Introduction

This document describes how to troubleshoot Power over Ethernet (PoE) on Catalyst 9000 PoE-capable switching platforms.

Prerequisites

Requirements

Cisco recommends that you have knowledge of these topics:

• Catalyst 9000 Series switches

• Power over Ethernet

Components Used

This document is not restricted to specific software and hardware versions. PoE is supported on PoE capable switch and line card models in Catalyst 9200, Catalyst 9300 and Catalyst 9400 product family. The example outputs in this document are based on a number of software and hardware versions from the Catalyst 9000 product family.

The information in this document was created from the devices in a specific lab environment. All of the devices used in this document started with a cleared (default) configuration. If your network is live, ensure that you understand the potential impact of any command.

Background Information

Catalyst 9000 switches support different kinds of PoE standards.

• Pre-standard PoE devices are detected & classified at layer 1 by switch the Physical Layer Device (PHY), power is supplied at a default level, and/or higher power levels are negotiated with Cisco Discovery Protocol (CDP).

• IEEE 802.3af (PoE) and 802.3at (PoE+) powered devices (PDs) are detected by a PoE controller on Catalyst 9000 switch/line card (sometimes there are more than one), and appropriate power level can be classified prior to power on via IEEE classification, as well as negotiated later.

• Cisco UPoE (Universal Power over Ethernet) device detection and classification functions just like standards-based, but the 30W limit is raised to 60W by negotiation (post-power-up) through Link Layer Discovery Protocol (LLDP) to obtain inline power over additional wires.

• Cisco UPoE+ is based on IEEE 802.3bt & is available on selective Catalyst 9000 products and can provide up to 90W per port.

PoE switch models

• Catalyst 9000 switches and line cards with "P" in their product ID support PoE+ on a group of ports or all ports. For example, C9200L-48P-4G, C9200-24P, C9300-48P, C9400-LC-48P and so on.

• Catalyst 9000 switches and line cards with "U" in their product ID support UPoE on a group of ports or all ports. For example, C9300-24U, C9400-LC-48UX, and so on.

• Catalyst 9000 switches and line cards with "H" in their product ID support UPoE+ on a group of ports or all ports. For example, C9300-48H, C9400-LC-48H and so on.

Note: PoE capability alone does not guarantee PoE assignment. Refer to the data sheet for other restrictions & requirements like supported port range, needed power supplies and minimum software version and so on.

Terminology

• PoE - Power over Ethernet

• PoE+ - PoE+ standard increases maximum power that can be drawn by a powered device from 15.4 to 30W per port

• UPoE - Universal PoE. Cisco proprietary technology that extends the IEEE 802.3at PoE standard to provide the capability to source up to 60W of power over per port

• IF_ID - Interface Identifier, internal unique value that represents a specific interface

• Platform Manager - Internal software component in Cisco IOS® XE

• Chassis Manager - Internal software component in Cisco IOS XE

• IOMD - Input Output Module Driver. Internal software component in Cisco IOS XE

• MCU - Micro Controller Unit

• PD - Powered Device (IP Phones, Access Points, Cameras and so on.)

• PSE - Power Sourcing Equipment, like a PoE capable Catalyst 9000 switch.

PoE Class

Standards-based Cisco PoE equipment conforms to the IEEE standards for five power classifications for powered devices. When Cisco PoE switch detects a powered device and grants a power request, the switch can adjust the power budget (available power) in accordance to powered-device IEEE classification.

PoE classes describe a range of power used by a specific powered device. Some powered devices require more power than others, and power classes allowed switches to manage a power budget or available power. When a powered device is detected and its class is identified, the switch allocates (reserves) the appropriate power range.

The switch can determine the IEEE power class of the powered device through application of 20V DC to the line and then measurement of the resultant current flow. IEEE-compliant powered devices produce a very specific current flow in response to the 20 VDC applied by the switch.

Class	Maximum Power Level Required from the Device
0 (class status unknown)	15.4 W
1	4 W
2	7 W
3	15.4 W

4	30 W
5	45 W
6	60 W
7	75 W
8	90 W

PoE LEDs on switchports

This table explains the meaning of LED color status on the switch.

Color	Description
Off	PoE mode is not selected. None of the 10/100/1000 ports have been denied power or are in a fault condition.
Green	PoE mode is selected, and the port light emit diode (LEDs) shows the PoE mode status.
Intermittent amber	PoE mode is not selected. At least one of the 10/100/1000 ports has been denied power, or at least one of the 10/100/1000 ports has a PoE mode fault.

General Troubleshooting Guidelines

Verify environmental conditions and symptoms

⚠ Does the powered device (PD) in question not power up at all, or does it power up briefly and then power down?

⚠ Did problem start during initial installation, or did it begin a period of time where the device worked normally?

⚠ If problem started after the powered device worked normally, what changed? Were there any hardware or software changes? Any environmental changes (temperature, humidity, air flow, and so on)? Any electrical changes (maintenance, outage, interference, and so on)?

⚠ Did anything occur in the local network when the problem occurred? Use the `show logging` command to review the switch log and Simple Network Management Protocol (SNMP) traps (if configured). If so, could

it be related to another problem specific to that local network?

â€¢ Does the problem happen at a specific time of day or night? If so, are there any known environmental/electrical changes at that particular time/day?

â€¢ Was any network event noticed at the same time? A traffic flood, storm, loop, increased network congestion, higher than normal resource utilization (CPU, interfaces, and so on) could lead to temporary loss of connectivity between PD and another network element, which can cause the PD to reboot.

Verify specifics around powered device and switch

â€¢ What type of device is used (Cisco legacy, 802.3af, 802.3at, UPOE?), and does the Catalyst 9000 variant in question support this type?

â€¢ Is enough inline power available from the power supply on respective switch member/line card?

â€¢ Do all ports of one switch member/line card not provide PoE or only few?

â€¢ What about ports on different PoE controllers on the same switch/line card? (Non-UPoE models have 4 ports per controller and UPoE has 2 ports per controller)

â€¢ Is more than one line card/switch member of a chassis/stack affected?

â€¢ Do only newly connected ports not provide PoE, and are already-connected ports operate OK on same switch member/line card?

â€¢ If one of the already-connected port (PoE status OK) on same switch member/line card is bounced (shut/no shut), does the PoE functionality break or continue to work fine?

â€¢ Is data connectivity affected or it is just the PoE functionality?

â€¢ Is the problem restricted to one type/model of PD?

â€¢ Any PoE syslog messages seen?

â€¢ What are the switch models, types of linecards and PDs used?

â€¢ Does `show power inline [detail]` accurately reflect power status on the port?

Common PoE Problems

No PoE on Only One Port

Step 1: Verify that the powered device works on other ports and that the problem is only on one port.

Step 2: Use the `show run` and `show interface status` commands to verify that the port is not shut down or err-disabled.

Step 3: Use the `show run` command to verify that the `power inline never` interface is not configured on the port.

Step 4: Verify that the ethernet cable from the phone to the switch port is good. Connect a known good non-PoE ethernet device (like a computer) and use the same ethernet cable to a known port that works, and make sure that it establishes a link and exchanges traffic with another host. If needed, replace the cable.

Step 5: Verify that the total cable length from the switch front panel to the powered device is not more than

100 meters. 100m includes the length of cable between two ends of patch panel (if in use).

Step 6: If patch panel is in use, connect the powered device directly to the switchport to rule out a problem with patch panel.

Step 7: If Ethernet cable is fairly long (> 50 m), disconnect the cable from the switch port. Use a shorter Ethernet cable to connect a known good data only device (like a computer) to this switch. Verify that the device establishes a data only Ethernet link and exchanges traffic with another host, or ping the IP address of switch VLAN SVI. Next, connect a powered device to this port, and see if it powers on.

Step 8: Use the `show power inline` and `show power inline detail` commands to compare the number of connected powered devices against the switch power budget (available PoE). Verify that switch power budget can power the device.

Step 9: Move to [Advanced Troubleshooting](#) section for advanced PoE troubleshooting and data collection.

No PoE on All or Group of Ports

Step 1: Use the `show interface status` command to verify that the ports are not shut down and not error disabled.

Step 2: Use the `show environment all`, `show interface status`, and `show power inline` commands to review power status if no powered device on any port can power on. Use the `show log` command to review alarms reported earlier by system messages. If you see an unusual state against the power supplies, focus on that first.

Step 3: If the trouble is on all ports, the PoE section of the power supply can be defective if the switch works normally except for PoE and if non-PoE devices can establish a data ethernet link on any port. If the trouble is on a consecutive group of ports but not all ports, there could be a defective PoE subsection in the switch.

Step 4: Check logs with the command `show logging`. Common PoE logs are described later. If there are any logs seen from this section, interpret the information gathered and take appropriate steps.

Step 5: Bounce the interface connected to switch port. If that does not help, try a switch reload by removal of the power cord, wait for 15 seconds and power is provided to the switch again.

Step 6: Watch out for any diagnostic failures during/after bootup.

Cisco Powered Device does not Work on Cisco Poe Switch

When a functional Cisco IP Phone, Cisco wireless access point or another Cisco powered device intermittently reloads or disconnects from inline power do these steps:

Step 1: Verify all electrical connections from the switch to the powered device. Any unreliable connection results in power interruptions and intermittent powered device operations, such as powered device disconnects and reloads.

Step 2: Verify that the total cable length from the switch front panel to the powered device inclusive of patch panel (if in use) is not more than 100 meters.

Step 3: Notice what changed in the electrical environment at the switch site. What is happened at the powered device when the disconnect occurs?

Step 4: Use the `show log` command to review syslog and events. Examine syslog timestamps to see whether any other error messages are reported by the switch at the same time that a disconnect occurs.

Step 5: Verify that a Cisco IP Phone does not loose connectivity to the call manager immediately before the

reload occurs. It can be a network problem, not a PoE problem. This can be determined by SPAN capture on the switch port while powered device disconnects and analysis of the capture file.

Step 6: If powered device allows PoE debugs or packet capture, turn them on for additional troubleshooting data points.

Step 7: Connect a non-PoE device to the port, and verify that it works. If a non-PoE device has link problems or a high error rate, the problem can be an unreliable cable connection between the switch port and the user.

Non-Cisco Powered Device does not Work on Cisco PoE Switch

When a non-Cisco powered device is connected to a Cisco PoE switch, but never powers up, or powers up and then quickly disconnects from power (powers down). Non-PoE devices work normally do these steps:

Step 1: Use the `show power inline` command to verify that the switch power budget (available PoE) is not depleted before or after the powered device is connected. Verify that sufficient power is available for the powered device type.

Step 2: Use the `show interface status` command to verify that the powered device is detected by the switch when connected.

Step 3: Use the `show logging` command to verify that the powered device does not cause a controller error on the port. If this occurs, it would be highlighted in a syslog.

Step 4: If powered device initially powers on and then disconnects, problem can be an initial current surge that exceeds a current-limit threshold for the switch port.

Step 5: Verify that the powered device is compatible with the Cisco switch. For example, if both units are standards-compliant, they are interoperable. CDP cannot be used to identify a non-Cisco device, and the switch must rely on accurate detection and classification through layer 1 classification or LLDP when a non-Cisco device is utilized. Ensure LLDP is operational on switch port.

Third-party Powered Device Scenarios

Scenario 1 - Attached PD is a requires more power than its class permits. But it does not support CDP/LLDP extension or it is kept disabled per organizational policy. As a result, the switchport continues to flap.

Recommendation –“ Configure static power

Use **power inline static** interface level configuration to give the maximum power to the PD irrespective of its class, PD architecture and the negotiation protocol in use. Use this step when maximum power needed by PD is not known.

```
C9000(config-if)#power inline static
```

If maximum power needed by a PD is known, this interface level configuration can be used instead.

```
C9000(config-if)#power inline static max <required_power>
```

Scenario 2 - Attached PD is PoE capable on both signal and spare pairs. But it does not support CDP/LLDP extension or it is kept disabled per organizational policy.

Recommendation - Configure 4 pair PoE if PD supports it.

Find out if PD supports 4 pair PoE with the command `show power inline <interface> detail`:

```
C9000#show power inline Gi1/0/1 detail
Interface: Gi1/0/1
Inline Power Mode: auto
Operational status: on
Device Detected: yes
Device Type: Ieee PD
<snip>
Four-Pair PoE Supported: Yes <++
Spare Pair Power Enabled: No
Four-Pair PD Architecture: Shared <++
```

Configure 4 pair PoE:

```
Cat9K(config-if)#power inline four-pair forced
```

Note: By default UPoE switch uses LLDP. Do not configure 4 pair PoE unless powered device is 4 pair capable and LLDP can not be used.

For additional troubleshooting refer to [Common PoE Syslog](#) and [Advanced Troubleshooting](#) sections.

Scenario 3 - Class 4 device needs 30W but does not support CDP/LLDP or it is kept disabled per organizational policy.

Recommendation - Configure 2-event classification or configure static max PoE

When a class 4 device gets detected, Cisco IOS allocates 30W without any CDP or LLDP negotiation. This means that even before the link comes up the class 4 power device gets 30W. Also, on the hardware level the switch does a 2-event classification which allows a class 4 PD to detect switch capability to provide 30W from hardware, register itself and it can move up to PoE+ level without any CDP/LLDP packet exchange. Once 2-event is enabled on a port, you need to manually shut/no shut the port or connect the PD again to start the IEEE detection again. Power budget allocation for a class-4 device is 30W if 2-event classification is enabled on the port, else it is 15.4W.

```
Cat9K(config-if)#power inline port 2-event
```

Note: A shut/no shut on port is needed for the `power inline port 2-event` command to be effective. Both

switch/line card and the PD must support 2-event classification for this command to work.

```
Cat9K(config-if)#power inline static max <value> <+> desired amount of power in milliwatts
```

Common PoE Syslog, Explanation & Actions

1. CONTROLLER PORT ERROR

A port error reported by the Power over Ethernet (PoE) controller is detected by the Cisco switch. Controller error has some common variants.

1.1 Tstart Error

```
ILPOWER-3-CONTROLLER_PORT_ERR: Controller port error, Interface Gi1/0/1: Power Controller reports power
```

Tstart is related to inrush current when a powered device comes up on a switch port. Tstart error means that inrush current's value measured by switch PoE controller was higher than allowed maximum.

It has been seen that this error in some cases can be related to quick plugging/unplugging of the powered device. This can happen when platform dependent PoE state-machine is in a transition state, and reinsertion of the PD triggered a new set of state machines steps which conflict with ones in transition.

To rule this out, it is recommended to unplug the powered device connected on the port where TStart error showed up. Wait till "powered down removed" and/or "link down" syslog is seen. Plug the powered device again and see if the syslog does not re-appear.

In some cases, Tstart errors could be related to longer or shorter Cat5 or Cat6 cable. Please ensure that the cable length (include cable length between patch panel ends) is within specs. Usage of a cable of different length could potentially fix the problem in some of these cases.

1.2 Power supply over heat

```
%ILPOWER-3-CONTROLLER_PORT_ERR: Controller port error, Interface Gi1/0/1: Power Controller reports power
```

The `power inline port 2-event` command could help in some cases that experience this scenario.

For this error on a Catalyst 9300L switch, review Cisco bug ID [CSCvs52594](#) and ensure you are on Cisco IOS XE version 16.12.3 or later

1.3 Imax Error

```
%ILPOWER-3-CONTROLLER_PORT_ERR: Controller port error, Interface Te3/0/1: Power Controller reports power
```

Imax error occurs when a PoE capable port on the switch draws more power than it negotiated. Additionally, Some non-Cisco devices can have an excessive surge in current when first connected to a PoE port which could trigger Imax error.

Typically this error is seen when the powered device (PD) attached to a given port draws more power than what is negotiated through CDP/LLDP negotiation.

Try a good PD on same port and see if that helps. If the issue follows a specific PD/model, please make sure that attached powered device is IEEE compliant.

For more information see, [Troubleshoot PoE Imax Errors on Catalyst 3650/3850 Switches.](#)

1.4 Other uncommon Controller Port Error logs

1. Power given, but Power Controller does not report **Power Good**.

```
%ILPOWER-3-CONTROLLER_PORT_ERR: Controller port error, Interface Gi1/0/20: Power given, but Power Control
%ILPOWER-5-IEEE_DISCONNECT: Interface Gi1/0/20: PD removed
%ILPOWER-5-DETECT: Interface Gi1/0/20: Power Device detected: IEEE PD
%ILPOWER-5-IEEE_DISCONNECT: Interface Gi1/0/20: PD removed
%ILPOWER-3-CONTROLLER_PORT_ERR: Controller port error, Interface Gi1/0/20: Power given, but Power Control
%ILPOWER-5-IEEE_DISCONNECT: Interface Gi1/0/20: PD removed
```

As part of PoE detection and classification, there is a negotiation between the PSE and PD which helps the PSE determine what class the PD is. Once PoE detection and classification completes, PoE is allocated. Under ideal scenarios, after PoE allocation, the PD reports **Power Good** back to the PSE and then the interface is brought up (layer 1 occurs after PoE).

If the PD fails to send the **Power Good** message or does not send the "power good" message in a timely manner, this error message is printed which results in a full restart of PoE negotiation. This can cause symptoms such as the device never fully links up or is constantly power cycling.

To further isolate the issue, PoE debugs and traces are required from the problematic state.

2. PWRGOOD SPARE PAIR

```
%ILPOWER-5-PWRGOOD_SPARE_PAIR: Interface Gi1/0/1: spare pair power good
```

Spare pair power request made by the powered device was successful and power is available on spare pair. This is not an error message but just an indication that the powered device requested power on spare pair of the Cat5 or Cat6 cable and it was granted. No further action is needed.

3. POWER CDP SHUT

```
%ILPOWER-5-ILPOWER_POWER_CDP_SHUT: Interface Gi3/0/1: inline power shut
```

```
%LINEPROTO-5-UPDOWN: Line protocol on Interface GigabitEthernet3/0/1, changed state to down
%LINK-3-UPDOWN: Interface GigabitEthernet3/0/1, changed state to down
%ILPOWER-7-DETECT: Interface Gi3/0/1: Power Device detected: IEEE PD
%ILPOWER-5-POWER_GRANTED: Interface Gi3/0/1: Power granted
```

This syslog means that inline power is shut because CDP detected that power consumption on this PoE switchport is greater than:

1. Allocation power, or
2. Hardware interface limit, or
3. User configured max power, or
4. available power on this switch.

If this is a transient issue, the issue resolves itself after the switchport bounces like in the example. If there is a prevailing problem, investigate and rule out the four points mentioned earlier.

In some scenarios, this error could be seen when both CDP and LLDP are enabled on the switchport and PoE debugs reveal use of both protocols in power negotiation. You can disable LLDP to alleviate the issue:

```
no lldp tlv-select power-management
OR
no lldp transmit / no lldp receive
```

In certain rare conditions, it is observed that this log could be a result of powered device's misbehavior. For example, PD requests a lower power value in initial negotiation and switch allocates the requested power to PD. Later same PD requests more power than earlier, higher than the previously allocated power. This triggers a CDP shut off and a port flap. Such scenarios can benefit from [Perpetual PoE or Fast PoE](#)

4. INVALID IEEE CLASS

```
%ILPOWER-5-INVALID_IEEE_CLASS: Interface Gi1/0/1: has detected invalid IEEE class: 8 device. Power denied
%ILPOWER-7-DETECT: Interface Gi1/0/1: Power Device detected: IEEE PD
```

This error is seen when connected powered device has invalid IEEE class. Switch does not power up the device. Refer to [PoE Class](#) to understand PoE classes.

If you use a non-Cisco powered device (PD), find out if the PD is the right class.

5. SHUT OVERDRAWN

```
%ILPOWER-3-SHUT_OVERDRAWN: Interface Gi1/0/1 is shutdown as it is consuming more than the maximum configured power
%ILPOWER-5-IEEE_DISCONNECT: Interface Gi1/0/1: PD removed
%PM-4-ERR_DISABLE: inline-power error detected on Gi1/0/1, putting Gi1/0/1 in err-disable state
```

This error means that switch decided to shut the interface down because it found the powered device consumed more than the maximum configured/negotiated power.

Ensure correct power is budgeted for this interface based on the power device electrical specifications or ratings. It is recommended to change the police cutoff power to a higher value to keep the device powered on.

If you use a non-Cisco powered device, find out the expected power needed vs what is drawn.

6. TSTART SPAREPAIR

```
%ILPOWER-5-TSTART_SPARE_PAIR: Interface Te3/0/1: spare pair power error: TSTART
```

This error means that the powered device connected to switchport tried to request power on spare Cat5 or Cat6 wire pair & switch detected a higher than expected current inrush (Tstart error) and as a result decided to shut off the power.

This error is often seen in conjunction with Imax error or other errors discussed. Do remedy procedures described for those sections that are dependent on the error seen.

7. SINGLE PAIRSET FAULT

```
%LINEPROTO-5-UPDOWN: Line protocol on Interface GigabitEthernet1/0/1, changed state to up
%ILPOWER-5-SINGLE_PAIRSET_FAULT: Interface Gi1/0/1: shutting down Alt-B pairset due to OVERCLS fault
%ILPOWER-5-SINGLE_PAIRSET_FAULT: Interface Gi1/0/1: shutting down Alt-B pairset due to OVERCLS fault
```

This error means that the dual signature powered device on the switchport has hit a critical fault on one pairset and hence that pairset is shutdown. The earlier example is taken from a UPoE+ capable powered device and switch.

8. PGOOD TIMEOUT SPARE PAIR

```
%ILPOWER-5-PGOOD_TIMEOUT_SPARE_PAIR: Interface Te1/0/1: spare pair power good timeout error
```

This error means that the powered device connected to switchport tried to request power on spare Cat5 or Cat6 wire pair but spare pair power good timeout error occurred and power on spare pair is not be supplied.

With a 802.3bt (UPoE+) switch, remember the Cisco switch that supports IEEE 802.3bt standard for Type 3 powered devices could be in 802.3at mode by default. 802.3bt mode can be enabled through the this configuration in global configuration mode. Note that this command power cycles the switch after the configuration. This step is not applicable for switch models that are not UPoE+ capable.

```
C9K(config)# hw-module switch 1 upoe-plus
!!!WARNING!!!This configuration will power cycle the switch to make it effective. Would you like to cont
```

Another possible solution could be to try and hardcode needed power on the switchport with the `power inline static` interface configuration.

In rare conditions, this error could be accompanied when a 802.2bt line card/switch is used.

```
%ILPOWER-5-SINGLE_PAIRSET_FAULT: Interface Gi1/0/1: shutting down Alt-B pairset due to OVERCLS fault
```

This would mean that the powered device is incapable to work with 802.3bt PoE system. Use a non-802.3bt PoE switch.

9. ILPOWER POWER DENY

```
%ILPOWER-5-IEEE_DISCONNECT: Interface Gi1/0/1: PD removed
%ILPOWER-7-DETECT: Interface Gi1/0/1: Power Device detected: IEEE PD
%ILPOWER-5-ILPOWER_POWER_DENY: Interface Gi1/0/1: inline power denied. Reason: insufficient power
```

This error means that there is not enough power that remains in the switch to supply to the Power over Ethernet (PoE) port.

This is likely due to total inline power greater than available power. Verify power budgeting. Install more power supplies if needed. Adjustment of power supply redundancy from redundant to combined can also help. For stacked systems, stack power can be considered to pool total power across stacks.

10. CONTROLLER POST ERR

```
%ILPOWER-3-CONTROLLER_POST_ERR: Inline Power Feature is disabled on this switch because
    Power On Self Test (POST) failed on this switch.
```

Switch decided to shut off PoE because Power On Self Test (POST) failed on this switch.

Verify Power over Ethernet (PoE) controller functionality test to health status of the power-sourcing equipment. Refer to the POST section under [PoE outputs and data collection](#) for more information.

11. IEEE DISCONNECT

```
%ILPOWER-7-DETECT: Interface Gi2/0/1: Power Device detected: Cisco PD
%ILPOWER-5-IEEE_DISCONNECT: Interface Gi2/0/1: PD removed
```

This error means that the powered device is no longer connected to the switch, or the connected powered device is switched to an external AC power source which caused switch to remove PoE on the port.

In some cases this error is accompanied by other errors, like:

```
%ILPOWER-5-IEEE_DISCONNECT: Interface Tw1/0/1: PD removed
%ILPOWER-3-CONTROLLER_PORT_ERR: Controller port error, Interface Tw1/0/1: Power is given, but State Machine is not in a valid state
%ILPOWER-5-IEEE_DISCONNECT: Interface Tw1/0/1: PD removed
```

In such cases take appropriate action dependent on the other error.

12. LOG OVERDRAWN

```
%ILPOWER-4-LOG_OVERDRAWN: Interface Gi1/0/1 is overdrawing power. it is consuming 2346 milliwatts whereas maximum configured power is 15400 milliwatts
%ILPOWER-5-IEEE_DISCONNECT: Interface Gi1/0/1: PD removed
```

Interface X overdrew power. it has consumed Y milliwatts whereas maximum configured power is Z milliwatts. This is just an informational log and switch continues to provide PoE on the port unless switch runs out of power (SHUT_OVERDRAWN) or another error.

Ensure correct power is budgeted for this interface based on the powered device's electrical specifications and ratings. It is recommended to change the police cutoff power appropriately if needed.

13. CLR OVERDRAWN

```
%ILPOWER-3-CONTROLLER_PORT_ERR: Controller port error, Interface Gi1/0/1: Power given, but State Machine is not in a valid state
%ILPOWER-4-LOG_OVERDRAWN: Interface Gi1/0/1 is overdrawing power. it is consuming 2346 milliwatts whereas maximum configured power is 15400 milliwatts
%ILPOWER-5-IEEE_DISCONNECT: Interface Gi1/0/1: PD removed
%ILPOWER-7-DETECT: Interface Gi1/0/1: Power Device detected: Cisco PD
%ILPOWER-5-CLR_OVERDRAWN: Interface Gi1/0/1 is NOT overdrawing power.
                           it is consuming 2346 milliwatts whereas maximum configured value is (15400) milliwatts
```

This informational log tells the user that interface X overdrew power earlier but is NOT anymore. it has consumed Y milliwatts whereas maximum configured value is Z milliwatts.

14. DET TIMEOUT SPARE PAIR

```
%ILPOWER-6-SET_ILPOWER: Set power allocated to POE to 17180 for slot 0
%ILPOWER-7-DETECT: Interface Gi4/0/1: Power Device detected: IEEE PD
%ILPOWER-5-POWER_GRANTED: Interface Gi4/0/1: Power granted
%ILPOWER-5-DET_TIMEOUT_SPARE_PAIR: Interface Gi4/0/1: spare pair detect timeout
```

This error means that powered device requested power on Cat5 or Cat6 spare wire power and in the process spare pair timeout was detected. As a result, power on spare pair is not supplied.

15. Power given, but Power Controller does not report Power Good

PoE Outputs and Data Collection

PoE syslog

Look for any relevant error messages described under [Common PoE syslog](#) section in `show logging` output. For example, PoE controller error, PoE budget error, power supply problem and so on.

POST status

POST tests the Power over Ethernet (PoE) controller functionality test to check the chip accessibility, firmware download, and health status of the power-sourcing equipment.

```
C9K#show post
Stored system POST messages:
Switch 1
-----
**snip**
POST: Inline Power Controller Tests : Begin <++ PoE related test
POST: Inline Power Controller Tests : End, Status Passed <++ Desirable outcome
```

Inline Power & Budget

Verify PoE budget and Inline Power status of a switch member/line card/interface. Use the `show power inline` command to review these factors:

- PoE power available per switch.
- PoE power used by all ports in the switch.
- PoE power used by each connected powered device.
- PoE power classification.

PoE Diagnostics

With online diagnostics, you can test and verify the hardware functionality of a device while the device is connected to a live network. Online diagnostics contain packet-switching tests that check different hardware components and verify the data path and control signals. Online diagnostics detect problems related but not limited to:

- PoE hardware components
- Interfaces
- Solder joints & board integrity

Here are some diagnostic tests that can be used. These can be run ondemand unlike [POST](#) that runs only during bootup. Before the test, read the information in the table to understand potential impact.

Platform	Test Name	Disruptive or Non Disruptive	Default Status	Recommendation	Initial Release
Catalyst 9200	DiagPoETest	Non Disruptive**	off	Run this test if you experience PoE controller issues with a port. This can be run only as a on-demand test.	16.9.2
Catalyst 9300	TestPoE	Disruptive*	off	Do not start this diagnostic test during normal switch operation unless recommended/assured by TAC. This test can be run if you experience PoE controller issues with a port and it can be run only as an on-demand test	16.6.1
Catalyst 9400	DiagPoETest	Non Disruptive**	off	Run this test if you experience PoE controller issues with a port. This can be run only as a on-demand test.	16.6.1

* Under review by Cisco if this could be made non-disruptive in future.

** Non-Disruptive test, safe to run during production.

```

Advanced Troubleshooting

This section contains PoE debugs and platform specific information that is useful to troubleshoot PoE issues. Some of these outputs do not make sense or would not be available in a human readable format to the end user. These have been found safe to run in production & would be useful if provided to Cisco TAC when a PoE is troubleshot.

InlinePower (ILP) Debugs for PoE

ILpower (ILP) is an internal Cisco IOS XE software component that runs within Cisco IOS Dameon (Cisco IOSd). ilpower implements PoE state machine which governs various steps of PoE functionality. Next, is an ilpower diagram which can be used as a reference in conjunction with Cisco IOSd debugs.

Examine debugs from each state machine step to understand at which step is the functionality broken. Compare these debugs from a PoE port that works and a PoE port that does not work with same/similar PDs can also be useful to identify anomalies.

1. Start these debugs:

```

debug condition interface GigabitEthernet <> <+ Specify interface number for conditional debugging. This
debug ilpower event
debug ilpower controller
debug ilpower powerman
  
```

2. Shut the port in question.

3. Turn off **logging console** and **terminal monitor** (**no logging console** from global configuration mode and **term no mon** from **user Exec** mode).

4. Back up the logging output if needed, since the next step resets the logging buffer. Example- show logging | redirect flash:showlogbackup.txt

5. Make sure logging buffer level is set to **debugging**. Increase the logging buffer size to at least 50K (logging buffer 50000). It is important to remember that this step clears historical logs.

6. Enable the conditional debugging and clear logging (clear logging).

7. Unshut the port in question and wait for 30-40 sec at least for PoE negotiation.

8. Turn off debugging with `undebug all` and collect the `show logging` to understand the debugs.

9. Undo all changes made in steps 2-7.

This is how a successful PoE transaction typically looks:

```

Catalyst 9200 Specific Data Collection

1. Collect `show tech-support PoE` .

```
C9200#show tech-support poe | redirect flash:shtechPOE9200.txt
```

2. Retrieve IFM mapping for respective switch member. Ensure you use the correct switch number on which the PoE problem exists. This is useful for TAC to interpret other collected outputs.

```
C9200#show platform software fed switch 1 ifm mappings
```

```

Interface          IF_ID Inst Asic Core Port SubPort Mac Cntx LPN GPN Type Active
GigabitEthernet1/0/1 0x7  0  0  0  4  0  12  4  1  1  NIF  Y
GigabitEthernet1/0/2 0x8  0  0  0  5  0  4  5  2  2  NIF  Y
GigabitEthernet1/0/3 0x9  0  0  0  6  0  14  6  3  3  NIF  Y
GigabitEthernet1/0/4 0xa  0  0  0  7  0  13  7  4  4  NIF  Y
**snip**

```

3. Collect Traces. This CLI creates a binary file in flash. It can be decoded by Cisco TAC to investigate deeper.

```
C9200#request platform software trace archive
```

```
C9200#dir flash: | in tar
```

```
48602 -rw- 404145 Jun 9 2020 03:12:36 +00:00 C9200L-48P-4X-1_1_RP_0_trace_archive-20200609-031235.tar.gz
```

```
C9200#
```

4. Collect further PoE Registers. This CLI creates a file in flash. It can be analyzed by Cisco TAC to investigate deeper.

```
C9200#show controllers power inline
```

For logs refer to /flash/poe_controller_logs_*

```
C9200#dir flash: | in poe
```

```
32472 -rw- 33566 Dec 4 2021 09:12:10 +00:00 poe_controller_logs_sw2_Sat-Dec-04-21-09:12:10.txt
```

Note: This CLI is officially supported on 17.6.x onwards.

Catalyst 9300 Specific Data Collection

1. Collect `show tech-support PoE` .

```
C9300#show tech-support poe | redirect flash:shtechPOE9300.txt
```

2. Useful show commands (also present in `show tech poe`) that can be individually collected and examined.

```
show clock
show version
show running-config
show env all
show power inline
show power inline police
show interface status
show platform software ilpower details
show stack-power budgeting
show stack-power detail
show controllers ethernet-controller phy detail
show controllers power inline module 1
show platform frontend-controller version 0 1
show platform frontend-controller manager 0 1
show platform frontend-controller subordinate 0 1
show platform software ilpower system 1
```

```
show power inline Gi<> detail
```

3. Collect frontend-controller version and controller dump.

3.1 show platform frontend-controller version 0 <switch number>.

```
C9348U#show platform frontend-controller version 0 1 <++ 1 is switch number here, use your respective
Switch 1 MCU:
Software Version 129
System Type      6
Device Id        2
Device Revision  0
Hardware Version 41
Bootloader Version 17
```

3.2 show controllers power inline module <switch number> .

```
show controllers power inline module 1 <++ 1 is switch number, use respective switch no. in question
```

3.3 Read controller registers.

```
test frontend-controller read-poe <MCU no> module <switch member#>
```

You must use the console access to print this output. Collect this output for all MCUs on the switch in question.

Note: For a UPoE module MCU number is 1-24 and for POE+ module MCU number is 1 -12.

```
test frontend-controller read-poe 1 module 1 <++ MCU #1 of switch 1,use respective switch number as appl
test frontend-controller read-poe 2 module 1 <++ MCU #2 of switch 1,use respective switch number as appl
test frontend-controller read-poe 3 module 1 <++ MCU #3 of switch 1,use respective switch number as appl
...
...
test frontend-controller read-poe 12 module 1 <++ MCU #12 of switch 1,use respective switch number as ap
...
... <++ Output for MCU 13-24 is applicable only to UPoE devices
...
test frontend-controller read-poe 24 module 1
```

Sample Output-

```
C9300#test frontend-controller read-poe 24 module 1
Switch 1 Power controller instance 24
Switch number:1
```

0x00 0x00 0x00 0x00 0x15 0x16 0x60 0xFF
0x00 0x00 0x00 0x02 0xAA 0x00 0x00 0x00
0x00 0x00 0x00 0x00 0x00 0x00 0x00 0x00
0x00 0x00 0x00 0x00 0x00 0x00 0x00 0x00
0x00 0x00 0x00 0x00 0x00 0x00 0x00
```

4. Retrieve IFM mapping for respective switch member. Ensure to use correct stackwise switch number on which PoE problem exists. This is useful for TAC to interpret other collected outputs.

```
C9348U#show platform software fed switch 1 ifm mappings
```

Interface	IF_ID	Inst	Asic	Core	Port	SubPort	Mac	Cntx	LPN	GPN	Type	Active
GigabitEthernet1/0/1	0x8	1	0	1	0	0	26	6	1	1	NIF	Y
GigabitEthernet1/0/2	0x9	1	0	1	1	0	6	7	2	2	NIF	Y
GigabitEthernet1/0/3	0xa	1	0	1	2	0	28	8	3	3	NIF	Y
GigabitEthernet1/0/4	0xb	1	0	1	3	0	27	9	4	4	NIF	Y

snip

5. Collect platform manager traces for TAC

5.1 Set PoE Trace level to verbose. Use respective switch number in question.

Prior to Cisco IOS XE version 16.11.x

```
set platform software trace platform-mgr switch <switch_num> r0 reearth verbose set platform software trace platform-mgr switch <switch_num> r0 poe verbose
```

Cisco IOS XE version 16.11.x onwards

```
set platform software trace chassis-manager switch <switch_num> r0 re_poe verbose set platform software trace chassis-manager switch <switch_num> r0 reearth verbose
```

```
set platform software trace chassis-manager switch 1 r0 re_poe verbose
set platform software trace chassis-manager switch 1 r0 reearth verbose
```

5.2 Shut/no shut the port in question.

```
interface gi1/0/4
sh
no shut <++ wait 2-4 sec before issuing no shut
```

5.3 Wait for 20-30 seconds.

5.4 Collect Traces.

The command `request platform software trace archive` creates a binary file in flash of Primary switch, must be decoded by TAC.

```
C9K#request platform software trace archive
```

```
C9K#dir flash: | in tar
```

```
434284 -rw- 7466248 June 07 2020 13:45:54 +01:00 DUT_1_RP_0_trace_archive-20191125-134539.tar.gz <++ u
```

5.5 Reset the Trace level to Info.

Prior to Cisco IOS XE version 16.11.x

```
set platform software trace platform-mgr switch <switch_num> r0 reearth info set platform software trace platform-mgr switch <switch_num>
r0 poe info
```

Cisco IOS XE version 16.11.x onwards

```
set platform software trace chassis-manager switch <switch_num> r0 re_poe info set platform software trace chassis-manager switch
<switch_num> r0 reearth info
```

Catalyst 9400 Specific Data Collection

1. Collect `show tech-support PoE` .

```
C9400#show tech-support poe | redirect bootflash:showtechpoe9400.txt
```

2. Useful show commands (also present in `show tech PoE`) that can be individually collected and examined.

```
show clock
show version
show running-config
show env all
```

```

show power inline
show power inline police
show interface status
show platform software ilpower details
show controllers ethernet-controller phy detail
show power inline upoe-plus (applicable to modules supporting UPoE+ like C9400-LC-48H)
**snip**

```

3. Collect platform specific information.

```

show platform software iomd redundancy show platform show tech-support platform | redirect bootflash:showtechplatform9400.txt

```

4. Collect Port Register dumps.

```

test platform hard poe get <line card slot #> global test platform hard poe get <line card#> port <port# in question for PoE>

```

```

test platform hard poe get 3 global <-- line card slot number 3, use respective line card number
test platform hard poe get 3 port 1 <-- line card slot number 3, port 1, use respective line card/port number

```

```

C9400#test platform hard poe get 2 global
Global Register for slot 2
0x00FFFFFF      0x00FFFFFF      0x80001304      0x000000C1
0x00000000      0x000000700     0x0FFD0FFD      0x00000015
0x00000000E     0x000000000     0x005AD258      0x00003A0A
0x000000700     0x000000000     0x00000000      0x00000000
0x000000000     0x000000000     0x00000000      0x00000000

```

```

POE FW loaded successfully <-- success
POE health status : GOOD <-- success
POE PSE FW ver :19
POE Abstraction layer FW ver = 14

```

5. Retrieve IFM mapping for ports. This is useful for TAC to interpret other collected outputs.

```

show platform software fed active ifm mappings

```

```

C9400#show platform software fed active ifm mappings

```

```

Interface          IF_ID Inst Asic Core Port SubPort Mac Cntx LPN GPN Type Active
GigabitEthernet1/0/1 0x8  0  0  0  0  0  4  4  1  101 NIF  Y
GigabitEthernet1/0/2 0x9  0  0  0  1  1  4  4  2  102 NIF  Y
GigabitEthernet1/0/3 0xa  0  0  0  2  2  4  4  3  103 NIF  Y
**snip**

```

6. Collect IOMD traces.

6.1 Set IOMD Trace level to verbose. Use respective module number in question.

```
set platform software trace iomd <module_number>/0 poe verbose.
```

```
set platform software trace iomd 3/0 poe verbose <++ Here 3 is line card slot#, use respective slot number>
```

6.2 Shut/no shut the port in question.

```
conf t
interface gi3/0/1
shut
! wait 2-4 sec before issuing no shut
no shut
```

6.3 Wait 40-60 sec.

6.4 Collect Traces.

The command `request platform software trace archive` creates a binary file in flash of Primary switch, must be decoded by TAC.

```
C9400#dir bootflash: | in tar
194692 -rw- 50261871 Jun 9 2020 02:53:36 +00:00 test94_RP_0_trace_archive-20200609-025326.tar.gz <++ upl>
```

6.5 Reset the Trace level to Info.

```
set platform software trace iomd <module number>/0 poe info
```

```
set platform software trace iomd 3/0 poe info <++ Here 3 is line card slot#, use respective slot number>
```

Last Resort / Intrusive Recovery Steps

If PoE does not recover through any of the steps mentioned and appears to be due to soft failure, other steps can be tried to attempt a recovery. Do note that these steps are intrusive and could cause a potential downtime. They can also erase data that is typically needed to root cause the problem. If root cause is important, please reach out to TAC and collect needed information before these steps.

1. Refer to [Recommended Cisco IOS XE releases for Catalyst 9000 switches](#) and upgrade to the

recommended release. Recommended releases contain fixes and optimizations that could potentially solve an issue known and resolved in past.

2. If stack-power is in use, remove the stack-power cables temporarily before any of these steps.
3. Try a reload of the switch member/line card in question
4. In a stackwise system (C9200, C9300), hard power cycle the member/active switch in question. This step is also needed if you perform an MCU reset.
5. To hard reset, unplug all input power cables to the stack and let it power down. Wait 10 seconds and plug the power cables again. For Catalyst 9400, try a hard reseal of the line card. Physically unseat the line card, wait for a few seconds and seat the card back.
6. If it is a high availability (HA) setup and the issue follows multiple members of a stack or multiple line cards of a C9400 chassis, please try HA failover/SSO (redundancy force-switchover)
7. If the issue persists and the switch member in question is part of a stack, try these steps:
 - a. Take the member switch out of stack and boot it standalone mode. See if that helps to recover PoE on that member switch.
 - b. If not, power off the member (standalone/ when out of stack), wait for 3-5 minutes before power is provided again.
8. For C9400, you can move the line card in question to a different slot or chassis, if feasible.
