Introduction

This document provides a sample configuration of a Cisco IOS® based access point for Extensible Authentication Protocol (EAP) authentication of wireless users against a database accessed by a RADIUS server.

Due to the passive role that the access point plays in EAP (bridges wireless packets from the client into wired packets destined to the authentication server, and vice versa), this configuration is used with virtually all EAP methods. These methods include (but are not limited to) LEAP, Protected EAP (PEAP)–MS–Challenge Handshake Authentication Protocol (CHAP) version 2, PEAP–Generic Token Card (GTC), EAP–Flexible Authentication via Secure Tunneling (FAST), EAP–Transport Layer Security (TLS), and EAP–Tunneled TLS (TTLS). You must appropriately configure the authentication server for each of these EAP methods.

This document covers how to configure the access point (AP) and the RADIUS server, which is Cisco Secure ACS in the configuration example in this document.

Prerequisites

Requirements

Ensure that you meet these requirements before you attempt this configuration:

- You are familiar with the Cisco IOS GUI or CLI.
- You are familiar with the concepts behind EAP authentication.

Components Used

The information in this document is based on these software and hardware versions:

- Cisco Aironet AP products that run Cisco IOS.
 - Assumption of only one Virtual LAN (VLAN) in the network.
 - A RADIUS authentication server product that successfully integrates into a user database.
 - ◆ These are the supported authentication servers for Cisco LEAP and EAP-FAST:
 - ◇ Cisco Secure Access Control Server (ACS)
 - ◇ Cisco Access Registrar (CAR)
 - ◇ Funk Steel Belted RADIUS
 - ◇ Interlink Merit
 - ◆ These are the supported authentication servers for the Microsoft PEAP-MS-CHAP version 2 and PEAP-GTC:
 - ◇ Microsoft Internet Authentication Service (IAS)
 - ◇ Cisco Secure ACS
 - ◇ Funk Steel Belted RADIUS
 - ◇ Interlink Merit
 - ◇ Any additional authentication server Microsoft can authorize.
- Note:** GTC or One-Time Passwords require additional services which require additional software on both the client and server side, as well as hardware or software token generators.
- ◆ Consult the manufacturer of the client supplicant for details on which authentication servers are supported with their products for EAP-TLS, EAP-TTLS and other EAP methods.

The information in this document was created from the devices in a specific lab environment. All of the devices used in this document started with a cleared (default) configuration. If your network is live, make sure that you understand the potential impact of any command.

Conventions

Refer to the Cisco Technical Tips Conventions for more information on document conventions.

Configure

This configuration describes how to configure EAP authentication on an IOS based AP. In the example in this document, LEAP is used as a method of EAP authentication with RADIUS server.

Note: Use the Command Lookup Tool (registered customers only) to obtain more information on the commands used in this section.

As with most password-based authentication algorithms, Cisco LEAP is vulnerable to dictionary attacks. This is not a new attack or new vulnerability of Cisco LEAP. The creation of a strong password policy is the most effective way to mitigate dictionary attacks. This includes the use of strong passwords and the periodical expiration of passwords. Refer to Dictionary Attack on Cisco LEAP to get more information about dictionary attacks and how to prevent them.

This document uses this configuration for both GUI and CLI:

- IP address of the AP is 10.0.0.106.
- IP address of the RADIUS server (ACS) is 10.0.0.3.

Network EAP or Open Authentication with EAP

In any EAP/802.1x based authentication method, you can question what the differences are between Network EAP and Open authentication with EAP. These items refer to the values in the Authentication Algorithm field in the headers of management and association packets. Most manufacturers of wireless clients set this field at the value 0 (Open authentication), then signal a desire to do EAP authentication later in the association process. Cisco sets the value differently, from the start of association with the Network EAP flag.

If your network has clients that are:

- Cisco clients Use Network–EAP.
- Third party clients (include CCX compliant products) Use Open with EAP.
- A combination of both Cisco and third party clients Choose both Network–EAP and Open with EAP.

Define Authentication Server

The first step in the EAP configuration is to define the authentication server and establish a relationship with it.

1. On the access point Server Manager tab (under the **Security > Server Manager** menu item), complete these steps:
 - a. Enter the IP address of the authentication server in the Server field.
 - b. Specify the Shared Secret and the ports.
 - c. Click **Apply** in order to create the definition and populate the dropdown lists.
 - d. Set the EAP Authentication type Priority 1 field to the server IP address under Default Server Priorities.
 - e. Click **Apply**.

The screenshot displays the Cisco 1200 Access Point configuration page. The main configuration area is titled 'SERVER MANAGER' and 'GLOBAL PROPERTIES'. The page shows the configuration for a 'Backup RADIUS Server' and 'Corporate Servers'. The 'Backup RADIUS Server' section includes fields for 'Backup RADIUS Server' (Hostname or IP Address) and 'Shared Secret'. The 'Corporate Servers' section shows a 'Current Server List' with a 'RADIUS' dropdown menu. A list of servers is shown, with '10.0.0.3' selected. The 'Server' field is set to '10.0.0.3' (Hostname or IP Address). The 'Shared Secret' field is empty. The 'Authentication Port (optional)' is set to '1645' (0-65536). The 'Accounting Port (optional)' is set to '1646' (0-65536). The 'Default Server Priorities' section shows 'EAP Authentication' with Priority 1 set to '10.0.0.3'. Other authentication methods like MAC, Accounting, Admin (RADIUS/TACACS+), and Proxy Mobile IP are also listed with their respective priorities.

You can also issue these commands from the CLI:

```
AP#configure terminal
```

Enter configuration commands, one per line. End with CNTL/Z.

```
AP(config)#aaa group server radius rad_eap
```

```
AP(config-sg-radius)#server 10.0.0.3 auth-port 1645 acct-port 1646
```

```
AP(config-sg-radius)#exit
```

```
AP(config)#aaa new-model
```

```
AP(config)#aaa authentication login eap_methods group rad_eap

AP(config)#radius-server host 10.0.0.3 auth-port 1645
acct-port 1646 key labap1200ip102

AP(config)#end

AP#write memory
```

2. The access point must be configured in the authentication server as an AAA client.

For example, in Cisco Secure ACS, this happens on the Network Configuration page where the name of the access point, IP address, shared secret and authentication method (RADIUS Cisco Aironet or RADIUS Cisco IOS/PIX) are defined. Refer to the documentation from the manufacturer for other non-ACS authentication servers.

The screenshot shows the 'Network Configuration' page in Cisco Secure ACS. The 'AAA Client' section is highlighted with a red circle. The fields are: Hostname (AP), AAA Client IP Address (10.0.0.106), Key (sharedsecret), and Authenticate Using (RADIUS (Cisco IOS/PIX)). There are also several checkboxes for logging and authentication options, all of which are currently unchecked. The 'Submit', 'Submit + Restart', and 'Cancel' buttons are at the bottom. A help panel on the right provides additional information and links.

Field	Value
AAA Client Hostname	AP
AAA Client IP Address	10.0.0.106
Key	sharedsecret
Authenticate Using	RADIUS (Cisco IOS/PIX)

- [AAA Client Hostname](#)
- [AAA Client IP Address](#)
- [Key](#)
- [Network Device Group](#)
- [Authenticate Using](#)
- [Single Connect TACACS+ AAA Client](#)
- [Log Update/Watchdog Packets from this AAA Client](#)
- [Log RADIUS Tunneling Packets from this AAA Client](#)
- [Replace RADIUS Port info with Username from this AAA Client](#)

AAA Client Hostname

The AAA Client Hostname is the name assigned to the AAA client.

[\[Back to Top\]](#)

Ensure that the authentication server is configured to perform the desired EAP authentication method. For example, for a Cisco Secure ACS that does LEAP, configure LEAP authentication on the System Configuration – Global Authentication Setup page. Click **System Configuration**, then click **Global Authentication Setup**. Refer to the documentation from the manufacturer for other non-ACS authentication servers or other EAP methods.

CISCO SYSTEMS **System Configuration**

	<p>Service Control</p> <p>Select to open the page from which you can stop or restart Cisco Secure ACS services.</p> <p>[Back to Top]</p>

This image shows Cisco Secure ACS configured for PEAP, EAP-FAST, EAP-TLS, LEAP and EAP-MD5.

Define Client Authentication Methods

Once the access point knows where to send client authentication requests, configure it to accept those methods.

Note: These instructions are for a WEP based installation. For WPA (which uses ciphers instead of WEP), refer to WPA Configuration Overview.

1. On the access point Encryption Manager tab (under the **Security > Encryption Manager** menu

item), complete these steps:

- a. Specify that you want to use **WEP encryption**.
- b. Specify that WEP is **Mandatory**.
- c. Verify that the key size is set to **128-bits**.
- d. Click **Apply**.

The screenshot shows the Cisco 1200 Access Point configuration interface. The page title is "Cisco 1200 Access Point". The left sidebar contains navigation options: HOME, EXPRESS SET-UP, EXPRESS SECURITY, NETWORK MAP, ASSOCIATION, NETWORK INTERFACES, SECURITY (Admin Access, Encryption Manager, SSID Manager, Server Manager, Local RADIUS Server, Advanced Security), SERVICES, WIRELESS SERVICES, SYSTEM SOFTWARE, and EVENT LOG. The main content area is titled "Security: Encryption Manager - Radio0-802.11B". Under "Encryption Modes", the "WEP Encryption" radio button is selected, and the "Mandatory" dropdown menu is highlighted with a red circle. Below this, the "Cisco Compliant TKIP Features" section has "Enable MIC" and "Enable Per Packet Keying" checkboxes. The "CIPHER" section shows "WEP 128 bit" selected. The "Encryption Keys" table has four rows, each with a radio button, a text input field, and a "128 bit" dropdown menu. The "Global Properties" section has "Broadcast Key Rotation Interval" set to "Disable Rotation" (selected) and "WPA Group Key Update" options.

Transmit Key	Encryption Key (Hexadecimal)	Key Size
Encryption Key 1: <input type="radio"/>	<input type="text"/>	128 bit
Encryption Key 2: <input checked="" type="radio"/>	<input type="text"/>	128 bit
Encryption Key 3: <input type="radio"/>	<input type="text"/>	128 bit
Encryption Key 4: <input type="radio"/>	<input type="text"/>	128 bit

You can also issue these commands from the CLI:

```
AP#configure terminal
```

Enter configuration commands, one per line. End with CNTL/Z.

```
AP(config)#interface dot11radio 0
```

```
AP(config-if)#encryption mode wep mandatory
```

```
AP(config-if)#end
```

AP#write memory

2. Complete these steps on the access point SSID Manager tab (under the **Security > SSID Manager** menu item):

- a. Select the desired SSID.
- b. Under "Authentication Methods Accepted," check the box labelled **Open** and use the dropdown list to choose **With EAP**.
- c. Check the box labelled **Network-EAP** if you have Cisco client cards. See the discussion in the Network EAP or Open Authentication with EAP section.
- d. Click **Apply**.

The screenshot displays the Cisco 1200 Access Point configuration page. The left sidebar contains a navigation menu with categories like HOME, EXPRESS SET-UP, SECURITY, and SERVICES. The main content area is titled "Cisco 1200 Access Point" and shows the configuration for "RADIO0-802.11B". The "Security: SSID Manager - Radio0-802.11B" section is active, showing "SSID Properties" and "Authentication Settings".

SSID Properties:

- Current SSID List: A list containing "< NEW >" and "labap1200".
- SSID: labap1200 (circled in red)
- VLAN: < NONE > (dropdown menu)
- Network ID: (input field) (0-4096)

Authentication Settings:

- Methods Accepted:
 - Open Authentication: with EAP (dropdown menu, circled in red)
 - Shared Authentication: < NO ADDITION > (dropdown menu)
 - Network EAP: < NO ADDITION > (dropdown menu, circled in red)
- Server Priorities:
 - EAP Authentication Servers: Use Defaults (selected) or Customize. Priority 1, 2, and 3 are all set to < NONE >.
 - MAC Authentication Servers: Use Defaults (selected) or Customize. Priority 1, 2, and 3 are all set to < NONE >.

A grey banner across the bottom of the configuration area reads: "Portions of this image not relevant to the discussion have been edited for clarity".

Global Radio0-802.11B SSID Properties:

- Set Guest Mode SSID: < NONE > (dropdown menu)
- Set Infrastructure SSID: < NONE > (dropdown menu) Force Infrastructure Devices to associate only to this SSID

Buttons for "Delete-Radio0", "Delete-All", "Apply", and "Cancel" are visible.

Page footer: Close Window Copyright (c) 1992-2004 by Cisco Systems, Inc.

You can also issue these commands from the CLI:

```
AP#configure terminal

Enter configuration commands, one per line.  End with CNTL/Z.

AP(config)#interface dot11radio 0

AP(config-if)#ssid labap1200

AP(config-if-ssid)#authentication open eap eap_methods

AP(config-if-ssid)#authentication network-eap eap_methods

AP(config-if-ssid)#end

AP#write memory
```

Once you confirm basic functionality with a basic EAP configuration, you can add additional features and key management at a later time. Layer more complex functions on top of functional foundations in order to make troubleshooting easier.

Verify

This section provides information you can use to confirm your configuration works properly.

Certain **show** commands are supported by the Output Interpreter Tool (registered customers only) , which allows you to view an analysis of **show** command output.

- **show radius server-group all** Displays a list of all configured RADIUS server-groups on the AP.

Troubleshoot

Troubleshoot Procedure

Complete these steps in order to troubleshoot your configuration.

1. In the client-side utility or software, create a new profile or connection with the same or similar parameters in order to ensure that nothing has become corrupted in the configuration of the client.
2. In order to eliminate the possibility of RF issues that prevent successful authentication, temporarily disable authentication as shown in these steps:
 - ◆ From the CLI, use the commands **no authentication open eap eap_methods**, **no authentication network-eap eap_methods** and **authentication open**.
 - ◆ From the GUI, on the SSID Manager page, un-check **Network-EAP**, check **Open**, and set the dropdown list back to **No Addition**.If the client successfully associates, then RF does not contribute to the association problem.
3. Verify that shared secret passwords are synchronized between the access point and the authentication server. Otherwise, you can receive this error message:

```
Invalid message authenticator in EAP request
```

- ◆ From the CLI, check the line **radius-server host x.x.x.x auth-port x acct-port x key <shared_secret>**.
- ◆ From the GUI, on the Server Manager page, re-enter the shared secret for the appropriate server in the box labelled "Shared Secret."

Note: In Cisco IOS Software releases prior to 12.2(15)JA, the syntax of this **debug** command is **debug dot11 aaa dot1x state-machine**.

- **debug dot11 aaa authenticator process** Displays the individual dialog entries of the negotiation between the client and the authentication server.

Note: In Cisco IOS Software releases prior to 12.2(15)JA, the syntax of this debug command is **debug dot11 aaa dot1x process**.

- **debug radius authentication** Displays the RADIUS negotiations between the server and client, both of which, are bridged by the AP. This is an output for **failed** authentication:
