_depth(adapter));
+ *
+ * But i2c_adapter_depth only works when the direct parent of the adapter is
+ * another adapter, as it is only meant for muxes. In our case there is an
+ * i2c-client and MFD instantiated platform_device in the parent->child chain
+ * between the 2 devices.
+ *
+ * So we override the default i2c_lock_operations and pass a hardcoded
+ * depth of 1 to rt_mutex_lock_nested, to make lockdep happy.
+ *
+ * Note that if there were to be a mux attached to our adapter, this would
+ * break things again since the i2c-mux code expects the root-adapter to have
+ * a locking depth of 0. But we always have only 1 client directly attached
+ * in the form of the Charger IC paired with the CHT Whiskey Cove PMIC.

+ */
Set up the frequency divider and sampling rate.

1. Set up the frequency divider and sampling rate.
2. I2CCR - a0h
4. If I2CSR[MAL] is set (an indication that SDA is stuck low), then go to step 5. If MAL is not set, then go to step 13.
5. I2CCR - 00h
6. I2CCR - 22h
7. I2CCR - a2h
9. Issue read to I2CDR.
11. I2CCR - 82h
12. Workaround complete. Skip the next steps.
13. Issue read to I2CDR.
15. I2CCR - 80h
