Introduction

This document describes how to troubleshoot CPU usage concerns, primarily due to interrupts, on the new Cisco IOS[®] XE platform.

Background Information

It is important to understand howCisco IOS® XE is built. WithCisco IOS® XE, Cisco has moved to a Linux kernel and all of the subsystems have been broken down into processes. All of the subsystems that were inside Cisco IOS before such as the modules drivers, High Availability (HA), and so on now run as software processes within the Linux Operating System (OS). Cisco IOS itself runs as a daemon within the Linux OS (IOSd).Cisco IOS® XE retains not only the same look and feel of the classic Cisco IOS®, but also its operation, support, and management.

Additionally, the document introduces several new commands on this platform that are integral in order to troubleshoot CPU usage problems.

Here are some useful definitions:

- Forwarding Engine Driver (FED): This is the heart of the Cisco Catalyst 3850 Series Switch and is responsible for all hardware programming/forwarding.
- Cisco IOSd: This is the Cisco IOS[®] daemon that runs on the Linux kernel. It is run as a software process within the kernel.
- Packet Delivery System (PDS): This is the architecture and process of how packets are delivered to and from various subsystems. As an example, it controls how packets are delivered from the FED to the IOSd and vice versa.
- Handle: A handle can be thought of as a pointer. It is a means to discover more detailed information about specific variables that are used in the outputs that the box produces. This is similar to the

concept of Local Target Logic (LTL) indices on the Cisco Catalyst 6500 Series Switch.

Case Study: Address Resolution Protocol (ARP) Interrupts

The troubleshoot and verification process in this section can be broadly used for high CPU usage due to interrupts.

Step 1: Identify the Process that Consumes CPU Cycles

The **show process cpu** command naturally displays how the CPU currently looks. Notice that the Cisco Catalyst 3850 Series Switch uses four cores, and you see the CPU usage listed for all four cores:

<#root>

3850-2#

```
show processes cpu sorted | exclude 0.0
```

Core	0:	CPU	util	iza	tion	for	five	seconds:	53%;	one	minute:	39%;	five	minutes:	41%
Core	1:	CPU	util	iza	tion	for	five	seconds:	43%;	one	minute:	57%;	five	minutes:	54%
Core	2:	CPU	util	iza	tion	for	five	seconds:	95%;	one	minute:	60%;	five	minutes:	58%
Core	3:	CPU	util	iza	tion	for	five	seconds:	32%;	one	minute:	31%;	five	minutes:	29%
PID		Runti	ime(m	s)	Invok	ked	uSecs	5 5Sec	1M-	in	5Min	TT	Y P	rocess	
8525		47256	50		23455	554	7525	31.37	30	. 84	30.83	0	i	osd	
5661		21574	152		92340)31	698	13.17	12	. 56	12.54	10	88 f	ed	
6206		19630)		74895	5	262	1.83	0.4	43	0.10	0	e	icored	
6197		72576	50		11967	7089	60	1.41	1.3	38	1.47	0	р	dsd	

From the output, it is clear that the Cisco IOS® daemon consumes a major portion of the CPU along with the FED, which is the heart of this box. When CPU usage is high due to interrupts, you see that Cisco IOSd and FED use a major portion of the CPU, and these subprocesses (or a subset of these) use the CPU:

- FED Punject TX
- FED Punject RX
- FED Punject replenish
- FED Punject TX complete

You can zoom into any of these processes with the **show process cpu detailed <process>** command. Since Cisco IOSd is responsible for the majority of the CPU usage, here is a closer look into that.

<#root>

The output (Cisco IOSd CPU output) shows that ARP Snoop, IP Host Track Process, and ARP Input are high. This is commonly seen when the CPU is interrupted due to ARP packets.

Step 2: Determine the CPU Queue that Causes the High CPU Usage Condition

The Cisco Catalyst 3850 Series Switch has a number of queues that cater to different types of packets (the FED maintains 32 RX CPU queues, which are queues that go directly to the CPU). It is important to monitor these queues in order to discover which packets are punted to the CPU and which are processed by the Cisco IOSd. These queues are per ASIC.

Note: There are two ASICs: 0 and 1. Ports 1 through 24 belong to ASIC 0.

In order to look at the queues, enter the **show platform punt statistics port-asic <port-asic <queue> direction** <rx|tx> command.

In the **show platform punt statistics port-asic 0 cpuq -1 direction rx** command, the -1 argument lists all of the queues. Therefore, this command lists all receive queues for Port-ASIC 0.

Now, you must identify which queue pushes a large number of packets at a high rate. In this example, an examination of the queues revealed this culprit:

RX pkt_hdr allocation failure : 0
RX INTACK count : 0
RX packets dq'd after intack : 0
Active RxQ event : 9906280
RX spurious interrupt : 0
<snip>

The queue number is 16 and the queue name is CPU_Q_PROTO_SNOOPING.

Another way to discover the culprit queue is to enter the **show platform punt client** command.

<#root>

3850-2#

show platform punt client

fallback	fallback pool: 98/1500/1600											
jumbo pool: 0/128/9300												

Determine the tag for which the most packets have been allocated. In this example, it is 65561.

Then, enter this command:

<#root>

3850-2#

show pds tag all | in Active Tags 65561

ActiveClient ClientTagsHandle NameTDASDAFDATBufDTBytD655617296672Punt RxProtoSnoop79821397079821397494316524

This output shows that the queue is Rx Proto Snoop.

The s before the 65561 in the output of the **show platform punt client** command means that the FED handle is suspended and overwhelmed by the number of incoming packets. If the s does not vanish, it means the queue is stuck permanently.

Step 3: Dump the Packet Sent to the CPU

In the results of the **show pds tag all** command, notice a handle, 7296672, is reported next to the Punt Rx Proto Snoop.

Use this handle in the **show pds client <handle> packet last sink** command. Notice that you must enable debug pds pktbuf-last before you use the command. Otherwise, you encounter this error:

<#root>

3850-2#

show pds client 7296672 packet last sink

```
% switch-2:pdsd:This command works in debug mode only. Enable debug using "debug pds pktbuf-last" command
```

With the debug enabled, you see this output:

<#root>

3850-2#

show pds client 7296672 packet last sink

Dumping Packet(54528) # 0 of Length 60

0030	06	07	08	09	0a	0b	0c	0d	0e	0f	10	11					

This command dumps the last packet received by the sink, which is Cisco IOSd in this example. This shows that it dumps the header and it can be decoded with Terminal-based Wireshark (TShark). The Meta-data is for internal use by the system, but the Data output provides actual packet information. The Meta-data, however, remains extremely useful.

Notice the line that starts with 0070. Use the first 16 bits after that as shown here:

<#root>

3850-2#

The culprit interface is identified here. Gig2/0/20 is where there is a traffic generator that pumps ARP traffic. If you shut this down, then it would resolve the problem and minimize the CPU usage.

Step 4: Use FED Tracing

The only drawback with the method discussed in the last section is that it only dumps the last packet that goes into the sink, and it cannot be the culprit.

A better way to troubleshoot this would be to use a feature called FED tracing. Tracing is a packet capture method (using various filters) that are pushed by the FED to the CPU. FED tracing is not as simple as the Netdr feature on the Cisco Catalyst 6500 Series Switch, however.

Here the process is broken into steps:

1. Enable detail tracking. By default, event tracing is on. You must enable detail tracing in order to capture the actual packets:

```
<#root>
3850-2#
set trace control fed-punject-detail enable
```

2. Fine-tune the capture buffer. Determine how deep your buffers are for detail tracing and increase as needed.

```
<#root>
3850-2#
show mgmt-infra trace settings fed-punject-detail
One shot Trace Settings:
Buffer Name: fed-punject-detail
Default Size: 32768
Current Size: 32768
Traces Dropped due to internal error: No
Total Entries Written: 0
One shot mode: No
One shot and full: No
Disabled: False
```

You can change the buffer size with this command:

<#root>

3850-2#

set trace control fed-punject-detail buffer-size <buffer size>

The values available to you are:

3. Add capture filters. You now need to add various filters for the capture. You can add different filters and either choose to match all or match any of those for your capture.

Filters are added with this command:

<#root> 3850-2#

set trace fed-punject-detail direction rx filter_add <filter>

These options are currently available:

<#root>

3850-2#

set trace fed-punject-detail direction rx filter_add ?

cpu-queue rxq 0..31 field field offset offset

Now you must link things together. Remember the culprit queue that was identified in Step 2 of this troubleshoot process? Since queue 16 is the queue that pushes a large number of packets towards the CPU, it makes sense to trace this queue and see what packets are punted to the CPU by it.

You can choose to trace any queue with this command:

<#root>

3850-2#

set trace fed-punject-detail direction rx filter_add cpu-queue

<start queue>

<end queue>

Here is the command for this example:

<#root>

3850-2#

set trace fed-punject-detail direction rx filter_add cpu-queue 16 16

You must choose either a match all or a match any for your filters and then enable the trace:

<#root>

3850-2#

set trace fed-punject-detail direction rx match_all

3850-2#

set trace fed-punject-detail direction rx filter_enable

4. Display filtered packets. You can display the packets captured with the **show mgmt-infra trace messages fed-punject-detail** command.

<#root> 3850-2# show mgmt-infra trace messages fed-punject-detail [11/25/13 07:05:53.814 UTC 2eb0c9 5661] 00 00 00 00 00 4e 00 40 07 00 02 08 00 00 51 3b 00 00 00 00 20 00 00 0e 00 00 00 00 00 01 00 74 00 00 00 04 00 54 41 02 00 00 00 00 00 00 00 00 00 [11/25/13 07:05:53.814 UTC 2eb0ca 5661] ff ff ff ff ff ff aa bb cc dd 00 00 08 06 00 01 08 00 06 04 00 01 aa bb cc dd 00 00 c0 a8 01 0a ff ff ff ff ff ff c0 a8 01 14 00 01 02 03 04 05 06 07 08 09 0a 0b 0c 0d 0e 0f 10 11 f6 b9 10 32 [11/25/13 07:05:53.814 UTC 2eb0cb 5661] Frame descriptors: [11/25/13 07:05:53.814 UTC 2eb0cc 5661] _____ systemTtl=0xe fdFormat=0x4 loadBalHash1=0x8 loadBalHash2=0x8

This output provides plenty of information and can typically be enough to discover where the packets come from and what is contained in them.

The first part of the header dump is again the Meta-data that is used by the system. The second part is the actual packet.

```
ff ff ff ff ff ff - destination MAC address
aa bb cc dd 00 00 - source MAC address
```

You can choose to trace this source MAC address in order to discover the culprit port (once you have identified that this is the majority of the packets that are punted from queue 16; this output only shows one instance of the packet and the other output/packets are clipped).

However, there is a better way. Notice that logs that are present after the header information:

```
[11/25/13 07:05:53.814 UTC 2eb0ce 5661] PUNT PATH (fed_punject_rx_process_packet:
830):RX: Q: 16, Tag: 65561
[11/25/13 07:05:53.814 UTC 2eb0cf 5661] PUNT PATH (fed_punject_get_physical_iif:
579):RX: Physical IIF-id 0x104d88000000033
```

The first log clearly tells you from which queue and tag this packet comes. If you were not aware of the queue earlier, this is a easy way to identify which queue it was.

The second log is even more useful because it provides the physical Interface ID Factory (IIF)-ID for the source interface. The hex value is a handle that can be used in order to dump information about that port:

<#root>

3850-2#

show platform port-asic ifm iif-id 0x0104d88000000033

```
Interface Table

Interface IIF-ID : 0x0104d8800000033

Interface Name : Gi2/0/20

Interface Block Pointer : 0x514d2f70

Interface State : READY

Interface Stauts : IFM-ADD-RCVD, FFM-ADD-RCVD

Interface Ref-Cnt : 6

Interface Epoch : 0

Interface Type : ETHER

Port Type : SWITCH PORT

Port Location : LOCAL

Slot : 2

```

You have once again identified the source interface and culprit.

Tracing is a powerful tool that is critical in order to troubleshoot high CPU usage problems and provides plenty of information in order to successfully resolve such a situation.

Sample Embedded Event Manager (EEM) Script for the Cisco Catalyst 3850 Series Switch

Use this command in order to trigger a log to be generated at a specific threshold:

```
process cpu threshold type total rising <CPU %> interval <interval in seconds>
switch <switch number>
```

The log generated with the command looks like this:

*Jan 13 00:03:00.271: %CPUMEM-5-RISING_THRESHOLD: 1 CPUMEMd[6300]: Threshold: : 50, Total CPU Utilzation

The log generated provides this information:

- The total CPU utilization at the time of the trigger. This is identified by Total CPU Utilization(total/Intr) :50/0 in this example.
- Top processes these are listed in the format of PID/CPU%. So in this example, these are:

8622/25 - 8622 is PID for IOSd and 25 implies that this process is using 25% CPU. 5753/12 - 5733 is PID for FED and 12 implies that this process is using 12% CPU.

The EEM script is shown here:

```
event manager applet highcpu
event syslog pattern "%CPUMEM-5-RISING_THRESHOLD"
action 0.1 syslog msg "high CPU detected"
action 0.2 cli command "enable"
action 0.3 cli command "show process cpu sorted | append nvram:<filename>.txt"
action 0.4 cli command "show process cpu detailed process <process name|process ID>
sorted | nvram:<filename>.txt"
action 0.5 cli command "show platform punt statistics port-asic 0 cpuq -1
direction rx | append nvram:<filename>.txt"
action 0.6 cli command "show platform punt statistics port-asic 1 cpuq -1
direction rx | append nvram:<filename>.txt"
action 0.7 cli command "conf t"
action 0.8 cli command "no event manager applet highcpu"
```

Note: The **process cpu threshold** command does not currently work in the 3.2.X train. Another point to remember is that this command looks at the average CPU utilization among the four cores and generates a log when this average reaches the percentage that has been defined in the command.

Cisco IOS XE 16.x or Later Releases

If you have Catalyst 3850 switches that run Cisco IOS® XE Software Release 16.x or later, see <u>Troubleshoot High CPU Usage in Catalyst Switch Platforms Running IOS-XE 16.x</u>.
