Introduction

This document explains the process to troubleshoot data-link switching plus (DLSw+) circuit connectivity.

Prerequisites

Requirements

There are no specific requirements for this document.

Components Used

This document is not restricted to specific software or hardware versions.

The information in this document was created from the devices in a specific lab environment. All of the devices used in this document started with a cleared (default) configuration. If your network is live, make sure that you understand the potential impact of any command.

Conventions

For more information on document conventions, refer to the Cisco Technical Tips Conventions.

Check Circuit Status

This section explains DLSw circuit status, possible reasons why a DLSw circuit gets stuck at a particular state, and some troubleshooting steps that can be taken to achieve circuit connectivity. This section also explains, in graphical format, the circuit establishment states and the output of the `show dlsw circuit` command. Finally, this section discusses some of the most common DLSw issues, such as:

- Causes for BADSSPHDR error messages.
- Why DLSw version 2 circuits may fail to connect when passed through a firewall.
- Issues that arise when you run DLSw on Multilayer Switch Feature Card (MSFC) or Multilayer Switch Feature Card 2 (MSFC2).
Direct LAN connections of 802.1q trunks into DLSw+

### DLSw+ Circuit Establishment States

**Note:** The most common cause for circuits to become stuck in the CKT_ESTABLISHED state is an inactive host Virtual Telecommunications Access Method (VTAM) Switched Major Node.

#### Circuit Start

Circuit start is a transient state that indicates that there is an outstanding response to a CANUREACH_CS message (null Exchange Identification [XID]) resolved by an ICANREACH_CS message. If you have a problem with a circuit stuck in the CKT_START state, it indicates an internal problem with the DLSw peer routers: a MAC or Service Access Point (SAP) pair is not being cleaned up, or there is a lack of available resources necessary to complete the state transition (for example, memory).

To troubleshoot a CKT_START problem, verify that the test poll and the null XID have both reached the peer partners, and verify that the peer partners have successfully responded. You should understand the network topology to the host; it is typically either the Front End Processor (FEP) or it is channel–attached through a Channel Interface Processor (CIP) card in a 7xxx router.

For FEP connections, verify that the router’s interface to the FEP is up and is working correctly. Ask the network operator to display (or display for yourself) the relevant LINE and Physical Unit (PU) definitions on the FEP, and verify that they are active. Verify that the Switched Major Node, for which the PU acts as a
If you are using a CIP card and you have verified connectivity to the host, then there could be a problem with the VTAM External Communications Adapter (XCA) Major Node. These are the most typical problems:

- The XCA Major Node is not in an active state.
- The path outwards from VTAM??called the Channel Unit Address??is not online or is not boxed within the channel subsystem.

Verify that you have free logical lines available underneath the XCA Major Node, for which VTAM CONNECT−IN can allocate a PU. In later versions of CIP microcode (CIP22.38, CIP24.15, CIP25.14, CIP26.10, and CIP27.4), the CIP adapter does not respond to test polls, if there are no more logical lines available.

Issue the **show extended channel x/2 max−llc2−sessions** command to verify that the maximum number of Logical Link Control (LLC) sessions has not been reached. The default is 256.

There could also be a problem with the SAP values in use. The CIP adapter listens to unique SAPs. All of the internal CIP adapters must be defined to VTAM in XCA Major Node definitions. The Adapter Number (ADAPNO) value on the XCA Major Node is used by VTAM as a reference to an internal adapter in the router. Each internal adapter configured on a CIP must have a unique ADAPNO for each media type. The XCA Major Node definition is where you configure which SAPs to open for each internal adapter.

The test poll and null XID verify that the XCA Major Node and the CIP adapter are listening to the correct SAP. If the CIP MAC adapter is open and has at least one SAP open, then it responds to tests without forwarding them to VTAM. Test frames are sent with DSAP 04 and SSAP 00. Verify the SAP values used between the end station, the CIP router, and the XCA Major Node with these commands:

```
NCCF     TME 10 NetView   CNM01 OPER6   03/31/00 13:56:01

!--- with the letter L, and generates 16 PUs, starting with
!--- the letter P.
!--- This can be seen in the previous DISPLAY NET output.

  CALL=INOUT  3270 DISPLAY TERMINAL
```

**Circuit Established**

A `CKT_ESTABLISHED` state indicates that the routers have set up the circuit successfully, but the end stations have not yet initiated their session across that circuit. Examine the Logical Link Control, type 2 (LLC2) session that has been established, to verify that this is the case.
router# show llc2

LLC2 Connections: total of 3 connections
  Virtual-TokenRing0  DTE: 4000.7507.fff 4000.7507.0099 04 04 state NORMAL

--- Virtual-TokenRing0 is the name of the interface on which the session is established.
--- 4000.7507.fff and 4000.7507.0099 are the source and destination MAC addresses. This is the address of the interface on which the connection is established.
--- NORMAL indicates that the current state of the LLC2 session is fully established and that normal communication is occurring.

V(S)=15, V(R)=15, Last N(R)=15, Local window=7, Remote Window=127
akmax=3, n2=10,
  xid-retry timer 0/0  ack timer 0/1000
  p timer 0/1000  idle timer 1220/10000
  rej timer 0/3200  busy timer 0/9600
  akdelay timer 0/100  txQ count 0/200
  RIF: 0830.0141.0641.0580

Circuits in this state can indicate a number of problems, such as problems with XID exchanges or devices not being varied on in VTAM. In Fast Sequenced Transport (FST) peers (or direct encapsulation peers that are not using local acknowledgement), the session is not locally terminated. The Routing Information Field (RIF) is terminated, but the session is completely pass-through. As such, you do not see circuits established for sessions across DLSw+ FST or direct peers (other than Frame Relay local-ack). Another common problem with XID exchange is having the wrong IDBLK/IDNUM or CPNAME values.

**Connected**

The CONNECTED state is the normal condition when a DLSw circuit is successfully connected.

**show dlsw circuit**??When you are troubleshooting DLSw circuit status problems, issue the **show dlsw circuits** privileged EXEC command:

```
show dlsw circuits [detail]
[mac-address address | sap-value value | circuit id]
```

- **detail**???(Optional) Displays circuit state information in expanded format.
- **mac-address address** ???(Optional) Specifies the MAC address to be used in the circuit search.
- **sap-value value** ???(Optional) Specifies the SAP to be used in the circuit search.
- **circuit id** ???(Optional) Specifies the circuit ID of the circuit index.
Refer to DLSw+ Configuration Commands and to the next diagram, to understand the output from this command.

**Common DLSw Issues**

**BADSSPHDR Error Messages**

This error message may appear on some DLSw routers:

```bash
%DLSWC-3-BADSSPHDR: bad ssp hdr in proc ssp - received remote correlator from
different peer = 0x200004B

-Traceback= 606FCD68 606FD008 606ED364 606F2B2C 6026B118 601F6438 601CAA10
  6020F6B0 6020E350 6020E484 601B3048 601B3034
Nov 23 06:10:33: %DLSWC-3-RECVSSP: SSP OP = 4( ICR ) received from peer x.x.x.x(2065)
Nov 23 06:10:33: %DLSWC-3-RECVSSP: SSP OP = 4( ICR ) expected from peer y.y.y.y(2065)
```

Those messages are informational, and this section explains why they might happen.

During address resolution (CANUREACH_EX), a router can get multiple responses back (ICANREACH_EX). The router that initiated the address resolution will cache all of the responses at the time of circuit bring–up. The originating router will send a directed CANUREACH message to one of the remote routers that responded...
during address resolution. The originating router runs a timer, to wait for an ICANREACH. If the ICANREACH is not received before the timeout, then the originating router sends another directed CANUREACH to one of the other remote routers that responded during address resolution. If for some reason like congestion, slow links, and so forth the ICANREACH from the first remote router arrives after the ICANREACH from the second remote router, you get the aforementioned error messages. The router receives an ICANREACH from IP address x.x.x.x, but it expected the ICANREACH from IP address y.y.y.y. If there are no connectivity problems, then these messages are displayed for informational purposes only; DLSw is considered to be working as designed. Refer to Cisco bug ID CSCdp50163 (registered customers only) for more information.

If, however, the DLSw network is experiencing connectivity problems, then the messages should be taken seriously and further investigation is required. Look for significant WAN delays, periodic DLSw peer timeouts in the network, or both. Additionally, determine if Network Address Translation (NAT) is used between the peers, because that might cause the connectivity problem. It might be worthwhile to turn off User Datagram Protocol (UDP) explorers, to see if these error messages cease: issue the `dlsw udp−disable` command, first introduced in Cisco IOS Software Release 11.2.F. If not, then a WAN trace of the Transmission Control Protocol (TCP) flows between the peers would be most helpful.

**Note:** The aforementioned error messages were also improperly reported in Cisco IOS Software Releases earlier than 11.2. Therefore, it is important that you run a release later than 11.2.

**DLSw Version 2 and Firewalls**

With the introduction of the Cisco DLSw UDP unicast feature in Cisco IOS Software Release 11.2(6)F, explorer frames and unnumbered information frames are sent via UDP unicast rather than TCP. Before DLSw version 2, this unicast feature required that a TCP connection existed before packets were sent via UDP. DLSw version 2, however, sends UDP/IP multicast and unicast before the TCP connection exists. Address resolution packets such as CANUREACH_EX, NETBIOS_NQ_ex, and so forth use multicast service, but the responses ICANREACH_ex and NAME_RECOGNIZED_ex are sent back via UDP unicast.

In a typical scenario, a firewall has been set up between the DLSw peers. Consequently, the DLSw circuits have to be established through the firewall. RFC 2166 (DLSw v2.0 Enhancements) states that the UDP source port can be any value. Cisco DLSw routers use source port 0. This presents a problem when DLSw circuits are passed through firewalls, which are typically setup to filter out port 0. This results in failures to connect DLSw circuits. The workaround is to enable the `dlsw udp−disable` global configuration command. If the `dlsw udp−disable` command is configured, then DLSw does not send packets via UDP unicast, and it does not advertise UDP unicast support in its capabilities exchange message.

For more information, refer to UDP/IP Multicast Service and Understanding the DLSw+ Introduction of the UDP Unicast Feature.

**MSFC and DLSw Issues**

There can be numerous issues when you run DLSw on a Multilayer Switch Feature Card (MSFC) or a Multilayer Switch Feature Card 2 (MSFC2). For comprehensive information about DLSw and MSFC, refer to DLSw+ and MSFC Frequently Asked Questions.

**802.1q Trunks into DLSw+**

The LLC2 from 802.1q encapsulated trunks into DLSw is first supported with DLSw TCP peers and transparent bridging by means of Cisco bug ID CSCdv26715 (registered customers only). As of Cisco IOS Software Release 12.2(6) and later, 802.1q and DLSw works.

Additionally, by means of these DDTS support for DLSw, Ethernet redundancy and dot1Q encapsulation with native VLAN is made available. Refer to the Release−notes and the First Fixed−in Version fields of these
DDTS reports:

- Cisco bug ID CSCdv26715 (registered customers only) brings the support for 802.1q into DLSw with TCP encapsulation only.
- Cisco bug ID CSCdy09469 (registered customers only) corrects the defect where DLSw does not work when the LAN interface is a FastEthernet interface that is configured for 802.1q encapsulation and native VLAN:

  ```
  interface FastEthernet0/0.500
  encapsulation dot1Q 500 native
  bridge-group 1
  ```
- Cisco bug ID CSCdw65810 (registered customers only) fixes the usage of DLSw Ethernet redundancy and 802.1q encapsulated trunks. There is still no support for DLSw FST with 802.1q.

If you select Cisco IOS Software Release 12.2(13.4) and later, DLSw with TCP encapsulation, then DLSw Ethernet redundancy supports the LLC2 from 802.1q encapsulated trunks with or without the `native` keyword.
