Introduction

This document provides a sample configuration for implementing traffic engineering (TE) on top of an existing Multiprotocol Label Switching (MPLS) network using Frame Relay and Open Shortest Path First (OSPF). Our example implements two dynamic tunnels (automatically set up by the ingress Label Switch Routers [LSR]) and two tunnels that use explicit paths.

TE is a generic name corresponding to the use of different technologies to optimize the utilization of a given backbone capacity and topology.

MPLS TE provides a way to integrate TE capabilities (such as those used on Layer 2 protocols like ATM) into Layer 3 protocols (IP). MPLS TE uses an extension to existing protocols (Intermediate System-to-Intermediate System (IS-IS), Resource Reservation Protocol (RSVP), OSPF) to calculate and establish unidirectional tunnels that are set according to the network constraint. Traffic flows are mapped on the different tunnels depending on their destination.

Prerequisites

Requirements

There are no specific requirements for this document.

Components Used

The information in this document is based on the software and hardware versions:

- Cisco IOS[®] Software Releases 12.0(11)S and 12.1(3a)T
- Cisco 3600 routers

The information in this document was created from the devices in a specific lab environment. All of the devices used in this document started with a cleared (default) configuration. If your network is live, make sure that you understand the potential impact of any command.

Conventions

Refer to [Cisco Technical Tips Conventions](#) for more information on document conventions.

Functional Components

The following table describes the functional components of this configuration example:

Component	Description
IP tunnel interfaces	Layer 2: an MPLS tunnel interface is the head of a Label Switched Path (LSP). It is configured with a set of resource requirements, such as bandwidth and priority. Layer 3: the LSP tunnel interface is the head-end of a unidirectional virtual link to the tunnel destination.
RSVP with TE extension	RSVP is used to establish and maintain LSP tunnels based on the calculated path using PATH and RSVP Reservation (RESV) messages. The RSVP protocol specification has been extended so that the RESV messages also distribute label information.
Link-State Interior Gateway Protocol (IGP) [IS-IS or OSPF with TE extension]	Used to flood topology and resource information from the link management module. IS-IS uses new Type-Length-Values (TLVs); OSPF uses type 10 Link-State Advertisements (also called Opaque LSAs).

MPLS TE path calculation module	Operates at the LSP head only and determines a path using information from the link-state database.
MPLS TE link management module	At each LSP hop, this module performs link call admission on the RSVP signaling messages, and bookkeeping of topology and resource information to be flooded by OSPF or IS-IS.
Label switching forwarding	Basic MPLS forwarding mechanism based on labels.

Configure

In this section, you are presented with the information to configure the features described in this document.

Note: Use the [Command Lookup Tool](#) ([registered](#) customers only) to find more information on the commands used in this document.

Network Diagram

This document uses this network setup:

Quick Configuration Guide

You can use the following steps to perform a quick configuration. Refer to [MPLS Traffic Engineering and Enhancements](#) for more detailed information.

1. Set up your network with the usual configuration. (In this case, we used Frame Relay.)

Note: It is mandatory to set up a loopback interface with an IP mask of 32 bits. This address will be used for the setup of the MPLS network and TE by the routing protocol. This loopback address must be reachable via the global routing table.

2. Set up a routing protocol for the MPLS network. It must be a link-state protocol (IS-IS or OSPF). In the routing protocol configuration mode, enter the following commands:
 - o For IS-IS:

```
metric-style [wide | both]
mpls traffic-eng router-id LoopbackN
mpls traffic-eng [level-1 | level-2 |]
```

- For OSPF:

```
mpls traffic-eng area X
mpls traffic-eng router-id LoopbackN (must have a 255.255.255.255 mas
```

3. Enable MPLS TE. Enter **ip cef** (or **ip cef distributed** if available in order to enhance performance) in the general configuration mode. Enable MPLS (**tag-switching ip**) on each concerned interface. Enter **mpls traffic-engineering tunnel** to enable MPLS TE, as well as RSVP for zero-bandwidth TE tunnels.
4. Enable RSVP by entering **ip rsvp bandwidth XXX** on each concerned interface for non-zero bandwidth tunnels.
5. Set up tunnels to be used for TE. There are many options that can be configured for MPLS TE Tunnel, but the **tunnel mode mpls traffic-eng** command is mandatory. The **tunnel mpls traffic-eng autoroute announce** command announces the presence of the tunnel by the routing protocol.

Note: Do not forget to use **ip unnumbered loopbackN** for the IP address of the tunnel interfaces.

This configuration shows two dynamic tunnels (Pescara_t1 and Pescara_t3) with different bandwidth (and priorities) going from the Pescara router to the Pesaro router, and two tunnels (Pesaro_t158 and Pesaro_t159) using an explicit path going from Pesaro to Pescara.

Configuration Files

This document uses the configurations shown below. Only the relevant parts of the configuration files are included. Commands used to enable MPLS are in blue text; commands specific to TE (including RSVP) are in **bold** text.

Verify

This section provides information you can use to confirm your configuration is working properly.

General show commands are illustrated in [Configuring MPLS Basic Traffic Engineering Using IS-IS](#). The following commands are specific to MPLS TE with OSPF and are illustrated below:

- **show ip ospf mpls traffic-eng link**
- **show ip ospf database opaque-area**

The [Output Interpreter Tool](#) ([registered](#) customers only) (OIT) supports certain **show** commands. Use the OIT to view an analysis of **show** command output.

Sample show Command Output

You can use the **show ip ospf mpls traffic-eng link** command to see what will be advertised by OSPF at a given router. The RSVP characteristics are shown in bold below, indicating the bandwidth that can be reserved, which is being advertised and used. You can see the bandwidth used by Pescara_t1 (at Priority 5) and Pescara_t3 (at Priority 6).

```
Pesaro# show ip ospf mpls traffic-eng link  
  
OSPF Router with ID (10.10.10.61) (Process ID 9)  
  
Area 9 has 1 MPLS TE links. Area instance is 3.  
  
Links in hash bucket 48.  
Link is associated with fragment 0. Link instance is 3  
Link connected to Point-to-Point network  
Link ID : 10.10.10.3 Pomerol  
Interface Address : 10.1.1.22  
Neighbor Address : 10.1.1.21  
Admin Metric : 195  
Maximum bandwidth : 64000  
Maximum reservable bandwidth : 64000  
Number of Priority : 8  
Priority 0 : 64000           Priority 1 : 64000  
Priority 2 : 64000           Priority 3 : 64000  
Priority 4 : 64000           Priority 5 : 32000  
Priority 6 : 24000           Priority 7 : 24000  
Affinity Bit : 0x0
```

The **show ip ospf database** command can be restrained to Type 10 LSAs and shows the database that is used by the MPLS TE process to calculate the best route (for TE) for dynamic tunnels (Pescara_t1 and Pescara_t3 in this example). This can be seen in the following partial output:

```
Pesaro# show ip ospf database opaque-area
```
