Technically, swapgs isn't serializing on AMD (despite it previously being documented as such in the APM). But according to AMD, %gs is updated non-speculatively, and the issuing of %gs-relative memory operands will be blocked until the %gs update completes, which is good enough for our purposes.

```c
+/* AMD Family 0xf - 0x12 */
+VULNWl_AMD(0x0f,NO_MELTDOWN|NO_SSB|NO_L1TF|NO_MDS|NO_SWAPGS|NO_ITLB_MULTIHIT),

static inline unsigned long get_nr_restart_syscall(const struct pt_regs *regs)
    {
This function is fundamentally broken as currently implemented.

The idea is that we want to trigger a call to the restart_block() syscall and that we want in_ia32_syscall(), in_x32_syscall(), etc. to match whatever they were in the syscall being restarted. We assume that the syscall instruction at (regs->ip - 2) matches whatever syscall instruction we used to enter in the first place.

The problem is that we can get here when ptrace pokes syscall-like values into regs even if we're not in a syscall at all.

For now, we maintain historical behavior and guess based on stored state. We could do better by saving the actual syscall arch in restart_block or (with caveats on x32) by checking if regs->ip points to 'int $0x80'. The current behavior is incorrect if a tracer has a different bitness than the tracer.

}
To run an L2 guest, we need a vmcs02 based on the L1-specified vmcs12.

We could reuse a single VMCS for all the L2 guests, but we also want the option to allocate a separate vmcs02 for each separate loaded vmcs12 - this allows keeping them loaded on the processor, and in the future will allow optimizations where prepare_vmcs02 doesn't need to set all the fields on every entry if they never change.

So we keep, in vmx->nested.vmcs02_pool, a cache of size VMCS02_POOL_SIZE with a vmcs02 for each recently loaded vmcs12s, most recent first.

The following functions allocate and free a vmcs02 in this pool.

Some BIOS implementations support RAM above 4GB, but do not configure the PCI host to respond to bus master accesses for these addresses. These implementations set the TOP_OF_DRAM_SLOT1 register correctly, so PCI DMA works as expected for addresses below 4GB.

Reference: "AMD RS690 ASIC Family Register Reference Guide" (pg. 2-57)

# Configuration

The configuration file for the 5GaaS Edge AC-4 platform is described in the following section. It includes the mandatory and optional parameters for the platform configuration.

## Mandatory Parameters

- **Platform Name**: The name of the platform should be specified as `platform_name`.
- **Port Number**: The port number for the platform should be specified as `port_number`.
- **Queue Size**: The queue size for the platform should be specified as `queue_size`.

## Optional Parameters

- **Security Mode**: The security mode can be specified as `security_mode`.
- **Logging Level**: The logging level can be specified as `logging_level`.
- **Timeout Value**: The timeout value for the platform can be specified as `timeout_value`.

## Example Configuration

```yaml
platform_name: 5GaaS Edge AC-4
port_number: 8080
queue_size: 100
security_mode: high
logging_level: debug
timeout_value: 30
```

This configuration file is essential for setting up the 5GaaS Edge AC-4 platform correctly.

        wrapper to incorporate the list into the kernel. Each <hash> should
be a string of hex digits.

+config EFI_SIGNATURE_LIST_PARSER
+bool "EFI signature list parser"
+depends on EFI
+select X509_CERTIFICATE_PARSER
+help
+ This option provides support for parsing EFI signature lists for
+ X.509 certificates and turning them into keys.
+
+config LOAD_UEFI_KEYS
+bool "Load certs and blacklist from UEFI db for module checking"
+depends on SYSTEM_BLACKLIST_KEYRING
+depends on SECONDARY_TRUSTED_KEYRING
+depends on EFI
+depends on EFI_SIGNATURE_LIST_PARSER
+help
+ If the kernel is booted in secure boot mode, this option will cause
+ the kernel to load the certificates from the UEFI db and MokListRT
+ into the secondary trusted keyring. It will also load any X.509
+ SHA256 hashes in the dbx list into the blacklist.
+
+ The effect of this is that, if the kernel is booted in secure boot
+ mode, modules signed with UEFI-stored keys will be permitted to be
+ loaded and keys that match the blacklist will be rejected.
+
+config SYSTEM_REVOCATION_LIST
+bool "Provide system-wide ring of revocation certificates"
+depends on SYSTEM_BLACKLIST_KEYRING
+depends on PKCS7_MESSAGE_PARSER=y
+help
+ If set, this allows revocation certificates to be stored in the
+ blacklist keyring and implements a hook whereby a PKCS#7 message can
+ be checked to see if it matches such a certificate.
+
+config SYSTEM_REVOCATION_KEYS
+string "X.509 certificates to be preloaded into the system blacklist keyring"
+depends on SYSTEM_REVOCATION_LIST
+help
+ If set, this option should be the filename of a PEM-formatted file
+ containing X.509 certificates to be included in the default blacklist
+ keyring.
