Introduction

This document explains how to configure and troubleshoot the Quality of Service (QoS) enhancements on the Cisco uBR7200 universal broadband router, to support voice and fax traffic. To implement this feature, you need Cisco IOS® Software Release 12.0.7XR2, or a release from the branch 12.1.1T, 12.1(1a)T1, or later.

Prerequisites

Requirements

Readers of this document should have knowledge of these topics:

- Data–over–Cable Service Interface Specifications (DOCSIS)
- Cisco IOS software
- Voice over IP (VoIP)

Components Used

The information in this document is based on these software and hardware versions:

- Cisco IOS Software Release 12.0.7XR2, or a release from the branch 12.1.1T, 12.1(1a)T1, or later.
- Cisco uBR7200
- DOCSIS–compliant Integrated Telephony Cable Modem (ITCM)

The information in this document was created from the devices in a specific lab environment. All of the devices used in this document started with a cleared (default) configuration. If your network is live, make sure that you understand the potential impact of any command.
Conventions

For more information on document conventions, refer to the Cisco Technical Tips Conventions.

Brief Theory Summary

DOCSIS 1.0+ implementation is DOCSIS 1.0 with QoS extensions for supporting real–time voice, fax, and video on a LAN.

DOCSIS 1.0+ is not a new or intermediate specification by cable labs. The whole DOCSIS 1.0+ architecture is a time–to–market solution provided by Cisco and certain cable modem (CM) vendors until DOCSIS 1.1 specifications and development are widely available.

DOCSIS 1.0+ provides additional QoS features for real–time voice, fax, and data packets from the ITCMs. These are the private extensions added to DOCSIS 1.0 in DOCSIS 1.0+:

- Two new CM–initiated dynamic MAC messages: Dynamic Service Addition (DSA) and Dynamic Service Deletion (DSD). These messages allow dynamic Service IDs (SIDs) to be created and deleted at runtime on a per–call basis.
- Unsolicited Grant Service (constant bit rate [CBR]–scheduling) on the upstream. This service provides a high quality QoS channel for the upstream CBR voice and fax packets from the ITCM.

For any given ITCM, the ability to provide separate downstream rates is based on the IP–precedence value in the packet. This helps in separating voice, signaling, and data traffic going to the same ITCM for rate–shaping purposes.

What Happens When the ITCM Registers with the CMTS?

When the Cable Modem Termination System (CMTS) receives the registration request, it creates a local database entry for the ITCM. A static SID is immediately assigned to the ITCM for the data service. For the phone line service, the CMTS creates some deferred service flows (for subsequent activation) in the database entry of the ITCM. No SIDs are assigned for the phone line service during registration.

Note: The number of deferred flows created by CMTS for ITCM at the time of registration depends on the value of the Number of Phone Lines parameter provisioned for the cable modem. The value can be any number starting from 0 (for example: 0, 1, 2, 3, and so forth).

What Happens When You Want to Place a Voice Call?

1. ITCM gets a new voice or fax call and determines the QoS parameters for that call using the codec type G.711 or G.729 received from the higher–layer voice–call–signaling protocol.
2. The ITCM sends a DSA request (DSA–REQ) to the uBR, requesting a new dynamic SID.
3. CMTS accesses the ITCMs database information (using the MAC address in the DSA–REQ message) and checks to see if this ITCM has any inactive or unadmitted (deferred) service flow. If the ITCM has an unused deferred flow and if the upstream (US) channel (to which ITCM is connected) has enough capacity to admit a new periodic CBR slot as requested in the DSA–REQ, then a new dynamic SID is created by CMTS.
4. CMTS responds to the ITCM request with a DSA response (DSA–RSP).
5. ITCM acknowledges the DSA–RSP. (The CMTS expects a DSA acknowledgment [DSA–ACK] from the ITCM every time it sends a DSA response.)
6. When the voice or fax call is cleared, ITCM sends a DSD−REQ MAC message to the CMTS, specifying the dynamic SID to be deleted.

7. CMTS deletes the dynamic SID and sends a DSD−RSP to the ITCM. For more explanation of DOCSIS 1.0+, refer to Frequently Asked Questions on DOCSIS 1.0+.

Configuration: the Different Steps to Follow

The example configuration in this document uses this network setup:

Cisco IOS Software Release 12.1(1a)T1 runs on the cable modems and on the Cisco uBR7246.

Profiles In CMTS

QoS Profile

At the CMTS, two special (voice– and fax–related) QoS profiles are dynamically configured and are available to the CMTS QoS code at any given time. These QoS profiles (G711 and G729) are configured with the special scheduling parameters for G.711 or G.729 type coder–decoders (codecs). The CMTS can obtain the specific parameters such as grant–size and grant–interval from the contents of the DSA–REQ message requesting this special scheduling treatment. You must configure QoS profile templates on CMTS for each unique codec parameter combination.

Note: QoS profiles for codecs G.711 and G.729 are dynamically created as soon as you configure phone lines in the configuration file of cable modems. They receive a default grant–interval of 20 milliseconds and a grant–size of 31.22 kbps (for G.729) and 87.2 kbps (for G.711).

This is the output from the `show cable qos profile` command when at least one phone line is configured in the configuration file of the cable modems:
If ITCM vendors use versions of the G.711 or G.729 codecs that are different from those used in that example, you must statically configure QoS profile templates on CMTS for each unique codec parameter combination (unsolicited grant–size and grant–interval).

This table shows you how to calculate the unsolicited grant–size and grant–intervals (for codecs G.711 and G.729):

<table>
<thead>
<tr>
<th>QoS Profile for G.711 Codec</th>
</tr>
</thead>
<tbody>
<tr>
<td>These are the corresponding numbers for a G.711 QoS profile:</td>
</tr>
<tr>
<td>Unsolicited grant size</td>
</tr>
<tr>
<td>Unsolicited grant interval</td>
</tr>
<tr>
<td>Reserved/peak rate</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>QoS Profile for G.729 Codec</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is how you calculate the total size of the DOCSIS cable MAC frame:</td>
</tr>
<tr>
<td>G.729 codec output per interval</td>
</tr>
<tr>
<td>Routing Table Protocol (RTP) header</td>
</tr>
<tr>
<td>User Datagram Protocol (UDP) header</td>
</tr>
<tr>
<td>IP header</td>
</tr>
<tr>
<td>Ethernet frame header and cyclic redundancy check (CRC)</td>
</tr>
<tr>
<td>DOCSIS Cable MAC header</td>
</tr>
</tbody>
</table>

| Total DOCSIS Cable MAC frame size | 89 bytes |

The grant interval of 20 milliseconds directly follows from the framing or packetization delay of the G.729 codec. The upstream reserved rate is obtained by only considering the Ethernet–level bandwidth usage of each G.729 codec output. This works out to a 78–byte Ethernet frame every 20 milliseconds, which equals 31.2 kbps.

In the Troubleshooting and Tips section, an example is provided to show you what happens in debug output if the grant–size or the grant–interval is not correctly specified for the codec used.
You can check your modulation profiles using the `show cable qos profile x verbose` command.

**Modulation Profile**

You can change the modulation profile to maximize the number of voice calls that you can get per upstream channel. This is a modulation profile that you can use:

```plaintext
cable modulation-profile 5

! This configuration line is entered on one line:

cable modulation-profile 5 short 2 52 35 8
qpsk scrambler 152 diff 72 shortened uw8
interface Cable3/0
cable upstream 5 minislot-size 4
cable upstream 5 modulation-profile 5
```

### Configuration of CMTS

```plaintext
cable modulation-profile 5 request 0 16 1 8 qpsk scrambler 152 no-diff 64 fixed uw16

cable modulation-profile 5 initial 5 34 0 48 qpsk scrambler 152 no-diff 128 fixed uw16

cable modulation-profile 5 station 5 34 0 48 qpsk scrambler 152 no-diff 128 fixed uw16

cable modulation-profile 5 short 6 75 6 8 16qam scrambler 152 no-diff 144 fixed uw8

cable modulation-profile 5 long 8 220 0 8 16qam scrambler 152 no-diff 160 fixed uw8

cable qos profile 5 ip-precedence 5 max-downstream 128

! This command was created automatically during CM registration;
! no cable qos permission creates 2 phone lines with IP precedence 5 and
! with 128K for max downstream, as specified in CM configuration file.

cable qos permission modems
cable time-server

**Profiles In Cable Modems**
DOCSIS Cable Modem Configuration File

Prepare the configuration file for cable modems using the DOCSIS customer premises equipment (CPE) Configurator. Specify the number of phone lines that you want. For the Cisco uBR924 cable modem, this value can be 0, 1, or 2, where 0 represents data-only with no voice ports and where 1 and 2 represent the number of phones. Specify the IP precedence settings used for separating voice and signaling from data and the rate limit.

In this example, the voice-transport precedence value (4) is set to a downstream rate limit of 128 kbps:

Value = 4; Rate Limit (kps) = 128000

Configuring the Dial Peers in the Cable Modem If You Use Static Configuration

Configure the dial peers and specify the IP precedence that you want to use for voice and fax traffic.

<table>
<thead>

ip precedence 5
Troubleshooting and Tips

This section provides useful **debug** and **show** commands for troubleshooting your configuration.

**Note:** Before issuing **debug** commands, refer to Important Information on Debug Commands.

Certain **show** commands are supported by the Output Interpreter Tool (registered customers only), which allows you to view an analysis of **show** command output.

These are some useful **debug** commands:

- **debug cable dynsrv** To debug all dynamic MAC messages (such as DSA−REQ, DSA−RSP, DSA−ACK, DSD−REQ, DSD−RSP) handling at the CMTS.
- **debug cable scheduler unsolicited−grants** To debug the average delay and maximum delay jitter on the unsolicited grants received.
- **debug cable scheduler admission−control** To see the MAC schedulers attempt to admit and unadmit a CBR slot.

**Note:** The new **debug** commands can only be enabled per interface or per SID. This makes the debug more manageable. Do not forget to enable **debug cable interface cable x/y** or **debug cable interface cable x/y SID** with each debug that you want.

These are some useful **show** commands:

- **show interfaces cable x/y SID**
- **show interfaces cable x/y upstream n**
- **show cable qos profile**
- **show cable qos profile z verbose**

Make a phone call from CM1 to CM2 and analyze what happens:

```
big-cmts# debug cable dynsrv
CMTS dynsrv debugging is on
big-cmts# debug cable interface cable 3/0

```

Two dynamic SIDs have been created for the voice call. They use QoS ID 3, which is the G729 profile.

```
cmte# show cable qos profile
```
For downstream traffic, you still use the primary SID (profile for data) and the corresponding QoS profile. (The IP precedence rate limiting provides a form of differentiation between voice and data. It is enabled for the downstream QoS profile number 5.)

Within DOCSIS 1.0+, the IP precedence settings are used for separating voice and signaling from data. In the case of a call where one endpoint is outside of the cable network, it is the responsibility of the outside network to ensure that all voice packets are appropriately colored before forwarding them to the CMTS. In the case of a call where both endpoints are on the cable network, it is the responsibility of the endpoint (customer) originating the traffic to color the voice packets before launching them into the network.

**Note:** You can use the **IP ToS overwrite** command (available since early uBR7200 releases) to set a non-default type of service (ToS) value in upstream packets received on SIDs belonging to CBR profiles. That way, an operator can be sure that packets received on dynamic CBR SIDs will have the right pattern before they are forwarded into the WAN link by the uBR7200 (this protects against ITCM doing any wrong coloring).

Consider this example:

```plaintext
   cmts(config)# cable qos profile 3 tos-overwrite 0xE0 0xA0

toS value : 0xA0

   !---  First 3 bits of ToS field: 101, which is an IP precedence of 5.

toS mask : 0xE0

   !---  Remember that IP precedence uses the first 3 bits of the ToS field
   !---  from the IPv4 header.
