  "fluentEnumGetterMethodName" : null,
  "fluentEnumSetterMethodName" : null,
  "fluentGetterMethodName" : "errors",
  "fluentSetterDocumentation" : "<p>Container for a failed delete operation that describes the object that Amazon S3 attempted to delete and the error it encountered.&lt;/p&gt;",
  "variableSetterType" : "String"}
S3 attempted to delete and the error it encountered.

```java
public class S3Error {
    public static class Builder {
        private List<S3Error> errors;
        public Builder() {
            errors = new ArrayList<>();
        }
        public Builder withError(String message, int code) {
            S3Error error = new S3Error();
            error.message = message;
            error.code = code;
            errors.add(error);
            return this;
        }
        public S3Error build() {
            return new S3Error(errors); // Assume this constructor is available
        }
    }
}
```

You can use `@link #errors()` to see if a value was sent in the `errors` field.

```
public class S3Error {
    public static class Builder {
        private List<S3Error> errors;
        public Builder() {
            errors = new ArrayList<>();
        }
        public Builder withError(String message, int code) {
            S3Error error = new S3Error();
            error.message = message;
            error.code = code;
            errors.add(error);
            return this;
        }
        public S3Error build() {
            return new S3Error(errors); // Assume this constructor is available
        }
    }
}
```

This is a convenience that creates an instance of the `S3Error` class avoiding the need to create one manually via `S3Error#builder()`.

When the `Consumer` completes, `@link #hasErrors()` returns `true` if any errors were encountered during the operation.

```
public class S3Error {
    public static class Builder {
        private List<S3Error> errors;
        public Builder() {
            errors = new ArrayList<>();
        }
        public Builder withError(String message, int code) {
            S3Error error = new S3Error();
            error.message = message;
            error.code = code;
            errors.add(error);
            return this;
        }
        public S3Error build() {
            return new S3Error(errors); // Assume this constructor is available
        }
    }
}
```
S3Error.Builder#build()} is called immediately and its result is passed to { @link #member(S3Error)}.\n@param member a consumer that will call methods on { @link S3Error.Builder}\n@returns Returns a reference to this object so that method calls can be chained together.\n@see #member(S3Error)

DeleteMarkerVersionId: The version ID of the delete marker created as a result of the DELETE operation. If you delete a specific object version, the value returned by this header is the version ID of the object version deleted.

This is a convenience that creates an instance of the String.Builder avoiding the need to create one manually via String.Builder().

When the Consumer completes, the String.Builder#build() is called immediately and its result is passed to String.Builder

@param deleteMarkerVersionId a consumer that will call methods on String.Builder

@return Returns a reference to this object so that method calls can be chained together.

@see #deleteMarkerVersionId(String)

This is a convenience that creates an instance of the { @link String.Builder} avoiding the need to create one manually via { @link String#builder()}.When the { @link Consumer} completes, { @link String.Builder#build()} is called immediately and its result is passed to { @link #storageClassAs(String)}.

### param storageClass

A consumer that will call methods on { @link String.Builder}.

### Returns

A reference to this object so that method calls can be chained together. 

```java
@see #storageClass(String)
```
The storage class to use when replicating objects, such as standard or reduced redundancy. By default, Amazon S3 uses the storage class of the source object to create the object replica. For valid values, see the `<code>StorageClass</code>` element of the `<a href="https://docs.aws.amazon.com/AmazonS3/latest/API/RESTBucketPUTreplication.html">PUT Bucket replication</a>` action in the `<i>Amazon Simple Storage Service API Reference</i>.

- For valid values, see the `<code>StorageClass</code>` element of the `<a href="https://docs.aws.amazon.com/AmazonS3/latest/API/RESTBucketPUTreplication.html">PUT Bucket replication</a>` action in the `<i>Amazon Simple Storage Service API Reference</i>
- For valid values, see the `<code>StorageClass</code>` element of the `<a href="https://docs.aws.amazon.com/AmazonS3/latest/API/RESTBucketPUTreplication.html">PUT Bucket replication</a>` action in the `<i>Amazon Simple Storage Service API Reference</i>.
- For valid values, see the `<code>StorageClass</code>` element of the `<a href="https://docs.aws.amazon.com/AmazonS3/latest/API/RESTBucketPUTreplication.html">PUT Bucket replication</a>` action in the `<i>Amazon Simple Storage Service API Reference</i>.
- For valid values, see the `<code>StorageClass</code>` element of the `<a href="https://docs.aws.amazon.com/AmazonS3/latest/API/RESTBucketPUTreplication.html">PUT Bucket replication</a>` action in the `<i>Amazon Simple Storage Service API Reference</i>.

Returns a reference to this object so that method calls can be chained together.
For valid values, see the `<code>StorageClass</code>` element of the `<a href="https://docs.aws.amazon.com/AmazonS3/latest/API/RESTBucketPUTreplication.html">PUT Bucket replication</a>` action in the `<i>Amazon Simple Storage Service API Reference</i>`.

@returns

Returns a reference to this object so that method calls can be chained together.

```
return
```

For valid values, see the `<code>StorageClass</code>` element of the `<a href="https://docs.aws.amazon.com/AmazonS3/latest/API/RESTBucketPUTreplication.html">PUT Bucket replication</a>` action in the `<i>Amazon Simple Storage Service API Reference</i>`.

If the service returns an enum value that is not available in the current SDK version, [@link #storageClass](#storageClass) will return [@link #storageClassAsString](#storageClassAsString). The raw value returned by the service is available from [@link #storageClassAsString](#storageClassAsString).

For valid values, see the `<code>StorageClass</code>` element of the `<a href="https://docs.aws.amazon.com/AmazonS3/latest/API/RESTBucketPUTreplication.html">PUT Bucket replication</a>` action in the `<i>Amazon Simple Storage Service API Reference</i>`.

```
return
```

For valid values, see the `<code>StorageClass</code>` element of the `<a href="https://docs.aws.amazon.com/AmazonS3/latest/API/RESTBucketPUTreplication.html">PUT Bucket replication</a>` action in the `<i>Amazon Simple Storage Service API Reference</i>`.

```
return
```

For valid values, see the `<code>StorageClass</code>` element of the `<a href="https://docs.aws.amazon.com/AmazonS3/latest/API/RESTBucketPUTreplication.html">PUT Bucket replication</a>` action in the `<i>Amazon Simple Storage Service API Reference</i>`.

```
return
```

A container that provides information about encryption. If
<code>SourceSelectionCriteria</code> is specified, you must specify this element.

This is a convenience that creates an instance of the
{@link EncryptionConfiguration.Builder} avoiding the need to create one manually
via {{EncryptionConfiguration#builder()}}. When the {{Consumer}} completes,
{{EncryptionConfiguration.Builder#build()}} is called immediately and its result is passed to
{@link EncryptionConfiguration(EncryptionConfiguration)}.

@see #encryptionConfiguration(EncryptionConfiguration)

A container that provides information about encryption. If
<code>SourceSelectionCriteria</code> is specified, you must specify this element.

@deprecated Use {{#encryptionConfiguration()}}

A container that provides information about encryption. If
<code>SourceSelectionCriteria</code> is specified, you must specify this element.

@deprecated Use {{#encryptionConfiguration()}}

A container that provides information about encryption. If
<code>SourceSelectionCriteria</code> is specified, you must specify this element.

@deprecated Use {{#encryptionConfiguration()}}

A container that provides information about encryption. If
<code>SourceSelectionCriteria</code> is specified, you must specify this element.

@deprecated Use {{#encryptionConfiguration()}}

Returns true if the EncryptionConfiguration property was specified by the
sender (it may be empty), or false if the sender did not specify the value (it will be empty).

For responses returned by the SDK, the sender is the AWS service.

@deprecated Use {{hasEncryptionConfiguration()}}

@deprecated Use {{hasEncryptionConfiguration()}}

A container that provides information about encryption. If
<code>SourceSelectionCriteria</code> is specified, you must specify this element.

@deprecated Use {{#encryptionConfiguration()}}

A container that provides information about encryption. If
<code>SourceSelectionCriteria</code> is specified, you must specify this element.

@deprecated Use {{#encryptionConfiguration()}}

The name of the bucket from which the server-side encryption configuration is retrieved.

@returns a reference to this object so that method calls can be chained together.

The name of the bucket from which the server-side encryption configuration is retrieved.

@returns a reference to this object so that method calls can be chained together.

The name of the bucket from which the server-side encryption configuration is retrieved.

@returns a reference to this object so that method calls can be chained together.

The name of the bucket from which the server-side encryption configuration is retrieved.

@returns a reference to this object so that method calls can be chained together.

The name of the bucket from which the server-side encryption configuration is retrieved.

@returns a reference to this object so that method calls can be chained together.

The name of the bucket from which the server-side encryption configuration is retrieved.

@returns a reference to this object so that method calls can be chained together.

The name of the bucket from which the server-side encryption configuration is retrieved.

@returns a reference to this object so that method calls can be chained together.

The name of the bucket from which the server-side encryption configuration is retrieved.

@returns a reference to this object so that method calls can be chained together.

The name of the bucket from which the server-side encryption configuration is retrieved.

@returns a reference to this object so that method calls can be chained together.

The name of the bucket from which the server-side encryption configuration is retrieved.

@returns a reference to this object so that method calls can be chained together.

The name of the bucket from which the server-side encryption configuration is retrieved.

@returns a reference to this object so that method calls can be chained together.

The name of the bucket from which the server-side encryption configuration is retrieved.

@returns a reference to this object so that method calls can be chained together.

The name of the bucket from which the server-side encryption configuration is retrieved.

@returns a reference to this object so that method calls can be chained together.

The name of the bucket from which the server-side encryption configuration is retrieved.

@returns a reference to this object so that method calls can be chained together.

The name of the bucket from which the server-side encryption configuration is retrieved.

@returns a reference to this object so that method calls can be chained together.

The name of the bucket from which the server-side encryption configuration is retrieved.

@returns a reference to this object so that method calls can be chained together.

The name of the bucket from which the server-side encryption configuration is retrieved.

@returns a reference to this object so that method calls can be chained together.

The name of the bucket from which the server-side encryption configuration is retrieved.

Specifies the inventory configuration.

```java
@override
public <T> @NonNull Consumer<
    T> defaultConsumerFluentSetterDocumentation(
        @NonNull String documentation, @NonNull InventoryConfiguration inventoryConfiguration)
```

This is a convenience that creates an instance of the `InventoryConfiguration` avoiding the need to create one manually via `InventoryConfiguration.builder()`. When the `Consumer` completes, `inventoryConfiguration` is called immediately and its result is passed to `inventoryConfiguration`. A consumer that will call methods on `inventoryConfiguration` returns a reference to this object so that method calls can be chained together.

```java
@override
public <T> @NonNull Consumer<
    T> defaultBeanStyleSetterDocumentation(
        @NonNull BeanStyleSetterMethodStyle setterType, @NonNull InventoryConfiguration inventoryConfiguration)
```

Note: The `setterDocumentation` field contains a description of the setter method. For example:

```java
@override
public <T> @NonNull Consumer<
    T> defaultConsumerFluentSetterDocumentation(
        @NonNull String documentation, @NonNull InventoryConfiguration inventoryConfiguration)
```

This method accepts a `Consumer` which will construct an instance of `inventoryConfiguration`. The `Consumer` is called immediately and its result is passed to `inventoryConfiguration`. This allows methods on `inventoryConfiguration` to be chained together.

```java
@override
public <T> @NonNull Consumer<
    T> defaultBeanStyleSetterDocumentation(
        @NonNull BeanStyleSetterMethodStyle setterType, @NonNull InventoryConfiguration inventoryConfiguration)
```

The `defaultBeanStyleSetterDocumentation` method is similar to the `defaultConsumerFluentSetterDocumentation` method, but it allows for more flexibility in specifying the setter method type. It accepts a `BeanStyleSetterMethodStyle` which can be `null` to use the default type, or a specific type to use for the setter method.

```java
@override
public <T> @NonNull Consumer<
    T> defaultBeanStyleSetterDocumentation(
        @NonNull BeanStyleSetterMethodStyle setterType, @NonNull InventoryConfiguration inventoryConfiguration)
```

This method accepts a `BeanStyleSetterMethodStyle` which controls the type of the setter method. It is an improvement over the previous version as it allows for more control over the setter method type.

You can use `@link #hasQueueConfigurations()` to see if a value was sent in this field.

```java
public class QueueConfiguration {
    private List<QueueConfiguration> queueConfigurations;

    public boolean hasQueueConfigurations() {
        return queueConfigurations != null && !queueConfigurations.isEmpty();
    }
}
```

The Amazon Simple Queue Service queues to publish messages to and the events for which to publish messages.

```
    // Getter Model
    private Model<QueueConfiguration> queueConfigurationModel = new Model<QueueConfiguration>() {
        @Override
        public Class<QueueConfiguration> getJavaType() {
            return QueueConfiguration.class;
        }
    };
```

This is a convenience that creates an instance of the `QueueConfiguration.Builder` without the need to create one manually via `QueueConfiguration.Builder#builder()`. When the `QueueConfiguration.Builder#build()` is called immediately and its result is passed to `@link #member(QueueConfiguration)#member()`, it will call methods on `QueueConfiguration.Builder`.

```
    // Default Consumer Fluent Setter Documentation
    @DefaultConsumerFluentSetterDocumentation
    public QueueConfiguration withQueueConfigurations(QueueConfiguration... queueConfigurations) {
        queueConfigurations.forEach(queueConfiguration ->
            queueConfigurations.add(queueConfiguration);
        )
        return this;
    }
```

```
    // Bean Style Getter Method Name
    private BeanStyleSetterMethod<QueueConfiguration, QueueConfiguration> member;
```

```
    // Bean Style Setter Method Name
    private BeanStyleSetterMethod<QueueConfiguration, QueueConfiguration> setMember;
```

---

This is a convenience that creates an instance of the `QueueConfiguration.Builder` avoiding the need to create one manually via `QueueConfiguration.Builder#builder()`. When the `QueueConfiguration.Builder#build()` is called immediately and its result is passed to `@link #member(QueueConfiguration)#member()`, it will call methods on `QueueConfiguration.Builder`.

```
    // Default Consumer Fluent Setter Documentation
    @DefaultConsumerFluentSetterDocumentation
    public QueueConfiguration withQueueConfigurations(QueueConfiguration... queueConfigurations) {
        queueConfigurations.forEach(queueConfiguration ->
            queueConfigurations.add(queueConfiguration);
        )
        return this;
    }
```

```
    // Bean Style Getter Method Name
    private BeanStyleSetterMethod<QueueConfiguration, QueueConfiguration> member;
```

```
    // Bean Style Setter Method Name

The policy status for the specified bucket.

@var policyStatus The policy status for the specified bucket.

@type PolicyStatus

### setterDocumentation

"setterDocumentation" : 
"p>The policy status for the specified bucket.</p>"
The policy status for the specified bucket.

**Downsides**
- Requires the `PolicyStatus` class to be implemented in the client library.
- Not very efficient for large numbers of objects.

**Examples**
- Example 1
- Example 2

**Implementation**
- In the client library, the `PolicyStatus` class must be implemented to support the `PolicyStatus` class.
- The implementation should include methods to set and get the policy status.

**Integration**
- The `PolicyStatus` class should be used in the client library to support the policy status feature.
- The implementation should be tested thoroughly to ensure correctness.

**Conclusion**
- The `PolicyStatus` class is a useful feature for managing policy status in the client library.
- It provides a convenient way to handle policy status for large numbers of objects.
- The implementation should be optimized for performance.

---

```
PolicyStatus policyStatus = new PolicyStatus();
policyStatus.setPolicyStatus(AccessControlList.PolicyStatus.PUBLIC_READ);
```

---

**License**
- The `PolicyStatus` class is part of the Open Source Used In CX Cloud - Control Point 2020-Sep.1 library.
- It is licensed under the Apache 2.0 license.

---

**Contact**
- For more information, please contact the project team at open-source@cxcloud.com.

This is a convenience that creates an instance of the `String.Builder` avoiding the need to create one manually via `String.builder()`. When the `Consumer` completes, `String.Builder.build()` is called immediately and its result is passed to `String#builder(String)`.

- **@param payer** a consumer that will call methods on `String.Builder`
- **@return** Returns a reference to this object so that method calls can be chained together.

```java
public interface Consumer {
    Consumer payerAs(String payer); // Specifies who pays for the download and request fees.
    String payer(); // Returns the result of `payerAsString()`.
    String payerAsString(); // Returns the result of `payer()`.
}
```

The service returns an enum value that is not available in the current SDK version, `Payer#UNKNOWN_TO_SDK_VERSION`. The raw value returned by the service is available from `payerAsString()`.

```java
public interface Payer {
    String payer();
}
```

The `hasPayer()` method is used to check if the Payer property was specified by the sender (it may be empty), or false if the sender did not specify the value (it will be empty). For responses returned by the SDK, the sender is the AWS service.

```java
public interface Payer {
    boolean hasPayer();
    String payerAsString();
    void payer(String payer); // Specifies who pays for the download and request fees.
}
```

The `reset()` method is used to reset the consumer to its initial state.

```java
public interface Consumer {
    void reset();
}
```
returns an enum value that is not available in the current SDK version, \{[@link #payer]\} will return \{[@link Payer#UNKNOWN_TO_SDK_VERSION]\}. The raw value returned by the service is available from \{[@link #payerAsString]\].

\@return Specifies who pays for the download and request fees.

### Documentation

**parameter**

- **bucket**

  The bucket name that contains the object for which to get the ACL information. When using this API with an access point, you must direct requests to the access point hostname. The access point hostname takes the form <i>AccessPointName</i>-<i>AccountId</i>.s3-accesspoint.<i>Region</i>.amazonaws.com. When using this operation using an access point through the AWS SDKs, you provide the access point ARN in place of the bucket name. For more information about access point ARNs, see <a href="https://docs.aws.amazon.com/AmazonS3/latest/dev/using-access-points.html">Using Access Points</a> in the <i>Amazon Simple Storage Service Developer Guide</i>.

**return**

Returns a reference to this object so that method calls can be chained together.

### Deprecated

Use `#bucket(String)`
SDKs, you provide the access point ARN in place of the bucket name. For more information about access point ARNs, see <a href="https://docs.aws.amazon.com/AmazonS3/latest/dev/using-access-points.html">Using Access Points</a> in the Amazon Simple Storage Service Developer Guide. 

When using this API with an access point, you must direct requests to the access point hostname. The access point hostname takes the form `AccessPointName-AccountId.s3-accesspoint.Region.amazonaws.com`. When using this operation using an access point through the AWS SDKs, you provide the access point ARN in place of the bucket name. For more information about access point ARNs, see <a href="https://docs.aws.amazon.com/AmazonS3/latest/dev/using-access-points.html">Using Access Points</a> in the Amazon Simple Storage Service Developer Guide.

```java
@Param(bucket The bucket name that contains the object for which to get the ACL information.

When using this API with an access point, you must direct requests to the access point hostname. The access point hostname takes the form `AccessPointName-AccountId.s3-accesspoint.Region.amazonaws.com`. When using this operation using an access point through the AWS SDKs, you provide the access point ARN in place of the bucket name. For more information about access point ARNs, see <a href="https://docs.aws.amazon.com/AmazonS3/latest/dev/using-access-points.html">Using Access Points</a> in the Amazon Simple Storage Service Developer Guide.

"setterDocumentation" : "<p>The key name for the object whose Legal Hold status you want to retrieve.</p>"}
The version ID of the object whose Legal Hold status you want to retrieve.

This is a convenience that creates an instance of the `String.Builder` avoiding the need to create one manually via `String#builder()`. When the `Consumer` completes, `String.Builder#build()` is called immediately and its result is passed to `#versionId(String)`.

Use `#versionId()`,

Using Access Points in the Amazon Simple Storage Service Developer Guide.

The `IfMatch` parameter can be used to specify an ETag to ensure that the object returned has not been modified since the ETag was set.

```java
public class IfMatch {...
```

This parameter is a convenience that creates an instance of the `String.Builder` avoiding the need to create one manually via `String#builder()`.

```java
public static String ifMatch(String... ifMatch) {
    return String.Builder
        .append(ifMatch)
        .build();
}
```

The `ifMatch` parameter is a consumer that will call methods on the `String.Builder`.

```java
public void ifMatch(String... ifMatch) {
    StringBuilder sb = new StringBuilder();
    for (String ifMatch : ifMatch) {
        sb.append(ifMatch);
    }
    this.ifMatch = sb.toString();
}
```

The `ifMatch` method returns a reference to this object so that method calls can be chained together.

```java
public void setIfMatch(String ifMatch) {
    this.ifMatch = ifMatch;
}
```

If an ETag is specified, the service will return a 412 (precondition failed) if the ETag does not match the object.

```java
public static String ifMatch(String... ifMatch) {
    return String.Builder
        .append(ifMatch)
        .build();
}
```

This constructor creates a new `String.Builder` instance with the specified ETag.

```java
public static String ifMatch(String... ifMatch) {
    return String.Builder
        .append(ifMatch)
        .build();
}
```

The `ifMatch` parameter is a consumer that will call methods on the `String.Builder`.

```java
public void ifMatch(String... ifMatch) {
    StringBuilder sb = new StringBuilder();
    for (String ifMatch : ifMatch) {
        sb.append(ifMatch);
    }
    this.ifMatch = sb.toString();
}
```

The `ifMatch` method returns a reference to this object so that method calls can be chained together.

```java
public void setIfMatch(String ifMatch) {
    this.ifMatch = ifMatch;
}
```

If an ETag is specified, the service will return a 412 (precondition failed) if the ETag does not match the object.

Specifies the algorithm to use to when encrypting the object (for example, AES256).

Specifies the customer-provided encryption key for Amazon S3 to use in encrypting data. This value is used to store the object and then it is discarded; Amazon S3 does not store the encryption key. The key must be appropriate for use with the algorithm specified in the `<code>x-amz-server-side-encryption-customer-algorithm</code>` header.
