Introduction

This sample configuration studies a VoIP with Point to Point Protocol (PPP) over low bandwidth leased line configuration. The document includes background technical information on the configured features, design guidelines, and basic verification and troubleshooting strategies.

It is important to note that in the configuration below, the two routers are connected back-to-back over a leased line. In most topologies however, the voice enabled routers can exist anywhere. Usually, the voice routers use LAN connectivity to other routers which are connected to the WAN (in other words, a PPP leased line). This is important because if your voice routers are not directly connected via PPP over a leased line, all WAN configuration commands must be configured on those routers connected to the WAN, and not on the voice routers, as shown in the configurations below.

Before You Begin

Conventions

For more information on document conventions, see the [Cisco Technical Tips Conventions](#).

Prerequisites

There are no specific prerequisites for this document.

Components Used

These configurations were tested with the following equipment:

- Two Cisco 3640s with Cisco IOS® Software Release 12.2.6a (IP Plus)
- IP RTP Priority was introduced in Cisco IOS Release 12.0(5)T.
- LLQ was introduced in Cisco IOS Release 12.0(7)T.
- LFI was introduced in Cisco IOS Release 11.3.
- Cisco IOS releases beyond 12.0.5T contain significant performance improvements for cRTP.

QoS Design Guidelines for VoIP Over PPP Links

This section provides design guidelines to configure Voice over IP over PPP leased lines (with an emphasis on low speed links). There are two basic requirements for good voice quality:

- Minimal [end-to-end delay](#) and [jitter avoidance](#) (delay variation).
- Link bandwidth requirements optimized and correctly engineered.

To guarantee the above requirements, there are several important guidelines to be followed:

Guideline	Description
Strict Priority for Voice Traffic (IP RTP Priority or LLQ)	Method to provide strict priority for voice traffic.
Link Fragmentation and Interleaving (LFI)	May be a mandatory requirement for low-speed links.
RTP Compression	Not required to provide good voice quality, but reduces call bandwidth consumption. The general advice regarding RTP compression is to apply it after having a working configuration with good voice quality (simplifies troubleshooting).
Call Admission Control (CAC)	Not covered in this document. CAC is used to control the number of calls that can be established over the link. For example, if the WAN link between the two gateways has the bandwidth to carry only two VoIP calls, admitting a third call may impair the voice quality of all three calls. For more information refer to: VoIP Call Admission Control

To summarize, for the low-speed PPP link with router/gateways as only sources of voice traffic two features are mandatory:

1. Strict Priority for Voice Traffic
2. [Link Fragmentation and Interleaving \(LFI\)](#)

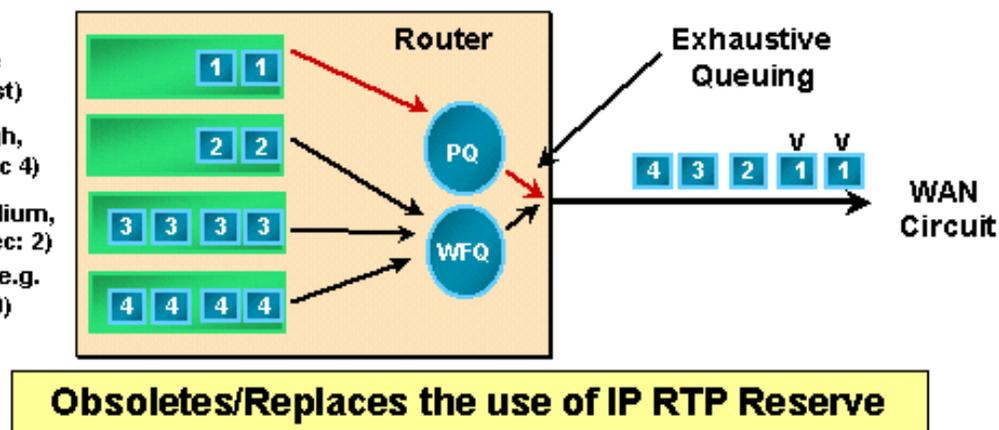

Strict Priority for Voice Traffic (IP RTP Priority or LLQ)

As of Cisco IOS® Software Release 12.2, there are two primary methods to provide strict priority for the voice traffic:

- IP RTP Priority (also called PQ/WFQ: Priority Queue / Weighted Fair Queuing)
- Low Latency Queuing (also called PQ/CBWFQ: Priority Queue / Class Based Weighted Fair Queuing).

IP RTP Priority

IP RTP Priority creates a strict-priority queue for a set of RTP packet flows belonging to a range of UDP destination ports. While the actual ports used are dynamically negotiated between end-devices or gateways, all Cisco VoIP products utilize the same UDP port range (16384-32767). Once the router recognizes the VoIP traffic, it places it into the strict priority queue. When the priority queue is empty, the other queues are processed according to standard [Weighted Fair Queuing \(WFQ\)](#). IP RTP Priority does not become active until there is congestion in the interface. The following image illustrates the operation of IP RTP Priority:

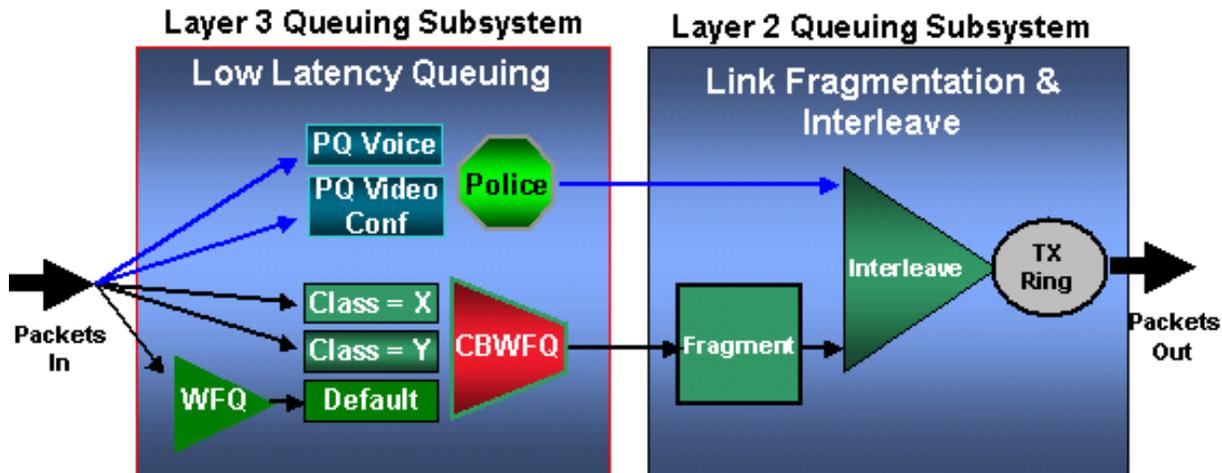

Note: IP RTP Priority allows bursting the priority queue (PQ) when there is available bandwidth on the default queue (WFQ), but will strictly police the priority queue contents when there is congestion on the interface.

Low Latency Queuing

LLQ is a feature that provides a strict priority queue (PQ) to [Class-Based Weighted Fair Queuing \(CBWFQ\)](#). LLQ enables a single strict PQ within CBWFQ at the class level. With LLQ, delay-sensitive data (in the PQ) is dequeued and sent first. In a VoIP with LLQ implementation, voice traffic is placed in the strict PQ.

The PQ is policed to ensure that the fair queues are not starved of bandwidth. When you configure the PQ, you specify in Kbps the maximum amount of bandwidth available to the PQ. When the interface is congested, the PQ is serviced until the load reaches the configured Kbps value in the priority statement. Excess traffic is then dropped to avoid the problem with Cisco's legacy priority-group feature of starving the lower priority queues.

This method is more complex and flexible than IP RTP Priority. The choice between the methods should be based on the patterns of traffic in your real network and your actual needs.

LLQ vs. IP RTP Priority

The following table summarizes the main differences between LLQ and IP RTP Priority and provides some guidelines of when to use each method.

Low Latency Queuing (LLQ)	IP RTP Priority
<p>Match Voice Traffic Based on:</p> <ul style="list-style-type: none"> Access-lists (for UDP port range, hosts addresses, IP header ToS fields: IP Precedence, DSCP, and more) IP RTP port range IP ToS (Type of Service) Fields: DCSP and/or IP Precedence Protocols and Input Interfaces All valid match criteria used in CBWFQ <p>Advantages:</p>	<p>Match Voice Traffic Based on:</p> <ul style="list-style-type: none"> Based on RTP / UDP port range: 16384-32767 <p>Advantages:</p> <ul style="list-style-type: none"> Simple configuration <p>Disadvantages:</p> <ul style="list-style-type: none"> RTCP traffic (VoIP Signaling) served in WFQ queue <p>Note: The RTP protocol uses RTCP (Real Time Control Protocol) to control delivery of RTP packets. While RTP ports use even numbers, RTCP ports use odd numbers in the range of 16384-32767.</p>

- More flexibility on how traffic is matched and directed to the strict PQ and CBWFQ
- Can configure additional classes to guarantee bandwidth for other traffic such as: VoIP Signaling and Video.

Disadvantages:

- Complex configuration

IP RTP Priority places RTP ports in the PQ, whereas RTCP ports are served in the default weighted fair queue.

- Serves VoIP traffic in the PQ, but any other traffic that needs preferential treatment and bandwidth guarantee is served in WFQ. While WFQ can differentiate flows with weights (based on IP Precedence), it cannot ensure bandwidth guarantee for any flow.

Guidelines

- The choice between them should be based on the patterns of traffic in your real network and your actual needs.
- If you need to provide strict priority to your voice traffic, and other traffic can be treated as a single type (data), then the IP RTP Priority will do a good job for your network with a simple configuration.
- If you plan to prioritize voice traffic based on other criteria other than UDP ports (for example [DiffServ PHB](#)), LLQ is necessary.

For more information on the correlation and differences of queuing methods, refer to [Congestion Management Overview](#).

LLQ Configuration Guidelines

Follow these guidelines to configure LLQ:

1. Create a Class Map for VoIP Traffic and Define Match Criteria

The following commands explain how to complete this task:

```
maui-voip-sj(config)#class-map ?
WORD                class-map name
match-all          Logical-AND all matching statements under this classmap
match-any           Logical-OR all matching statements under this classmap
maui-voip-sj(config)#class-map match-all voice-traffic
```

!-- Choose a descriptive class_name.

```
maui-voip-sj(config-cmap)#match ?
access-group        Access group
any                 Any packets
class-map           Class map
cos                 IEEE 802.1Q/ISL class of service/user priority values
destination-address Destination address
```

```

input-interface      Select an input interface to match
ip                  IP specific values
mpls                Multi Protocol Label Switching specific values
not                 Negate this match result
protocol            Protocol
qos-group           Qos-group
source-address      Source address

```

```

!-- In this example we use the access-group matching option for its
!-- flexibility (it uses an access-list)

```

```

maui-voip-sj(config-cmap)#match access-group ?
  <1-2699> Access list index name      Named Access List
maui-voip-sj(config-cmap)#match access-group 102

```

```

!-- Now, create the access-list to match the class-map access-group:

```

```

maui-voip-sj(config)#access-list 102 permit udp any any range 16384 32776

```

```

!-- Safest and easiest way is to match with UDP port range 16384-32767
!-- This is the port range Cisco IOS H.323 products utilize to transmit
!-- VoIP packets.

```

The following access-lists can also be used to match voice traffic with the **match access-group** command:

```

access-list 102 permit udp any any precedence critical
!-- This list filters traffic based on the IP packet TOS: Precedence field.
!-- Note: Ensure that other non-voice traffic does NOT uses the
!-- same precedence value.

```

```

access-list 102 permit udp any any dscp ef
!-- In order for this list to work, ensure that VoIP packets are tagged with
!-- the dscp ef code before they exit on the LLQ WAN interface.
!-- For more information on DSCP refer to:
!-- Implementing Quality of Service Policies with DSCP
!-- Note: If endpoints are not trusted on their packet marking, you can mark
!-- incoming traffic by applying an inbound service policy on an inbound
!-- interface. This procedure is out of the scope of this doc.

```

```

Access-list 102 permit udp host 192.10.1.1 host 192.20.1.1

```

```

!-- This access-list can be used in cases where the VoIP devices cannot
!-- do precedence or dscp marking and you cannot determine the
!-- VoIP UDP port range.

```

The following are other matching methods that can be used instead of access-groups:

- Starting with Cisco IOS Release 12.1.2.T, IP RTP Priority functionality is implemented for LLQ. This feature matches the priority class contents looking at the UDP ports configured and is subject to the limitation of serving only even ports in the PQ.

```

class-map voice

```

```
match ip rtp 16384 16383
```

- The following two methods operate under the assumption that VoIP packets are marked at the originating hosts or matched and marked in the router before applying the outbound LLQ operation.

```
class-map voice
  match ip precedence 5
```

or

```
class-map voice
  match ip dscp ef
```

Note: Starting with IOS Release 12.2.2T, VoIP dial-peers can mark voice bearer and signaling packets prior to the LLQ operation. This allows a scalable way of marking and matching VoIP packets via DSCP code values for LLQ.

2. Create a Class Map for VoIP Signaling and Define Match Criteria (Optional)

The following commands explain how to complete this task:

```
class-map voice-signaling
  match access-group 103
!
access-list 103 permit tcp any eq 1720 any
access-list 103 permit tcp any any eq 1720
```

Note: VoIP calls can be established using H.323, SIP, MGCP or Skinny (Proprietary Protocol used by Cisco Call Manager). The above example assumed H.323 Fast Connect. The following list serves as reference for the ports used by VoIP Signaling / Control Channels:

- H.323/H.225 = TCP 1720
- H.323/H.245 = TCP 11xxx (Standard Connect)
- H.323/H.245 = TCP 1720 (Fast Connect)
- H.323/H.225 RAS = TCP 1719
- Skinny = TCP 2000-2002 (CM Encore)
- ICCP = TCP 8001-8002 (CM Encore)
- MGCP = UDP 2427, TCP 2428 (CM Encore)
- SIP= UDP 5060, TCP 5060 (configurable)

3. Create a Policy Map and Associate to the VoIP Class-Maps

The purpose of the policy map is to define how the link resources will be shared or assigned to the different map classes. The following commands explain how to complete this task:

```
maui-voip-sj(config)#policy-map VOICE-POLICY

!-- Choose a descriptive policy_map_name.

maui-voip-sj(config-pmap)#class voice-traffic
maui-voip-sj(config-pmap-c)#priority ?
<8-2000000> Kilo Bits per second

!-- Configure the voice-traffic class to the strict Priority
!-- Queue (priority command) and assign the bandwidth.
```

```
maui-voip-sj(config-pmap)#class voice-signaling
maui-voip-sj(config-pmap-c)#bandwidth 8
```

```
!-- Assign 8 Kbps to the voice-signaling class
```

```
maui-voip-sj(config-pmap)#class class-default
maui-voip-sj(config-pmap-c)#fair-queue
```

```
!-- The remaining data traffic is treated as Weighted Fair Queue
```

Note: Although it is possible to queue various types of real-time traffic to the PQ, we recommend that you direct only voice traffic to it. Real-time traffic such as video could introduce variation in delay (the PQ is a FIFO - First In First Out - queue). Voice traffic requires that delay be nonvariable in order to avoid jitter.

Note: The sum of the values for **priority** and **bandwidth** statements needs to be less than or equal to 75% of the link bandwidth. Otherwise **service-policy** cannot be assigned to the link (to see the error messages, ensure that **logging console** is enabled for console access and **terminal monitor** is enabled for telnet access).

Note: When configuring VoIP over a 64 Kbps link to support two voice calls, it is common to allocate more than 75% (48Kbps) of the link bandwidth to the PQ. In such cases, you can use the command [max-reserved-bandwidth 80](#) to raise available bandwidth to 80% (51 Kbps).

For more information on the **bandwidth** and **priority** commands refer to: [Comparing the bandwidth and priority Commands of a QoS Service Policy](#)

4. Enable LLQ: Apply the Policy Map to the Outbound WAN Interface

The following commands explain how to complete this task:

```
maui-voip-sj(config)#interface multilink 1
maui-voip-sj(config-if)#service-policy output VOICE-POLICY
```

```
!-- In this scenario(MLPPP LFI), the service policy is applied to
!-- the Multilink interface.
```

IP RTP Priority Configuration Guidelines

To configure IP RTP Priority use the following guidelines:

- Router(config-if)#**ip rtp priority starting-rtp-port-#port-#-rangebandwidth**

Command	Description
starting-rtp-port-number	Lower bound of UDP port. The lowest port number to which the packets are sent. For VoIP, set this value to 16384.

port-number-range	The range of UDP destination ports. A number, which added to the starting-rtp-port-number , yields the highest UDP port number. For VoIP, set this value to 16383 (32767 - 16384 = 16383)
bandwidth	Maximum allowed bandwidth (kbps) in the priority queue. Set this number according to the number of simultaneous calls the system will support.

Sample Configuration:

```
interface Multilink1

    !--- Some output omitted

    bandwidth 64
    ip address 172.22.130.2 255.255.255.252
    ip tcp header-compression
    fair-queue
    no cdp enable
    ppp multilink
    ppp multilink fragment-delay 10
    ppp multilink interleave
    multilink-group 1
    ip rtp header-compression iphc-format
    ip rtp priority 16384 16383 45
```

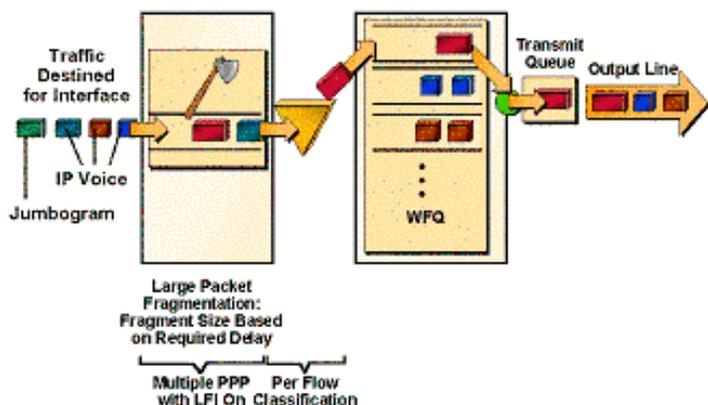

Link Fragmentation and Interleaving (LFI): Multilink PPP

While 1500 bytes is a common size for data packets, a typical VoIP packet (carrying G.729 voice frames) can be around 66 bytes (20 bytes voice payload, 6 bytes layer-2 header, 20 bytes RTP & UDP header, and 20 Bytes IP header).

Now, imagine a 56Kbps leased line link where voice and data traffic coexist. If a voice packet is ready to be serialized just when a data packet starts being transmitted over the link, then there is a problem. The delay-sensitive voice packet will have to wait 214 msec before being transmitted ([it takes 214 msec to serialize a 1500 bytes packet over a 56Kbps link](#)).

As you can see, large data packets can adversely delay delivery of small voice packets, reducing speech quality. Fragmenting these large data packets into smaller ones and interleaving voice packets among the fragments reduces jitter and delay. The Cisco IOS [Link Fragmentation and Interleaving \(LFI\)](#) feature helps satisfy the real-time delivery requirements of VoIP. The following image illustrates the operation of LFI.

Link Fragmentation and Interleaving (LFI)

As shown in Table 1, the amount of serialization delay (the time it takes to actually place the bits onto an interface) introduced on low-speed WAN links can be significant, considering that the target end-to-end one-way delay should not exceed 150ms. (ITU-T G.114 recommendation specifies 150 ms maximum one-way end-to-end.

Table 1. Serialization Delay for Various Frame Sizes on Low-Speed Links $\text{Serialization Delay} = \text{frame size (bits)} / \text{link bandwidth (bps)}$

	1 Byte	64 Bytes	128 Bytes	256 Bytes	512 Bytes	1024 Bytes	1500 Bytes
56 kbps	143 us	9 ms	18 ms	36 ms	72 ms	144 ms	214 ms
64 kbps	125 us	8 ms	16 ms	32 ms	64 ms	126 ms	187 ms
128 kbps	62.5 us	4 ms	8 ms	16 ms	32 ms	64 ms	93 ms
256 kbps	31 us	2 ms	4 ms	8 ms	16 ms	32 ms	46 ms
512 kbps	15.5 us	1 ms	2 ms	4 ms	8 ms	16 ms	32 ms
768 kbps	10 us	640 us	1.28 ms	2.56 ms	5.12 ms	10.24 ms	15 ms
1536 kbps	5 us	320 us	640 us	1.28 ms	2.56 ms	5.12 ms	7.5 ms

Note: For voice applications, recommended serialization delay (per hop basis) is 10 ms and should not exceed 20 ms.

The link fragment size is configurable in millisecond (msec) time measurements with the command **ppp multilink fragment-delay**. LFI requires that **ppp multilink** be configured on the interface with **ppp multilink interleave** turned on. For more information on configuring LFI, refer to the section.

Note: In cases where you have more than a dedicated half T1 connection (768 Kbps), you do not need a fragmentation feature. (You will, however, still need a QoS mechanism, such as LLQ or IP RTP Priority). The half T1 offers enough bandwidth to allow voice packets to enter and leave the queue without delay issues. Also, you may not need Compression for Real-time Protocol (cRTP), which helps conserve bandwidth by compressing IP RTP headers, in the case of a half T1.

Compressed Real-time Protocol (cRTP)

Note: cRTP is not required to ensure good voice quality. It is a feature that reduces bandwidth consumption. Configure cRTP after all other conditions are met and the voice quality is good. This procedure can save troubleshooting time by isolating potential cRTP issues.

Based on RFC 2508, the RTP header compression feature compresses the IP/UDP/RTP header from 40 Bytes to 2 or 4 bytes, reducing unnecessary bandwidth consumption. It is a hop-by-hop compression scheme; therefore, cRTP must be configured on both ends of the link (unless the **passive** option is configured). To configure cRTP, use the following command at interface level:

- Router(config-if)#**ip rtp header-compression** [passive]

Since the compression process can be CPU-intensive, RTP header compression is implemented in the fast switching and CEF switching paths as the 12.0.(7)T release of IOS. Sometimes these implementations are broken and then the only way that works will be processed switched. Cisco only recommends using cRTP with links lower than 768 Kbps, unless the router is running at a low CPU utilization rate. Monitor the router's CPU utilization and disable cRTP if it's above 75%.

Note: When you configure the command **ip rtp header-compression**, the router adds the command **ip tcp header-compression** to the configuration by default. This is used to compress the headers TCP/IP packets. Header compression is particularly useful on networks with a large percentage of small packets, such as those supporting many Telnet connections. The TCP header compression technique, described fully in RFC 1144, is supported on serial lines using HDLC or PPP encapsulation.

To compress the TCP headers without enabling cRTP, use the command:

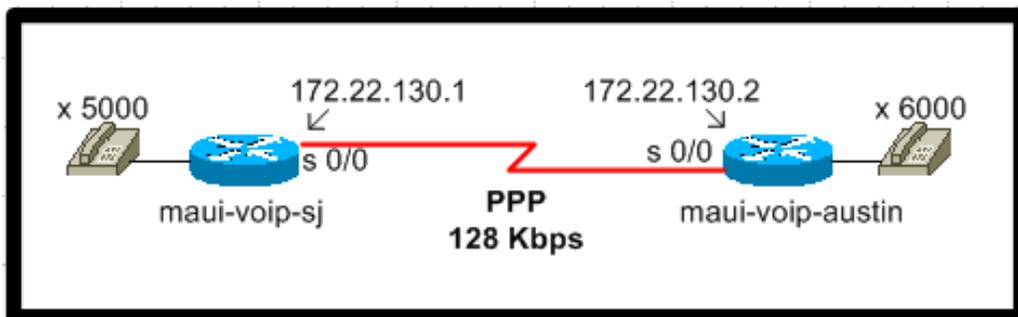

- Router(config-if)#**ip tcp header-compression** [passive]

For more information: [Compressed Real-time Transport Protocol](#)

Other Bandwidth Reduction Tips

- Use low bit-rate coder/decoders (codec) on the VoIP call legs; G.729 (8 Kbps) is recommended. (This is the default codec on the VoIP dial-peers). To configure different codecs use the command **router(config-dial-peer)#codec** under the desired voip dial-peer.
- Although dual tone multifrequency (DTMF) is usually transported accurately when using high-bit-rate voice codecs such as G.711, low-bit-rate codecs (such as G.729 and G.723.1) are highly optimized for voice patterns and tend to distort DTMF tones. This approach can result in problems accessing interactive voice response (IVR) systems. The **dtmf relay** command solves the problem of DTMF distortion by transporting DTMF tones "out of band" or separate from the encoded voice stream. If low bit-rate codecs (G.729, G.723) are used, turn on **dtmf relay** under the VoIP dial-peer.
- A typical conversation may contain 35-50% silence. Using Voice Activity Detection (VAD), silence packets are suppressed. For VoIP bandwidth planning, assume VAD will reduce bandwidth by 35%. VAD is configured by default under the VoIP dial-peers. To enable/disable VAD, use the commands **router(config-dial-peer)#vad** and **router(config-dial-peer)# no vad** under the desired voip dial-peers.

Verification and Troubleshooting Commands

Before attempting any debug commands, please see [Important Information on Debug Commands](#). For more info on the commands below, refer to the [Sample show and debug Output](#) section of this document.

Interface Commands:

- **show interface [serial | multilink]** - Use this command to check that status of the serial interface. Make sure the serial and multilink interface are up and open.
- [Troubleshooting Serial Line Problems](#)

LFI Commands:

- **show ppp multilink** - This command displays bundle information for the Multilink PPP bundles.

- **debug ppp multilink fragments** - This debug command displays information about individual multilink fragments and interleaving events. This command output also identifies the sequence number of the packet and the fragment sizes.

LLQ / IP RTP Priority Commands:

- **show policy-map interface multilink *interface#*** - This command is very useful to see the LLQ operation and to see any drops in the PQ. For more information on the various fields of this command, refer to: [Understanding Packet Counters in show policy-map interface Output](#)
- **show policy-map *policy_map_name*** - Displays information about the policy-map configuration.
- **show queue *interface-type interface-number*** - Lists fair queuing configuration and statistics for a particular interface.
- **Debug priority** - This debug command displays priority queuing events and shows if dropping occurs in this queue. Please also see: [Troubleshooting Output Drops with Priority Queuing](#)
- **show class-map *class_name*** - Displays information about the class-map configuration.
- **Show call active voice** - This command is useful to check for lost packets at the DSP level.

Other Commands / References:

- **show ip rtp header-compression** - Displays RTP header compression statistics.
- [Troubleshoot & Debug VoIP Calls - the Basics](#)
- [VoIP Debug Commands](#)

Known Issues:

- CSCds43465: "LLQ, Policer, Shaper should take CRTP compression feedback" To view Release Notes, refer to [Bug Toolkit](#) . You need to be registered to use the tool.

Guidelines:

Basic troubleshooting steps once the ppp link is up and running (MLPPP, Fragmentation, Interleaving):

1. **show call active voice** - To check for the lost packets at the DSP level.
2. **show interface** - To check for the general serial line or interface problems. Drops on the interface does not mean a problem yet, but it is preferable to drop the packet from the low priority queue before it reach the interface queue.
3. **show policy-map interface** - To check for the LLQ drops and queuing configuration. Should not report any drops that violate the policy.
4. **show ip rtp header-compression** - to check for the cRTP specific problems.

Sample show and debug Output

```
!-----  
!  
!----- To capture sections of this output, the LLQ PQ bandwidth  
!----- was lowered and large data traffic was placed  
!----- on the link to force some packets drops.  
!-----  
!  
!----- Packet Drop Verification (During an Active Call)  
  
!--- Assuming your ppp link is up & running, the 1st step of voice  
!--- quality problems verification is to check for lost packets  
!--- at the DSP. Use the command: "show call active voice"  
!--- Note: - NOT "show call active voice brief"  
  
maui-voip-austin#show call active voice
