Introduction

This document describes basic information needed to configure your router, such as how addresses are broken down and how subnetting works.

Prerequisites

Requirements

Cisco recommends that you have a basic understanding of binary and decimal numbers.

Components Used

This document is not restricted to specific software and hardware versions.
The information in this document was created from the devices in a specific lab environment. All of the devices used in this document started with a cleared (default) configuration. If your network is live, ensure that you understand the potential impact of any command.

Additional Information

If definitions are helpful to you, use these vocabulary terms to get you started:

Address - The unique number ID assigned to one host or interface in a network.

Subnet - A portion of a network that shares a particular subnet address.

Subnet mask - A 32-bit combination used to describe which portion of an address refers to the subnet and which part refers to the host.

Interface - A network connection.

If you have already received your legitimate address(es) from the Internet Network Information Center (InterNIC), you are ready to begin. If you do not plan to connect to the Internet, Cisco strongly suggests that you use reserved addresses from RFC 1918 □.

Learn how to assign each interface on the router an IP address with a unique subnet. There are examples included to help tie everything together.

Understand IP Addresses

An IP address is an address used in order to uniquely identify a device on an IP network. The address is made up of 32 binary bits, which can be divisible into a network portion and host portion with the help of a subnet mask. The 32 binary bits are broken into four octets (1 octet = 8 bits). Each octet is converted to decimal and separated by a period (dot). For this reason, an IP address is said to be expressed in dotted decimal format (for example, 172.16.81.100). The value in each octet ranges from 0 to 255 decimal, or 00000000 - 11111111 binary.

Here is how binary octets convert to decimal: The right most bit, or least significant bit, of an octet holds a value of $2^0$. The bit just to the left of that holds a value of $2^1$. This continues until the left-most bit, or most significant bit, which holds a value of $2^7$. So if all binary bits are a one, the decimal equivalent would be 255 as shown here:

```
  1 1 1 1 1 1 1 1
128 64 32 16 8 4 2 1 (128+64+32+16+8+4+2+1=255)
```

Here is a sample octet conversion when not all of the bits are set to 1.

```
  0 1 0 0 0 0 0 1
  0 64 0 0 0 0 0 1 (0+64+0+0+0+0+0+1=65)
```

And this sample shows an IP address represented in both binary and decimal.
These octets are broken down to provide an addressing scheme that can accommodate large and small networks. There are five different classes of networks, A to E. This document focuses on classes A to C, since classes D and E are reserved, and discussion of them is beyond the scope of this document.

Note: Also note that the terms Class A, Class B and so on are used in this document in order to help facilitate the understanding of IP addressing and subnetting. These terms are rarely used in the industry anymore because of the introduction of classless interdomain routing (CIDR).

Given an IP address, its class can be determined from the three high-order bits (the three left-most bits in the first octet). Figure 1 shows the significance in the three high order bits and the range of addresses that fall into each class. For informational purposes, Class D and Class E addresses are also shown.

Figure 1

In a Class A address, the first octet is the network portion, so the Class A example in Figure 1 has a major network address of 1.0.0.x - 127.255.255.x (where x can go from 0 to 255). Octets 2, 3, and 4 (the next 24 bits) are for the network manager to divide into subnets and hosts as he/she sees fit. Class A addresses are used for networks that have more than 65,536 hosts (actually, up to 16777214 hosts!).

In a Class B address, the first two octets are the network portion, so the Class B example in Figure 1 has a
major network address of 128.0.0.x - 191.255.255.x. Octets 3 and 4 (16 bits) are for local subnets and hosts. Class B addresses are used for networks that have between 256 and 65534 hosts.

In a Class C address, the first three octets are the network portion. The Class C example in Figure 1 has a major network address of 192.0.0.x - 223.255.255.x. Octet 4 (8 bits) is for local subnets and hosts - perfect for networks with less than 254 hosts.

**Network Masks**

A network mask helps you know which portion of the address identifies the network and which portion of the address identifies the node. Class A, B, and C networks have default masks, also known as natural masks, as shown here:

Class A: 255.0.0.0  
Class B: 255.255.0.0  
Class C: 255.255.255.0

An IP address on a Class A network that has not been subnetted would have an address/mask pair similar to: 10.20.15.1 255.0.0.0. In order to see how the mask helps you identify the network and node parts of the address, convert the address and mask to binary numbers.

<table>
<thead>
<tr>
<th>Address</th>
<th>Binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.20.15.1</td>
<td>00001010.00010100.00001111.00000001</td>
</tr>
<tr>
<td>255.0.0.0</td>
<td>11111111.00000000.00000000.00000000</td>
</tr>
</tbody>
</table>

Once you have the address and the mask represented in binary, then identification of the network and host ID is easier. Any address bits which have corresponding mask bits set to 1 represent the network ID. Any address bits that have corresponding mask bits set to 0 represent the node ID.

<table>
<thead>
<tr>
<th>Address</th>
<th>Binary</th>
<th>Network ID</th>
<th>Host ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.20.15.1</td>
<td>00001010.00010100.00001111.00000001</td>
<td>netid = 00001010 = 10</td>
<td>hostid = 00010100.00001111.00000001 = 20.15.1</td>
</tr>
</tbody>
</table>

**Understand Subnetting**

Subnetting allows you to create multiple logical networks that exist within a single Class A, B, or C network. If you do not subnet, you are only able to use one network from your Class A, B, or C network, which is unrealistic.

Each data link on a network must have a unique network ID, and every node on that link is a member of the same network. If you break a major network (Class A, B, or C) into smaller subnetworks, it allows you to create a network of interconnecting subnetworks. Each data link on this network would then have a unique
network/subnetwork ID. Any device, or gateway, that connects \( n \) networks/subnetworks has \( n \) distinct IP addresses, one for each network / subnetwork that it interconnects.

In order to subnet a network, extend the natural mask with some of the bits from the host ID portion of the address in order to create a subnetwork ID. For example, given a Class C network of 192.168.5.0 which has a natural mask of 255.255.255.0, you can create subnets in this manner:

\[
\begin{align*}
192.168.5.0 & \quad - \quad 11000000.10101000.00000101.00000000 \\
255.255.255.224 & \quad - \quad 11111111.11111111.11111111.11100000 \\
\hline
\end{align*}
\]

By extending the mask to be 255.255.255.224, you have taken three bits (indicated by sub) from the original host portion of the address and used them to make subnets. With these three bits, it is possible to create eight subnets. With the other five host ID bits, each subnet can have up to 32 host addresses, 30 of which can actually be assigned to a device since host ids of all zeros or all ones are not allowed (it is very important to remember this). So, with this in mind, these subnets have been created.

\[
\begin{align*}
192.168.5.0 & \quad 255.255.255.224 \quad \text{host address range 1 to 30} \\
192.168.5.32 & \quad 255.255.255.224 \quad \text{host address range 33 to 62} \\
192.168.5.64 & \quad 255.255.255.224 \quad \text{host address range 65 to 94} \\
192.168.5.96 & \quad 255.255.255.224 \quad \text{host address range 97 to 126} \\
192.168.5.128 & \quad 255.255.255.224 \quad \text{host address range 129 to 158} \\
192.168.5.160 & \quad 255.255.255.224 \quad \text{host address range 161 to 190} \\
192.168.5.192 & \quad 255.255.255.224 \quad \text{host address range 193 to 222} \\
192.168.5.224 & \quad 255.255.255.224 \quad \text{host address range 225 to 254} \\
\end{align*}
\]

Note: There are two ways to denote these masks. First, since you use three bits more than the natural Class C mask, you can denote these addresses as a 3-bit subnet mask. Or, secondly, the mask of 255.255.255.224 can also be denoted as /27 as there are 27 bits that are set in the mask. This second method is used with CIDR. With this method, one of these networks can be described with the notation prefix/length. For example, 192.168.5.32/27 denotes the network 192.168.5.32 255.255.255.224. When appropriate, the prefix/length notation is used to denote the mask throughout the rest of this document.

The network subnetwork scheme in this section allows for eight subnets, and the network can appear as:

Figure 2
Notice that each of the routers in Figure 2 is attached to four subnetworks, one subnetwork is common to both routers. Also, each router has an IP address for each subnetwork to which it is attached. Each subnetwork could potentially support up to 30 host addresses.

This brings up an interesting point. The more host bits you use for a subnet mask, the more subnets you have available. However, the more subnets available, the less host addresses available per subnet. For example, a Class C network of 192.168.5.0 and a mask of 255.255.255.224 (/27) allows you to have eight subnets, each with 32 host addresses (30 of which could be assigned to devices). If you use a mask of 255.255.255.240 (/28), the breakdown is:

192.168.5.0  -  11000000.10101000.00000101.00000000
255.255.255.240 - 11111111.11111111.11111111.11110000
--------------------------|sub |---

Since you now have four bits to make subnets with, you only have four bits left for host addresses. So in this case you can have up to 16 subnets, each of which can have up to 16 host addresses (14 of which can be assigned to devices).

Look at how a Class B network can be subnetted. If you have network 172.16.0.0, then you know that its natural mask is 255.255.0.0 or 172.16.0.0/16. Extending the mask to anything beyond 255.255.0.0 means you are subnetting. You can quickly see that you have the ability to create a lot more subnets than with the Class C network. If you use a mask of 255.255.248.0 (/21), how many subnets and hosts per subnet does this allow for?

172.16.0.0  -  10101100.00010000.00000000.00000000
255.255.248.0 - 11111111.11111111.11111111.11110000
------------------| sub |---------

You use five bits from the original host bits for subnets. This allows you to have 32 subnets ($2^5$). When the five bits for subnetting are used, you are left with 11 bits for host addresses. This allows each subnet so have 2048 host addresses ($2^{11}$), 2046 of which could be assigned to devices.
Note: In the past, there were limitations to the use of a subnet 0 (all subnet bits are set to zero) and all ones subnet (all subnet bits set to one). Some devices would not allow the use of these subnets. Cisco Systems devices allow the use of these subnets when the `ip subnet-zero` command is configured.

Examples

Sample Exercise 1

Now that you understand subnetting, put this knowledge to use. In this example, you are given two address / mask combinations, written with the prefix/length notation, which have been assigned to two devices. Your task is to determine if these devices are on the same subnet or different subnets. You can use the address and mask of each device in order to determine to which subnet each address belongs.

DeviceA: 172.16.17.30/20
DeviceB: 172.16.28.15/20

Determine the Subnet for DeviceA:

```
172.16.17.30  -   10101100.00010000.00010001.00011110
255.255.240.0 -   11111111.11111111.11110000.00000000
-----------------| sub|------------
subnet =          10101100.00010000.00010000.00000000 = 172.16.16.0
```

Look at the address bits that have a corresponding mask bit set to one, and set all the other address bits to zero (this is equivalent to when you perform a logical AND between the mask and address). It shows you to which subnet this address belongs. In this case, Device A belongs to subnet 172.16.16.0.

Determine the Subnet for DeviceB:

```
172.16.28.15  -   10101100.00010000.00011100.00001111
255.255.240.0 -   11111111.11111111.11110000.00000000
-----------------| sub|------------
subnet =          10101100.00010000.00010000.00000000 = 172.16.16.0
```

From these determinations, Device A and Device B have addresses that are part of the same subnet.

Sample Exercise 2

Given the Class C network of 192.168.5.0/24, subnet the network to create the network in Figure 3 with the host requirements shown.

Figure 3
As you look at the network shown in Figure 3, you can see that you are required to create five subnets. The largest subnet must support 28 host addresses. Is this possible with a Class C network? And if so, then how?

In order to start, look at the subnet requirement. In order to create the five needed subnets, you would need to use three bits from the Class C host bits. Two bits would only allow you four subnets ($2^2$).

Since you need three subnet bits, that leaves you with five bits for the host portion of the address. How many hosts does this support? $2^5 = 32$ (30 usable). This meets the requirement.

Therefore, you have determined that it is possible to create this network with a Class C network. An example of how you can assign the subnetworks is:

<table>
<thead>
<tr>
<th>Subnet ID</th>
<th>IP Address</th>
<th>Host Address Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>netA:</td>
<td>192.168.5.0/27</td>
<td>1 to 30</td>
</tr>
<tr>
<td>netB:</td>
<td>192.168.5.32/27</td>
<td>33 to 62</td>
</tr>
<tr>
<td>netC:</td>
<td>192.168.5.64/27</td>
<td>65 to 94</td>
</tr>
<tr>
<td>netD:</td>
<td>192.168.5.96/27</td>
<td>97 to 126</td>
</tr>
<tr>
<td>netE:</td>
<td>192.168.5.128/27</td>
<td>129 to 158</td>
</tr>
</tbody>
</table>

VLSM

In all of the previous examples of subnetting, notice that the same subnet mask was applied for all the subnets. This means that each subnet has the same number of available host addresses. You need this in some cases, but, in most cases when there is the same subnet mask for all subnets, it wastes address space. For example, in the Sample Exercise 2 section, a class C network was split into eight equal-size subnets; however, each subnet did not utilize all available host addresses, which resulted in wasted address space. Figure 4 illustrates this wasted address space.

Figure 4
<table>
<thead>
<tr>
<th>Network</th>
<th>Subnet</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.168.5.0/24</td>
<td>NetA: 192.168.5.0/27</td>
</tr>
<tr>
<td></td>
<td>NetB: 192.168.5.32/27</td>
</tr>
<tr>
<td>unused subnet</td>
<td>NetC: 192.168.5.64/27</td>
</tr>
<tr>
<td>unused subnet</td>
<td>NetD: 192.168.5.96/27</td>
</tr>
<tr>
<td>unused subnet</td>
<td>NetE: 192.168.5.128/27</td>
</tr>
<tr>
<td></td>
<td>192.168.5.160.27</td>
</tr>
<tr>
<td></td>
<td>192.168.5.192/27</td>
</tr>
<tr>
<td></td>
<td>192.168.5.224.27</td>
</tr>
</tbody>
</table>
illustrates which of the subnets used. NetA, NetC, and NetD have a lot of unused host address space. It is possible that this was a deliberate design accounting for future growth, but in many cases, this is just wasted address space due to the fact that the same subnet mask is used for all the subnets.

Variable Length Subnet Masks (VLSM) allow you to use different masks for each subnet, thereby they use address space efficiently.

**VLSM Example**

Given the same network and requirements as in Sample Exercise 2 develop a subnetting scheme with the use of VLSM, given:

- netA: must support 14 hosts
- netB: must support 28 hosts
- netC: must support 2 hosts
- netD: must support 7 hosts
- netE: must support 28 host

Determine what mask allows the required number of hosts.

- netA: requires a /28 (255.255.255.240) mask to support 14 hosts
- netB: requires a /27 (255.255.255.224) mask to support 28 hosts
- netC: requires a /30 (255.255.255.252) mask to support 2 hosts
- netD*: requires a /28 (255.255.255.240) mask to support 7 hosts
- netE: requires a /27 (255.255.255.224) mask to support 28 hosts

* a /29 (255.255.255.248) would only allow 6 usable host addresses therefore netD requires a /28 mask.

The easiest way to assign the subnets is to assign the largest first. For example, you can assign in this manner:

- netB: 192.168.5.0/27 host address range 1 to 30
- netE: 192.168.5.32/27 host address range 33 to 62
- netA: 192.168.5.64/28 host address range 65 to 78
- netD: 192.168.5.80/28 host address range 81 to 94
- netC: 192.168.5.96/30 host address range 97 to 98

This can be graphically represented as shown in Figure 5:

Figure 5
Figure 5 illustrates how VLSM helped save more than half of the address space.

CIDR was introduced in order to improve both address space utilization and routing efficiency. CIDR moves away from the traditional IP classes (Class A, Class B, Class C, and so on). In CIDR, an IP network is defined using a /prefix-length notation.

For more information on CIDR, see RFC 1518 and RFC 1519.

Special Subnets

31-bit Subnets

A 30-bit subnet mask allows for four IPv4 addresses: two host addresses, one all-zeros network, and one all-ones network. The mask is 255.255.255.254 or /31. The /31 subnet can be used on true point-to-point links, such as serial or POS interfaces. However, they can also be used anywhere.

Example

192.168.1.0 and 192.168.1.1 are on the subnet 192.168.1.0/31.

R1(config)#interface gigabitEthernet 0/1
R1(config-if)#ip address 192.168.1.0 255.255.255.254
% Warning: use /31 mask on non point-to-point interface cautiously

The warning is printed because gigabitEthernet is a broadcast segment.

### 32-bit Subnets

A subnet mask of 255.255.255.255 (a /32 subnet) describes a subnet with only one IPv4 host address. These subnets cannot be used to assign address to network links because they always need more than one address per link. The use of /32 is strictly reserved for use on links that can have only one address. The example for Cisco routers is the loopback interface. These interfaces are internal interfaces and do not connect to other devices. As such, they can have a /32 subnet.

#### Example

interface Loopback0
  ip address 192.168.2.1 255.255.255.255

### Appendix

**Sample Configuration**

Routers A and B are connected via serial interface.

**Router A**

```
hostname routera
!
ip routing
!
int e 0
ip address 172.16.50.1 255.255.255.0 !(subnet 50)
int e 1 ip address 172.16.55.1 255.255.255.0 !(subnet 55)
int s 0 ip address 172.16.60.1 255.255.255.0 !(subnet 60) int s 0
ip address 172.16.65.1 255.255.255.0 (subnet 65)
!S 0 connects to router B
router rip
network 172.16.0.0
```

**Router B**

```
hostname routerb
```
ip routing
!
int e 0
ip address 192.168.10.200 255.255.255.240
!(subnet 192)
int e 1
ip address 192.168.10.66 255.255.255.240
!(subnet 64)
int s 0
ip address 172.16.65.2 (same subnet as router A's s 0)
!Int s 0 connects to router A
router rip
network 192.168.10.0
network 172.16.0.0
