Freescale Data-Path Acceleration Architecture Frame Manager (FMan) support
+
+config DPAA_ERRATUM_A050385
+bool
+depends on ARM64 & FSL_DPAA
+default y
+help
+DPAA FMan erratum A050385 software workaround implementation:
+align buffers, data start, SG fragment length to avoid FMan DMA
+splits.
+FMAN DMA read or writes under heavy traffic load may cause FMAN
+internal resource leak thus stopping further packet processing.
+The FMAN internal queue can overflow when FMAN splits single
+read or write transactions into multiple smaller transactions
+such that more than 17 AXI transactions are in flight from FMAN
+to interconnect. When the FMAN internal queue overflows, it can
+stall further packet processing. The issue can occur with any
+one of the following three conditions:
+1. FMAN AXI transaction crosses 4K address boundary (Errata
+A010022)
+2. FMAN DMA address for an AXI transaction is not 16 byte
+aligned, i.e. the last 4 bits of an address are non-zero
+3. Scatter Gather (SG) frames have more than one SG buffer in
+the SG list and any one of the buffers, except the last
+buffer in the SG list has data size that is not a multiple
+of 16 bytes, i.e., other than 16, 32, 48, 64, etc.
+With any one of the above three conditions present, there is
+likelihood of stalled FMAN packet processing, especially under
+stress with multiple ports injecting line-rate traffic.

+ * hns_nic_get_headlen - determine size of header for RSC/LRO/GRO/FCOE
+ * @data: pointer to the start of the headers
+ * @max: total length of section to find headers in
+*/
This function is meant to determine the length of headers that will be recognized by hardware for LRO, GRO, and RSC offloads. The main motivation of doing this is to only perform one pull for IPv4 TCP packets so that we can do basic things like calculating the gso_size based on the average data per packet.

```c
static unsigned int hns_nic_get_headlen(unsigned char *data, u32 flag,
    unsigned int max_size)
{
    unsigned char *network;
    u8 hlen;

    /* this should never happen, but better safe than sorry */
    if (max_size < ETH_HLEN)
        return max_size;

    /* initialize network frame pointer */
    network = data;

    /* set first protocol and move network header forward */
    network += ETH_HLEN;

    /* handle any vlan tag if present */
    if (hnae_get_field(flag, HNS_RXD_VLAN_M, HNS_RXD_VLAN_S)
        == HNS_RX_FLAG_VLAN_PRESENT) {
        if (!(typeof(max_size))(network - data) > (max_size - VLAN_HLEN))
            return max_size;

        /* access ihl as a u8 to avoid unaligned access on ia64 */
        hlen = (network[0] & 0x0F) << 2;

        /* verify hlen meets minimum size requirements */
        if (hlen < sizeof(struct iphdr))
            return network - data;

        /* record next protocol if header is present */
        } else if (hnae_get_field(flag, HNS_RXD_L3ID_M, HNS_RXD_L3ID_S)
