Global Variables

The spinlock protecting the list.

List of callbacks, in registration order.

The current done bit.

The list generation.

* This is increased whenever the list has been modified. The callback routine
* make use of this to avoid having restart at the list head after each callback.

This is called by the native code.

@param idCpu The CPU id the event applies to.
@param enmEvent The event.

DECLHIDDEN(void) rtMpNotificationDoCallbacks(RTMPEVENT enmEvent, RTCPUID idCpu)
{
    PRTMPNOTIFYREG pCur;
    RTSPINLOCK hSpinlock;

    /* This is a little bit tricky as we cannot be holding the spinlock
    * while calling the callback. This means that the list might change
    * while we're walking it, and that multiple events might be running
    * concurrently (depending on the OS).
    *
    * So, the first measure is to employ a 32-bitmask for each
    * record where we'll use a bit that rotates for each call to
    * this function to indicate which records that has been
    * processed. This will take care of both changes to the list
    * and a reasonable amount of concurrent events.
    *
    * In order to avoid having to restart the list walks for every
    * callback we make, we'll make use a list generation number that is
    * incremented everytime the list is changed. So, if it remains
    * unchanged over a callback we can safely continue the iteration.

#include <VBox/VMMDevCoreTypes.h>
#include <VBox/VBoxGuestCoreTypes.h>

/** @defgroup grp_vboxguest VirtualBox Guest Additions Device Driver
 * Also know as VBoxGuest.
 */

/** @defgroup grp_vboxguest_ioc VirtualBox Guest Additions Driver Interface
 * @note This is considered internal in ring-3, please use the VbgIR3 functions.
 * - I/O controls for user and/or kernel mode starts at 0.
 * - IDC specific requests descends from 127.
 * - Bits 7 and 6 are currently reserved for future hacks.
 */

/** @remarks When creating new IOCTL interfaces keep in mind that not all OSes supports
    reporting back the output size. (This got messed up a little bit in VBoxDrv.)
    The request size is also a little bit tricky as it's passed as part of the
    request code on unix. The size field is 14 bits on Linux, 12 bits on *BSD,
    13 bits Darwin, and 8-bits on Solaris. All the BSDs and Darwin kernels
    will make use of the size field, while Linux and Solaris will not. We're of
    course using the size to validate and/or map/lock the request, so it has
    to be valid.
    For Solaris we will have to do something special though, 255 isn't
    sufficient for all we need. A 4KB restriction (BSD) is probably not
    too problematic (yet) as a general one.
    More info can be found in SUPDRVIOC.h and related sources.

+/** @} */
```

The above code snippet is a part of a C program, defining various IOCTLs (Input/Output Control) for communication between the host and guest operating systems. It includes macros for the definitions and structures related to logging and event waiting. The `VBGL_IOCTL_LOG` and `VBGL_IOCTL_WAIT_FOR_EVENTS` are used for logging and waiting for events, respectively, with specific sizes and structures defined for these functionalities. The `VBGLIOCLOG` and `VBGLIOCWAITFOREVENTS` structures are used to encapsulate the log message and event information, respectively. The `RT_FLEXIBLE_ARRAY_IN_NESTED_UNION` is a macro used to define a flexible array size within a union. The `VBGLREQHDR` is a common header structure that is used across different IOCTLs.

+ * IOCTL to for acquiring and releasing guest capabilities.
+ *
+ * This is used for multiple purposes:
+ * 1. By doing @a acquire r3 client application (e.g. VBoxTray) claims it will
+ *    use the given session for performing operations like @a seamless or
+ *    @a auto-resize, thus, if the application terminates, the driver will
+ *    automatically cleanup the caps reported to host, so that host knows guest
+ *    does not support them anymore
+ * 2. In a multy-user environment this will not allow r3 applications (like
+ *    VBoxTray) running in different user sessions simultaneously to interfere
+ *    with each other. An r3 client application (like VBoxTray) is responsible
+ *    for Acquiring/Releasing caps properly as needed.
+ *
+ * VERR_RESOURCE_BUSY is returned if any capabilities in the fOrMask are
+ * currently acquired by some other VBoxGuest session.
+ *

+
+/** @page pg_guest_lib VirtualBox Guest Library
+ *
+ * This is a library for abstracting the additions driver interface. There are
+ * multiple versions of the library depending on the context. The main
+ * distinction is between kernel and user mode where the interfaces are very
+ * different.
+ *
+ *
+ * @section sec_guest_lib_ring0 Ring-0
+ *
+ * In ring-0 there are two version:
+ *  - VBOX_LIB_VBGL_R0_BASE / VBoxGuestR0LibBase for the VBoxGuest main driver,
+ *    who is responsible for managing the VMMDev virtual hardware.
+ *  - VBOX_LIB_VBGL_R0 / VBoxGuestR0Lib for other (client) guest drivers.
+ *
+ *
+ * The library source code and the header have a define VBGL_VBOXGUEST, which is
+ * defined for VBoxGuest and undefined for other drivers. Drivers must choose
+ * right library in their makefiles and set VBGL_VBOXGUEST accordingly.
+ *
+ * The libraries consists of:
+ *  - common code to be used by both VBoxGuest and other drivers;
+ *  - VBoxGuest specific code;
+ *  - code for other drivers which communicate with VBoxGuest via an IOCTL.
+ *
+ *
+ * @section sec_guest_lib_ring3 Ring-3
+ *
+ * There are more variants of the library here:
+ *  - VBOX_LIB_VBGL_R3 / VBoxGuestR3Lib for programs.
+ *  - VBOX_LIB_VBGL_R3_XFREE86 / VBoxGuestR3LibXFree86 for old style XFree
+ *    drivers which uses special loader and or symbol resolving strategy.
+ *  - VBOX_LIB_VBGL_R3_SHARED / VBoxGuestR3LibShared for shared objects / DLLs /
+ *    Dylibs.
+ *
+ */

+    /** Height of the pointer in scanlines. */
+    uint32_t height;
+    /** Pointer data. */
+    *
+    ****
+    * The data consists of 1 bpp AND mask followed by 32 bpp XOR (color) mask.
+    *
+    * For pointers without alpha channel the XOR mask pixels are 32 bit values: (lsb)BGR0(msb).
+    * For pointers with alpha channel the XOR mask consists of (lsb)BGRA(msb) 32 bit values.
+    *
+    * Guest driver must create the AND mask for pointers with alpha channel, so if host does not
+    * support alpha, the pointer could be displayed as a normal color pointer. The AND mask can
+    * be constructed from alpha values. For example alpha value >= 0xf0 means bit 0 in the AND mask.
+    *
+    * The AND mask is 1 bpp bitmap with byte aligned scanlines. Size of AND mask,
+    * therefore, is cbAnd = (width + 7) / 8 * height. The padding bits at the
+    * end of any scanline are undefined.
+    *
+    * The XOR mask follows the AND mask on the next 4 bytes aligned offset:
+    * uint8_t *pXor = pAnd + (cbAnd + 3) & ~3
Bytes in the gap between the AND and the XOR mask are undefined.
XOR mask scanlines have no gap between them and size of XOR mask is:
\[ cXor = \text{width} \times 4 \times \text{height}. \]

Preallocate 4 bytes for accessing actual data as p->pointerData.

```
    char pointerData[4];
```

+/**
+ * Service interface version.
+ *
+ * Includes layout of both VBOXHGCMSCVFNTABLE and VBOXHGCMSCVHELPERS.
+ *
+ * A service can work with these structures if major version
+ * is equal and minor version of service is <= version of the
+ * structures.
+ *
+ * For example when a new helper is added at the end of helpers
+ * structure, then the minor version will be increased. All older
+ * services still can work because they have their old helpers
+ * unchanged.
+ *
+ * Revision history.
+ * 1.1->2.1 Because the pfncntact now also has the pvClient parameter.
+ * 2.1->2.2 Because pfnsaveState and pfnloadState were added
+ * 2.2->3.1 Because pfnHostCall is now synchronous, returns rc, and parameters were changed
+ * 3.1->3.2 Because pfnRegisterExtension was added
+ * 3.2->3.3 Because pfnDiconnectClient helper was added
+ * 3.3->4.1 Because the pvservice entry and parameter was added
+ * 4.1->4.2 Because the VBOX_HGCM_SVC_PARM_CALLBACK parameter type was added

+ * 4.2->5.1 Removed the VBOX_HGCM_SVC_PARM_CALLBACK parameter type, as
+ * this problem is already solved by service extension callbacks

/** @defgroup grp_rt_asm    ASM - Assembly Routines 
 * @ingroup grp_rt 
 * @remarks The difference between ordered and unordered atomic operations are that 
 * the former will complete outstanding reads and writes before continuing 
 * while the latter doesn't make any promises about the order. Ordered 
 * operations doesn't, it seems, make any 100% promise wrt to whether 
 * the operation will complete before any subsequent memory access. 
 * (please, correct if wrong.) 
 * ASMAAtomicSomething operations are all ordered, while ASMAAtomicUoSomething 
 * are unordered (note the Uo). 
 * @remarks Some remarks about __volatile__: Without this keyword gcc is allowed to reorder 
 * or even optimize assembler instructions away. For instance, in the following code 
 * the second rdmsr instruction is optimized away because gcc treats that instruction 
 * as deterministic: 
 * @code 
 * static inline uint64_t rdmsr_low(int idx) 
 */
Open Source Used In 5GaaS Edge AC-4 33853

{  
uint32_t low;
__asm__ ("rdmsr" : "a"(low) : "c"(idx) : "edx");
}

...  

uint32_t msr1 = rdmsr_low(1);
foo(msr1);
msr1 = rdmsr_low(1);
bar(msr1);
@endcode

The input parameter of rdmsr_low is the same for both calls and therefore gcc will use the result of the first call as input parameter for bar() as well. For rdmsr this is not acceptable as this instruction is _not_ deterministic. This applies to reading machine status information in general.

### Atomic Read Handles

#### Ordinary

- **Function**: `ASMAtomicUoReadHandle` (variants for 32-bit and 64-bit architectures)
- **Parameters**:
  - `pu`: Pointer to the variable to read.
  - `puRes`: Where to store the result.

- **Remarks**
  - This function is designed to work with handles that may have different sizes across platforms or compilers.
  - It's particularly useful for variables that are not guaranteed to have a consistent size.

#### Example Usage

```c
*uint32_t RT_FAR *(phRes) = ASMAtomicReadU32((uint32_t volatile RT_FAR *)(ph));
```

- **Notes**
  - The function requires the size of `pu` and `puRes` to be checked against the expected size.
  - It uses atomic read operations to ensure data consistency in multi-threaded environments.

---

---

### Description

Finds the next set bit in a bitmap.

* @returns Index of the next set bit.
* @returns -1 if no set bit was found.
* @param pvBitmap Pointer to the bitmap.
* @param cBits The number of bits in the bitmap. Multiple of 32.
* @param iBitPrev The bit returned from the last search.
* The search will start at iBitPrev + 1.

---

+/** @defgroup grp_rt_assert  Assert - Assertions
+ * @ingroup grp_rt
+ *
+ * Assertions are generally used to check preconditions and other
+ * assumptions. Sometimes it is also used to catch odd errors or errors
+ * that one would like to inspect in the debugger. They should not be
+ * used for errors that happen frequently.
+ *
+ * IPRT provides a host of assertion macros, so many that it can be a bit
+ * overwhelming at first. Don't despair, there is a system (surprise).
+ *
+ * First there are four families of assertions:
+ *      - Assert        - The normal strict build only assertions.
+ *      - AssertLogRel  - Calls LogRel() in non-strict builds, otherwise like Assert.
+ *      - AssertRelease - Triggers in all builds.
+ *      - AssertFatal   - Triggers in all builds and cannot be continued.
+ *
+ * Then there are variations wrt to argument list and behavior on failure:
+ *      - Msg           - Custom RTStrPrintf-like message with the assertion message.
+ *      - Return        - Return the specific rc on failure.
+ *      - ReturnVoid    - Return (void) on failure.
+ *      - Break         - Break (out of switch/loop) on failure.
+ *      - Stmt          - Execute the specified statement(s) on failure.
+ *      - RC            - Assert RT_SUCCESS.
+ *      - RCSuccess    - Assert VINF_SUCCESS.
+ *
+ * @remarks As you might have noticed, the macros don't follow the
+ * coding guidelines wrt to macros supposedly being all uppercase
+ * and underscored. For various reasons they don't, and nobody
+ * has complained yet. Wonder why... :-)
+ *
+ * @remarks Each project has its own specific guidelines on how to use
+ * assertions, so the above is just trying to give you the general idea
+ * from the IPRT point of view.

### AssertReturnStmt

*AssertReturnStmt* is a macro that allows you to assert that an expression is true, and if it isn't execute a given statement before returning. It is particularly useful in RT_STRICT mode to ensure that the code behaves as expected.

**Purpose**

- **Expression which should be true.**
- **Statement to execute before returning on failure.**
- **What is to be presented to return.**

**Usage**

```c
AssertReturnStmt(expr, stmt, rc)
```

### Examples

1. **In RT_STRICT mode**
   ```c
   RTAssertMsg1Weak(#expr, __LINE__, __FILE__, RT_GCC_EXTENSION __PRETTY_FUNCTION__); \
   RTAssertPanic(); \
   return (rc); \
   } \
   } while (0)
   #endif
   
   /** @def AssertReturnStmt
   * Assert that an expression is true, if it isn't execute the given statement and 
   * return rc.
   * 
   * In RT_STRICT mode it will hit a breakpoint before executing the statement and 
   * returning.
   * 
   * @param   expr    Expression which should be true.
   * @param   stmt    Statement to execute before returning on failure.
   * @param   rc      What is to be presented to return.
   * */
   #ifdef RT_STRICT
   # define AssertReturnStmt(expr, stmt, rc) \
   do { \
   if (RT_LIKELY(!!(expr))) \
   { /* likely */ } \
   else \
   { \
   RTAssertMsg1Weak(#expr, __LINE__, __FILE__, __PRETTY_FUNCTION__); \

/** @def RT_LIKELY
 * Give the compiler a hint that an expression is very likely to hold true.
 */
/**
 * Some compilers support explicit branch prediction so that the CPU backend
 * can hint the processor and also so that code blocks can be reordered such
 * that the predicted path sees a more linear flow, thus improving cache
IPRT provides the macros **RT_LIKELY()** and **RT_UNLIKELY()** as a way to utilize
this compiler feature when present.

A few notes about the usage:

- Generally, order your code use **RT_LIKELY()** instead of **RT_UNLIKELY()**.
- Generally, use **RT_UNLIKELY()** with error condition checks (unless you
  have some _strong_ reason to do otherwise, in which case document it),
  and/or **RT_LIKELY()** with success condition checks, assuming you want
  to optimize for the success path.
- Other than that, if you don't know the likelihood of a test succeeding
  from empirical or other 'hard' evidence, don't make predictions unless
  you happen to be a Dirk Gently character.
- These macros are meant to be used in places that get executed a lot. It
  is wasteful to make predictions in code that is executed rarely (e.g.
  at subsystem initialization time) as the basic block reordering that this
  affects can often generate larger code.
- Note that **RT_SUCCESS()** and **RT_FAILURE()** already makes use of **RT_LIKELY()**
  and **RT_UNLIKELY()**. Should you wish for prediction free status checks,
  use the **RT_SUCCESS_NP()** and **RT_FAILURE_NP()** macros instead.

__@returns__ the boolean result of the expression.

__@returns__ the boolean result of the expression.

__@see__ **RT_LIKELY()**

__@see__ **RT_LIKELY()**

__@deprecated__ Please use **RT_LIKELY()** instead wherever possible! That gives us
  a better chance of the windows compilers to generate favorable code
  too. The belief is that the compiler will by default assume the
  if-case is more likely than the else-case.

+ /** @def RT ALIGN */
+ * Align macro.
+ * @param u Value to align.
+ * @param uAlignment The alignment. Power of two!
+ * @remark Be extremely careful when using this macro with type which sizeof != sizeof int.
When possible use any of the other RT_ALIGN_* macros. And when that's not possible, make 101% sure that uAlignment is specified with a right sized type.

Specifying an unsigned 32-bit alignment constant with a 64-bit value will give you a 32-bit return value!

In short: Don't use this macro. Use RT_ALIGN_T() instead.

```
#define RT_ALIGN(u, uAlignment)                 ( ((u) + ((uAlignment) - 1)) & ~((uAlignment) - 1) )
```

```
/** @def RT_ALIGN_T
 * Align macro.
 * @param   u           Value to align.
 * @param   uAlignment  The alignment. Power of two!
 * @param   type        Integer type to use while aligning.
 * @remark  This macro is the preferred alignment macro, it doesn't have any of the pitfalls RT_ALIGN has.
 */

+ *
+ * @note   See notes for RT_FLEXIBLE_ARRAY.
GCC does not permit using this in a union. So, for unions you must use RT_FLEXIBLE_ARRAY_IN_NESTED_UNION instead.

The union version of RT_FLEXIBLE_ARRAY.

GCC does not support flexible array members in unions, 6.1.x actively checks for this. Visual C++ 2010 seems happy with it.

See notes for RT_FLEXIBLE_ARRAY.

The union version of RT_FLEXIBLE_ARRAY_NESTED.

For compilers (like DTrace) that does not grok nameless unions, we have a little hack to make them palatable.

For compilers (like DTrace) that does not grok nameless structs (it is non-standard C++), we have a little hack to make them palatable.

+ * any part of the code, as it is only used by the tools that create message
+ * catalogs. This macro is a no-op as far as the compiler and code generation
+ * is concerned.
If you want to both mark a string for translation and translate it, use _() .

#define N_(s) (s)

#define _(s) gettext(s)

#define __PRETTY_FUNCTION__

With GNU C we'd like to use the builtin __PRETTY_FUNCTION__, so define that
for the other compilers.

#define RT_STRICT
The #define RT_STRICT controls whether or not assertions and other runtime
checks should be compiled in or not. This is defined when DEBUG is defined.
If RT_NO_STRICT is defined, it will unconditionally be undefined.

If you want assertions which are not subject to compile time options use
the AssertRelease*() flavors.

**@def DECLEXPORT_CLASS**
How to declare an exported class. Place this macro after the ’class’ keyword in the declaration of every class you want to export.

**@note** It is necessary to use this macro even for inner classes declared inside the already exported classes. This is a GCC specific requirement, but it seems not to harm other compilers.

```c
#ifdef(_MSC_VER) || defined(RT_OS_OS2)
#define DECLEXPORT_CLASS __declspec(dllexport)
#elif defined(RT_USE_VISIBILITY_DEFAULT)
#define DECLEXPORT_CLASS __attribute__((visibility("default")))
#else
#define DECLEXPORT_CLASS
#endif
```

**@def DECLIMPORT_CLASS**
How to declare an imported class Place this macro after the ‘class’ keyword in the declaration of every class you want to export.

**@note** It is necessary to use this macro even for inner classes declared inside the already exported classes. This is a GCC specific requirement, but it seems not to harm other compilers.

```c
#ifdef(_MSC_VER) || (defined(RT_OS_OS2) && !defined(__IBMC__) && !defined(__IBMCPP__))
#define DECLIMPORT_CLASS __declspec(dllimport)
#elif defined(RT_USE_VISIBILITY_DEFAULT)
#define DECLIMPORT_CLASS __attribute__((visibility("default")))
#else
#define DECLIMPORT_CLASS
#endif
```

**@def WORKAROUND_MSVC7_ERROR_C2593_FOR_BOOL_OP**
Macro to work around error C2593 of the not-so-smart MSVC 7.x ambiguity resolver. The following snippet clearly demonstrates the code causing this error:

```c
@code
class A
{
    public:
        operator bool() const { return false; }
        operator int*() const { return NULL; }
    }

table main()
{
    A a;
    if (!a);
```
if (a && 0);
    return 0;
  }
  }
  }
@endcode

The code itself seems pretty valid to me and GCC thinks the same.

This macro fixes the compiler error by explicitly overloading implicit

global operators !, && and || that take the given class instance as one of
their arguments.

The best is to use this macro right after the class declaration.

@note The macro expands to nothing for compilers other than MSVC.

@param Cls Class to apply the workaround to

Donate read+write+execute memory to the exec heap.

This API is specific to AMD64 and Linux/GNU. A kernel module that desires to use RTMemExecAlloc on AMD64 Linux/GNU will have to donate some statically allocated memory in the module if it wishes for GCC generated code to work. GCC can only generate modules that work in the address range ~2GB to ~0 currently.

The API only accept one single donation.

@returns IPRT status code.

+RTR0DECL(int) RTR0MemUserCopyTo(RTR3PTR R3PtrDst, void const *pvSrc, size_t cb);
Tests if the specified address is in the user addressable range.

This function does not check whether the memory at that address is accessible or anything of that sort, only if the address itself is in the user mode range.

@returns true if it's in the user addressable range. false if not.

@param R3Ptr The user mode pointer to test.

@remarks Some systems may have overlapping kernel and user address ranges. One prominent example of this is the x86 version of Mac OS X. Use RTR0MemAreKrnlAndUsrDifferent() to check.

RTR0DECL(bool) RTR0MemUserIsValidAddr(RTR3PTR R3Ptr);

Tests if the specified address is in the kernel mode range.

This function does not check whether the memory at that address is accessible or anything of that sort, only if the address itself is in the kernel mode range.

@returns true if it's in the kernel range. false if not.

@param pv The alleged kernel mode pointer.

@remarks Some systems may have overlapping kernel and user address ranges. One prominent example of this is the x86 version of Mac OS X. Use RTR0MemAreKrnlAndUsrDifferent() to check.

RTR0DECL(bool) RTR0MemKernelIsValidAddr(void *pv);

Are user mode and kernel mode address ranges distinctly different.

This determines whether RTR0MemKernelIsValidAddr and RTR0MemUserIsValidAddr can be used for deciding whether some arbitrary address is a user mode or a kernel mode one.

@returns true if they are, false if not.

RTR0DECL(bool) RTR0MemAreKrnlAndUsrDifferent(void);

Copy memory from a potentially unsafe kernel mode location and into a safe (kernel) buffer.

@retval VINF_SUCCESS on success.
@retval VERR_ACCESS_DENIED on error.
@retval VERR_NOT_SUPPORTED if not (yet) supported.

- @param pvDst The destination address (safe).
- @param pvSrc The source address (potentially unsafe).

+ */
+RTDECL(int) RTPathIsSame(const char *pszPath1, const char *pszPath2);
The comparison takes platform-dependent details into account, such as:

- On DOS-like platforms, both separator chars (\| and \/) are considered to be equal.
- On platforms with case-insensitive file systems, mismatching characters are uppercased and compared again.

- @returns @< 0 if the first path less than the second path.
- @returns 0 if the first path identical to the second path.
- @returns @> 0 if the first path greater than the second path.

- @returns @true when \a pszPath starts with \a pszParentPath (or when they are identical), or @false otherwise.

- @returns @true when \a pszPath starts with \a pszParentPath (or when they are identical), or @false otherwise.

- @returns @true when \a pszPath starts with \a pszParentPath (or when they are identical), or @false otherwise.

- This means that either the path and the parent path matches completely, or that the path is to some file or directory residing in the tree given by the parent directory.

- The path comparison takes platform-dependent details into account, see RTPathCompare() for details.

- @returns @true when \a pszPath starts with \a pszParentPath (or when they are identical), or @false otherwise.

- No trailing directory slash!

- This API doesn't currently handle root directory compares in a manner consistent with the other APIs. RTPathStartsWith(pszSomePath, \"/\") will not work if pszSomePath isn't \"\".

### Macros for Validate the Flags

```c
#define RTSEMWAIT_FLAGS_ARE_VALID(flags)    
   ((flags) & UINT32_C(0xffffff80))    
   && ((flags) & RTSEMWAIT_FLAGS_INDEFINITE)    
   ? (((flags) & UINT32_C(0x20)) ^ (((flags) >> 1) & UINT32_C(0x20)) ) == UINT32_C(0x20)    
   : (((flags) & UINT32_C(0x25)) ^ (((flags) >> 1) & UINT32_C(0x25)) ) == UINT32_C(0x25)    
```

### Event Semaphore

Event semaphores can be used for inter-thread communication when one thread wants to notify another thread that something happened. A thread can block ("wait") on an event semaphore until it is signalled by another thread; see RTSemEventCreate, RTSemEventSignal and RTSemEventWait.

```c
* @ { */
  + * Event semaphores can be used for inter-thread communication when one thread
  + * wants to notify another thread that something happened. A thread can block

 +
+ /** @defgroup grp_rt_sems_mutex RTSemMutex - Mutex semaphores. */
Mutex semaphores protect a section of code or data to which access must be exclusive. Only one thread can hold access to a critical section at one time. See RTSemMutexCreate, RTSemMutexRequest and RTSemMutexRelease.

@remarks These are less efficient than "fast mutexes" and "critical sections", which IPRT implements as well; see @ref grp_rt_sems_fast_mutex and @ref grp_rt_critsect.

@returns iprt status code.

+ * @returns iprt status code.
+ * @param   pszString       UTF-8 string to convert.
+ * @param   cchString       The maximum size in chars (the type) to convert.
+ *                          The conversion stop when it reaches cchString or
+ *                          the string terminator (\0'). Use RTSTR_MAX to
+ *                          translate the entire string.
+ * @param   ppsz            If cch is non-zero, this must either be pointing to
RTStrToLatin1ExTag((pszString), (cchString), (ppsz), (cch), (pcch), RTSTR_TAG)

+ * Translates pszString from UTF-8 to Latin1, allocating the result buffer if
  + * requested (custom tag).
  + *
  + * @returns iprt status code.
  + *
  + * @param pszString UTF-8 string to convert.
  + *
  + * @param cchString The maximum size in chars (the type) to convert.
  + *
  + * The conversion stop when it reaches cchString or
  + *
  + * the string terminator ('\0'). Use RTSTR_MAX to
  + *
  + * translate the entire string.
  + *
  + * @param ppsz If cch is non-zero, this must either be pointing to
  + *
  + * pointer to a buffer of the specified size, or
  + *
  + * pointer to a NULL pointer. If *ppsz is NULL or cch
  + *
  + * is zero a buffer of at least cch items will be
  + *
  + * allocated to hold the translated string. If a
  + *
  + * buffer was requested it must be freed using
  + *
  + * RTStrFree().
  + *
  + * @param cch The buffer size in bytes. This includes the
  + *
  + * terminator.
  + *
  + * @param pcch Where to store the length of the translated string,
  + *
  + * excluding the terminator. (Optional)
  + *
  + *
  + * This may be set under some error conditions,
  + *
  + * however, only for VERR_BUFFER_OVERFLOW and
  + *
  + * VERR_NO_STR_MEMORY will it contain a valid string
  + *
  + * length that can be used to resize the buffer.
  + *
  + * @param pszTag Allocation tag used for statistics and such.
  + * /

+/** @page pg_rt_str_format The IPRT Format Strings
+ *
+ * IPRT implements most of the commonly used format types and flags with the
+ * exception of floating point which is completely missing. In addition IPRT
+ * provides a number of IPRT specific format types for the IPRT typedefs and
+ * other useful things. Note that several of these extensions are similar to
+ * \%p and doesn't care much if you try add formating flags/width/precision.
+ *
+ * * Group 0a, The commonly used format types:
+ *
+  * - \%s   - Takes a pointer to a zero terminated string (UTF-8) and
+  * prints it with the optionally adjustment (width, -) and
+  * length restriction (precision).
+  * - \%ls  - Same as \%s except that the input is UTF-16 (output UTF-8).
+  * - \%LS  - Same as \%s except that the input is UCS-32 (output UTF-8).
+  * - \%S   - Same as \%s, used to convert to current codeset but this is
+  * now done by the streams code. Deprecated, use \%s.
```
- \%IS - Ditto. Deprecated, use \%ls.
- \%LS - Ditto. Deprecated, use \%LS.
- \%c - Takes a char and prints it.
- \%d - Takes a signed integer and prints it as decimal. Thousand separator (\'), zero padding (0), adjustment (+), width,
  precision
- \%i - Same as \%d.
- \%u - Takes an unsigned integer and prints it as decimal. Thousand separator (\'), zero padding (0), adjustment (+), width,
  precision
- \%x - Takes an unsigned integer and prints it as lowercased hexadecimal. The special hash (#) flag causes a '0x' prefixed to be printed. Zero padding (0), adjustment (+), width, precision.
- \%X - Same as \%x except that it is uppercased.
- \%o - Takes an unsigned (?) integer and prints it as octal. Zero padding (0), adjustment (+), width, precision.
- \%p - Takes a pointer (void technically) and prints it. Zero padding (0), adjustment (+), width, precision.

The \%d, \%i, \%u, \%x, \%X and \%o format types support the following argument type specifiers:
- \%ll - long long (uint64_t).
- \%L - long long (uint64_t).
- \%l - long (uint32_t, uint64_t)
- \%h - short (int16_t).
- \%hh - char (int8_t).
- \%H - char (int8_t).
- \%z - size_t.
- \%j - intmax_t (int64_t).
- \%t - ptrdiff_t.

The type in parentheses is typical sizes, however when printing those types you are better off using the special group 2 format types below (\%RX32 and such).

+ * Group 0b, IPRT format tricks:
  + * - %M - Replaces the format string, takes a string pointer.
  + * - %N - Nested formatting, takes a pointer to a format string followed by the pointer to a va_list variable. The va_list variable will not be modified and the caller must do va_end() on it. Make sure the va_list variable is NOT in a parameter list or some gcc versions/targets may get it all wrong.

+ * Group 1, the basic runtime typedefs (excluding those which obviously are pointer):
  + * - \%RTbool - Takes a bool value and prints 'true', 'false', or '!%d!'.
+ * - `%RTfile`  - Takes a `#RTFILE` value.
+ * - `%RTfmode`  - Takes a `#RTFMODE` value.
+ * - `%RTfoff`  - Takes a `#RTFOFF` value.
+ * - `%RTfp16`  - Takes a `#RTFAR16` value.
+ * - `%RTfp32`  - Takes a `#RTFAR32` value.
+ * - `%RTfp64`  - Takes a `#RTFAR64` value.
+ * - `%RTgid`  - Takes a `#RTGID` value.
+ * - `%RTino`  - Takes a `#RTINODE` value.
+ * - `%RTint`  - Takes a `#RTINT` value.
+ * - `%RTiop`  - Takes a `#RTIOPORT` value.
+ * - `%RTldrm`  - Takes a `#RTLDRMOD` value.
+ * - `%RTmac`  - Takes a `#PCRTMAC` pointer.
+ * - `%RTnaddr`  - Takes a `#PCRTNETADDR` value.
+ * - `%RTnaipv4`  - Takes a `#RTNETADDRIPV4` value.
+ * - `%RTnaipv6`  - Takes a `#PCRTNETADDRIPV6` value.
+ * - `%RTnthrd`  - Takes a `#RTNATIVETHREAD` value.
+ * - `%RTproc`  - Takes a `#RTPROCESS` value.
+ * - `%RTptr`  - Takes a `#RTINTPTR` or `#RTUINTPTR` value (but not void *).
+ * - `%RTreg`  - Takes a `#RTCCUINTREG` value.
+ * - `%RTsem`  - Takes a `#RTSEMEVENT`, `#RTSEMEVENTMULTI`, `#RTSEMMUTEX`, `#RTSEMFASTMUTEX`, or `#RTSEMRW` value.
+ * - `%RTsock`  - Takes a `#RTSOCKET` value.
+ * - `%RTthrd`  - Takes a `#RTTHREAD` value.
+ * - `%RTuid`  - Takes a `#RTUID` value.
+ * - `%RTuint`  - Takes a `#RTUINT` value.
+ * - `%RTunicp`  - Takes a `#RTUNICP` value.
+ * - `%RTuuid`  - Takes a `#PCRTUUID` and will print the UUID as a string.
+ * - `%RTxuint`  - Takes a `#RTUINT` or `#RTINT` value, formatting it as hex.
+ * - `%RGi`  - Takes a `#RTGCINT` value.
+ * - `%RGp`  - Takes a `#RTGCPHYS` value.
+ * - `%Gr`  - Takes a `#RTGCUINTREG` value.
+ * - `%RGu`  - Takes a `#RTGCUINT` value.
+ * - `%RGv`  - Takes a `#RTGCPTR`, `#RTGCINTPTR` or `#RTGCUINTPTR` value.
+ * - `%RGx`  - Takes a `#RTGCINT` or `#RTGCINT` value, formatting it as hex.
+ * - `%RHi`  - Takes a `#RTHCINT` value.
+ * - `%RHp`  - Takes a `#RTHCPHY` value.
+ * - `%Rhr`  - Takes a `#RTHCUINTREG` value.
+ * - `%RHu`  - Takes a `#RTHCUINT` value.
+ * - `%RHv`  - Takes a `#RTHCPTR`, `#RTHCINTPTR` or `#RTHCUINTPTR` value.
+ * - `%Rhx`  - Takes a `#RTHCUINT` or `#RTHCINT` value, formatting it as hex.
+ * - `%RRv`  - Takes a `#RTRCPTR`, `#RTRCINTPTR` or `#RTRCUINTPTR` value.
+ * - `%RCi`  - Takes a `#RTINT` value.
+ * - `%Rcp`  - Takes a `#RTCCPHYS` value.
+ * - `%RCr`  - Takes a `#RTCCUINTREG` value.
+ * - `%RCu`  - Takes a `#RTUINT` value.
+ * - \%RCv - Takes a #uintptr_t, #intptr_t, void * value.
+ * - \%RCx - Takes a #RTUINT or #RTINT value, formatting it as hex.
+ *
+ *
+ * Group 2, the generic integer types which are preferred over relying on what
+ * bit-count a 'long', 'short', or 'long long' has on a platform. This are
+ * highly preferred for the [u]intXX_t kind of types:
+ * - \%RI\[8|16|32|64\] - Signed integer value of the specified bit count.
+ * - \%RU\[8|16|32|64\] - Unsigned integer value of the specified bit count.
+ * - \%RX\[8|16|32|64\] - Hexadecimal integer value of the specified bit count.
+ *
+ *
+ * Group 3, hex dumpers and other complex stuff which requires more than simple
+ * formatting:
+ * - \%Rhxd - Takes a pointer to the memory which is to be dumped in typical
+ * hex format. Use the precision to specify the length, and the width to
+ * set the number of bytes per line. Default width and precision is 16.
+ * - \%RhxD - Same as \%Rhxd, except that it skips duplicate lines.
+ * - \%Rhxs - Takes a pointer to the memory to be displayed as a hex string,
+ * i.e. a series of space separated bytes formatted as two digit hex value.
+ * Use the precision to specify the length. Default length is 16 bytes.
+ * The width, if specified, is ignored.
+ * - \%Rrc - Takes an integer iprt status code as argument. Will insert the
+ * status code define corresponding to the iprt status code.
+ * - \%Rrs - Takes an integer iprt status code as argument. Will insert the
+ * short description of the specified status code.
+ * - \%Rrf - Takes an integer iprt status code as argument. Will insert the
+ * full description of the specified status code.
+ * - \%Rra - Takes an integer iprt status code as argument. Will insert the
+ * status code define + full description.
+ * - \%Rwc - Takes a long Windows error code as argument. Will insert the status
+ * code define corresponding to the Windows error code.
+ * - \%Rwf - Takes a long Windows error code as argument. Will insert the
+ * full description of the specified status code.
+ * - \%Rwa - Takes a long Windows error code as argument. Will insert the
+ * error code define + full description.
+ * - \%Rhrc - Takes a COM/XPCOM status code as argument. Will insert the status
+ * code define corresponding to the Windows error code.
+ * - \%Rhrf - Takes a COM/XPCOM status code as argument. Will insert the
+ * full description of the specified status code.
+ * - \%Rhra - Takes a COM/XPCOM error code as argument. Will insert the
+ * error code define + full description.
+ * - \%Rfn - Pretty printing of a function or method. It drops the
+ * return code and parameter list.
+ * - \%Rbn - Prints the base name. For dropping the path in
+ * order to save space when printing a path name.
- Same as \%ls except inlut is big endian UTF-16.

- \%Rw? simply prints the argument in a form of 0xXXXXXXXX.

- Group 4, structure dumpers:
  - \%RDtimespec - Takes a PCRTTIMESPEC.

- Group 5, XML / HTML escapers:
  - \%RMas - Takes a string pointer (const char *) and outputs it as an attribute value with the proper escaping.
  - This typically ends up in double quotes.

  - \%RMes - Takes a string pointer (const char *) and outputs it as an element with the necessary escaping.

- Group 6, CPU Architecture Register dumpers:
  - \%RAX64[reg] - Takes a 64-bit register value if the register is 64-bit or smaller. Check the code wrt which registers are implemented.
