   - The ptmx device node is located in the same directory as the devpts mount where the pts device nodes are located.
   - This is e.g. the case when calling open on the /dev/pts/ptmx device node when the devpts filesystem is mounted at /dev/pts.
   - The ptmx device node is located outside the devpts filesystem mount where the pts device nodes are located. For example, the ptmx device is a symlink, separate device node, or bind-mount.
   - A supported scenario is bind-mounting /dev/pts/ptmx to /dev/ptmx and then calling open on /dev/ptmx. In this case a suitable pts subdirectory can be found in the common parent directory /dev of the devpts mount and the ptmx bind-mount, after resolving the /dev/ptmx bind-mount.
   - If no suitable pts subdirectory can be found this function will fail.
   - This is e.g. the case when bind-mounting /dev/pts/ptmx to /ptmx.

int err;
int i;
The ability to raceily run the kernel stack unwinder on a running task and then observe the unwinder output is scary; while it is useful for debugging kernel issues, it can also allow an attacker to leak kernel stack contents. Doing this in a manner that is at least safe from races would require some work to ensure that the remote task can not be scheduled; and even then, this would still expose the unwinder as local attack surface. Therefore, this interface is restricted to root.

#include <linux/buffer_head.h>
#include "qnx4.h"
/+*
+ * A qnx4 directory entry is an inode entry or link info
+ * depending on the status field in the last byte. The
+ * first byte is where the name start either way, and a
+ * zero means it's empty.
+ *
+ * Also, due to a bug in gcc, we don't want to use the
+ * real (differently sized) name arrays in the inode and
+ * link entries, but always the 'de_name[]' one in the
+ * fake struct entry.
+ *
+ * See
+ *
+ * https://gcc.gnu.org/bugzilla/show_bug.cgi?id=99578#c6
+ *
+ * for details, but basically gcc will take the size of the
+ * 'name' array from one of the used union entries randomly.
+ *
+ * This use of 'de_name[]' (48 bytes) avoids the false positive
+ * warnings that would happen if gcc decides to use 'inode.di_name'
+ * (16 bytes) even when the pointer and size were to come from
+ * 'link.dl_name' (48 bytes).
+ *
+ * In all cases the actual name pointer itself is the same, it's
+ * only the gcc internal 'what is the size of this field' logic
+ * that can get confused.

EXPORT_SYMBOL(iterate_dir);

/*
 * POSIX says that a dirent name cannot contain NULL or a '/'.
 * It's not 100% clear what we should really do in this case.
 * The filesystem is clearly corrupted, but returning a hard
 * error means that you now don't see any of the other names
 * either, so that isn't a perfect alternative.
 * And if you return an error, what error do you use? Several
* filesystems seem to have decided on EUCLEAN being the error
* code for EFSCORRUPTED, and that may be the error to use. Or
* just EIO, which is perhaps more obvious to users.
*
* In order to see the other file names in the directory, the
* caller might want to make this a "soft" error: skip the
* entry, and return the error at the end instead.
*
* Note that this should likely do a "memchr(name, 0, len)"
* check too, since that would be filesystem corruption as
* well. However, that case can't actually confuse user space,
* which has to do a strlen() on the name anyway to find the
* filename length, and the above "soft error" worry means
* that it's probably better left alone until we have that
* issue clarified.
*

#ifndef __XFS_ATTR_H__
#define __XFS_ATTR_H__

+ struct xfs_inode;
+ struct xfs_da_args;
+ struct xfs_attr_list_context;
+
+ Large attribute lists are structured around Btrees where all the data
+ elements are in the leaf nodes. Attribute names are hashed into an int,
+ then that int is used as the index into the Btree. Since the hashval
+ of an attribute name may not be unique, we may have duplicate keys.
+ The internal links in the Btree are logical block offsets into the file.
+
+ Small attribute lists use a different format and are packed as tightly
+ as possible so as to fit into the literal area of the inode.
+
+ External interfaces

 * We do not hold the inode locked across the entire rolling transaction
 * here. We only need to hold it for the first transaction that
 * xfs_ifree() builds, which may mark the inode XFS_ISTALE if the
 * underlying cluster buffer is freed. Relogging an XFS_ISTALE inode
 * here breaks the relationship between cluster buffer invalidation and
 * stale inode invalidation on cluster buffer item journal commit
 * completion, and can result in leaving dirty stale inodes hanging
 * around in memory.
 * *
 * We have no need for serialising this inode operation against other
 * operations - we freed the inode and hence reallocation is required
 * and that will serialise on reallocating the space the deferops need
 * to free. Hence we can unlock the inode on the first commit of
 * the transaction rather than roll it right through the deferops. This
 * avoids relogging the XFS_ISTALE inode.
 * *
 * We check that xfs_ifree() hasn't grown an internal transaction roll
 * by asserting that the inode is still locked when it returns.

 * In the fallback code below, we need to compute the minimum and
 * maximum values representable in a given type. These macros may also
 * be useful elsewhere, so we provide them outside the
 * COMPILER_HAS_GENERIC_BUILTIN_OVERFLOW block.
 *
 * It would seem more obvious to do something like
 *
 * define type_min(T) (T)(is_signed_type(T) ? (T)1 << (8*sizeof(T)-1) : 0)
 * define type_max(T) (T)(is_signed_type(T) ? ((T)1 << (8*sizeof(T)-1)) - 1 : ~(T)0)
 *
 * Unfortunately, the middle expressions, strictly speaking, have
 * undefined behaviour, and at least some versions of gcc warn about
 * the type_max expression (but not if -fsanitize=undefined is in
+ * effect; in that case, the warning is deferred to runtime...).
+ *
+ * The slightly excessive casting in type_min is to make sure the
+ * macros also produce sensible values for the exotic type _Bool. [The
+ * overflow checkers only almost work for _Bool, but that's
+ * a-feature-not-a-bug, since people shouldn't be doing arithmetic on
+ * _Bools. Besides, the gcc builtins don't allow _Bool* as third
+ * argument.]

/** check_shl_overflow() - Calculate a left-shifted value and check overflow
 *
 * @a: Value to be shifted
 * @s: How many bits left to shift
 * @d: Pointer to where to store the result
 * Computes *@d = (@a << @s)
 */

}
Returns true if *d* cannot hold the result or when 'a << s' doesn't make sense. Example conditions:
- 'a << s' causes bits to be lost when stored in *d.*
- 's' is garbage (e.g. negative) or so large that the result of
- 'a << s' is guaranteed to be 0.
- 'a' is negative.
- 'a << s' sets the sign bit, if any, in '*d'.

*d* will hold the results of the attempted shift, but is not considered "safe for use" if false is returned.

```c
#define check_shl_overflow(a, s, d) ({
+typeof(a) _a = a;
+typeof(s) _s = s;
+typeof(d) _d = d;
+u64 _a_full = _a;
+unsigned int _to_shift =
+_s >= 0 && _s < 8 * sizeof(*d) ? _s : 0;
+*d = (_a_full << _to_shift);
+(_to_shift != _s || *_d < 0 || _a < 0 ||
+(*_d >> _to_shift) != _a);
+})
```

`array_size()` - Calculate size of 2-dimensional array.

```c
static inline __must_check size_t array_size(size_t a, size_t b)
{
+if (check_mul_overflow(a, b, &bytes))
+return SIZE_MAX;
+
+return bytes;
+
+}
```

`array3_size()` - Calculate size of 3-dimensional array.

```c
+* @a: dimension one
+* @b: dimension two
+* Calculates size of 2-dimensional array: @a * @b.
+*
+* Returns: number of bytes needed to represent the array or SIZE_MAX on overflow.

+ * The above is typically ordered against the wakeup, which does:
need_sleep = false;

wake_up_state(p, TASK_UNINTERRUPTIBLE);

need_sleep = false;
wake_up_state(p, TASK_UNINTERRUPTIBLE);

Where wake_up_state() (and all other wakeup primitives) imply enough barriers to order the store of the variable against wakeup.

once it observes the TASK_UNINTERRUPTIBLE store the waking CPU can issue a TASK_RUNNING store which can collide with __set_current_state(TASK_RUNNING).

This is obviously fine, since they both store the exact same value.

However, with slightly different timing the wakeup TASK_RUNNING store can also collide with the TASK_UNINTERRUPTIBLE store. Loosing that store is not a problem either because that will result in one extra go around the loop and our @cond test will save the day.

Also see the comments of try_to_wake_up().

 * usual consistency guarantee. It is one wmb cheaper, because we can
 * collapse the two back-to-back wmb(s).
```

Could you please clarify the context or the specific question related to this code snippet? It appears to be a fragment from a Linux kernel source code, involving file selection and some system calls related to console management.
Note that, writes surrounding the barrier should be declared atomic (e.g. via WRITE_ONCE): a) to ensure the writes become visible to other threads atomically, avoiding compiler optimizations; b) to document which writes are meant to propagate to the reader critical section. This is necessary because neither writes before and after the barrier are enclosed in a seq-writer critical section that would ensure readers are aware of ongoing writes.
